The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

• **automatic_sp_privileges**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--automatic-sp-privileges=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>automatic_sp_privileges</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also Section 24.2.2, “Stored Routines and MySQL Privileges”.

• **auto_generate_certs**
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--auto-generate-certs=[{OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>auto_generate_certs</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable is available if the server was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). It controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

For more information about SSL file autogeneration, including file names and characteristics, see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `sha256_password_auto_generate_rsa_keys` and `caching_sha2_password_auto_generate_rsa_keys` system variables are related but control autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- `avoid_temporal_upgrade`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--avoid-temporal-upgrade=[{OFF</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>avoid_temporal_upgrade</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated and will be removed in a future MySQL release.
### back_log

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--back-log=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>back_log</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is the value of `max_connections`, which enables the permitted backlog to adjust to the maximum permitted number of connections.

### basedir

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--basedir=dir_name</td>
</tr>
<tr>
<td>System Variable</td>

</tbody>
</table>

Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

If enabled, the server stores all temporary tables on disk rather than in memory. This prevents most `The table tbl_name is full` errors for `SELECT` operations that require a large temporary table, but also slows down queries for which in-memory tables would suffice.

The default value for new connection is `OFF` (use in-memory temporary tables). Normally, it should never be necessary to enable this variable. When in-memory `internal` temporary tables are managed by the `TempTable` storage engine (the default), and the maximum amount of memory that can be occupied by the `TempTable` storage engine is exceeded, the `TempTable` storage engine starts storing data to temporary files on disk. When in-memory temporary tables are managed by the `MEMORY` storage engine, in-memory tables are automatically converted to disk-based tables as required. For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **bind_address**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--bind-address=addr</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>bind_address</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>*</code></td>
</tr>
</tbody>
</table>

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces. To specify how the server should listen for TCP/IP connections, set the `bind_address` system variable at server startup. The server also has an `admin_address` system variable that enables administrative connections on a dedicated interface. See Section 8.12.4.1, “How MySQL Handles Client Connections”.

If `bind_address` is specified, its value must satisfy these requirements:

- Prior to MySQL 8.0.13, `bind_address` accepts a single address value, which may specify a single non-wildcard IP address or host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*, 0.0.0.0, or ::`).

- As of MySQL 8.0.13, `bind_address` accepts a single value as just described, or a list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address or host name; none can specify a wildcard address format (`*, 0.0.0.0, or ::`).
IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is *, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default. If the option specifies a list of multiple values, this value is not permitted.

- If the address is 0.0.0.0, the server accepts TCP/IP connections on all server host IPv4 interfaces. If the option specifies a list of multiple values, this value is not permitted.

- If the address is ::, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the option specifies a list of multiple values, this value is not permitted.

- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to ::ffff:127.0.0.1, clients can connect using --host=127.0.0.1 or --host=::ffff:127.0.0.1.

- If the address is a "regular" IPv4 or IPv6 address (such as 127.0.0.1 or ::1), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If binding to any address fails, the server produces an error and does not start.

Examples:

- **bind_address=***

  The server listens on all IPv4 or IPv6 addresses, as specified by the * wildcard.

- **bind_address=198.51.100.20**

  The server listens only on the 198.51.100.20 IPv4 address.

- **bind_address=198.51.100.20,2001:db8:0:f101::1**

  The server listens on the 198.51.100.20 IPv4 address and the 2001:db8:0:f101::1 IPv6 address.

- **bind_address=198.51.100.20,***

  This produces an error because wildcard addresses are not permitted when **bind_address** names a list of multiple values.

**When bind_address names a single value (wildcard or non-wildcard), the server listens on a single socket, which for a wildcard address may be bound to multiple network interfaces. When bind_address names a list of multiple values, the server listens on one socket per value, with each socket bound to a single network interface. The number of sockets is linear with the number of values specified. Depending on operating system connection-acceptance efficiency, long value lists might incur a performance penalty for accepting TCP/IP connections.**

**Because file descriptors are allocated for listening sockets, it may be necessary to increase the open_files_limit system variable.**
If you intend to bind the server to a specific address, be sure that the `mysql.user` system table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to *, you can connect to it using all existing accounts. But if you bind the server to ::1, it accepts connections only on that address. In that case, first make sure that the 'root'@'::1' account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- **block_encryption_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--block-encryption-mode=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>block_encryption_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>aes-128-ecb</code></td>
</tr>
</tbody>
</table>

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where `keylen` is the key length in bits and `mode` is the encryption mode. The value is not case-sensitive. Permitted `keylen` values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or wolfSSL:

- For OpenSSL, permitted `mode` values are: ECB, CBC, CFB1, CFB8, CFB128, OFB
- For wolfSSL, permitted `mode` values are: ECB, CBC

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.

- **bulk_insert_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--bulk-insert-buffer-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>bulk_insert_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
</tbody>
</table>

### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value (64-bit platforms)</strong></td>
<td><strong>18446744073709551615</strong></td>
</tr>
<tr>
<td><strong>Maximum Value (32-bit platforms)</strong></td>
<td><strong>4294967295</strong></td>
</tr>
</tbody>
</table>

**MyISAM** uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...)`, `(...)`, `...`, and `LOAD DATA` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- **caching_sha2_password_auto_generate_rsa_keys**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--caching-sha2-password-auto-generate-rsa-keys[=(OFF</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.4</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>caching_sha2_password_auto_generate_rsa_keys</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable is available if the server was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). The server uses it to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

For more information about RSA file autogeneration, including file names and characteristics, see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- **caching_sha2_password_private_key_path**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--caching-sha2-password-private-key-path=file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td>caching_sha2_password_private_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>private_key.pem</td>
</tr>
</tbody>
</table>

This variable specifies the path name of the RSA private key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

**Important**

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `caching_sha2_password`, see Section 6.4.1.3, "Caching SHA-2 Pluggable Authentication".

• `caching_sha2_password_public_key_path`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--caching-sha2-password-public-key-path=file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td>caching_sha2_password_public_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>public_key.pem</td>
</tr>
</tbody>
</table>

This variable specifies the path name of the RSA public key file for the `caching_sha2_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

For information about `caching_sha2_password`, including information about how clients request the RSA public key, see Section 6.4.1.3, "Caching SHA-2 Pluggable Authentication".

• `character_set_client`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>character_set_client</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 10.4, “Connection Character Sets and Collations”.) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.

- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See Impermissible Client Character Sets.

- `character_set_connection`

- `character_set_database`
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.1)</td>
<td>utf8mb4</td>
</tr>
<tr>
<td>Default Value (8.0.0)</td>
<td>latin1</td>
</tr>
<tr>
<td>Footnote</td>
<td>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.</td>
</tr>
</tbody>
</table>

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as character_set_server.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

The global character_set_database and collation_database system variables are deprecated and will be removed in a future version of MySQL.

Assigning a value to the session character_set_database and collation_database system variables is deprecated and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- character_set_filesystem

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--character-set-filesystem=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>character_set_filesystem</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>binary</td>
</tr>
</tbody>
</table>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from character_set_client to character_set_filesystem before the file opening attempt occurs. The default value is binary, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set character_set_filesystem to 'utf8mb4'.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- character_set_results
### character_set_results

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>character_set_results</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.1)</td>
<td>utf8mb4</td>
</tr>
<tr>
<td>Default Value (8.0.0)</td>
<td>utf8</td>
</tr>
</tbody>
</table>

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

- **character_set_server**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--character-set-server=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>character_set_server</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.1)</td>
<td>utf8mb4</td>
</tr>
<tr>
<td>Default Value (8.0.0)</td>
<td>latin1</td>
</tr>
</tbody>
</table>

The server’s default character set. See [Section 10.14, “Character Set Configuration”](#). If you set this variable, you should also set `collation_server` to specify the collation for the character set.

- **character_set_system**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>character_set_system</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8</td>
</tr>
</tbody>
</table>

The character set used by the server for storing identifiers. The value is always utf8.

- **character_sets_dir**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--character-sets-dir=dir_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>character_sets_dir</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory where character sets are installed. See Section 10.14, “Character Set Configuration”.

- **check_proxy_users**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--check-proxy-users[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>check_proxy_users</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`.

If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request. However, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

- For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
- For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

For information about user proxying, see Section 6.2.18, “Proxy Users”.

- **collation_connection**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>collation_connection</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The collation of the connection character set. `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).

- **collation_database**
## Property Settings

### collation_database

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>collation_database</strong></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong> (&gt;= 8.0.1)</td>
<td>utf8mb4_0900_ai_ci</td>
</tr>
<tr>
<td><strong>Default Value</strong> (8.0.0)</td>
<td>latin1_swedish_ci</td>
</tr>
</tbody>
</table>

**Footnote**: This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as **collation_server**.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.9.1, “System Variable Privileges”](#).

The global **character_set_database** and **collation_database** system variables are deprecated and will be removed in a future version of MySQL.

Assigning a value to the session **character_set_database** and **collation_database** system variables is deprecated and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- **collation_server**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--collation-server=name</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>collation_server</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong> (&gt;= 8.0.1)</td>
<td>utf8mb4_0900_ai_ci</td>
</tr>
<tr>
<td><strong>Default Value</strong> (8.0.0)</td>
<td>latin1_swedish_ci</td>
</tr>
</tbody>
</table>

The server's default collation. See [Section 10.14, “Character Set Configuration”](#).

- **completion_type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--completion-type=#</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>completion_type</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>NO_CHAIN</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>NO_CHAIN, CHAIN, RELEASE</td>
</tr>
</tbody>
</table>

**Completion_type**

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_CHAIN (or 0)</td>
<td>COMMIT and ROLLBACK are unaffected. This is the default value.</td>
</tr>
<tr>
<td>CHAIN (or 1)</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)</td>
</tr>
<tr>
<td>RELEASE (or 2)</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK RELEASE, respectively. (The server disconnects after terminating the transaction.)</td>
</tr>
</tbody>
</table>

**completion_type** affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, “Statements That Cause an Implicit Commit”. It also does not apply for XA COMMIT, XA ROLLBACK, or when autocommit=1.

- **concurrent_insert**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--concurrent-insert[=#]</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>concurrent_insert</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>AUTO</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>NEVER</td>
</tr>
</tbody>
</table>
If **AUTO** (the default), MySQL permits **INSERT** and **SELECT** statements to run concurrently for **MyISAM** tables that have no free blocks in the middle of the data file. If you start **mysqld** with **--skip-new**, this variable is set to **NEVER**.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEVER</td>
<td>Disables concurrent inserts</td>
</tr>
<tr>
<td>(or 0)</td>
<td></td>
</tr>
<tr>
<td>AUTO</td>
<td>(Default) Enables concurrent insert for <strong>MyISAM</strong> tables that do not have holes</td>
</tr>
<tr>
<td>(or 1)</td>
<td></td>
</tr>
<tr>
<td>ALWAYS</td>
<td>Enables concurrent inserts for all <strong>MyISAM</strong> tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.</td>
</tr>
<tr>
<td>(or 2)</td>
<td></td>
</tr>
</tbody>
</table>

See also Section 8.11.3, “Concurrent Inserts”.

- **connect_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--connect-timeout=#</strong></td>
</tr>
<tr>
<td>System Variable</td>
<td><strong>connect_timeout</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

The number of seconds that the **mysql** server waits for a connect packet before responding with **Bad handshake**. The default value is 10 seconds.

Increasing the **connect_timeout** value might help if clients frequently encounter errors of the form **Lost connection to MySQL server at 'XXX', system error: errno**.
• **core_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>core_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to write a core file if the server crashes. This variable is set by the `--core-file` option.

• **create_admin_listener_thread**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--create-admin-listener-thread=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>create_admin_listener_thread</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to use a dedicated listening thread for client connections on the administrative network interface (see Section 8.12.4.1, “How MySQL Handles Client Connections”). The default is to implement the administrative interface using the listener thread used for ordinary connections.

Depending on factors such as platform type and workload, you may find one setting for this variable yields better performance than the other setting.

Setting `create_admin_listener_thread` has no effect if `admin_address` is not specified because in that case the server maintains no administrative network interface.

• **cte_max_recursion_depth**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--cte-max-recursion-depth=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td>cte_max_recursion_depth</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
The common table expression (CTE) maximum recursion depth. The server terminates execution of any CTE that recurses more levels than the value of this variable. For more information, see Limiting Common Table Expression Recursion.

- **datadir**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--datadir=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>datadir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If the server will be started automatically (that is, in contexts for which you cannot assume what the current directory will be), it is best to specify the `datadir` value as an absolute path.

- **date_format**

This system variable was removed in MySQL 8.0.3.

- **datetime_format**

This system variable was removed in MySQL 8.0.3.

- **debug**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--debug[=debug_options]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>debug</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td><code>d:t:i:O,mysql.trace</code></td>
</tr>
<tr>
<td>Default Value (Unix)</td>
<td><code>d:t:i:o,/tmp/mysql.trace</code></td>
</tr>
</tbody>
</table>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

Assigning a value that begins with + or - cause the value to added to or subtracted from the current value:
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| P:T     |
+---------+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

For more information, see Section 29.5.4, “The DBUG Package”.

- debug_sync

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>debug_sync</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the

-DENABLE_DEBUG_SYNC=1

CMake option (see Section 2.9.4, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of debug_sync is OFF. If the server is started with

--debug-sync-timeout=N

where N is a timeout value greater than 0, Debug Sync is enabled and the value of debug_sync is ON - current signal followed by the signal name. Also, N becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- default_authentication_plugin
**Server System Variables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--default-authentication-plugin=plugin_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>default_authentication_plugin</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value (&gt;= 8.0.4)</strong></td>
<td><code>caching_sha2_password</code></td>
</tr>
<tr>
<td><strong>Default Value (&lt;= 8.0.3)</strong></td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td><strong>Valid Values (&gt;= 8.0.3)</strong></td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td></td>
<td><code>sha256_password</code></td>
</tr>
<tr>
<td></td>
<td><code>caching_sha2_password</code></td>
</tr>
<tr>
<td><strong>Valid Values (&lt;= 8.0.2)</strong></td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td></td>
<td><code>sha256_password</code></td>
</tr>
</tbody>
</table>

The default authentication plugin. These values are permitted:

- **`mysql_native_password`**: Use MySQL native passwords; see [Section 6.4.1.1, “Native Pluggable Authentication”](#).
- **`sha256_password`**: Use SHA-256 passwords; see [Section 6.4.1.2, “SHA-256 Pluggable Authentication”](#).
- **`caching_sha2_password`**: Use SHA-256 passwords; see [Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”](#).

**Note**

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see `caching_sha2_password` as the Preferred Authentication Plugin.

The `default_authentication_plugin` value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not explicitly specify an authentication plugin.
- For an account created with the following statement, the server associates the account with the default authentication plugin and assigns the account the given password, hashed as required by that plugin:

```
cREATE USER ... IDENTIFIED BY 'cleartext password';
```

- **`default_collation_for_utf8mb4`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_collation_for_utf8mb4</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Valid Values</td>
<td>utf8mb4_0900_ai_ci</td>
</tr>
<tr>
<td></td>
<td>utf8mb4_general_ci</td>
</tr>
</tbody>
</table>

For internal use by replication. This system variable is set to the default collation for the utf8mb4 character set. The value of the variable is replicated from a master to a slave so that the slave can correctly process data originating from a master with a different default collation for utf8mb4. This variable is primarily intended to support replication from a MySQL 5.7 or older master server to a MySQL 8.0 slave server, or group replication with a MySQL 5.7 primary node and one or more MySQL 8.0 secondaries. The default collation for utf8mb4 in MySQL 5.7 is utf8mb4_general_ci, but utf8mb4_0900_ai_ci in MySQL 8.0. The variable is not present in releases earlier than MySQL 8.0, so if the slave does not receive a value for the variable, it assumes the master is from an earlier release and sets the value to the previous default collation utf8mb4_general_ci.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

The default utf8mb4 collation is used in the following statements:

- SHOW COLLATION and SHOW CHARACTER SET.
- CREATE TABLE and ALTER TABLE having a CHARACTER SET utf8mb4 clause without a COLLATION clause, either for the table character set or for a column character set.
- CREATE DATABASE and ALTER DATABASE having a CHARACTER SET utf8mb4 clause without a COLLATION clause.
- Any statement containing a string literal of the form _utf8mb4'some text' without a COLLATE clause.
- default_password_lifetime

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--default-password-lifetime=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>default_password_lifetime</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>
This variable defines the global automatic password expiration policy. The default `default_password_lifetime` value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer \( N \), it indicates the permitted password lifetime; passwords must be changed every \( N \) days.

The global password expiration policy can be overridden as desired for individual accounts using the password expiration option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, "Password Management".

- `default_storage_engine`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--default-storage-engine=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>default_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_table_encryption`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--default-table-encryption={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>default_table_encryption</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Defines the default encryption setting applied to schemas and general tablespaces when they are created without specifying an `ENCRYPTION` clause.

The `default_table_encryption` variable is only applicable to user-created schemas and general tablespaces. It does not govern encryption of the `mysql` system tablespace.
Setting the runtime value of `default_table_encryption` requires the `SYSTEM_VARIABLES_ADMIN` and `TABLE_ENCRYPTION_ADMIN` privileges, or the `SUPER` privilege.

`default_table_encryption` supports `SET PERSIST` and `SET PERSIST_ONLY` syntax. See Section 5.1.9.3, “Persisted System Variables”. For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

- `default_tmp_storage_engine`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--default-tmp-storage-engine=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>default_tmp_storage_engine</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_week_format`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--default-week-format=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>default_week_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default mode value to use for the `WEEK()` function. See Section 12.7, “Date and Time Functions”.

- `delay_key_write`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--delay-key-write=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>delay_key_write</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
This variable specifies how to use delayed key writes. It applies only to **MyISAM** tables. Delayed key writing causes key buffers not to be flushed between writes. See also [Section 16.2.1, “MyISAM Startup Options”](#).

This variable can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>OFF</code></td>
<td><code>DELAY_KEY_WRITE</code> is ignored.</td>
</tr>
<tr>
<td><code>ON</code></td>
<td>MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.</td>
</tr>
<tr>
<td><code>ALL</code></td>
<td>All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.</td>
</tr>
</tbody>
</table>

**Note**

If you set this variable to `ALL`, you should not use **MyISAM** tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all **MyISAM** tables by starting the server with the `--myisam-recover-options` option (for example, `--myisam-recover-options=BACKUP,FORCE`). See [Section 5.1.7, “Server Command Options”](#), and [Section 16.2.1, “MyISAM Startup Options”](#).

**Warning**

If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>

</tbody>
</table>
This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- **disabled_storage_engines**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--disabled-storage-engines=engine[,engine]...</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>disabled_storage_engines</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty_string</td>
</tr>
</tbody>
</table>

This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new `MyISAM` or `FEDERATED` tables from being created, start the server with these lines in the server option file:

```
[mysqld]
disabled_storage_engines="MyISAM,FEDERATED"
```

By default, `disabled_storage_engines` is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an `ER_DISABLED_STORAGE_ENGINE` error.

disabled_storage_engines does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

It is permitted to set the `default_storage_engine` or `default_tmp_storage_engine` system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

`disabled_storage_engines` is disabled and has no effect if the server is started with any of these options: `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

Note

Setting `disabled_storage_engines` might cause an issue with `mysql_upgrade`. For details, see Section 4.4.5, "mysql_upgrade — Check and Upgrade MySQL Tables".

- **disconnect_on_expired_password**

<table>
<thead>
<tr>

### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>disconnect_on_expired_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expires passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.

- If the client does not indicate that it can handle expires passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
  - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
  - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see Section 6.2.16, “Server Handling of Expired Passwords”.

- `div_precision_increment`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--div-precision-increment=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>div_precision_increment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>30</td>
</tr>
</tbody>
</table>

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```sql
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
```
Server System Variables

### dragnet.log_error_filter_rules

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--dragnet.log-error-filter-rules=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>dragnet.log_error_filter_rules</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>IF prio&gt;=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.</code></td>
</tr>
</tbody>
</table>

The filter rules that control operation of the `log_filter_dragnet` error log filter component. If `log_filter_dragnet` is not installed, `dragnet.log_error_filter_rules` is unavailable. If `log_filter_dragnet` is installed but not enabled, changes to `dragnet.log_error_filter_rules` have no effect.

As of MySQL 8.0.12, the `dragnet.Status` status variable can be consulted to determine the result of the most recent assignment to `dragnet.log_error_filter_rules`.

Prior to MySQL 8.0.12, successful assignments to `dragnet.log_error_filter_rules` at runtime produce a note confirming the new value:

```sql
mysql> SET GLOBAL dragnet.log_error_filter_rules = 'IF prio <> 0 THEN unset prio."
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
************** 1. row **************
Level: Note
Code: 4569
Message: filter configuration accepted:
  SET @@GLOBAL.dragnet.log_error_filter_rules=
    'IF prio!=ERROR THEN unset prio.';
```

The value displayed by `SHOW WARNINGS` indicates the "decompiled" canonical representation after the rule set has been successfully parsed and compiled into internal form. Semantically, this canonical form is identical to the value assigned to `dragnet.log_error_filter_rules`, but there may be some differences between the assigned and canonical values, as illustrated by the preceding example:

- The `<>` operator is changed to `!=`.
- The numeric priority of 0 is changed to the corresponding priority symbol `ERROR`.
- Optional spaces are removed.

For additional information, see Section 5.4.2.3, “Types of Error Log Filtering”, and Section 5.5.3, “Error Log Components”.
• **end_markers_in_json**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--end-markers-in-json[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>end_markers_in_json</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether optimizer JSON output should add end markers. See MySQL Internals: The end_markers_in_json System Variable.

• **eq_range_index_dive_limit**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--eq-range-index-dive-limit=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>eq_range_index_dive_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up col_name values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains $N$ equality ranges. The optimizer can make row estimates using index dives or index statistics. If eq_range_index_dive_limit is greater than 0, the optimizer uses existing index statistics instead of index dives if there are eq_range_index_dive_limit or more equality ranges. Thus, to permit use of index dives for up to $N$ equality ranges, set eq_range_index_dive_limit to $N + 1$. To disable use of index statistics and always use index dives regardless of $N$, set eq_range_index_dive_limit to 0.

For more information, see Equality Range Optimization of Many-Valued Comparisons.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

• **error_count**
Server System Variables

The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.6.17, “SHOW ERRORS Syntax”.

• event_scheduler

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--event-scheduler[=value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>event_scheduler</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value (<code>&gt;= 8.0.3</code>)</td>
<td>ON</td>
</tr>
<tr>
<td>Default Value (<code>&lt;= 8.0.2</code>)</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, DISABLED</td>
</tr>
</tbody>
</table>

This variable indicates the status of the Event Scheduler; possible values are ON, OFF, and DISABLED, with the default being ON. This variable and its effects on the Event Scheduler’s operation are discussed in greater detail in the Overview section of the Events chapter.

• explicit_defaults_for_timestamp

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--explicit-defaults-for-timestamp[={OFF</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>explicit_defaults_for_timestamp</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (<code>&gt;= 8.0.2</code>)</td>
<td>ON</td>
</tr>
<tr>
<td>Default Value (<code>&lt;= 8.0.1</code>)</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This system variable determines whether the server enables certain nonstandard behaviors for default values and NULL-value handling in `TIMESTAMP` columns. By default, `explicit_defaults_for_timestamp` is enabled, which disables the nonstandard behaviors. Disabling `explicit_defaults_for_timestamp` results in a warning.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:
• **TIMESTAMP** columns not explicitly declared with the **NULL** attribute are automatically declared with the **NOT NULL** attribute. Assigning such a column a value of **NULL** is permitted and sets the column to the current timestamp.

• The first **TIMESTAMP** column in a table, if not explicitly declared with the **NULL** attribute or an explicit **DEFAULT** or **ON UPDATE** attribute, is automatically declared with the **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** attributes.

• **TIMESTAMP** columns following the first one, if not explicitly declared with the **NULL** attribute or an explicit **DEFAULT** attribute, are automatically declared as **DEFAULT '0000-00-00 00:00:00'** (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned **'0000-00-00 00:00:00'** and no warning occurs.

Depending on whether strict SQL mode or the **NO_ZERO_DATE** SQL mode is enabled, a default value of **'0000-00-00 00:00:00'** may be invalid. Be aware that the **TRADITIONAL** SQL mode includes strict mode and **NO_ZERO_DATE**. See Section 5.1.11, “Server SQL Modes”.

The nonstandard behaviors just described are deprecated and will be removed in a future MySQL release.

If **explicit_defaults_for_timestamp** is enabled, the server disables the nonstandard behaviors and handles **TIMESTAMP** columns as follows:

• It is not possible to assign a **TIMESTAMP** column a value of **NULL** to set it to the current timestamp. To assign the current timestamp, set the column to **CURRENT_TIMESTAMP** or a synonym such as **NOW()**.

• **TIMESTAMP** columns not explicitly declared with the **NOT NULL** attribute are automatically declared with the **NULL** attribute and permit **NULL** values. Assigning such a column a value of **NULL** sets it to **NULL**, not the current timestamp.

• **TIMESTAMP** columns declared with the **NOT NULL** attribute do not permit **NULL** values. For inserts that specify **NULL** for such a column, the result is either an error for a single-row insert or if strict SQL mode is enabled, or **'0000-00-00 00:00:00'** is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of **NULL** set it to the current timestamp.

• **TIMESTAMP** columns explicitly declared with the **NOT NULL** attribute and without an explicit **DEFAULT** attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of **'0000-00-00 00:00:00'** and a warning occurs. This is similar to how MySQL treats other temporal types such as **DATETIME**.

• No **TIMESTAMP** column is automatically declared with the **DEFAULT CURRENT_TIMESTAMP** or **ON UPDATE CURRENT_TIMESTAMP** attributes. Those attributes must be explicitly specified.

• The first **TIMESTAMP** column in a table is not handled differently from **TIMESTAMP** columns following the first one.

If **explicit_defaults_for_timestamp** is disabled at server startup, this warning appears in the error log:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see documentation for more details).
```
As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup.

**Note**

*explicit_defaults_for_timestamp* is itself deprecated because its only purpose is to permit control over deprecated *TIMESTAMP* behaviors that are to be removed in a future MySQL release. When removal of those behaviors occurs, *explicit_defaults_for_timestamp* will have no purpose and will be removed as well.

For additional information, see Section 11.3.4, “Automatic Initialization and Updating for *TIMESTAMP* and *DATETIME*”.

- **external_user**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>external_user</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is NULL. See Section 6.2.18, “Proxy Users”.

- **flush**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--flush={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

If **ON**, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”. This variable is set to **ON** if you start `mysqld` with the `--flush` option.

**Note**

If **flush** is enabled, the value of **flush_time** does not matter and changes to **flush_time** have no effect on flush behavior.

- **flush_time**
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--flush-time=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>flush_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

**Note**

If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- **foreign_key_checks**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>foreign_key_checks</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”.

Setting this variable has the same effect on `NDB` tables as it does for `InnoDB` tables. Typically you leave this setting enabled during normal operation, to enforce referential integrity. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”.

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

**Note**

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` will not be verified for consistency.
Dropping an index required by a foreign key constraint is not permitted, even with `foreign_keyChecks=0`. The foreign key constraint must be removed before dropping the index.

- **ft_boolean_syntax**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ft-boolean-syntax=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ft_boolean_syntax</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>`+ -&gt;&lt;()~*:&quot;&amp;</td>
</tr>
</tbody>
</table>

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 12.9.2, “Boolean Full-Text Searches”.

The default variable value is `'+ -><()~*:"&|'`. The rules for changing the value are as follows:

- Operator value is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `:, &`, and `|`) are reserved for future extensions.

- **ft_max_word_len**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ft-max-word-len=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ft_max_word_len</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

The maximum length of the word to be included in a MyISAM FULLTEXT index.

**Note**

FULLTEXT indexes on MyISAM tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.  

---
### ft_min_word_len

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ft-min-word-len=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ft_min_word_len</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The minimum length of the word to be included in a MyISAM FULLTEXT index.

**Note**

FULLTEXT indexes on MyISAM tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

### ft_query_expansion_limit

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ft-query-expansion-limit=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ft_query_expansion_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

The number of top matches to use for full-text searches performed using WITH QUERY EXPANSION.

### ft_stopword_file

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ft-stopword-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ft_stopword_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The file from which to read the list of stopwords for full-text searches on MyISAM tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory.
All the words from the file are used; comments are not honored. By default, a built-in list of stopwords is used (as defined in the storage/myisam/ft_static.c file). Setting this variable to the empty string ('') disables stopword filtering. See also Section 12.9.4, “Full-Text Stopwords”.

**Note**

FULLTEXT indexes on MyISAM tables must be rebuilt after changing this variable or the contents of the stopword file. Use REPAIR TABLE tbl_name QUICK.

- **general_log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--general-log[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>general_log</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>

<td>OFF</td>
</tr>
</tbody>
</table>

Whether the general query log is enabled. The value can be 0 (or OFF) to disable the log or 1 (or ON) to enable the log. The default value depends on whether the --general_log option is given. The destination for log output is controlled by the log_output system variable; if that value is NONE, no log entries are written even if the log is enabled.

- **general_log_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--general-log-file=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>general_log_file</td>
</tr>
<tr>
<td>Scope</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- **have_compress**
  - YES if the `zlib` compression library is available to the server, NO if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- **have_crypt**
  - This system variable was removed in MySQL 8.0.3.

- **have_dynamic_loading**
  - YES if `mysqld` supports dynamic loading of plugins, NO if not. If the value is NO, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- **have_geometry**
  - YES if the server supports spatial data types, NO if not.

- **have_openssl**
  - This variable is an alias for `have_ssl`.

- **have_profiling**
  - YES if statement profiling capability is present, NO if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See Section 13.7.6.31, “SHOW PROFILES Syntax”.
  - This variable is deprecated and will be removed in a future MySQL release.

- **have_query_cache**
  - The query cache was removed in MySQL 8.0.3. `have_query_cache` is deprecated, always has a value of NO, and will be removed in a future MySQL release.

- **have_rtree_keys**
  - YES if `RTREE` indexes are available, NO if not. (These are used for spatial indexes in `MyISAM` tables.)

- **have_ssl**
  - YES if `mysqld` supports SSL connections, NO if not. DISABLED indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see Section 6.3.4, “Building MySQL with Support for Encrypted Connections”.

754
• **have_statement_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Whether the statement execution timeout feature is available (see [Statement Execution Time Optimizer Hints](#)). The value can be **NO** if the background thread used by this feature could not be initialized.

• **have_symlink**

**YES** if symbolic link support is enabled, **NO** if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If the server is started with the `--skip-symbolic-links` option, the value is **DISABLED**.

This variable has no meaning on Windows.

**Note**

Symbolic link support, along with the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default. The related `have_symlink` system variable also is deprecated and will be removed in a future version of MySQL.

• **histogram_generation_max_mem_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--histogram-generation-max-mem-size=#</code></td>

</tr>
</tbody>
</table>

The maximum amount of memory available for generating histogram statistics. See [Section 8.9.6, “Optimizer Statistics”](#), and [Section 13.7.3.1, “ANALYZE TABLE Syntax”](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 5.1.9.1, “System Variable Privileges”](#).
Server System Variables

- **host_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--host-cache-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>host_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65536</td>
</tr>
</tbody>
</table>

This variable controls the size of the host cache, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. Setting the size to 0 disables the host cache. Changing the cache size at runtime causes an implicit `FLUSH HOSTS` operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

The default value is autosized to 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0 at runtime.

For more information about how the host cache works, see Section 8.12.4.2, "DNS Lookup Optimization and the Host Cache".

- **hostname**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>hostname</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The server sets this variable to the server host name at startup.

- **identity**

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- **init_connect**
**Server System Variables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--init-connect=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>init_connect</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters.

For users that have the `CONNECTION_ADMIN` or `SUPER` privilege, the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `CONNECTION_ADMIN` or `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

As of MySQL 8.0.5, `init_connect` execution is skipped for any client user with an expired password. This is done because such a user cannot execute arbitrary statements, and thus `init_connect` execution will fail, leaving the client unable to connect. Skipping `init_connect` execution enables the user to connect and change password.

The server discards any result sets produced by statements in the value of `init_connect`.

- **information_schema_stats_expiry**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--information-schema-stats-expiry=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>information_schema_stats_expiry</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>86400</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

Some `INFORMATION_SCHEMA` tables contain columns that provide table statistics:

- `STATISTICS/Cardinality`
- `TABLES/Auto_Increment`
- `TABLES/Avg_Row_Length`
- `TABLES/Checksum`
- `TABLES/Check_Time`
- `TABLES/Create_Time`
- `TABLES/Data_Free`
- `TABLES/Data_Length`
- `TABLES/Index_Length`
Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the `mysql.index_stats` and `mysql.table_stats` dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the `mysql.index_stats` and `mysql.table_stats` dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire.

The `information_schema_stats_expiry` session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use `ANALYZE TABLE`.

To always retrieve the latest statistics directly from the storage engine and bypass cached values, set `information_schema_stats_expiry` to 0.

Querying statistics columns does not store or update statistics in the `mysql.index_stats` and `mysql.table_stats` dictionary tables under these circumstances:

- When cached statistics have not expired.
- When `information_schema_stats_expiry` is set to 0.
- When the server is started in `read_only`, `super_read_only`, `transaction_read_only`, or `innodb_read_only` mode.
- When the query also fetches Performance Schema data.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

For related information, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

- `init_file`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--init-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>init_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must
be on a single line and should not include comments. For more information, see the description of `--init-file`.

- **innodb_xxx**

  InnoDB system variables are listed in Section 15.13, “InnoDB Startup Options and System Variables”. These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- **insert_id**

  The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- **interactive_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--interactive-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>interactive_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

  The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- **internal_tmp_disk_storage_engine**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--internal-tmp-disk-storage-engine=#</code></td>
</tr>
<tr>
<td>Removed</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>internal_tmp_disk_storage_engine</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>INNODB</td>
</tr>
<tr>
<td>Valid Values</td>
<td>MYISAM, INNODB</td>
</tr>
</tbody>
</table>
Important

In MySQL 8.0.16 and later, on-disk internal temporary tables always use the InnoDB storage engine; as of MySQL 8.0.16, this variable has been removed and is thus no longer supported.

Prior to MySQL 8.0.16, this variable determines the storage engine used for on-disk internal temporary tables (see Storage Engine for On-Disk Internal Temporary Tables). Permitted values are MYISAM and INNODB (the default).

- `internal_tmp_mem_storage_engine`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--internal-tmp-mem-storage-engine=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>internal_tmp_mem_storage_engine</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>TempTable</td>
</tr>
<tr>
<td>Valid Values</td>
<td>TempTable</td>
</tr>
<tr>
<td></td>
<td>MEMORY</td>
</tr>
</tbody>
</table>

The storage engine for in-memory internal temporary tables (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Permitted values are `TempTable` (the default) and `MEMORY`.

The optimizer uses the storage engine defined by `internal_tmp_mem_storage_engine` for in-memory internal temporary tables.

- `join_buffer_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--join-buffer-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>join_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>128</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td><code>18446744073709547520</code></td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless Batched Key Access (BKA) is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB−1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB−1 with a warning).

For additional information about join buffering, see Section 8.2.1.6, “Nested-Loop Join Algorithms”. For information about Batched Key Access, see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.

- `keep_files_on_create`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--keep-files-on-create[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keep_files_on_create</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to ON (1), in which case MyISAM will not overwrite existing files and returns an error instead. The default value is OFF (0).

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`
Index blocks for MyISAM tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` is 4GB−1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes: on a system whose primary function is to run MySQL using the MyISAM storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to MyISAM.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 8.2.5.1, “Optimizing INSERT Statements”.

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 13.7.6, “SHOW Syntax”.) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

\[1 - \left( \frac{\text{Key_blocks_unused} \times \text{key_cache_block_size}}{\text{key_buffer_size}} \right)\]
This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks result in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_age_threshold**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--key-cache-age-threshold=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>key_cache_age_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

  This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_block_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--key-cache-block-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>key_cache_block_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>512</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

  The size in bytes of blocks in the key cache. The default value is 1024. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_division_limit**
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--key-cache-division-limit=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>key_cache_division_limit</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>

</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
</tbody>
</table>

Whether `mysqld` was compiled with options for large file support.

- **large_pages**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--large-pages[=OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>large_pages</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Platform Specific</strong></td>
<td>Linux</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether large page support is enabled (via the `--large-pages` option). See Section 8.12.3.2, “Enabling Large Page Support”.

- **large_page_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>large_page_size</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
</tbody>
</table>
If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See Section 8.12.3.2, “Enabling Large Page Support”.

- **last_insert_id**

  The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- **lc_messages**

  The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See Section 10.11, “Setting the Error Message Language”.

- **lc_messages_dir**

  The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See Section 10.11, “Setting the Error Message Language”.

- **lc_time_names**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lc-time-names=value</td>
</tr>
<tr>
<td>System Variable</td>
<td>lc_time_names</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting. For further information, see Section 10.15, "MySQL Server Locale Support".

- `license`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>license</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>GPL</td>
</tr>
</tbody>
</table>

The type of license the server has.

- `local_infile`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--local-infile=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>local_infile</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td>OFF</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls server-side LOCAL capability for `LOAD DATA` statements. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that have `LOCAL` enabled on the client side.

To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled, respectively. `local_infile` can also be set at runtime. For more information, see Section 6.1.6, "Security Issues with `LOAD DATA LOCAL`".
### lock_wait_timeout

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lock-wait-timeout=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>lock_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` also defines the amount of time that a `LOCK INSTANCE FOR BACKUP` statement waits for a lock before giving up.

### locked_in_memory

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>locked_in_memory</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

Whether `mysqld` was locked in memory with `--memlock`.

### log_error

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-error[=file_name]</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_error</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>

Whether `mysqld` was locked in memory with `--memlock`. 
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The default error log destination. If the destination is the console, the value is `stderr`. Otherwise, the destination is a file and the `log_error` value is the file name. See Section 5.4.2, “The Error Log”.

- **log_error_filter_rules**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-error-filter-rules=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>Removed</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_error_filter_rules</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>set by server</code></td>
</tr>
</tbody>
</table>

The filter rules for error logging. This variable is unused. It was removed in MySQL 8.0.4.

- **log_error_services**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-error-services=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_error_services</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>log_filter_internal; log_sink_internal</code></td>
</tr>
</tbody>
</table>

The components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed. Any loadable (not built in) component named in the `log_error_services` value must first be installed with `INSTALL COMPONENT`. For more information, see Section 5.4.2.1, “Error Log Component Configuration”.

- **log_error_suppression_list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-error-suppression-list=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
</tbody>
</table>
The \texttt{log_error_suppression_list} system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of \texttt{WARNING} or \texttt{INFORMATION}. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. This variable affects filtering performed by the \texttt{log_filter_internal} error log filter component, which is enabled by default (see Section 5.5.3, “Error Log Components”). If \texttt{log_filter_internal} is disabled, \texttt{log_error_suppression_list} has no effect.

The \texttt{log_error_suppression_list} value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the \texttt{MY-} prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

\begin{verbatim}
ER_SERVER_SHUTDOWN_COMPLETE
MY-000031
000031
MY-31
31
\end{verbatim}

Symbolic values are preferable to numeric values for readability and portability. For information about the permitted error symbols and numbers, see Section B.3, “Error Message Reference”.

The effect of \texttt{log_error_suppression_list} combines with that of \texttt{log_error_verbosity}. For additional information, see Section 5.4.2.4, “Priority-Based Error Log Filtering (log_filter_internal)”.

- \texttt{log_error_verbosity}
The `log_error_verbosity` system variable specifies the verbosity for handling events intended for the error log. This variable affects filtering performed by the `log_filter_internal` error log filter component, which is enabled by default (see Section 5.5.3, “Error Log Components”). If `log_filter_internal` is disabled, `log_error_verbosity` has no effect.

Events intended for the error log have a priority of `ERROR`, `WARNING`, or `INFORMATION`. `log_error_verbosity` controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

<table>
<thead>
<tr>
<th>Permitted Message Priorities</th>
<th>log_error_verbosity Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR</td>
<td>1</td>
</tr>
<tr>
<td>ERROR, WARNING</td>
<td>2</td>
</tr>
<tr>
<td>ERROR, WARNING, INFORMATION</td>
<td>3</td>
</tr>
</tbody>
</table>

There is also a priority of `SYSTEM`. System messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. For additional information, see Section 5.4.2.4, “Priority-Based Error Log Filtering (log_filter_internal)”.

- `log_output`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-output=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_output</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TABLE</code>, <code>FILE</code>, <code>NONE</code></td>
</tr>
</tbody>
</table>

The destination or destinations for general query log and slow query log output. The value is a list one or more comma-separated words chosen from `TABLE`, `FILE`, and `NONE`. `TABLE` selects logging to the `general_log` and `slow_log` tables in the `mysql` system database. `FILE` selects logging to log files. `NONE` disables logging. If `NONE` is present in the value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select both log output destinations.

This variable selects log output destinations, but does not enable log output. To do that, enable the `general_log` and `slow_query_log` system variables. For `FILE` logging, the `general_log_file` and `slow_query_log_file` system variables determine the log file locations. For more information, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”.

- `log_queries_not_using_indexes`
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-queries-not-using-indexes[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_queries_not_using_indexes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether queries that do not use indexes are logged to the slow query log. See Section 5.4.5, “The Slow Query Log”.

- **`log_slow_admin_statements`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-slow-admin-statements[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_slow_admin_statements</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- **`log_slow_extra`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-slow-extra[={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_slow_extra</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If the slow query log is enabled and the output destination includes `FILE`, the server writes additional fields to log file lines that provide information about slow statements. See Section 5.4.5, “The Slow Query Log”. `TABLE` output is unaffected.

- **`log_syslog`**
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-syslog=[{OFF</td>
</tr>
<tr>
<td>Deprecated</td>
<td>8.0.2 (removed in 8.0.13)</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_syslog</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (Windows, &lt;= 8.0.1)</td>
<td>ON</td>
</tr>
<tr>
<td>Default Value (Unix, &lt;= 8.0.1)</td>
<td>OFF</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td>ON (when error logging to system log is enabled)</td>
</tr>
</tbody>
</table>

Prior to MySQL 8.0, this variable controlled whether to perform error logging to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

In MySQL 8.0, the `log_sink_sysseventlog` log component implements error logging to the system log (see Section 5.4.2.7, “Error Logging to the System Log”), so this type of logging can be enabled by adding that component to the `log_error_services` system variable. `log_syslog` is removed. (Prior to MySQL 8.0.13, `log_syslog` exists but is deprecated and has no effect.)

- `log_syslog_facility`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-syslog-facility=value</code></td>
</tr>
<tr>
<td>Removed</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_syslog_facility</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>daemon</code></td>
</tr>
</tbody>
</table>

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.facility`.

- `log_syslog_include_pid`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-syslog-include-pid=[{OFF</td>
</tr>
<tr>
<td>Removed</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_syslog_include_pid</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.include_pid`.

- **log_syslog_tag**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-syslog-tag=tag</code></td>
</tr>
<tr>
<td>Removed</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_syslog_tag</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>empty string</code></td>
</tr>
</tbody>
</table>

This variable was removed in MySQL 8.0.13 and replaced by `syseventlog.tag`.

- **log_timestamps**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-timestamps=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_timestamps</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>UTC</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>UTC</code></td>
</tr>
<tr>
<td></td>
<td><code>SYSTEM</code></td>
</tr>
</tbody>
</table>

This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDTh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

- **log_throttle_queries_not_using_indexes**
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-throttle-queries-not-using-indexes=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_throttle_queries_not_using_indexes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see Section 5.4.5, “The Slow Query Log”.

- **log_warnings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-warnings[=#]</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_warnings</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.3. Use the `log_error_verbosity` system variable instead.

- **long_query_time**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--long-query-time=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>long_query_time</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the `Slow_query_log` is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. See Section 5.4.5, “The Slow Query Log”.

- **low_priority_updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--low-priority-updates[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>low_priority_updates</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- **lower_case_file_system**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>lower_case_file_system</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case-sensitive, `ON` means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- **lower_case_table_names**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lower-case-table-names[=#]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>lower_case_table_names</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>2</td>
</tr>
</tbody>
</table>

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see Section 9.2.2, "Identifier Case Sensitivity".

On Windows the default value is 1. On macOS, the default value is 2. On Linux, a value of 2 is not supported; the server forces the value to 0 instead.

You should not set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` letter case. With MyISAM, accessing table names using different letter cases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable affects the behavior of replication filtering options with regard to case sensitivity. For more information, see Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are based on the setting defined when the server is initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

• **mandatory_roles**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--mandatory-roles=value</code></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.2</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>mandatory_roles</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>empty string</code></td>
</tr>
</tbody>
</table>

Roles the server should treat as mandatory. In effect, these roles are automatically granted to every user, although setting `mandatory_roles` does not actually change any user accounts, and the granted roles are not visible in the `mysql.role_edges` system table.
Server System Variables

The variable value is a comma-separated list of role names. Example:

```
SET PERSIST mandatory_roles = '`role1`@`%`,`role2',role3,role4@localhost';
```

Setting the runtime value of `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege normally required to set a global system variable runtime value.

Role names consist of a user part and host part in `user_name@host_name` format. The host part, if omitted, defaults to `%`. For additional information, see Section 6.2.5, “Specifying Role Names”.

The `mandatory_roles` value is a string, so user names and host names, if quoted, must be written in a fashion permitted for quoting within quoted strings.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see Activating Roles). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled; otherwise, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles that do not exist when assigned to `mandatory_roles` but are created later may require special treatment to be considered mandatory. For details, see Defining Mandatory Roles.

`SHOW GRANTS` displays mandatory roles according to the rules described in Section 13.7.6.21, “SHOW GRANTS Syntax”.

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-allowed-packet=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_allowed_packet</code></td>
</tr>
<tr>

<td>67108864</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.2)</td>
<td>4194304</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>
```
The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 64MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server will not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- **max_connect_errors**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-connect-errors=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_connect_errors</code></td>

<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it. To flush the host cache, execute a `FLUSH HOSTS` statement, a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table, or a `mysqladmin flush-hosts` command.

For more information about how the host cache works, see Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”.
### max_connections

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-connections=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>max_connections</td>
</tr>

<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

### max_digest_length

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-digest-length=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>max_digest_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the `performance_schema_max_digest_length` system variable as a limit on the maximum length of digests that it stores. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see Section 26.10, “Performance Schema Statement Digests and Sampling”.

### `max_error_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-error-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_error_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.3)</td>
<td>1024</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.2)</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The maximum number of error, warning, and information messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

### `max_execution_time`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-execution-time=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_execution_time</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The execution timeout for SELECT statements, in milliseconds. If the value is 0, timeouts are not enabled.

**max_execution_time** applies as follows:

- The global `max_execution_time` value provides the default for the session value for new connections. The session value applies to SELECT executions executed within the session that include no `MAX_EXECUTION_TIME(N)` optimizer hint or for which `N` is 0.

- **max_execution_time** applies to read-only SELECT statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.

- **max_execution_time** is ignored for SELECT statements in stored programs.

### max_heap_table_size

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-heap-table-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_heap_table_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16777216</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>16384</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>1844674407370954752</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable sets the maximum size to which user-created MEMORY tables are permitted to grow. The value of the variable is used to calculate MEMORY table `MAX_ROWS` values. Setting this variable has no effect on any existing MEMORY table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing MEMORY tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”.

**max_heap_table_size** is not replicated. See Section 17.4.1.21, “Replication and MEMORY Tables”, and Section 17.4.1.38, “Replication and Variables”, for more information.

- **max_insert_delayed_threads**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_insert_delayed_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because DELAYED inserts are not supported), and will be removed in a future release.

- `max_join_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-join-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_join_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows. For more information, see Using Safe-Updates Mode (`--safe-updates`).

Setting this variable to a value other than 0 resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

- `max_length_for_sort_data`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-length-for-sort-data=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_length_for_sort_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (&gt;= 8.0.1)</td>
<td>4096</td>
</tr>
<tr>
<td>Default Value (8.0.0)</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>

</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>65536</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>3</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum value of the `points_per_circle` argument to the `ST_Buffer_Strategy()` function.

- `max_prepared_stmt_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-prepared-stmt-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_prepared_stmt_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16382</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- `max_seeks_for_key`
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-seeks-for-key=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_seeks_for_key</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>

<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 13.7.6.22, “SHOW INDEX Syntax”). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-sort-length=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_sort_length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>8388608</td>
</tr>
</tbody>
</table>

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for GROUP BY, ORDER BY, and DISTINCT operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see Section 8.2.1.15, “ORDER BY Optimization”

- `max_sp_recursion_depth`
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-sp-recursion-depth=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_sp_recursion_depth</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_tmp_tables`
  
  This system variable was removed in MySQL 8.0.3.

- `max_user_connections`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-user-connections=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_user_connections</code></td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.

- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE_USER` or `ALTER_USER` statement. See Section 6.2.20, “Setting Account Resource Limits”.

</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

### mecab_rc_file

<table>
<thead>

</tbody>
</table>

The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see Section 12.9.9, “MeCab Full-Text Parser Plugin”.

For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the [MeCab Documentation](https://google.github.io/MeCab/) on the Google Developers site.
### Server System Variables

<table>

</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.4.2.11, “The table is full”.

- **myisam_max_sort_file_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-max-sort-file-size=#</code></td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>myisam_max_sort_file_size</code></td>
</tr>
<tr>
<td>Scope</td>

<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>9223372036854775807</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>2147483648</td>
</tr>
</tbody>
</table>

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If MyISAM index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- **myisam_mmap_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-mmap-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>myisam_mmap_size</code></td>

<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>7</td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum amount of memory to use for memory mapping compressed MyISAM files. If many compressed MyISAM tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- **myisam_recover_options**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>myisam_recover_options</code></td>
</tr>
</tbody>
</table>
The value of the `--myisam-recover-options` option. See Section 5.1.7, "Server Command Options".

- **myisam_repair_threads**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-repair-threads=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>myisam_repair_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If this value is greater than 1, MyISAM table indexes are created in parallel (each index in its own thread) during the Repair by sorting process. The default value is 1.

**Note**

Multithreaded repair is still beta-quality code.

- **myisam_sort_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-sort-buffer-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>myisam_sort_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
The size of the buffer that is allocated when sorting MyISAM indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTERTABLE`.

- **myisam_stats_method**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-stats-method=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>myisam_stats_method</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>nulls_unequal</code></td>
</tr>
</tbody>
</table>
  | Valid Values                     | `nulls_equal
nulls_unequal
nulls_ignored` |

How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For `nulls_unequal`, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For `nulls_ignored`, NULL values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.8, “InnoDB and MyISAM Index Statistics Collection”.

- **myisam_use_mmap**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--myisam-use-mmap[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>myisam_use_mmap</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Use memory mapping for reading and writing MyISAM tables.
Server System Variables

- **mysql_native_password_proxy_users**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--mysql-native-password-proxy-users=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysql_native_password_proxy_users</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether the `mysql_native_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see Section 6.2.18, “Proxy Users”.

- **named_pipe**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--named-pipe=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>named_pipe</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>

<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

(Windows only.) Indicates whether the server supports connections over named pipes.

- **named_pipe_full_access_group**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--named-pipe-full-access-group=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>named_pipe_full_access_group</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><em>everyone</em></td>
</tr>
<tr>
<td>Valid Values</td>
<td><em>everyone</em></td>
</tr>
<tr>
<td>Valid Values</td>
<td>empty string</td>
</tr>
</tbody>
</table>
(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the `named_pipe` system variable is enabled to support named-pipe connections. Newer MySQL client software can open named pipe connections without any additional configuration, however, older client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use older named-pipe clients. Initially, the value is set to `'*everyone*'` by default, which permits users of the Everyone group on Windows to continue using older clients until the older clients are upgraded. In contrast, setting the value to an empty string means that no Windows user will be granted full access to the named pipe. The default value `'*everyone*'` provides a language-independent way of referring to the Everyone group on Windows.

Ideally, a new Windows local group name (for example, `mysql_old_client_users`) should be created in Windows and then used to replace the default value for this variable when access to older client software is absolutely necessary. In this case, limit the membership of the group to as few users as possible, removing users from the group when their client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the older named-pipe client is denied access until the user is added to the group by a Windows administrator, and then the user logs out and logs in (required by Windows).

- **net_buffer_length**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--net-buffer-length=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>net_buffer_length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16384</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- **net_read_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--net-read-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>net_read_timeout</code></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--net-retry-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>net_retry_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--net-write-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>net_write_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `new`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--new[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>new</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Disabled by</td>
<td><code>skip-new</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always `OFF`.

In NDB Cluster, setting this variable to `ON` makes it possible to employ partitioning types other than `KEY` or `LINEAR KEY` with NDB tables. This feature is experimental only, and not supported in production. For additional information, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- `ngram_token_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ngram-token-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ngram_token_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

Defines the n-gram token size for the n-gram full-text parser. The `ngram_token_size` option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see Section 12.9.8, “ngram Full-Text Parser”.

- `offline_mode`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--offline-mode[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>offline_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Whether the server is in “offline mode”, which has these characteristics:

- Connected client users who do not have the `CONNECTION_ADMIN` or `SUPER` privilege are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.

- Connected client users who have the `CONNECTION_ADMIN` or `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.

- Replication slave threads are permitted to keep applying data to the server.

Only users who have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can control offline mode. To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. In offline mode, clients that are refused access receive an `ER_SERVER_OFFLINE_MODE` error.

- `old`

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See Section 8.9.4, “Index Hints”.) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- `old_alter_table`

`old_alter_table`
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see Section 13.1.9, “ALTER TABLE Syntax”.

`ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted. In earlier releases, `ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` deletes data stored in the partition and drops the partition.

- **old_passwords**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--old-passwords=value</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.11)</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>old_passwords</code></td>
</tr>
<tr>

<tr>
<td>Default Value</td>
<td><code>5000, with possible adjustment</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td><code>platform dependent</code></td>
</tr>
</tbody>
</table>
The number of file descriptors available to `mysqld` from the operating system. `mysqld` reserves descriptors with `setrlimit()`, using the value requested at startup by setting this variable or the `--open-files-limit` option to `mysqld_safe`. You should try increasing the value of this variable if `mysqld` gives you the error `Too many open files`. Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.

The runtime variable value indicates the number of file descriptors actually permitted by the system and might differ from the value requested at startup. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

1) `10 + max_connections + (table_open_cache * 2)`
2) `max_connections * 5`
3) operating system limit if positive
4) if operating system limit is Infinity:
   - `open_files_limit` value specified at startup, 5000 if none

The server attempts to obtain the number of file descriptors using the maximum of those three values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system will permit.

The value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than `ulimit -n`.

- `optimizer_prune_level`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--optimizer-prune-level=#</code></td>
</tr>
<tr>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

<table>
<thead>
<tr>
<th>Property</th>

<td>62</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>62</td>
</tr>
</tbody>
</table>

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- **optimizer_switch**

<table>

The **optimizer_switch** system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge-on,index_merge_union-on,
                    index_merge_sort_union-on,
                    index_merge_intersection-on,
                    engine_condition_pushdown-on,
                    index_condition_pushdown-on,
                    mrr-on,mrr_cost_based-on,
                    block_nested_loop-on,batched_key_access-off,
                    materialization-on,semijoin-on,loosescan-on,
                    firstmatch-on,duplicateweedout-on,
                    subquery_materialization_cost_based-on,
                    use_index_extensions-on,
                    condition_fanout_filter-on,derived_merge-on,
                    use_invisible_indexes-off,skip_scan-on
```
For more information about the syntax of this variable and the optimizer behaviors that it controls, see Section 8.9.2, “Switchable Optimizations”.

- **optimizer_trace**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--optimizer-trace=value</td>
</tr>
<tr>
<td>System Variable</td>

</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1</td>
</tr>
</tbody>
</table>

The offset of optimizer traces to display. For details, see MySQL Internals: Tracing the Optimizer.

- **performance_schema_xxx**

Performance Schema system variables are listed in Section 26.15, “Performance Schema System Variables”. These variables may be used to configure Performance Schema operation.

- **parser_max_mem_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--parser-max-mem-size=#</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>parser_max_mem_size</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value ((64-bit platforms))</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Default Value ((32-bit platforms))</td>
<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10000000</td>
</tr>
</tbody>
</table>
### Server System Variables

#### Maximum Value (64-bit platforms)
- Value: 18446744073709551615

#### Maximum Value (32-bit platforms)
- Value: 4294967295

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

- **partial_revokes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--partial-revokes=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>partial_revokes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF (if partial revokes do not exist) ON (if partial revokes exist)</td>
</tr>
</tbody>
</table>

Enabling this variable makes it possible to revoke privileges partially. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. For example, a user who has the global `UPDATE` privilege can be restricted from exercising this privilege on the `mysql` system schema. (Or, stated another way, the user is enabled to exercise the `UPDATE` privilege on all schemas except the `mysql` schema.) In this sense, the user's global `UPDATE` privilege is partially revoked.

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.

- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` in this case, first modify each account that has partially revoked privileges, either by re-granting the privileges or by removing the account.

For more information, including instructions for removing partial revokes, see Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

- **password_history**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--password-history=#</code></td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>password_history</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling reuse of previous passwords based on required minimum number of password changes. For an account password used previously, this variable indicates the number of subsequent account password changes that must occur before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on number of password changes.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD HISTORY DEFAULT` option.

The global number-of-changes password reuse policy can be overridden as desired for individual accounts using the `PASSWORD HISTORY` option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.2.15, “Password Management”](#).

- **password_require_current**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--password-require-current[={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>password_require_current</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling whether attempts to change an account password must specify the current password to be replaced.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD REQUIRE CURRENT DEFAULT` option.

The global verification-required policy can be overridden as desired for individual accounts using the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements. See [Section 6.2.15, “Password Management”](#).

- **password_reuse_interval**
**Server System Variables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--password-reuse-interval=#</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.3</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>password_reuse_interval</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable defines the global policy for controlling reuse of previous passwords based on time elapsed. For an account password used previously, this variable indicates the number of days that must pass before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on time elapsed.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD_REUSE INTERVAL DEFAULT` option.

The global time-elapsed password reuse policy can be overridden as desired for individual accounts using the `PASSWORD_REUSE INTERVAL` option of the `CREATE USER` and `ALTER USER` statements. See Section 6.2.15, “Password Management”.

- **persisted_globals_load**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--persisted-globals-load[={OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>persisted_globals_load</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether to load persisted configuration settings from the `mysqld-auto.cnf` file in the data directory. The server normally processes this file at startup after all other option files (see Section 4.2.2.2, “Using Option Files”). Disabling `persisted_globals_load` causes the server startup sequence to skip `mysqld-auto.cnf`.

To modify the contents of `mysqld-auto.cnf`, use the `SET PERSIST`, `SET PERSIST_ONLY`, and `RESET PERSIST` statements. See Section 5.1.9.3, “Persisted System Variables”.

- **persist_only_admin_x509_subject**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--persist-only-admin-x509-subject=string</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>persis_only_admin_x509_subject</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty_string</td>
</tr>
</tbody>
</table>

**SET PERSIST** and **SET PERSIST ONLY** enable system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see Section 13.7.5.1, “SET Syntax for Variable Assignment”). Persisting system variables enables runtime configuration changes that affect subsequent server restarts, which is convenient for remote administration not requiring direct access to MySQL server host option files. However, some system variables are nonpersistible or can be persisted only under certain restrictive conditions.

The `persist_only_admin_x509_subject` system variable specifies the SSL certificate X.509 Subject value that users must have to be able to persist system variables that are persist-restricted. The default value is the empty string, which disables the Subject check so that persist-restricted system variables cannot be persisted by any user.

If `persist_only_admin_x509_subject` is nonempty, users who connect to the server using an encrypted connection and supply an SSL certificate with the designated Subject value then can use `SET PERSIST ONLY` to persist persist-restricted system variables. For information about persist-restricted system variables and instructions for configuring MySQL to enable `persist_only_admin_x509_subject`, see Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”.

- **pid_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--pid-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>pid_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the process ID file. This variable can be set with the `--pid-file` option. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify the `--pid-file` option, you must specify a value. If you do not specify the `--pid-file` option, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysql_safe` to determine the server’s process ID. On Windows, this variable also affects the default error log file name. See Section 5.4.2, “The Error Log”.

- **plugin_dir**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--plugin-dir=dir_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>plugin_dir</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>BASEDIR/lib/plugin</td>
</tr>
</tbody>
</table>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- **port**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--port=port_num</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>port</code></td>

<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>3306</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- **preload_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--preload-buffer-size=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>preload_buffer_size</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>32768</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1024</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>1073741824</td>
</tr>
</tbody>
</table>
The size of the buffer that is allocated when preloading indexes.

- **print_identified_with_as_hex**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--print-identified-with-as-hex=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>print_identified_with_as_hex</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Password hash values displayed in the `IDENTIFIED WITH` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling `print_identified_with_as_hex` causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

- **profiling**

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See Section 13.7.6.31, “SHOW PROFILES Syntax”.

This variable is deprecated and will be removed in a future MySQL release.

- **profiling_history_size**

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 13.7.6.31, “SHOW PROFILES Syntax”.

This variable is deprecated and will be removed in a future MySQL release.

- **protocol_compression_algorithms**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--protocol-compression-algorithms=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>protocol_compression_algorithms</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>zlib,zstd,uncompressed</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>zlib</code></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>zstd</td>
</tr>
<tr>
<td></td>
<td>uncompressed</td>
</tr>
</tbody>
</table>

The compression algorithms that the server permits for incoming connections. These include connections by client programs and by servers participating in master/slave replication or Group Replication. Compression does not apply to X Protocol connections or connections for FEDERATED tables.

The variable value is a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- **zlib**: Permit connections that use the `zlib` compression algorithm.
- **zstd**: Permit connections that use the `zstd` compression algorithm (zstd 1.3).
- **uncompressed**: Permit uncompressed connections. If this algorithm name is not included in the `protocol_compression_algorithms` value, the server does not permit uncompressed connections. It permits only compressed connections that use whichever other algorithms are specified in the value, and there is no fallback to uncompressed connections.

The default value of `zlib, zstd, uncompressed` indicates that the server permits all compression algorithms.

For more information, see Section 4.2.6, “Connection Compression Control”.

- **protocol_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>protocol_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The version of the client/server protocol used by the MySQL server.

- **proxy_user**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>proxy_user</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See Section 6.2.18, “Proxy Users”.

- **pseudo_slave_mode**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>pseudo_slave_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This variable is for internal server use.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

In MySQL 8.0.14 and later, `pseudo_slave_mode` has the following effects on the handling of a statement that sets one or more unsupported or unknown SQL modes:

- If true, the server ignores the unsupported mode and raises a warning.
- If false, the server rejects the statement with `ER_UNSUPPORTED_SQL_MODE`.

`mysqlbinlog` sets this variable to true prior to executing any other SQL.

- `pseudo_thread_id`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>pseudo_thread_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

This variable is for internal server use.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- `query_alloc_block_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--query-alloc-block-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>query_alloc_block_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- **query_cache_limit**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query-cache-limit=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td>System Variable</td>
<td>query_cache_limit</td>
</tr>
<tr>
<td>Scope</td>

<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.3.

• `query_cache_wlock_invalidate`
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--query-cache-wlock-invalidate[={OFF</td>
</tr>
<tr>
<td>** Deprecated**</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td>** System Variable**</td>
<td><code>query_cache_wlock_invalidate</code></td>
</tr>
<tr>
<td>** Scope**</td>
<td>Global, Session</td>
</tr>
<tr>
<td>** Dynamic**</td>
<td>Yes</td>
</tr>
<tr>
<td>** SET_VAR Hint Applies**</td>
<td>No</td>
</tr>
<tr>
<td>** Type**</td>
<td>Boolean</td>
</tr>
<tr>
<td>** Default Value**</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.3.

- `query_prealloc_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--query-prealloc-size=#</code></td>
</tr>
<tr>
<td>** System Variable**</td>
<td><code>query_prealloc_size</code></td>
</tr>
<tr>
<td>** Scope**</td>
<td>Global, Session</td>
</tr>
<tr>
<td>** Dynamic**</td>
<td>Yes</td>
</tr>
<tr>
<td>** SET_VAR Hint Applies**</td>
<td>No</td>
</tr>
<tr>
<td>** Type**</td>
<td>Integer</td>
</tr>
<tr>
<td>** Default Value**</td>
<td>8192</td>
</tr>
<tr>
<td>** Minimum Value**</td>
<td>8192</td>
</tr>
<tr>
<td>** Maximum Value**</td>
<td>18446744073709551615 (64-bit platforms)</td>
</tr>
<tr>
<td>** Maximum Value**</td>
<td>4294967295 (32-bit platforms)</td>
</tr>
<tr>
<td>** Block Size**</td>
<td>1024</td>
</tr>
</tbody>
</table>

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>** System Variable**</td>
<td><code>rand_seed1</code></td>
</tr>
<tr>
<td>** Scope**</td>
<td>Session</td>
</tr>
<tr>
<td>** Dynamic**</td>
<td>Yes</td>
</tr>
<tr>
<td>** SET_VAR Hint Applies**</td>
<td>No</td>
</tr>
<tr>
<td>** Type**</td>
<td>Integer</td>
</tr>
</tbody>
</table>
The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- **`rand_seed2`**
  See the description for `rand_seed1`.

- **`range_alloc_block_size`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--range-alloc-block-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>range_alloc_block_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

  The size of blocks that are allocated when doing range optimization.

- **`range_optimizer_max_mem_size`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--range-optimizer-max-mem-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>range_optimizer_max_mem_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

  The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the
amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see Limiting Memory Use for Range Optimization.

- **rbr_exec_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>rbr_exec_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>STRICT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IDEMPOTENT, STRICT</td>
</tr>
</tbody>
</table>

For internal use by `mysqlbinlog`. This variable switches the server between IDEMPOTENT mode and STRICT mode. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors in BINLOG statements generated by `mysqlbinlog`. This mode is useful when replaying a row-based binary log on a server that causes conflicts with existing data. `mysqlbinlog` sets this mode when you specify the --idempotent option by writing the following to the output:

```
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- **read_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--read-buffer-size=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>read_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>131072</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8200</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147479552</td>
</tr>
</tbody>
</table>

Each thread that does a sequential scan for a MyISAM table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for ORDER BY.
Server System Variables

- For bulk insert into partitions.
- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

For more information about memory use during different operations, see Section 8.12.3.1, “How MySQL Uses Memory”.

- `read_only`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--read-only={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>read_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

When the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` or `SUPER` privilege. This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`.
- Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by slave threads, if the server is a replication slave. In replication setups, it can be useful to enable `read_only` on slave servers to ensure that slaves accept updates only from the master server and not from clients.
- Writes to the system table `mysql.gtid_executed`, which stores GTIDs for executed transactions that are not present in the current binary log file.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replication slaves can be performed with `mysqlcheck --all-databases --analyze`.
- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”.

Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

`read_rnd_buffer_size` table:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--read-rnd-buffer-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>read_rnd_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

This variable is used for reads from MyISAM tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a MyISAM table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 8.2.1.15, “ORDER BY Optimization”. Setting the variable to a large value can improve ORDER BY performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see Section 8.12.3.1, “How MySQL Uses Memory”. For information about Multi-Range Read optimization, see Section 8.2.1.10, “Multi-Range Read Optimization”.

`regexp_stack_limit`
**Server System Variables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--regexp-stack-limit=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>regexp_stack_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The maximum available memory in bytes for the internal stack used for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see Section 12.5.2, "Regular Expressions").

- **regexp_time_limit**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--regexp-time-limit=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>regexp_time_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The time limit for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see Section 12.5.2, "Regular Expressions"). This limit is expressed as the maximum permitted number of steps performed by the match engine, and thus affects execution time only indirectly. Typically, it is on the order of milliseconds.

- **require_secure_transport**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--require-secure-transport=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>require_secure_transport</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
**require_secure_transport**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with `REQUIRE SSL`, enabling `require_secure_transport` does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable `require_secure_transport` at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an `ER_NO_SECURE_TRANSPORTS_CONFIGURED` error.

See also [Configuring Encrypted Connections as Mandatory](#).

* `resultset_metadata`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>resultset_metadata</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>FULL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FULL \n NONE</td>
</tr>
</tbody>
</table>

For connections for which metadata transfer is optional, the client sets the `resultset_metadata` system variable to control whether the server returns result set metadata. Permitted values are `FULL` (return all metadata; this is the default) and `NONE` (return no metadata).

For connections that are not metadata-optional, setting `resultset_metadata` to `NONE` produces an error.

For details about managing result set metadata transfer, see Section 28.7.27, “C API Optional Result Set Metadata”.

* `secondary_engine_cost_threshold`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>

<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>256</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>256</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>524288</td>
</tr>
</tbody>
</table>

Defines a limit for the number of schema definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused schema definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `schema_definition_cache`.

A setting of 0 means that schema definition objects are only kept in the dictionary object cache while they are in use.

For more information, see Section 14.4, "Dictionary Object Cache".

- `secure_auth`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--secure-auth[={OFF</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>secure_auth</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.3.

- **secure_file_priv**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--secure-file-priv=dir_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>secure_file_priv</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>platform specific</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>empty string, dirname, NULL</td>
</tr>
</tbody>
</table>

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server will not create it.
- If set to `NULL`, the server disables import and export operations.

The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR` CMake option.

<table>
<thead>
<tr>
<th><code>INSTALL_LAYOUT</code> Value</th>
<th>Default <code>secure_file_priv</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>STANDALONE, WIN</td>
<td>empty</td>
</tr>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td><code>/var/lib/mysql-files</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>mysql-files</code> under the <code>CMAKE_INSTALL_PREFIX</code> value</td>
</tr>
</tbody>
</table>

The server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.
### server_id

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--server-id=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>server_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.3)</td>
<td>1</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.2)</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Specifies the server ID. This variable is set by the `--server-id` option. The `server_id` system variable is set to 1 by default. The server can be started with this default ID, but when binary logging is enabled, an informational message is issued if you did not specify a server ID explicitly using the `--server-id` option.

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication master or slave. For additional information, see Section 17.1.6.2, "Replication Master Options and Variables", and Section 17.1.6.3, "Replication Slave Options and Variables".

If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

For more information, see Section 17.1.2.2, “Setting the Replication Slave Configuration”.

### session_track_gtids

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--session-track-gtids=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>session_track_gtids</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>OWN_GTID</td>
</tr>
<tr>
<td></td>
<td>ALL_GTIDS</td>
</tr>
</tbody>
</table>

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication master or slave. For additional information, see Section 17.1.6.2, "Replication Master Options and Variables", and Section 17.1.6.3, "Replication Slave Options and Variables".

If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

For more information, see Section 17.1.2.2, “Setting the Replication Slave Configuration”. 
Server System Variables

Controls whether the server tracks GTIDs within the current session and returns them to the client. Depending on the variable value, at the end of executing each transaction, the server GTIDs are captured by the tracker and returned to the client. These `session_track_gtid` values are permitted:

- **OFF**: The tracker collects no GTIDs. This is the default.
- **OWN_GTID**: The tracker collects GTIDs generated by successfully committed read/write transactions.
- **ALL_GTIDS**: The tracker collects all GTIDs in the `gtid_executed` system variable at the time the current transaction commits, regardless of whether the transaction is read/write or read only.

`session_track_gtid` cannot be set within transactional context.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- **session_track_schema**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--session-track-schema=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>session_track_schema</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- **session_track_state_change**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--session-track-state-change=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>session_track_state_change</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:
Server System Variables

- The default schema (database).
- Session-specific values for system variables.
- User-defined variables.
- Temporary tables.
- Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

**Note**
Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name listed in the value of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- `session_track_system_variables`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--session-track-system-variables=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>session_track_system_variables</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code></td>
</tr>
</tbody>
</table>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names.
To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- `session_track_transaction_info`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--session-track-transaction-info=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>session_track_transaction_info</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, STATE, CHARACTERISTICS</td>
</tr>
</tbody>
</table>

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These `session_track_transaction_info` values are permitted:

- **OFF**: Disable transaction state tracking. This is the default.

- **STATE**: Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.

- **CHARACTERISTICS**: Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

  - **ISOLATION LEVEL**
  - **READ ONLY**
  - **READ WRITE**
  - **WITH CONSISTENT SNAPSHOT**

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the `transaction_isolation` and `transaction_read_only` system variables to correctly determine the session defaults. (To track these variables, list them in the value of the `session_track_system_variables` system variable.)

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.
• **sha256_password_auto_generate_rsa_keys**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sha256-password-auto-generate-rsa-keys={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>sha256_password_auto_generate_rsa_keys</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable is available if the server was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). The server uses it to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin; see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

For more information about RSA file autogeneration, including file names and characteristics, see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

• **sha256_password_private_key_path**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sha256-password-private-key-path=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>sha256_password_private_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>private_key.pem</td>
</tr>
</tbody>
</table>

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

---

**Important**

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.
For information about `sha256_password`, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”.

- **`sha256_password_proxy_users`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--sha256-password-proxy-users=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sha256_password_proxy_users</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see Section 6.2.18, “Proxy Users”.

- **`sha256_password_public_key_path`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sha256-password-public-key-path=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sha256_password_public_key_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>public_key.pem</code></td>
</tr>
</tbody>
</table>

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including information about how clients specify the RSA public key, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”.

- **`shared_memory`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--shared-memory=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>shared_memory</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

For information about `shared_memory`, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”.

828
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

(Windows only.) Whether the server permits shared-memory connections.

#### shared_memory_base_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--shared-memory-base-name=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>shared_memory_base_name</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>MYSQL</td>
</tr>
</tbody>
</table>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is MYSQL. The name is case-sensitive.

This variable applies only if the server is started with the `shared_memory` system variable enabled to support shared-memory connections.

#### show_compatibility_56

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--show-compatibility-56[=OFF</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.1)</td>
</tr>
<tr>
<td>System Variable</td>
<td>show_compatibility_56</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable was used in the transition period during which system and status variable information in INFORMATION_SCHEMA tables was moved to Performance Schema tables. That transition period ended in MySQL 8.0.1, at which time this variable was removed. For advice on migrating away from the INFORMATION_SCHEMA tables to the Performance Schema tables, see Migrating to Performance Schema System and Status Variable Tables.

#### show_create_tableverbosity
## Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--show-create-table-verbosity[={OFF</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>show_create_table_verbosity</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

**SHOW CREATE TABLE** normally does not show the **ROW_FORMAT** table option if the row format is the default format. Enabling this variable causes **SHOW CREATE TABLE** to display **ROW_FORMAT** regardless of whether it is the default format.

- **show_old_temporals**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--show-old-temporals[={OFF</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>show_old_temporals</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether **SHOW CREATE TABLE** output includes comments to flag temporal columns found to be in pre-5.6.4 format (**TIME**, **DATETIME**, and **TIMESTAMP** columns without support for fractional seconds precision). This variable is disabled by default. If enabled, **SHOW CREATE TABLE** output looks like this:

```sql
CREATE TABLE `mytbl` (
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
  `t` time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=utf8mb4
```

Output for the **COLUMN_TYPE** column of the **INFORMATION_SCHEMA.COLUMNS** table is affected similarly.

This variable is deprecated and will be removed in a future MySQL release.

- **skip_external_locking**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--skip-external-locking[={OFF</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>skip_external_locking</code></td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This is **OFF** if `mysqld` uses external locking (system locking), **ON** if external locking is disabled. This affects only MyISAM table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, "External Locking".

• **skip_name_resolve**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--skip-name-resolve[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>skip_name_resolve</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable is set from the value of the `--skip-name-resolve` option. If it is **OFF**, `mysqld` resolves host names when checking client connections. If it is **ON**, `mysqld` uses only IP numbers; in this case, all Host column values in the grant tables must be IP addresses or localhost. See Section 8.12.4.2, "DNS Lookup Optimization and the Host Cache".

• **skip_networking**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-networking</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>skip_networking</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

This is **ON** if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to **ON** with the `--skip-networking` option.

• **skip_show_database**
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-show-database</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>skip_show_database</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is **ON**, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is **OFF**, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

![Caution]

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- **slow_launch_time**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slow-launch-time=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slow_launch_time</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
</tbody>
</table>

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- **slow_query_log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--slow-query-log[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slow_query_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See Section 5.4.5, “The Slow Query Log”.

- **slow_query_log_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slow-query-log-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slow_query_log_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>host_name-slow.log</code></td>
</tr>
</tbody>
</table>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- **socket**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--socket={file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>socket</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Other)</td>
<td><code>/tmp/mysql.sock</code></td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td><code>MySQL</code></td>
</tr>
</tbody>
</table>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- **sort_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sort-buffer-size=#</code></td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sort_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32768</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see Section 8.2.1.15, “ORDER BY Optimization”.

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.4.3.5, “Where MySQL Stores Temporary Files”.

The maximum permissible setting for `sort_buffer_size` is 4GB−1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB−1 with a warning).

- `sql_auto_is_null`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sql_auto_is_null</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```
If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.15, “Information Functions”. If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

Prior to MySQL 8.0.16, the transformation of `WHERE auto_col IS NULL` to `WHERE auto_col = LAST_INSERT_ID()` was performed only when the statement was executed, so that the value of `sql_auto_is_null` during execution determined whether the query was transformed. In MySQL 8.0.16 and later, the transformation is performed during statement preparation.

The default value of `sql_auto_is_null` is `OFF`.

- `sql_big_selects`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sql_big_selects</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ON</code></td>
</tr>
</tbody>
</table>

If set to `OFF`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `ON`, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to `OFF`.

- `sql_buffer_result`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sql_buffer_result</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is `OFF`.

- `sql_log_off`
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>sql_log_off</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>
| **Valid Values**        | OFF (enable logging)  
                          | ON (disable logging) |

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is OFF (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to ON or OFF.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- sql_mode

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--sql-mode=name</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>sql_mode</td>
</tr>
<tr>

</tbody>
</table>
The current server SQL mode, which can be set dynamically. For details, see Section 5.1.11, “Server SQL Modes”.

Note
MySQL installation programs may configure the SQL mode during the installation process.
If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- **sql_notes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_notes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If enabled (the default), diagnostics of Note level increment warning_count and the server records them. If disabled, Note diagnostics do not increment warning_count and the server does not record them. mysqldump includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- **sql_quote_show_create**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_quote_show_create</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If enabled (the default), the server quotes identifiers for SHOW CREATE TABLE and SHOW CREATE DATABASE statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.7.6.10, “SHOW CREATE TABLE Syntax”, and Section 13.7.6.6, “SHOW CREATE DATABASE Syntax”.

- **sql_require_primary_key**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sql-require-primary-key=[OFF</td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>sql_require_primary_key</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether statements that create new tables or alter the structure of existing tables enforce the requirement that tables have a primary key.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

Enabling this variable helps avoid performance problems in row-based replication that can occur when tables have no primary key. Suppose that a table has no primary key and an update or delete modifies multiple rows. On the master server, this operation can be performed using a single table scan but, when replicated using row-based replication, results in a table scan for each row to be modified on the slave. With a primary key, these table scans do not occur.

sql_require_primary_key applies to both base tables and TEMPORARY tables, and changes to its value are replicated to slave servers.

When enabled, sql_require_primary_key has these effects:

- Attempts to create a new table with no primary key fail with an error. This includes CREATE TABLE ... LIKE. It also includes CREATE TABLE ... SELECT, unless the CREATE TABLE part includes a primary key definition.

- Attempts to drop the primary key from an existing table fail with an error, with the exception that dropping the primary key and adding a primary key in the same ALTER TABLE statement is permitted.

  Dropping the primary key fails even if the table also contains a UNIQUE NOT NULL index.

- Attempts to import a table with no primary key fail with an error.

- sql_safe_updates

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_safe_updates</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, UPDATE and DELETE statements that do not use a key in the WHERE clause or a LIMIT clause produce an error. This makes it possible to catch UPDATE and DELETE statements
where keys are not used properly and that would probably change or delete a large number of rows. The
default value is OFF.

For the mysql client, sql_safe_updates can be enabled by using the --safe-updates option. For more information, see Using Safe-Updates Mode (--safe-updates).

• sql_select_limit

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_select_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The maximum number of rows to return from SELECT statements. For more information, see Using Safe-Updates Mode (--safe-updates).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are \((2^{32}) - 1\) or \((2^{64}) - 1\). If you have changed the limit, the default value can be restored by assigning a value of DEFAULT.

If a SELECT has a LIMIT clause, the LIMIT takes precedence over the value of sql_select_limit.

• sql_warnings

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_warnings</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether single-row INSERT statements produce an information string if warnings occur. The default is OFF. Set the value to ON to produce an information string.

• ssl_ca

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ssl-ca=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>ssl_ca</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (&lt;= 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>
The path to a file with a list of trusted SSL Certificate Authorities.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_capath**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ssl-capath=dir_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>ssl_capath</td>

</tr>
<tr>
<td>Dynamic (&lt;= 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to a directory that contains trusted SSL CA certificates in PEM format.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_cert**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ssl-cert=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>ssl_cert</td>

<tr>
<td>Dynamic (&gt;= 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (&lt;= 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name of the SSL certificate file to use for establishing secure connections.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **ssl_cipher**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ssl-cipher=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>ssl_cipher</td>

<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to a directory that contains files containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.3, “SSL Library-Dependent Capabilities”.

As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.
• **ssl_fips_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ssl-fips-mode={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ssl_fips_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>OFF</code> (or 0)</td>
</tr>
<tr>
<td></td>
<td><code>ON</code> (or 1)</td>
</tr>
<tr>
<td></td>
<td><code>STRICT</code> (or 2)</td>
</tr>
</tbody>
</table>

Controls whether to enable FIPS mode on the server side. The `ssl_fips_mode` system variable differs from other `--ssl-xxx` options in that it is not used to control whether the server permits encrypted connections, but rather to affect which cryptographic operations are permitted. See Section 6.5, “FIPS Support”.

These `ssl_fips_mode` values are permitted:

- **OFF** (or 0): Disable FIPS mode.
- **ON** (or 1): Enable FIPS mode.
- **STRICT** (or 2): Enable “strict” FIPS mode.

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` is **OFF**. In this case, setting `ssl_fips_mode` to **ON** or **STRICT** at startup causes the server to produce an error message and exit.

• **ssl_key**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ssl-key=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ssl_key</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (&lt;= 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name of the SSL key file to use for establishing secure connections.
As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **stored_program_cache**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--stored-program-cache=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>stored_program_cache</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>16</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

The stored procedure and stored function caches exists in parallel with the stored program definition cache partition of the dictionary object cache. The stored procedure and stored function caches are per connection, while the stored program definition cache is shared. The existence of objects in the stored procedure and stored function caches have no dependence on the existence of objects in the stored program definition cache, and vice versa. For more information, see Section 14.4, “Dictionary Object Cache”.

- **stored_program_definition_cache**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--stored-program-definition-cache=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>stored_program_definition_cache</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>
Defines a limit for the number of stored program definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused stored program definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `stored_program_definition_cache`.

A setting of 0 means that stored program definition objects are only kept in the dictionary object cache while they are in use.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

For related information, see Section 14.4, "Dictionary Object Cache".

- `super_read_only`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--super-read-only=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>super_read_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If the `read_only` system variable is enabled, the server permits client updates only from users who have the `SUPER` privilege. If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Changes to `super_read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

- `syseventlog.facility`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--syseventlog.facility=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>syseventlog.facility</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>daemon</td>
</tr>
</tbody>
</table>

The facility for error log output written to `syslog` (what type of program is sending the message). This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See Section 5.4.2.7, “Error Logging to the System Log”.

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- `syseventlog.include_pid`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--syseventlog.include-pid[={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>syseventlog.include_pid</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether to include the server process ID in each line of error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See Section 5.4.2.7, “Error Logging to the System Log”.

This variable does not exist on Windows.

- `syseventlog.tag`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--syseventlog.tag=tag</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>syseventlog.tag</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty_string</td>
</tr>
</tbody>
</table>

The tag to be added to the server identifier in error log output written to `syslog` or the Windows Event Log. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See Section 5.4.2.7, “Error Logging to the System Log”.
By default, no tag is set, so the server identifier is simply MySQL on Windows, and mysql on other platforms. If a tag value of tag is specified, it is appended to the server identifier with a leading hyphen, resulting in a syslog identifier of mysql-tag (or MySQL-tag on Windows).

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- **system_time_zone**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>system_time_zone</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set system_time_zone. Typically the time zone is specified by the TZ environment variable. It also can be specified using the --timezone option of the mysqld_safe script.

The system_time_zone variable differs from time_zone. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.1.13, “MySQL Server Time Zone Support”.

- **table_definition_cache**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--table-definition-cache=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>table_definition_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>400</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

\[
\text{MIN}(400 + \text{table_open_cache} / 2, 2000)
\]
Server System Variables

For InnoDB, `table_definition_cache` acts as a soft limit for the number of open table instances in the InnoDB data dictionary cache. If the number of open table instances exceeds the `table_definition_cache` setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by `table_definition_cache`, because parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, `table_definition_cache` defines a soft limit for the number of InnoDB file-per-table tablespaces that can be open at one time, which is also controlled by `innodb_open_files`. If both `table_definition_cache` and `innodb_open_files` are set, the highest setting is used. If neither variable is set, `table_definition_cache`, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by `table_definition_cache` or `innodb_open_files`, the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

The table definition cache exists in parallel with the table definition cache partition of the dictionary object cache. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence objects in the other. For more information, see Section 14.4, “Dictionary Object Cache”.

- `table_encryption_privilege_check`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--table-encryption-privilege-check={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>table_encryption_privilege_check</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Controls the `TABLE_ENCRYPTION_ADMIN` privilege check that occurs when creating or altering a schema or general tablespace with encryption that differs from the `default_table_encryption` setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. The check is disabled by default.

Setting `table_encryption_privilege_check` at runtime requires the `SUPER` privilege.

`table_encryption_privilege_check` supports `SET PERSIST` and `SET PERSIST ONLY` syntax. See Section 5.1.9.3, “Persisted System Variables”.

For more information, see Defining an Encryption Default for Schemas and General Tablespaces.

- `table_open_cache`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--table-open-cache=</code></td>
</tr>
</tbody>
</table>
The number of open tables for all threads. Increasing this value increases the number of file descriptors that mysqld requires. You can check whether you need to increase the table cache by checking the Opened_tables status variable. See Section 5.1.10, “Server Status Variables”. If the value of Opened_tables is large and you do not use FLUSH TABLES often (which just forces all tables to be closed and reopened), then you should increase the value of the table_open_cache variable. For more information about the table cache, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

- **table_open_cache_instances**

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size table_open_cache/table_open_cache_instances. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- **tablespace_definition_cache**
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

Defines a limit for the number of tablespace definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused tablespace definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `tablespace_definition_cache`.

A setting of 0 means that tablespace definition objects are only kept in the dictionary object cache while they are in use.

For more information, see Section 14.4, "Dictionary Object Cache".

• `temptable_max_ram`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--temptable-max-ram=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>temptable_max_ram</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2097152</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{64}-1$</td>
</tr>
</tbody>
</table>

Defines the maximum amount of memory that can be occupied by the TempTable storage engine before it starts storing data on disk. The default value is 1073741824 bytes (1GiB). For more information, see Section 8.4.4, "Internal Temporary Table Use in MySQL".

• `temptable_use_mmap`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--temptable-use-mmap[={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>temptable_use_mmap</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

Defines whether the TempTable storage engine allocates space for internal in-memory temporary tables as memory-mapped temporary files when the amount of memory occupied by the TempTable storage engine exceeds the limit defined by the `temptable_max_ram` variable. When `temptable_use_mmap` is disabled, the TempTable storage engine uses InnoDB on-disk internal temporary tables instead. For more information, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **thread_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--thread-cache-size=#</code></td>

<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>16384</td>
</tr>
</tbody>
</table>

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see Section 5.1.10, “Server Status Variables”.

The default value is based on the following formula, capped to a limit of 100:

\[
8 + \frac{\text{max_connections}}{100}
\]

- **thread_handling**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--thread-handling=name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>thread_handling</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>one-thread-per-connection</td>
</tr>
<tr>
<td>Valid Values</td>
<td>no-threads</td>
</tr>
<tr>
<td></td>
<td>one-thread-per-connection</td>
</tr>
<tr>
<td></td>
<td>loaded-dynamically</td>
</tr>
</tbody>
</table>

The thread-handling model used by the server for connection threads. The permissible values are **no-threads** (the server uses a single thread to handle one connection) and **one-thread-per-connection** (the server uses one thread to handle each client connection). **no-threads** is useful for debugging under Linux; see Section 29.5, “Debugging and Porting MySQL”.

- **thread_pool_algorithm**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread-pool-algorithm=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>thread_pool_algorithm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.

- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_pool_high_priority_connection**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread-pool-high-priority-connection=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>thread_pool_high_priority_connection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- `thread_pool_max_unused_threads`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread-pool-max-unused-threads=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>thread_pool_max_unused_threads</td>
</tr>
<tr>
<td>Scope</td>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4096</td>
</tr>
</tbody>
</table>

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of $N$ where $N$ is greater than 0 means 1 consumer thread and $N-1$ reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- `thread_pool_prio_kickup_timer`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread-pool-prio-kickup-timer=#</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>

<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1000</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967294</td>
</tr>
</tbody>
</table>

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to \(2^{32} - 2\).

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_pool_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--thread-pool-size=#</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>thread_pool_size</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>16</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>64</td>
</tr>
</tbody>
</table>

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, “MySQL Enterprise Thread Pool”

- **thread_pool_stall_limit**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--thread-pool-stall-limit=#</td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>thread_pool_stall_limit</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>600</td>
</tr>
</tbody>
</table>

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See Section 5.6.3, "MySQL Enterprise Thread Pool"

- **thread_stack**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread-stack=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>thread_stack</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, &gt;= 8.0.2)</td>
<td>286720</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, &lt;= 8.0.1)</td>
<td>262144</td>
</tr>
<tr>
<td>Default Value (32-bit platforms, &gt;= 8.0.2)</td>
<td>221184</td>
</tr>
<tr>
<td>Default Value (32-bit platforms, &lt;= 8.0.1)</td>
<td>196608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>
The stack size for each thread. The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- **time_format**

This system variable was removed in MySQL 8.0.3.

- **time_zone**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>time_zone</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies (&gt;= 8.0.17)</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies (&lt;= 8.0.16)</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, "use the value of system_time_zone"). The value can be specified explicitly at server startup with the --default-time-zone option. See Section 5.1.13, "MySQL Server Time Zone Support".

**Note**

If set to SYSTEM, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- **timestamp**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>timestamp</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
</tbody>
</table>

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. timestamp_value should be a Unix epoch timestamp (a value like that returned by UNIX_TIMESTAMP(), not a value in 'YYYY-MM-DD hh:mm:ss' format) or DEFAULT.

Setting timestamp to a constant value causes it to retain that value until it is changed again. Setting timestamp to DEFAULT causes its value to be the current date and time as of the time it is accessed.

In MySQL 8.0, timestamp is a DOUBLE rather than BIGINT because its value includes a microseconds part.
**Server System Variables**

**SET timestamp** affects the value returned by `NOW()` but not by `SYSDATE()`.

This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case **SET timestamp** affects both functions.

- **tls_ciphersuites**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tls-ciphersuites=ciphersuite_list</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>tls_ciphersuites</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

Which TLSv1.3 ciphersuites the server permits for encrypted connections. The value is a list of one or more colon-separated ciphersuite names. The ciphersuites that can be named for this variable depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- **tls_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tls-version=protocol_list</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>tls_version</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 8.0.16)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (&lt;= 8.0.15)</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.16)</td>
<td>TLSv1,TLSv1.1,TLSv1.2,TLSv1.3 (OpenSSL 1.1.1 and higher)</td>
</tr>
<tr>
<td></td>
<td>TLSv1,TLSv1.1,TLSv1.2 (otherwise)</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.11, &lt;= 8.0.15)</td>
<td>TLSv1,TLSv1.1,TLSv1.2</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.4)</td>
<td>TLSv1,TLSv1.1,TLSv1.2 (OpenSSL)</td>
</tr>
<tr>
<td></td>
<td>TLSv1,TLSv1.1 (yaSSL)</td>
</tr>
</tbody>
</table>

Which protocols the server permits for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. For details, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

858
As of MySQL 8.0.16, this variable is dynamic and can be modified at runtime to affect the SSL context the server uses for new connections. See Server-Side Runtime Configuration for Encrypted Connections. Prior to MySQL 8.0.16, this variable can be set only at server startup.

- **tmp_table_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--tmp-table-size=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>tmp_table_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16777216</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created MEMORY tables.

The actual limit is determined from whichever of the values of `tmp_table_size` and `max_heap_table_size` is smaller. If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table. See Storage Engine for On-Disk Internal Temporary Tables, for more information.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **tmpdir**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--tmpdir=dir_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>tmpdir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path of the directory to use for creating temporary files. It might be useful if your default /tmp directory resides on a partition that is too small to hold temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.
Server System Variables

tmpdir can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replication slave, and you are using a non-permanent location for tmpdir, consider setting a different temporary directory for the slave using the slave_load_tmpdir variable. For a replication slave, the temporary files used to replicate LOAD DATA statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section 8.4.3.5, “Where MySQL Stores Temporary Files”.

- transaction_alloc_block_size

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--transaction-alloc-block-size=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>transaction_alloc_block_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of transaction_prealloc_size.

- transaction_isolation

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--transaction-isolation=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>transaction_isolation</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
<td>READ-UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ, SERIALIZABLE</td>
</tr>
</tbody>
</table>

The transaction isolation level. The default is REPEATABLE-READ.
The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the `--transaction-isolation` server option.

At runtime, the isolation level can be set directly using the `SET` statement to assign a value to the `transaction_isolation` system variable, or indirectly using the `SET TRANSACTION` statement. If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_isolation = 'READ-COMMITTED';
```

Setting the global `transaction_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_isolation` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_isolation`:

- To set the session isolation level, use any of these syntaxes:

```
SET @@SESSION.transaction_isolation = value;
SET SESSION transaction_isolation = value;
SET transaction_isolation = value;
```

For each of those syntaxes, these semantics apply:

- Sets the isolation level for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction isolation level.
- Corresponds to `SET SESSION TRANSACTION ISOLATION LEVEL` (with the `SESSION` keyword).

- To set the next-transaction isolation level, use this syntax:

```
SET @@transaction_isolation = value;
```

For that syntax, these semantics apply:

- Sets the isolation level only for the next single transaction performed within the session.
• Subsequent transactions revert to the session isolation level.

• Not permitted within transactions.

• Corresponds to `SET TRANSACTION ISOLATION LEVEL` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_isolation` system variable, see Section 13.3.7, “SET TRANSACTION Syntax”.

• `transaction_prealloc_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--transaction-prealloc-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>transaction_prealloc_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

• `transaction_read_only`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--transaction-read-only[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>transaction_read_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

The transaction access mode. The value can be `OFF` (read/write; the default) or `ON` (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.
To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `transaction_read_only` system variable, or indirectly using the `SET TRANSACTION` statement. For example, use this `SET` statement to set the global value:

```sql
SET GLOBAL transaction_read_only = ON;
```

Setting the global `transaction_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```sql
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_read_only`,

- To set the session access mode, use any of these syntaxes:

  ```sql
  SET @@SESSION.transaction_read_only = value;
  SET SESSION transaction_read_only = value;
  SET transaction_read_only = value;
  ```

  For each of those syntaxes, these semantics apply:
  
  - Sets the access mode for all subsequent transactions performed within the session.
  
  - Permitted within transactions, but does not affect the current ongoing transaction.
  
  - If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.
  
  - Corresponds to `SET SESSION TRANSACTION {READ WRITE | READ ONLY}` (with the `SESSION` keyword).

- To set the next-transaction access mode, use this syntax:

  ```sql
  SET @@transaction_read_only = value;
  ```

  For that syntax, these semantics apply:
  
  - Sets the access mode only for the next single transaction performed within the session.
  
  - Subsequent transactions revert to the session access mode.
  
  - Not permitted within transactions.
• Corresponds to `SET TRANSACTION {READ WRITE | READ ONLY}` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_read_only` system variable, see Section 13.3.7, “SET TRANSACTION Syntax”.

• `tx_isolation`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes (removed in 8.0.3)</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>tx_isolation</code></td>

<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.3. Use `transaction_read_only` instead.

• `unique_checks`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>unique_checks</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB.

Setting this variable to 0 does not require storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- **updatable_views_with_limit**

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a LIMIT clause. (Such updates often are generated by GUI tools.) An update is an UPDATE or DELETE statement. Primary key here means a PRIMARY KEY, or a UNIQUE index in which no column can contain NULL.

The variable can have two values:

- **1** or **YES**: Issue a warning only (not an error message). This is the default value.

- **0** or **NO**: Prohibit the update.

- **use_secondary_engine**

This variable is introduced in version 8.0.13 and controls whether the use of an InnoDB-based secondary index is enabled or disabled.
Server System Variables

For future use.

- **validate_password.xxx**

  The `validate_password` component implements a set of system variables having names of the form `validate_password.xxx`. These variables affect password testing by that component; see Section 6.4.3.2, “Password Validation Options and Variables”.

- **validate_user_plugins**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-user-plugins[=\{OFF|ON\}]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_user_plugins</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ON</code></td>
</tr>
</tbody>
</table>

  If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

  - The account requires an authentication plugin that is not loaded.
  - The account requires the `sha256_password` or `caching_sha2_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by the plugin.

  Enabling `validate_user_plugins` slows down server initialization and `FLUSH_PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

- **version**

  The version number for the server. The value might also include a suffix indicating server build or configuration information. `-debug` indicates that the server was built with debugging support enabled.

- **version_comment**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>version_comment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The CMake configuration program has a `COMPILATION_COMMENT_SERVER` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. (Prior to MySQL 8.0.14, `version_comment` is set by the `COMPILATION_COMMENT` option.) See Section 2.9.4, “MySQL Source-Configuration Options”.

- **version_compile_machine**
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>

</tbody>
</table>
### Using System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (Windows)</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- **warning_count**

  The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.6.40, “SHOW WARNINGS Syntax”.

- **windowing_use_high_precision**

  Whether to compute window operations without loss of precision. See Section 8.2.1.20, “Window Function Optimization”.

---

#### 5.1.9 Using System Variables

The MySQL server maintains many system variables that configure its operation. Section 5.1.8, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables may also be installed by server plugins or components:

- System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the `audit_log` plugin implements a system variable named `audit_log_policy`.

- System variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.
There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.2, “Specifying Program Options”.)

- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of `1024`, `1024^2` or `1024^3`; that is, units of kilobytes, megabytes, or gigabytes, respectively. As of MySQL 8.0.14, a suffix can also be `T`, `P`, and `E` to indicate a multiplier of `1024^4`, `1024^5` or `1024^6`. Thus, the following command starts the server with an InnoDB log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb-log-file-size=16M --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
innodb_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `innodb_log_file_size` from being increased to more than 32MB at runtime, use the option `--maximum-innodb-log-file-size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see Section 5.1.9.2, “Dynamic System Variables”. To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. The following examples briefly illustrate this syntax:

- Set a global system variable:

  ```
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  ```

- Persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value):

  ```
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```

- Persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value):

  ```
  SET PERSIST_ONLY back_log = 1000;
  SET @@PERSIST_ONLY.back_log = 1000;
  ```
• Set a session system variable:

```sql
SET SESSION sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see Section 13.7.5.1, “SET Syntax for Variable Assignment”. For a description of the privilege requirements for setting and persisting system variables, see Section 5.1.9.1, “System Variable Privileges”

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```sql
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```sql
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

**Note**

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```sql
mysql> SHOW VARIABLES;
+---------------------------------+-----------------------------------+
| Variable_name                   | Value                             |
+---------------------------------+-----------------------------------+
| auto_increment_increment        | 1                                 |
| auto_increment_offset           | 1                                 |
| automatic_sp_privileges         | ON                                |
| back_log                        | 151                               |
| basedir                         | /home/mysql/                      |
| binlog_cache_size               | 32768                             |

</tbody>
</table>

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

For `SHOW VARIABLES`, if you specify neither `GLOBAL` nor `SESSION`, MySQL returns `SESSION` values.

The reason for requiring the `GLOBAL` keyword when setting `GLOBAL`-only variables but not when retrieving them is to prevent problems in the future:

- Were a `SESSION` variable to be removed that has the same name as a `GLOBAL` variable, a client with privileges sufficient to modify global variables might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own session.
- Were a `SESSION` variable to be added with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 5.1.9.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both:

- For dynamic system variables, the `SET` statement can be used to change their global or session runtime value (or both), to affect operation of the current server instance. (For information about dynamic variables, see Section 5.1.9.2, “Dynamic System Variables”.)
- For certain global system variables, `SET` can be used to persist their value to the `mysql-auto.cnf` file in the data directory, to affect server operation for subsequent startups. (For information about persisting system variables and the `mysql-auto.cnf` file, see Section 5.1.9.3, “Persisted System Variables”.)
- For persisted global system variables, `RESET PERSIST` can be used to remove their value from `mysql-auto.cnf`, to affect server operation for subsequent startups.

This section describes the privileges required for operations that assign values to system variables at runtime. This includes operations that affect runtime values, and operations that persist values.

To set a global system variable, use a `SET` statement with the appropriate keyword. These privileges apply:

- To set a global system variable runtime value, use the `SET GLOBAL` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
Using System Variables

- To persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value), use the `SET_PERSIST` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

- To persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value), use the `SET_PERSIST_ONLY` statement, which requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges. `SET_PERSIST_ONLY` can be used for both dynamic and read-only system variables, but is particularly useful for persisting read-only variables, for which `SET_PERSIST` cannot be used.

- Some global system variables are persist-restricted (see Section 5.1.9.4, "Nonpersistible and Persist-Restricted System Variables"). To persist these variables, use the `SET_PERSIST_ONLY` statement, which requires the privileges described previously. In addition, you must connect to the server using an encrypted connection and supply an SSL certificate with the Subject value specified by the `persist_only_admin_x509_subject` system variable.

To remove a persisted global system variable from the `mysqld-auto.cnf` file, use the `RESET_PERSIST` statement. These privileges apply:

- For dynamic system variables, `RESET_PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

- For read-only system variables, `RESET_PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.

- For persist-restricted variables, `RESET_PERSIST` does not require an encrypted connection to the server made using a particular SSL certificate.

If a global system variable has any exceptions to the preceding privilege requirements, the variable description indicates those exceptions. Examples include `default_table_encryption` and `mandatory_roles`, which require additional privileges. These additional privileges apply to operations that set the global runtime value, but not operations that persist the value.

To set a session system variable runtime value, use the `SET_SESSION` statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value may have effects outside the current session and thus is a restricted operation that can be done only by users who have a special privilege:

- As of MySQL 8.0.14, the privilege required is `SESSION_VARIABLES_ADMIN`.

  **Note**
  Any user who has `SYSTEM_VARIABLES_ADMIN` or `SUPER` effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

- Prior to MySQL 8.0.14, the privilege required is `SYSTEM_VARIABLES_ADMIN` or `SUPER`.

If a session system variable is restricted, the variable description indicates that restriction. Examples include `binlog_format` and `sql_log_bin`. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

`SESSION_VARIABLES_ADMIN` enables administrators to minimize the privilege footprint of users who may previously have been granted `SYSTEM_VARIABLES_ADMIN` or `SUPER` for the purpose of enabling them to modify restricted session system variables. Suppose that an administrator has created the following role to confer the ability to set restricted session system variables:
CREATE ROLE set_session_sysvars;
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO set_session_sysvars;

Any user granted the set_session_sysvars role (and who has that role active) is able to set restricted session system variables. However, that user is also able to set global system variables, which may be undesirable.

By modifying the role to have SESSION_VARIABLES_ADMIN instead of SYSTEM_VARIABLES_ADMIN, the role privileges can be reduced to the ability to set restricted session system variables and nothing else. To modify the role, use these statements:

GRANT SESSION_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
REVOKE SYSTEM_VARIABLES_ADMIN ON *.* FROM set_session_sysvars;

Modifying the role has an immediate effect: Any account granted the set_session_sysvars role no longer has SYSTEM_VARIABLES_ADMIN and is not able to set global system variables without being granted that ability explicitly. A similar GRANT/REVOKE sequence can be applied to any account that was granted SYSTEM_VARIABLES_ADMIN directly rather than by means of a role.

5.1.9.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See Section 13.7.5.1, “SET Syntax for Variable Assignment". For a description of the privilege requirements for setting system variables, see Section 5.1.9.1, “System Variable Privileges"

The following table lists all dynamic system variables applicable within mysqld.

The table lists each variable’s data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, ON or OFF. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from the ENUM data type used for table columns, for which the first enumeration value corresponds to 1.

### 5.1.9.3 Persisted System Variables

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. `SET` can also be used to persist certain global system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. `RESET PERSIST` removes persisted settings from `mysqld-auto.cnf`.

The following discussion describes aspects of persisting system variables:

- **Overview of Persisted System Variables**
- **Syntax for Persisting System Variables**
- **Obtaining Information About Persisted System Variables**
- **Format and Server Handling of the mysqld-auto.cnf File**

#### Overview of Persisted System Variables

The capability of persisting global system variables at runtime enables server configuration that persists across server startups. Although many system variables can be set at startup from a `my.cnf` option file, or at runtime using the `SET` statement, those methods of configuring the server either require login access to the server host, or do not provide the capability of persistently configuring the server at runtime or remotely:

- Modifying an option file requires direct access to that file, which requires login access to the MySQL server host. This is not always convenient.
• Modifying system variables with `SET GLOBAL` is a runtime capability that can be done from clients run locally or from remote hosts, but the changes affect only the currently running server instance. The settings are not persistent and do not carry over to subsequent server startups.

To augment administrative capabilities for server configuration beyond what is achievable by editing option files or using `SET GLOBAL`, MySQL provides variants of `SET` syntax that persist system variable settings to a file named `mysqld-auto.cnf` file in the data directory. Examples:

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;

SET PERSIST_ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

MySQL also provides a `RESET PERSIST` statement for removing persisted system variables from `mysqld-auto.cnf`.

Server configuration performed by persisting system variables has these characteristics:

- Persisted settings are made at runtime.
- Persisted settings are permanent. They apply across server restarts.
- Persisted settings can be made from local clients or clients who connect from a remote host. This provides the convenience of remotely configuring multiple MySQL servers from a central client host.
- To persist system variables, you need not have login access to the MySQL server host or file system access to option files. Ability to persist settings is controlled using the MySQL privilege system. See Section 5.1.9.1, “System Variable Privileges”.
- An administrator with sufficient privileges can reconfigure a server by persisting system variables, then cause the server to use the changed settings immediately by executing a `RESTART` statement.
- Persisted settings provide immediate feedback about errors. An error in a manually entered setting might not be discovered until much later. `SET` statements that persist system variables avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration.

**Syntax for Persisting System Variables**

These `SET` syntax options are available for persisting system variables:

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@PERSIST.` qualifier:

  ```
  SET PERSIST max_connections = 1000;
  SET @@PERSIST.max_connections = 1000;
  ```

  Like `SET GLOBAL`, `SET PERSIST` sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY.` qualifier:

  ```
  SET PERSIST_ONLY back_log = 1000;
  ```
Using System Variables

```
SET @@PERSIST_ONLY.back_log = 1000;
```

Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqlld-auto.cnf`. However, unlike `PERSIST`, `PERSIST_ONLY` does not modify the global variable runtime value. This makes `PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

For more information about `SET`, see Section 13.7.5.1, “SET Syntax for Variable Assignment”.

These `RESET PERSIST` syntax options are available for removing persisted system variables:

- To remove all persisted variables from `mysqlld-auto.cnf`, use `RESET PERSIST` without naming any system variable:

  ```
  RESET PERSIST;
  ```

- To remove a specific persisted variable from `mysqlld-auto.cnf`, name it in the statement:

  ```
  RESET PERSIST system_var_name;
  ```

  This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqlld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

  ```
  RESET PERSIST IF EXISTS system_var_name;
  ```

  For more information about `RESET PERSIST`, see Section 13.7.7.7, “RESET PERSIST Syntax”.

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqlld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted. See Section 5.1.9.4, “Nonpersistible and Persist-Restricted System Variables”.

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable will not exist when the server reads the `mysqlld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

Obtaining Information About Persisted System Variables

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqlld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See Section 26.12.13.1, “Performance Schema persisted_variables Table”.

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See Section 26.12.13.2, “Performance Schema variables_info Table”.
**RESET PERSIST** affects the contents of the *persisted_variables* table because the table contents correspond to the contents of the *mysqld-auto.cnf* file. On the other hand, because **RESET PERSIST** does not change variable values, it has no effect on the contents of the *variables_info* table until the server is restarted.

**Format and Server Handling of the mysqld-auto.cnf File**

The *mysqld-auto.cnf* file uses a JSON format like this (reformatted slightly for readability):

```json
{
  "Version": 1,
  "mysql_server": {
    "max_connections": {
      "Value": "152",
      "Metadata": {
        "Timestamp": 1.519921356e+15,
        "User": "root",
        "Host": "localhost"
      }
    },
    "transaction_isolation": {
      "Value": "READ-COMMITTED",
      "Metadata": {
        "Timestamp": 1.519921553e+15,
        "User": "root",
        "Host": "localhost"
      }
    },
    "mysql_server_static_options": {
      "innodb_api_enable_mdl": {
        "Value": "0",
        "Metadata": {
          "Timestamp": 1.519921573e+15,
          "User": "root",
          "Host": "localhost"
        }
      },
      "log_slave_updates": {
        "Value": "1",
        "Metadata": {
          "Timestamp": 1.519921582e+15,
          "User": "root",
          "Host": "localhost"
        }
      }
    }
  }
}
```

At startup, the server processes the *mysqld-auto.cnf* file after all other option files (see Section 4.2.2.2, “Using Option Files”). The server handles the file contents as follows:

- If the **persisted_globals_load** system variable is disabled, the server ignores the *mysqld-auto.cnf* file.

- Only read-only variables persisted using **SET PERSIST_ONLY** appear in the "**mysql_server_static_options**" section. All variables present inside this section are appended to the command line and processed with other command-line options.

- All remaining persisted variables are set by executing the equivalent of a **SET GLOBAL** statement later, just before the server starts listening for client connections. These settings therefore do not take effect until late in the startup process, which might be unsuitable for certain system variables. It may be preferable to set such variables in *my.cnf* rather than in *mysqld-auto.cnf*.
Management of the `mysql.auto.cnf` file should be left to the server. Manipulation of the file should be performed only using `SET` and `RESET PERSIST` statements, not manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:

  ```sql
  RESET PERSIST;
  ```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persistedGlobalsLoad` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysql.auto.cnf` file. However, as noted previously, removing this file results in a loss of all persisted settings.

### 5.1.9.4 Nonpersistible and Persist-Restricted System Variables

`SET PERSIST` and `SET PERSISTONLY` enable global system variables to be persisted to the `mysql.auto.cnf` option file in the data directory (see Section 13.7.5.1, “SET Syntax for Variable Assignment”). However, not all system variables can be persisted, or can be persisted only under certain restrictive conditions. Here are some reasons why a system variable might be nonpersistible or persist-restricted:

- Session system variables cannot be persisted. Session variables cannot be set at server startup, so there is no reason to persist them.

- A global system variable might involve sensitive data such that it should be settable only by a user with direct access to the server host.

- A global system variable might be read only (that is, set only by the server). In this case, it cannot be set by users at all, whether at server startup or at runtime.

- A global system variable might be intended only for internal use.

Nonpersistible system variables cannot be persisted under any circumstances. As of MySQL 8.0.14, persist-restricted system variables can be persisted with `SET PERSISTONLY`, but only by users for which the following conditions are satisfied:

- The `persistOnlyAdminX509Subject` system variable is set to an SSL certificate X.509 Subject value.

- The user connects to the server using an encrypted connection and supplies an SSL certificate with the designated Subject value.

- The user has sufficient privileges to use `SET PERSISTONLY` (see Section 5.1.9.1, “System Variable Privileges”).

For example, `protocol_version` is read only and set only by the server, so it cannot be persisted under any circumstances. On the other hand, `bind_address` is persist-restricted, so it can be set by users who satisfy the preceding conditions.

The following system variables are nonpersistible. This list may change with ongoing development:

- `audit_log_current_session`
- `audit_log_filter_id`
- `character_set_system`
- `core_file`
- `have_statement_timeout`
- `have_symlink`
Using System Variables

Persist-restricted system variables are those that are read only and can be set on the command line or in an option file, other than `persist_only_admin_x509_subject` and `persisted_globals_load`. This list may change with ongoing development.

<table>

</tbody>
</table>

Persist-restricted system variables are those that are read only and can be set on the command line or in an option file, other than `persist_only_admin_x509_subject` and `persisted_globals_load`. This list may change with ongoing development.
To configure the server to enable persisting persist-restricted system variables, use this procedure:

1. Ensure that MySQL is configured to support encrypted connections. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

2. Designate an SSL certificate X.509 Subject value that signifies the ability to persist persist-restricted system variables, and generate a certificate that has that Subject. See Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.

3. Start the server with `persist_only_admin_x509_subject` set to the designated Subject value. For example, put these lines in your server `my.cnf` file:

   ```
   [mysqld]
   persist_only_admin_x509_subject="subject-value"
   ```

   The format of the Subject value is the same as used for `CREATE USER ... REQUIRE SUBJECT`. See Section 13.7.1.3, “CREATE USER Syntax”.

   You must perform this step directly on the MySQL server host because `persist_only_admin_x509_subject` itself cannot be persisted at runtime.

4. Restart the server.

5. Distribute the SSL certificate that has the designated Subject value to users who are to be permitted to persist persist-restricted system variables.

Suppose that `myclient-cert.pem` is the SSL certificate to be used by clients who can persist persist-restricted system variables. Display the certificate contents using the `openssl` command:

```shell
shell> openssl x509 -text -in myclient-cert.pem
Certificate:
  Data:
    Version: 3 (0x2)
    Serial Number: 2 (0x2)
    Signature Algorithm: md5WithRSAEncryption
    Issuer: C=US, ST=IL, L=Chicago, O=MyOrg, OU=CA, CN=MyCN
    Validity
      Not Before: Oct 18 17:03:03 2018 GMT
      Not After : Oct 15 17:03:03 2028 GMT
    Subject: C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```
The `openssl` output shows that the certificate Subject value is:

```
C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```

To specify the Subject for MySQL, use this format:

```
/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN
```

Configure the server `my.cnf` file with the Subject value:

```
[mysqld]
persist_only_admin_x509_subject="/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN"
```

Restart the server so that the new configuration takes effect.

Distribute the SSL certificate (and any other associated SSL files) to the appropriate users. Such a user then connects to the server with the certificate and any other SSL options required to establish an encrypted connection.

To use X.509, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified. For example:

```
shell> mysql --ssl-key=myclient-key.pem --ssl-cert=myclient-cert.pem --ssl-ca=mycacert.pem
```

Assuming that the user has sufficient privileges to use `SET PERSIST_ONLY`, persist-restricted system variables can be persisted like this:

```
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
Query OK, 0 rows affected (0.00 sec)
```

If the server is not configured to enable persisting persist-restricted system variables, or the user does not satisfy the required conditions for that capability, an error occurs:

```
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
ERROR 1238 (HY000): Variable 'socket' is a non persistent read only variable
```

### 5.1.9.5 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
• **key_cache_age_threshold**

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 8.10.2, “The MyISAM Key Cache”.

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

• For a given type of structured variable, each instance must have a name that is unique within variables of that type. However, instance names need not be unique across structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

• The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

• If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache` is.

• `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@GLOBAL.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
```
In this case, the server sets the size of the default key cache to 256KB. (You could also have written
--default.key_buffer_size=256K.) In addition, the server creates a second key cache named
extra_cache that has a size of 128KB, with the size of block buffers for caching table index blocks set to
2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

shell> mysqld --key_buffer_size=6M \
    --hot_cache.key_buffer_size=2M \
    --cold_cache.key_buffer_size=2M

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache
named hot_cache to a size of 10MB, use either of these statements:

mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;

To retrieve the cache size, do this:

mysql> SELECT @@GLOBAL.hot_cache.key_buffer_size;

However, the following statement does not work. The variable is not interpreted as a compound name, but
as a simple string for a LIKE pattern-matching operation:

mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';

This is the exception to being able to use structured variable names anywhere a simple variable name may
occur.

5.1.10 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can
view these variables and their values by using the SHOW [GLOBAL | SESSION] STATUS statement (see
Section 13.7.6.35, “SHOW STATUS Syntax”). The optional GLOBAL keyword aggregates the values over
all connections, and SESSION shows the values for the current connection.

mysql> SHOW GLOBAL STATUS;
+-----------------------------------+------------+
| Variable_name                     | Value      |
+-----------------------------------+------------+
| Aborted_clients                   | 0          |
| Aborted_connects                  | 0          |
| Bytes_received                    | 155372598  |
| Bytes_sent                        | 1176560426 |
| ...                                |            |
| Connections                       | 30023      |
| Created_tmp_disk_tables           | 0          |
| Created_tmp_files                 | 3          |
| Created_tmp_tables                | 2          |
| ...                                |            |
| Threads_created                   | 217        |
| Threads_running                   | 88         |
| Uptime                            | 1389872    |
+-----------------------------------+------------+
Many status variables are reset to 0 by the **FLUSH STATUS** statement.

This section provides a description of each status variable. For a status variable summary, see **Section 5.1.6, “Server Status Variable Reference”**.

The status variables have the following meanings.

- **Aborted_clients**
  
  The number of connections that were aborted because the client died without closing the connection properly. See **Section B.4.2.10, “Communication Errors and Aborted Connections”**.

- **Aborted_connects**
  
  The number of failed attempts to connect to the MySQL server. See **Section B.4.2.10, “Communication Errors and Aborted Connections”**.

  For additional connection-related information, check the **Connection_errors_XXX** status variables and the **host_cache** table.

- **Binlog_cache_disk_use**
  
  The number of transactions that used the temporary binary log cache but that exceeded the value of **binlog_cache_size** and used a temporary file to store statements from the transaction.

  The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the **Binlog_stmt_cache_disk_use** status variable.

- **Acl_cache_items_count**
  
  The number of cached privilege objects. Each object is the privilege combination of a user and its active roles.

- **Binlog_cache_use**
  
  The number of transactions that used the binary log cache.

- **Binlog_stmt_cache_disk_use**
  
  The number of nontransactional statements that used the binary log statement cache but that exceeded the value of **binlog_stmt_cache_size** and used a temporary file to store those statements.

- **Binlog_stmt_cache_use**
  
  The number of nontransactional statements that used the binary log statement cache.

- **Bytes_received**
  
  The number of bytes received from all clients.

- **Bytes_sent**
  
  The number of bytes sent to all clients.

- **Caching_sha2_password_rsa_public_key**
  
  The public key used by the **caching_sha2_password** authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the **caching_sha2_password_private_key_path**.
and `caching_sha2_password_public_key_path` system variables. The value of `Caching_sha2_password_rsa_public_key` comes from the latter file.

- **Com_XXX**

  The `Com_XXX` statement counter variables indicate the number of times each `XXX` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

  The discussion at the beginning of this section indicates how to relate these statement-counting status variables to other such variables.

  All of the `Com_stmt_XXX` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

  The `Com_stmt_XXX` status variables are as follows:

  - `Com_stmt_prepare`
  - `Com_stmt_execute`
  - `Com_stmt_fetch`
  - `Com_stmt_send_long_data`
  - `Com_stmt_reset`
  - `Com_stmt_close`

  Those variables stand for prepared statement commands. Their names refer to the `COM_XXX` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

  `Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server, for example, after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

  `Com_explain_other` indicates the number of `EXPLAIN FOR CONNECTION` statements executed. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

  `Com_change_repl_filter` indicates the number of `CHANGE REPLICATION FILTER` statements executed.

- **Compression**

  Whether the client connection uses compression in the client/server protocol.

  As of MySQL 8.0.18, this status variable is deprecated. It will be removed in a future MySQL version. See Legacy Connection Compression Configuration.
• **Compression_algorithm**

  The name of the compression algorithm in use for the current connection to the server. The value can be any algorithm permitted in the value of the `protocol_compression_algorithms` system variable. For example, the value is `uncompressed` if the connection does not use compression, or `zlib` if the connection uses the `zlib` algorithm.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This variable was added in MySQL 8.0.18.

• **Compression_level**

  The compression level in use for the current connection to the server. The value is 6 for `zlib` connections (the default `zlib` algorithm compression level), 1 to 22 for `zstd` connections, and 0 for `uncompressed` connections.

  For more information, see Section 4.2.6, “Connection Compression Control”.

  This variable was added in MySQL 8.0.18.

• **Connection_errors_xxx**

  These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

• **Connection_errors_accept**

  The number of errors that occurred during calls to `accept()` on the listening port.

• **Connection_errors_internal**

  The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

• **Connection_errors_max_connections**

  The number of connections refused because the server `max_connections` limit was reached.

• **Connection_errors_peer_address**

  The number of errors that occurred while searching for connecting client IP addresses.

• **Connection_errors_select**

  The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

• **Connection_errors_tcpwrap**

  The number of connections refused by the `libwrap` library.

• **Connections**
Server Status Variables

The number of connection attempts (successful or not) to the MySQL server.

- **Created_tmp_disk_tables**

  The number of internal on-disk temporary tables created by the server while executing statements.

  If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **Created_tmp_files**

  How many temporary files `mysqld` has created.

- **Created_tmp_tables**

  The number of internal temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- **Current_tls_ca**

  The active `ssl_ca` value in the SSL context that the server uses for new connections. This context value may differ from the current `ssl_ca` system variable value if the system variable has been changed but `ALTER INSTANCE RELOAD TLS` has not subsequently been executed to reconfigure the SSL context from the context-related system variable values and update the corresponding status variables. (This potential difference in values applies to each corresponding pair of context-related system and status variables. See `Server-Side Runtime Configuration for Encrypted Connections`.)

  This variable was added in MySQL 8.0.16.

- **Current_tls_capath**

  The active `ssl_capath` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- **Current_tls_cert**
Server Status Variables

The active `ssl_cert` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

This variable was added in MySQL 8.0.16.

- `Current_tls_cipher`

  The active `ssl_cipher` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Current_tls_ciphersuites`

  The active `tls_ciphersuites` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Current_tls_crl`

  The active `ssl_crl` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Current_tls_crlpath`

  The active `ssl_crlpath` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Current_tls_key`

  The active `ssl_key` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Current_tls_version`

  The active `tls_version` value in the SSL context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

  This variable was added in MySQL 8.0.16.

- `Delayed_errors`
Server Status Variables

This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- **Delayed_insert_threads**
  This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- **Delayed_writes**
  This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- **dragnet.Status**
  The result of the most recent assignment to the `dragnet.log_error_filter_rules` system variable, empty if no such assignment has occurred.

  This variable was added in MySQL 8.0.12.

- **Flush_commands**
  The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- **group_replication_primary_member**
  Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

  The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

- **Handler_commit**
  The number of internal `COMMIT` statements.

- **Handler_delete**
  The number of times that rows have been deleted from tables.

- **Handler_external_lock**
  The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- **Handler_mrr_init**
  The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- **Handler_prepare**
A counter for the prepare phase of two-phase commit operations.

- **Handler_read_first**
  
The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed).

- **Handler_read_key**
  
The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- **Handler_read_last**
  
The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests.

- **Handler_read_next**
  
The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- **Handler_read_prev**
  
The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- **Handler_read_rnd**
  
The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- **Handler_read_rnd_next**
  
The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- **Handler_rollback**
  
The number of requests for a storage engine to perform a rollback operation.

- **Handler_savepoint**
  
The number of requests for a storage engine to place a savepoint.

- **Handler_savepoint_rollback**
  
The number of requests for a storage engine to roll back to a savepoint.

- **Handler_update**
  
The number of requests to update a row in a table.

- **Handler_write**
The number of requests to insert a row in a table.

- **Innodb_available_undo_logs**
  
  `Innodb_available_undo_logs` was removed in MySQL 8.0.2. The number of available rollback segments per tablespace may be retrieved using `SHOW VARIABLES LIKE 'innodb rollback_segments';`

- **Innodb_buffer_pool_dump_status**
  
  The progress of an operation to record the pages held in the InnoDB buffer pool, triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.
  
  For related information and examples, see Section 15.8.3.7, “Saving and Restoring the Buffer Pool State”.

- **Innodb_buffer_pool_load_status**
  
  The progress of an operation to warm up the InnoDB buffer pool by reading in a set of pages corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.
  
  For related information and examples, see Section 15.8.3.7, “Saving and Restoring the Buffer Pool State”.

- **Innodb_buffer_pool_bytes_data**
  
  The total number of bytes in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when compressed tables cause the buffer pool to hold pages of different sizes.

- **Innodb_buffer_pool_pages_data**
  
  The number of pages in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. When using compressed tables, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- **Innodb_buffer_pool_bytes_dirty**
  
  The total current number of bytes held in dirty pages in the InnoDB buffer pool. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when compressed tables cause the buffer pool to hold pages of different sizes.

- **Innodb_buffer_pool_pages_dirty**
  
  The current number of dirty pages in the InnoDB buffer pool.

- **Innodb_buffer_pool_pages_flushed**
  
  The number of requests to flush pages from the InnoDB buffer pool.

- **Innodb_buffer_pool_pages_free**
  
  The number of free pages in the InnoDB buffer pool.

- **Innodb_buffer_pool_pages_latched**
The number of latched pages in the InnoDB buffer pool. These are pages currently being read or written, or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the UNIV_DEBUG system is defined at server build time.

- Innodb_buffer_pool_pages_misc
  The number of pages in the InnoDB buffer pool that are busy because they have been allocated for administrative overhead, such as row locks or the adaptive hash index. This value can also be calculated as Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data. When using compressed tables, Innodb_buffer_pool_pages_misc may report an out-of-bounds value (Bug #59550).

- Innodb_buffer_pool_pages_total
  The total size of the InnoDB buffer pool, in pages. When using compressed tables, the reported Innodb_buffer_pool_pages_data value may be larger than Innodb_buffer_pool_pages_total (Bug #59550)

- Innodb_buffer_pool_read_ahead
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread.

- Innodb_buffer_pool_read_ahead_evicted
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- Innodb_buffer_pool_read_ahead_rnd
  The number of “random” read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order.

- Innodb_buffer_pool_read_requests
  The number of logical read requests.

- Innodb_buffer_pool_reads
  The number of logical reads that InnoDB could not satisfy from the buffer pool, and had to read directly from disk.

- Innodb_buffer_pool_resize_status
  The status of an operation to resize the InnoDB buffer pool dynamically, triggered by setting the innodb_buffer_pool_size parameter dynamically. The innodb_buffer_pool_size parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See Configuring InnoDB Buffer Pool Size Online for related information.

- Innodb_buffer_pool_wait_free
  Normally, writes to the InnoDB buffer pool happen in the background. When InnoDB needs to read or create a page and no clean pages are available, InnoDB flushes some dirty pages first and waits for that operation to finish. This counter counts instances of these waits. If innodb_buffer_pool_size has been set properly, this value should be small.

- Innodb_buffer_pool_write_requests
Server Status Variables

The number of writes done to the InnoDB buffer pool.

- **Innodb_data_fsyncs**
  The number of fsync() operations so far. The frequency of fsync() calls is influenced by the setting of the `innodb_flush_method` configuration option.

- **Innodb_data_pending_fsyncs**
  The current number of pending fsync() operations. The frequency of fsync() calls is influenced by the setting of the `innodb_flush_method` configuration option.

- **Innodb_data_pending_reads**
  The current number of pending reads.

- **Innodb_data_pending_writes**
  The current number of pending writes.

- **Innodb_data_read**
  The amount of data read since the server was started (in bytes).

- **Innodb_data_reads**
  The total number of data reads (OS file reads).

- **Innodb_data_writes**
  The total number of data writes.

- **Innodb_data_written**
  The amount of data written so far, in bytes.

- **Innodb_dblwr_pages_written**
  The number of pages that have been written to the doublewrite buffer. See Section 15.11.1, “InnoDB Disk I/O”.

- **Innodb_dblwr_writes**
  The number of doublewrite operations that have been performed. See Section 15.11.1, “InnoDB Disk I/O”.

- **Innodb_have_atomic_builtins**
  Indicates whether the server was built with atomic instructions.

- **Innodb_log_waits**
  The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- **Innodb_log_write_requests**
  The number of write requests for the InnoDB redo log.
Server Status Variables

- **Innodb_log_writes**
  The number of physical writes to the InnoDB redo log file.

- **Innodb_num_open_files**
  The number of files InnoDB currently holds open.

- **Innodb_os_log_fsyncs**
  The number of fsync() writes done to the InnoDB redo log files.

- **Innodb_os_log_pending_fsyncs**
  The number of pending fsync() operations for the InnoDB redo log files.

- **Innodb_os_log_pending_writes**
  The number of pending writes to the InnoDB redo log files.

- **Innodb_os_log_written**
  The number of bytes written to the InnoDB redo log files.

- **Innodb_page_size**
  InnoDB page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- **Innodb_pages_created**
  The number of pages created by operations on InnoDB tables.

- **Innodb_pages_read**
  The number of pages read from the InnoDB buffer pool by operations on InnoDB tables.

- **Innodb_pages_written**
  The number of pages written by operations on InnoDB tables.

- **Innodb_row_lock_current_waits**
  The number of row locks currently being waited for by operations on InnoDB tables.

- **Innodb_row_lock_time**
  The total time spent in acquiring row locks for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_avg**
  The average time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_max**
  The maximum time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_waits**
  The number of times operations on InnoDB tables had to wait for a row lock.
Server Status Variables

- **Innodb_rows_deleted**
  The number of rows deleted from InnoDB tables.

- **Innodb_rows_inserted**
  The number of rows inserted into InnoDB tables.

- **Innodb_rows_read**
  The number of rows read from InnoDB tables.

- **Innodb_rows_updated**
  The number of rows updated in InnoDB tables.

- **Innodb_truncated_status_writes**
  The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- **Key_blocks_not_flushed**
  The number of key blocks in the MyISAM key cache that have changed but have not yet been flushed to disk.

- **Key_blocks_unused**
  The number of unused blocks in the MyISAM key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.1.8, “Server System Variables”.

- **Key_blocks_used**
  The number of used blocks in the MyISAM key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- **Key_read_requests**
  The number of requests to read a key block from the MyISAM key cache.

- **Key_reads**
  The number of physical reads of a key block from disk into the MyISAM key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- **Key_write_requests**
  The number of requests to write a key block to the MyISAM key cache.

- **KeyWrites**
  The number of physical writes of a key block from the MyISAM key cache to disk.

- **Last_query_cost**
  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.
In MySQL 8.0.16 and later, this variable shows the cost of queries that have multiple query blocks, summing the cost estimates of each query block, estimating how many times non-cacheable subqueries are executed, and multiplying the cost of those query blocks by the number of subquery executions. (Bug #92766, Bug #28786951) Prior to MySQL 8.0.16, \texttt{Last\_query\_cost} was computed accurately only for simple, “flat” queries, but not for complex queries such as those containing subqueries or \texttt{UNION}. (For the latter, the value was set to 0.)

- \texttt{Last\_query\_partial\_plans}

  The number of iterations the query optimizer made in execution plan construction for the previous query. \texttt{Last\_query\_cost} has session scope.

- \texttt{Locked\_connects}

  The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see Section 6.2.19, “Account Locking”.

- \texttt{Max\_execution\_time\_exceeded}

  The number of \texttt{SELECT} statements for which the execution timeout was exceeded.

- \texttt{Max\_execution\_time\_set}

  The number of \texttt{SELECT} statements for which a nonzero execution timeout was set. This includes statements that include a nonzero \texttt{MAX\_EXECUTION\_TIME} optimizer hint, and statements that include no such hint but execute while the timeout indicated by the \texttt{max\_execution\_time} system variable is nonzero.

- \texttt{Max\_execution\_time\_set\_failed}

  The number of \texttt{SELECT} statements for which the attempt to set an execution timeout failed.

- \texttt{Max\_used\_connections}

  The maximum number of connections that have been in use simultaneously since the server started.

- \texttt{Max\_used\_connections\_time}

  The time at which \texttt{Max\_used\_connections} reached its current value.

- \texttt{Not\_flushed\_delayed\_rows}

  This status variable is deprecated (because \texttt{DELAYED} inserts are not supported), and will be removed in a future release.

- \texttt{mecab\_charset}

  The character set currently used by the MeCab full-text parser plugin. For related information, see Section 12.9.9, “MeCab Full-Text Parser Plugin”.

- \texttt{Ongoing\_anonymous\_transaction\_count}

  Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- \texttt{Ongoing\_anonymous\_gtid\_violating\_transaction\_count}
Server Status Variables

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=ANONYMOUS` and that violate GTID consistency.

- **Ongoing_automatic_gtid_violating_transaction_count**
  This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=AUTOMATIC` and that violate GTID consistency.

- **Open_files**
  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- **Open_streams**
  The number of streams that are open (used mainly for logging).

- **Open_table_definitions**
  The number of cached table definitions.

- **Open_tables**
  The number of tables that are open.

- **Opened_files**
  The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- **Opened_table_definitions**
  The number of table definitions that have been cached.

- **Opened_tables**
  The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- **Performance_schema_xxx**
  Performance Schema status variables are listed in Section 26.16, “Performance Schema Status Variables”. These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- **Prepared_stmt_count**
  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- **Qcache_free_blocks**
  This status variable was removed in MySQL 8.0.3.

- **Qcache_free_memory**
  This status variable was removed in MySQL 8.0.3.
Server Status Variables

- **Qcache_hits**
  
  This status variable was removed in MySQL 8.0.3.

- **Qcache_inserts**
  
  This status variable was removed in MySQL 8.0.3.

- **Qcache_lowmem_prunes**
  
  This status variable was removed in MySQL 8.0.3.

- **Qcache_not_cached**
  
  This status variable was removed in MySQL 8.0.3.

- **Qcache_queries_in_cache**
  
  This status variable was removed in MySQL 8.0.3.

- **Qcache_total_blocks**
  
  This status variable was removed in MySQL 8.0.3.

- **Queries**
  
  The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the **Questions** variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- **Questions**

  The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the **Queries** variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- **Rpl_semi_sync_master_clients**

  The number of semisynchronous slaves.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_avg_wait_time**

  The average time in microseconds the master waited for a slave reply. This variable is always 0, is deprecated and it will be removed in a future version.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_wait_time**
The total time in microseconds the master waited for slave replies. This variable is always 0, is deprecated and it will be removed in a future version.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_waits**

  The total number of times the master waited for slave replies.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_times**

  The number of times the master turned off semisynchronous replication.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_tx**

  The number of commits that were not acknowledged successfully by a slave.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_status**

  Whether semisynchronous replication currently is operational on the master. The value is ON if the plugin has been enabled and a commit acknowledgment has occurred. It is OFF if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_timefunc_failures**

  The number of times the master failed when calling time functions such as gettimeofday().

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_avg_wait_time**

  The average time in microseconds the master waited for each transaction.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_wait_time**

  The total time in microseconds the master waited for transactions.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_waits**

  The total number of times the master waited for transactions.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_pos_backtraverse**
The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_sessions**
  
  The number of sessions currently waiting for slave replies.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_yes_tx**
  
  The number of commits that were acknowledged successfully by a slave.

  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_slave_status**
  
  Whether semisynchronous replication currently is operational on the slave. This is ON if the plugin has been enabled and the slave I/O thread is running, OFF otherwise.

  This variable is available only if the slave-side semisynchronous replication plugin is installed.

- **Rsa_public_key**
  
  This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”). Its value is the public key used by the sha256_password authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the sha256_password_private_key_path and sha256_password_public_key_path system variables. The value of Rsa_public_key comes from the latter file.

  For information about sha256_password, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”.

- **Secondary_engine_execution_count**
  
  For future use. This variable was added in MySQL 8.0.13.

- **Select_full_join**
  
  The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- **Select_full_range_join**
  
  The number of joins that used a range search on a reference table.

- **Select_range**
  
  The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- **Select_range_check**
  
  The number of joins without keys that check for key usage after each row. If this value is not 0, you should carefully check the indexes of your tables.
- **Select_scan**
  
  The number of joins that did a full scan of the first table.

- **Slave_heartbeat_period**
  
  This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the `HEARTBEAT_INTERVAL` column of the `replication_connection_configuration` table.

- **Slave_last_heartbeat**
  
  This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the `LAST_HEARTBEAT_TIMESTAMP` column of the `replication_connection_status` table.

- **Slave_open_temp_tables**
  
  The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see Section 17.4.1.30, “Replication and Temporary Tables”. This variable reports the total count of open temporary tables for all replication channels.

- **Slave_received_heartbeats**
  
  This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the `COUNT_RECEIVED_HEARTBEATS` column of the `replication_connection_status` table.

- **Slave_retried_transactions**
  
  This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the `COUNT_TRANSACTIONS_RETRIES` column of the `replication_applier_status` table.

- **Slave_rows_last_search_algorithm_used**
  
  The search algorithm that was most recently used by this slave to locate rows for row-based replication. The result shows whether the slave used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

  The method used depends on the setting for the `slave_rows_search_algorithms` system variable, and the keys that are available on the relevant table.

  This variable is available only for debug builds of MySQL.

- **Slave_running**
  
  This variable is obsolete and was removed in MySQL 8.0.1. Instead, use the `SERVICE_STATE` column of the `replication_connection_status` and `replication_applier_status` tables.

- **Slow_launch_threads**
  
  The number of threads that have taken more than `slow_launch_time` seconds to create.

- **Slow_queries**
  
  The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see Section 5.4.5, “The Slow Query Log”.

- **Sort_merge_passes**
Server Status Variables

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- **Sort_range**
  The number of sorts that were done using ranges.

- **Sort_rows**
  The number of sorted rows.

- **Sort_scan**
  The number of sorts that were done by scanning the table.

- **Ssl_accept_renegotiates**
  The number of negotiates needed to establish the connection.

- **Ssl_accepts**
  The number of accepted SSL connections.

- **Ssl_callback_cache_hits**
  The number of callback cache hits.

- **Ssl_cipher**
  The current encryption cipher (empty for unencrypted connections).

- **Ssl_cipher_list**
  The list of possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites. See Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- **Ssl_client_connects**
  The number of SSL connection attempts to an SSL-enabled master.

- **Ssl_connect_renegotiates**
  The number of negotiates needed to establish the connection to an SSL-enabled master.

- **Ssl_ctx_verify_depth**
  The SSL context verification depth (how many certificates in the chain are tested).

- **Ssl_ctx_verify_mode**
  The SSL context verification mode.

- **Ssl_default_timeout**
  The default SSL timeout.

- **Ssl_finished_accepts**
The number of successful SSL connections to the server.

- **Ssl_finished_connects**
  The number of successful slave connections to an SSL-enabled master.

- **Ssl_server_not_after**
  The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

  ```
  mysql> SHOW STATUS LIKE 'Ssl_server_not%';
  +-----------------------+--------------------------+
  | Variable_name         | Value                    |
  +-----------------------+--------------------------+
  | Ssl_server_not_after  | Apr 28 14:16:39 2025 GMT |
  | Ssl_server_not_before | May  1 14:16:39 2015 GMT |
  +-----------------------+--------------------------+
  ```

- **Ssl_server_not_before**
  The first date for which the SSL certificate is valid.

- **Ssl_session_cache_hits**
  The number of SSL session cache hits.

- **Ssl_session_cache_misses**
  The number of SSL session cache misses.

- **Ssl_session_cache_mode**
  The SSL session cache mode.

- **Ssl_session_cache_overflows**
  The number of SSL session cache overflows.

- **Ssl_session_cache_size**
  The SSL session cache size.

- **Ssl_session_cache_timeouts**
  The number of SSL session cache timeouts.

- **Ssl_sessions_reused**
  How many SSL connections were reused from the cache.

- **Ssl_used_session_cache_entries**
  How many SSL session cache entries were used.

- **Ssl_verify_depth**
  The verification depth for replication SSL connections.

- **Ssl_verify_mode**
The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

```c
#define SSL_VERIFY_NONE                 0x00
#define SSL_VERIFY_PEER                 0x01
#define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
#define SSL_VERIFY_CLIENT_ONCE          0x04
```

- **SSL_VERIFY_PEER** indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. **SSL_VERIFY_CLIENT_ONCE** indicates that a request for the client certificate will be done only in the initial handshake.

- **Ssl_version**
  The SSL protocol version of the connection (for example, TLSv1). If the connection is not encrypted, the value is empty.

- **Table_locks_immediate**
  The number of times that a request for a table lock could be granted immediately.

- **Table_locks_waited**
  The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- **Table_open_cache_hits**
  The number of hits for open tables cache lookups.

- **Table_open_cache_misses**
  The number of misses for open tables cache lookups.

- **Table_open_cache_overflows**
  The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache/table_open_cache_instances`.

- **Tc_log_max_pages_used**
  For the memory-mapped implementation of the log that is used by mysqld when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (InnoDB is the only applicable engine.)

- **Tc_log_page_size**
  The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`. 
• **Tc_log_page_waits**

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

• **Threads_cached**

The number of threads in the thread cache.

• **Threads_connected**

The number of currently open connections.

• **Threads_created**

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

• **Threads_running**

The number of threads that are not sleeping.

• **Uptime**

The number of seconds that the server has been up.

• **Uptime_since_flush_status**

The number of seconds since the most recent `FLUSH STATUS` statement.

### 5.1.11 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- **Setting the SQL Mode**
- **The Most Important SQL Modes**
- **Full List of SQL Modes**
- **Combination SQL Modes**
- **Strict SQL Mode**
- **Comparison of the IGNORE Keyword and Strict SQL Mode**

For answers to questions often asked about server SQL modes in MySQL, see Section A.3, “MySQL 8.0 FAQ: Server SQL Mode”.

920
When working with InnoDB tables, consider also the innodb_strict_mode system variable. It enables additional error checks for InnoDB tables.

Setting the SQL Mode

The default SQL mode in MySQL 8.0 includes these modes: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, and NO_ENGINE_SUBSTITUTION.

To set the SQL mode at server startup, use the --sql-mode="modes" option on the command line, or sql-mode="modes" in an option file such as my.cnf (Unix operating systems) or my.ini (Windows). modes is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using --sql-mode="" on the command line, or sql-mode="" in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session sql_mode system variable using a SET statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the GLOBAL variable requires the SYSTEM_VARIABLES_ADMIN or SUPER privilege and affects the operation of all clients that connect from that time on. Setting the SESSION variable affects only the current client. Each client can change its session sql_mode value at any time.

To determine the current global or session sql_mode setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

Important

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and slave.

For more information, see Section 23.6, “Restrictions and Limitations on Partitioning”.

The Most Important SQL Modes

The most important sql_mode values are probably these:

- ANSI
This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special combination modes listed at the end of this section.

• **STRICT_TRANS_TABLES**

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

• **TRADITIONAL**

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special combination modes listed at the end of this section.

**Note**

With **TRADITIONAL** mode enabled, an **INSERT** or **UPDATE** aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both **STRICT_TRANS_TABLES** or **STRICT_ALL_TABLES** enabled.

**Full List of SQL Modes**

The following list describes all supported SQL modes:

• **ALLOW_INVALID_DATES**

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to **DATE** and **DATETIME** columns. It does not apply to **TIMESTAMP** columns, which always require a valid date.

With **ALLOW_INVALID_DATES** disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable **ALLOW_INVALID_DATES**.

• **ANSI_QUOTES**

Treat " as an identifier quote character (like the ` quote character) and not as a string quote character. You can still use ` to quote identifiers with this mode enabled. With **ANSI_QUOTES** enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

• **ERROR_FOR_DIVISION_BY_ZERO**

The **ERROR_FOR_DIVISION_BY_ZERO** mode affects handling of division by zero, which includes **MOD(N,0)**. For data-change operations (**INSERT**, **UPDATE**), its effect also depends on whether strict SQL mode is enabled.

• If this mode is not enabled, division by zero inserts **NULL** and produces no warning.
• If this mode is enabled, division by zero inserts NULL and produces a warning.

• If this mode and strict mode are enabled, division by zero produces an error, unless IGNORE is given as well. For INSERT IGNORE and UPDATE IGNORE, division by zero inserts NULL and produces a warning.

For SELECT, division by zero returns NULL. Enabling ERROR_FOR_DIVISION_BY_ZERO causes a warning to be produced as well, regardless of whether strict mode is enabled.

ERROR_FOR_DIVISION_BY_ZERO is deprecated. ERROR_FOR_DIVISION_BY_ZERO is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if ERROR_FOR_DIVISION_BY_ZERO is enabled without also enabling strict mode or vice versa.

Because ERROR_FOR_DIVISION_BY_ZERO is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

• HIGH_NOT_PRECEDENCE

The precedence of the NOT operator is such that expressions such as NOT a BETWEEN b AND c are parsed as NOT (a BETWEEN b AND c). In some older versions of MySQL, the expression was parsed as (NOT a) BETWEEN b AND c. The old higher-precedence behavior can be obtained by enabling the HIGH_NOT_PRECEDENCE SQL mode.

mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1

• IGNORE_SPACE

Permit spaces between a function name and the () character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, “Schema Object Names”. For example, because there is a COUNT() function, the use of count as a table name in the following statement causes an error:

mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
The table name should be quoted:

mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)

The IGNORE_SPACE SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether IGNORE_SPACE is enabled.

For further discussion of IGNORE_SPACE, see Section 9.2.4, “Function Name Parsing and Resolution”.

• NO_AUTO_VALUE_ON_ZERO
Server SQL Modes

**NO_AUTO_VALUE_ON_ZERO** affects handling of **AUTO_INCREMENT** columns. Normally, you generate the next sequence number for the column by inserting either **NULL** or 0 into it. **NO_AUTO_VALUE_ON_ZERO** suppresses this behavior for 0 so that only **NULL** generates the next sequence number.

This mode can be useful if 0 has been stored in a table’s **AUTO_INCREMENT** column. (Storing 0 is not a recommended practice, by the way.) For example, if you dump the table with **mysqldump** and then reload it, MySQL normally generates new sequence numbers when it encounters the 0 values, resulting in a table with contents different from the one that was dumped. Enabling **NO_AUTO_VALUE_ON_ZERO** before reloading the dump file solves this problem. For this reason, **mysqldump** automatically includes in its output a statement that enables **NO_AUTO_VALUE_ON_ZERO**.

- **NO_BACKSLASH_ESCAPES**

  Disable the use of the backslash character (\) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other.

- **NO_DIR_IN_CREATE**

  When creating a table, ignore all **INDEX DIRECTORY** and **DATA DIRECTORY** directives. This option is useful on slave replication servers.

- **NO_ENGINE_SUBSTITUTION**

  Control automatic substitution of the default storage engine when a statement such as **CREATE TABLE** or **ALTER TABLE** specifies a storage engine that is disabled or not compiled in.

  By default, **NO.Engine.Substitution** is enabled.

  Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

  With **NO_ENGINE_SUBSTITUTION** disabled, for **CREATE TABLE** the default engine is used and a warning occurs if the desired engine is unavailable. For **ALTER TABLE**, a warning occurs and the table is not altered.

  With **NO_ENGINE_SUBSTITUTION** enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- **NO_UNSIGNED_SUBTRACTION**

  Subtraction between integer values, where one is of type **UNSIGNED**, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

  ```
  mysql> SET sql_mode = '';
  Query OK, 0 rows affected (0.00 sec)
  mysql> SELECT CAST(0 AS UNSIGNED) - 1;
  ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in 'cast(0 as unsigned) - 1'
  ```

  If the **NO_UNSIGNED_SUBTRACTION** SQL mode is enabled, the result is negative:

  ```
  mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
  mysql> SELECT CAST(0 AS UNSIGNED) - 1;
  +-------------------------+
<table>
<thead>
<tr>
<th>CAST(0 AS UNSIGNED) - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
</tr>
</tbody>
</table>
  ```
If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, even if any operand is unsigned. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```sql
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
|-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned | NO   |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
|-------+------------+------+-----+---------+-------+
| c2    | bigint(21) | NO   |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See Section 12.10, "Cast Functions and Operators".

- **NO_ZERO_DATE**

  The `NO_ZERO_DATE` mode affects whether the server permits `0000-00-00` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, `0000-00-00` is permitted and inserts produce no warning.
  
  - If this mode is enabled, `0000-00-00` is permitted and inserts produce a warning.
  
  - If this mode and strict mode are enabled, `0000-00-00` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `0000-00-00` is permitted and inserts produce a warning.

`NO_ZERO_DATE` is deprecated. `NO_ZERO_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- **NO_ZERO_IN_DATE**

  The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as `2010-00-01` or `2010-01-00`, but not `0000-00-00`. To control whether the server permits `0000-00-00`, use the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.
• If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.

• If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.

• If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless IGNORE is given as well. For INSERT IGNORE and UPDATE IGNORE, dates with zero parts are inserted as '0000-00-00' and produce a warning.

NO_ZERO_IN_DATE is deprecated. NO_ZERO_IN_DATE is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if NO_ZERO_IN_DATE is enabled without also enabling strict mode or vice versa.

Because NO_ZERO_IN_DATE is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

• ONLY_FULL_GROUP_BY

Reject queries for which the select list, HAVING condition, or ORDER BY list refer to nonaggregated columns that are neither named in the GROUP BY clause nor are functionally dependent on (uniquely determined by) GROUP BY columns.

A MySQL extension to standard SQL permits references in the HAVING clause to aliased expressions in the select list. The HAVING clause can refer to aliases regardless of whether ONLY_FULL_GROUP_BY is enabled.

For additional discussion and examples, see Section 12.20.3, "MySQL Handling of GROUP BY".

• PAD_CHAR_TO_FULL_LENGTH

By default, trailing spaces are trimmed from CHAR column values on retrieval. If PAD_CHAR_TO_FULL_LENGTH is enabled, trimming does not occur and retrieved CHAR values are padded to their full length. This mode does not apply to VARCHAR columns, for which trailing spaces are retained on retrieval.

Note

As of MySQL 8.0.13, PAD_CHAR_TO_FULL_LENGTH is deprecated. It will be removed in a future version of MySQL.
Query OK, 0 rows affected (0.00 sec)

```
mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------+-----------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>CHAR_LENGTH(c1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>xy</td>
<td>10</td>
</tr>
</tbody>
</table>
+------------+-----------------+
1 row in set (0.00 sec)
```

• **PIPES_AS_CONCAT**

  Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

• **REAL_AS_FLOAT**

  Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

• **STRICT_ALL_TABLES**

  Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see Strict SQL Mode.

• **STRICT_TRANS_TABLES**

  Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see Strict SQL Mode.

• **TIME_TRUNCATE_FRACTIONAL**

  Control whether rounding or truncation occurs when inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column having the same type but fewer fractional digits. The default behavior is to use rounding. If this mode is enabled, truncation occurs instead. The following sequence of statements illustrates the difference:

  ```
  CREATE TABLE t (id INT, tval TIME(1));
  SET sql_mode='';
  INSERT INTO t (id, tval) VALUES(1, 1.55);
  SET sql_mode='TIME_TRUNCATE_FRACTIONAL';
  INSERT INTO t (id, tval) VALUES(2, 1.55);
  ```

  The resulting table contents look like this, where the first value has been subject to rounding and the second to truncation:

  ```
  mysql> SELECT id, tval FROM t ORDER BY id;
  +------+------------+
  | id   | tval       |
  +------+------------+
  |    1 | 00:00:01.6 |
  |    2 | 00:00:01.5 |
  +------+------------+
  ```

  See also Section 11.3.5, “Fractional Seconds in Time Values”.

**Combination SQL Modes**

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

• **ANSI**
Server SQL Modes

Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, and `ONLY_FULL_GROUP_BY`.

`ANSI` mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```sql
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, `MAX(t1.b)` cannot aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

See Section 1.8, “MySQL Standards Compliance”.

- **TRADITIONAL**

  `TRADITIONAL` is equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

**Strict SQL Mode**

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see Section 13.7.6.40, “SHOW WARNINGS Syntax”). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See Section 5.1.8, “Server System Variables”.)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.

- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
Server SQL Modes

- For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.

- For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.7, “Data Type Default Values”.

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes \( \text{MOD}(N, 0) \):

  For data-change operations (`INSERT`, `UPDATE`):

  - If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
  - If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERTIGNORE` and `UPDATEIGNORE`, division by zero inserts `NULL` and produces a warning.

  For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits '0000-00-00' as a valid date:

  - If strict mode is not enabled, '0000-00-00' is permitted and inserts produce no warning.
  - If strict mode is enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERTIGNORE` and `UPDATEIGNORE`, '0000-00-00' is permitted and inserts produce a warning.

  For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as '2010-00-01' or '2010-01-00'):

  - If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
  - If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERTIGNORE` and `UPDATEIGNORE`, dates with zero parts are inserted as '0000-00-00' (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see Comparison of the IGNORE Keyword and Strict SQL Mode.

Strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes.

Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string 'abc' into an integer column).
### Server SQL Modes

#### Operational Mode

<table>
<thead>
<tr>
<th></th>
<th>When Statement Default is Error</th>
<th>When Statement Default is Warning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without <code>IGNORE</code> or strict SQL mode</td>
<td>Error</td>
<td>Warning</td>
</tr>
<tr>
<td>With <code>IGNORE</code></td>
<td>Warning</td>
<td>Warning (same as without <code>IGNORE</code> or strict SQL mode)</td>
</tr>
<tr>
<td>With strict SQL mode</td>
<td>Error (same as without <code>IGNORE</code> or strict SQL mode)</td>
<td>Error</td>
</tr>
<tr>
<td>With <code>IGNORE</code> and strict SQL mode</td>
<td>Warning</td>
<td>Warning</td>
</tr>
</tbody>
</table>

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

#### The Effect of `IGNORE` on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting.

For example, if the table `t` has a primary key column `i`, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```sql
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```sql
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2  Duplicates: 1  Warnings: 1
```

These statements support the `IGNORE` keyword:

- **CREATE TABLE ... SELECT**: `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.
- **DELETE**: `IGNORE` causes MySQL to ignore errors during the process of deleting rows.
- **INSERT**: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.
Server SQL Modes

- **LOAD DATA, LOAD XML**: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.

- **UPDATE**: With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following errors:

```
ER_BAD_NULL_ERROR
ER_DUP_ENTRY
ER_DUP_ENTRY_WITH_KEY_NAME
ER_DUP_KEY
ER_NO_PARTITION_FOR_GIVEN_VALUE
ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT
ER_NO_REFERENCED_ROW_2
ER_NO_REFERENCED_ROW_2
ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET
ER_ROW_IS_REFERENCED_2
ER_SUBQUERY_NO_1_ROW
ER_VIEW_CHECK_FAILED
```

The Effect of Strict SQL Mode on Statement Execution

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.

For example, in non-strict SQL mode, inserting the string 'abc' into an integer column results in conversion of the value to 0 and a warning:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)
mysql> SHOW WARNINGS;
+---------+------+--------------------------------------------------------+
| Level   | Code | Message                                                |
|---------+------|--------------------------------------------------------|
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+---------+------|--------------------------------------------------------+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see Section 5.1.11, “Server SQL Modes”.

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- **ALTER TABLE**
• CREATE TABLE
• CREATE TABLE ... SELECT
• DELETE (both single table and multiple table)
• INSERT
• LOAD DATA
• LOAD XML
• SELECT SLEEP()
• UPDATE (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a NOT NULL column that has no explicit DEFAULT clause in its definition.

5.1.12 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

• MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

    shell> mysql -h ::1

To use this capability, two things must be true:

• Your system must be configured to support IPv6. See Section 5.1.12.1, “Verifying System Support for IPv6”.

• The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the bind_address system variable set to an appropriate value. See Section 5.1.8, “Server System Variables”.

IPv6 Support

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See Section 6.2.4, “Specifying Account Names”. IPv6 addresses can be specified in account names in statements such as `CREATE USER, GRANT, and REVOKE`. For example:

```sql
mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See Section 12.24, “Miscellaneous Functions”.

- From MySQL 8.0.14, Group Replication group members can use IPv6 addresses for communications within the group. A group can contain a mix of members using IPv6 and members using IPv4. See Section 18.4.6, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.12.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```plaintext
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- Windows
- Gentoo Linux
- Ubuntu Linux
- Linux (Generic)
- macOS

### 5.1.12.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces.

Set the `bind_address` system variable at server startup to specify the TCP/IP connections that a server instance accepts. As of MySQL 8.0.13, you can specify multiple values for this option, including any combination of IPv6 addresses, IPv4 addresses, and host names that resolve to IPv6 or IPv4 addresses. Alternatively, you can specify one of the wildcard address formats that permit listening on multiple network interfaces. A value of `*`, which is the default, or a value of `::`, permit both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”. 

---

933
5.1.12.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect
to the local server using the ::1 local host address. The instructions given here assume that your system
supports IPv6.

1. Start the MySQL server with an appropriate bind_address setting to permit it to accept IPv6
connections. For example, put the following lines in the server option file and restart the server:

```sql
[mysqld]
bind_address = *
```

Specifying * (or ::) as the value for bind_address permits both IPv4 and IPv6 connections on all
server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you
can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for bind_address.
This example specifies the local host addresses for both IPv4 and IPv6:

```sql
[mysqld]
bind_address = 127.0.0.1,::1
```

For more information, see the bind_address description in Section 5.1.8, “Server System Variables”.

2. As an administrator, connect to the server and create an account for a local user who will connect from
the ::1 local IPv6 host address:

```sql
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see Section 6.2.4, “Specifying Account
Names”. In addition to the CREATE USER statement, you can issue GRANT statements that give specific
privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the mysql client to connect to the server using the new account:

```sql
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```sql
mysql> STATUS
...
Connection: ::1 via TCP/IP
...
mysql> SELECT CURRENT_USER(), @@bind_address;
```

5.1.12.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is
similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has
its own nonlocal IPv6 address. The example uses these addresses:

Server host: 2001:db8:0:f101::1
IPv6 Support

Client host: 2001:db8:0:f101::2

These addresses are chosen from the nonroutable address range recommended by IANA for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see Section 5.1.12.5, “Obtaining an IPv6 Address from a Broker”.

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

   ```
   [mysqld]
   bind_address = *
   ```

   Specifying * (or ::) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this as of MySQL 8.0.13 by specifying a comma-separated list of values for `bind_address`. This example specifies an IPv4 address as well as the required server host IPv6 address:

   ```
   [mysqld]
   bind_address = 198.51.100.20,2001:db8:0:f101::1
   ```

   For more information, see the `bind_address` description in Section 5.1.8, “Server System Variables”.

2. On the server host (2001:db8:0:f101::1), create an account for a user who will connect from the client host (2001:db8:0:f101::2):

   ```
   mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
   ```

3. On the client host (2001:db8:0:f101::2), invoke the `mysql` client to connect to the server using the new account:

   ```
   shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
   ```

4. Try some simple statements that show connection information:

   ```
   mysql> STATUS
   ... Connection: 2001:db8:0:f101::1 via TCP/IP ...
   ```

   ```
   mysql> SELECT CURRENT_USER(), @@bind_address;
   +-----------------------------------+----------------+
   | CURRENT_USER()                    | @@bind_address |
   +-----------------------------------+----------------+
   | remoteipv6user@2001:db8:0:f101::2 | ::             |
   +-----------------------------------+----------------+
   ```

5.1.12.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The Wikipedia IPv6 Tunnel Broker page lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. You can specify * (or
MySQL Server Time Zone Support

::) as the bind_address value, or bind the server to the specific IPv6 address provided by the broker. For more information, see the bind_address description in Section 5.1.8, “Server System Variables”.

Note that if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you might be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the gogoc IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

http://gogonet.gogo6.com

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

http://gogonet.gogo6.com/page/freenet6-registration

3. As root, install gogoc:

shell> emerge gogoc

4. Edit /etc/gogoc/gogoc.conf to set the userid and password values. For example:

userid=gogouser
passwd=gogopass

5. Start gogoc:

shell> /etc/init.d/gogoc start

To start gogoc each time your system boots, execute this command:

shell> rc-update add gogoc default

6. Use ping6 to try to ping a host:

shell> ping6 ipv6.google.com

7. To see your IPv6 address:

shell> ifconfig tun

5.1.13 MySQL Server Time Zone Support

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

- Time Zone Variables
- Populating the Time Zone Tables
MySQL Server Time Zone Support

- Staying Current with Time Zone Changes
- Time Zone Leap Second Support

For information about time zone settings in replication setups, please see Section 17.4.1, “Replication Features and Issues”.

Time Zone Variables

MySQL Server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine automatically and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezone` option provides another way to set the system time zone. The permissible values for `TZ` and `--timezone` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is `SYSTEM`, which indicates that the server time zone is the same as the system time zone.

  **Note**
  
  If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

  The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

  ```
  default-time-zone='timezone'
  ```

  If you have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

  ```
  SET GLOBAL time_zone = timezone;
  ```

- Per-session time zones. Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

  ```
  SET time_zone = timezone;
  ```

  The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

  The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.
The current global and session time zone values can be retrieved like this:

```sql
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

timezone values can be given in several formats, none of which are case sensitive:

- As the value 'SYSTEM', indicating that the server time zone is the same as the system time zone.
- As a string indicating an offset from UTC, such as '+10:00' or '-6:00'.
- As a named time zone, such as 'Europe/Helsinki', 'US/Eastern', or 'MET'. Named time zones can be used only if the time zone information tables in the mysql database have been created and populated.

### Populating the Time Zone Tables

Several tables in the mysql system schema exist to store time zone information (see Section 5.3, “The mysql System Schema”). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

**Note**

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See Staying Current with Time Zone Changes.

If your system has its own zoneinfo database (the set of files describing time zones), use the mysql_tzinfo_to_sql program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system has no zoneinfo database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the zoneinfo directory path name to mysql_tzinfo_to_sql and send the output into the mysql program. For example:

```bash
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```

The mysql command shown here assumes that you connect to the server using an account such as root that has privileges for modifying tables in the mysql system schema. Adjust the connection parameters as required.

mysql_tzinfo_to_sql reads your system's time zone files and generates SQL statements from them. mysql processes those statements to load the time zone tables.

mysql_tzinfo_to_sql also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke mysql_tzinfo_to_sql like this:

  ```bash
  mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
  ```

  With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.
MySQL Server Time Zone Support

• If your time zone must account for leap seconds, initialize leap second information like this, where `tz_file` is the name of your time zone file:

```
mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
```

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no zoneinfo database (for example, Windows), you can use a package containing SQL statements that is available for download at the MySQL Developer Zone:

`https://dev.mysql.com/downloads/timezones.html`

**Warning**

Do *not* use a downloadable time zone package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

To use an SQL-statement time zone package that you have downloaded, unpack it, then load the unpacked file contents into the time zone tables:

```
mysql -u root -p mysql < file_name
```

Then restart the server.

**Warning**

Do *not* use a downloadable time zone package that contains MyISAM tables. That is intended for older MySQL versions. MySQL now uses InnoDB for the time zone tables. Trying to replace them with MyISAM tables will cause problems.

**Staying Current with Time Zone Changes**

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

• The operating system time affects the value that the MySQL server uses for times if its time zone is set to SYSTEM. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.

• If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

• If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:
  • If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.
  • For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.
MySQL Server Time Zone Support

For instructions for both methods, see Populating the Time Zone Tables. mysqld caches time zone information that it looks up, so after updating the time zone tables, restart mysqld to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server’s time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+----------+
| COUNT(*) |
+----------+
|        0 |
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones will obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
  CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') AS time1,
  CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+---------------------+---------------------+
```

After updating the tables, you should see the correct result:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+---------------------+---------------------+
```

Time Zone Leap Second Support

Leap second values are returned with a time part that ends with :59:59. This means that a function such as NOW() can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with :59:60 or :59:61 are considered invalid.
If it is necessary to search for \texttt{TIMESTAMP} values one second before the leap second, anomalous results may be obtained if you use a comparison with '\texttt{YYYY-MM-DD hh:mm:ss}' values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal \texttt{TIMESTAMP} values (which are in UTC) and displayed values (which have time zone correction applied).

```sql
CREATE TABLE t1 (
    a INT,
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    PRIMARY KEY (ts)
);
```

Query OK, 0 rows affected (0.01 sec)

```sql
-- change to UTC
SET time_zone = '+00:00';
```

Query OK, 0 rows affected (0.00 sec)

```sql
-- Simulate NOW() = '2008-12-31 23:59:59'
SET timestamp = 1230767999;
```

Query OK, 0 rows affected (0.00 sec)

```sql
-- Simulate NOW() = '2008-12-31 23:59:60'
SET timestamp = 1230768000;
```

Query OK, 0 rows affected (0.00 sec)

```sql
-- values differ internally but display the same
SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
```

```
+----+---------------------+--------------------+
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
<th>UNIX_TIMESTAMP(ts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2008-12-31 23:59:59</td>
<td>1230767999</td>
</tr>
<tr>
<td>2</td>
<td>2008-12-31 23:59:59</td>
<td>1230768000</td>
</tr>
</tbody>
</table>
+----+---------------------+--------------------+
2 rows in set (0.00 sec)
```

```sql
-- only the non-leap value matches
SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
```

```
+----+---------------------+
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2008-12-31 23:59:59</td>
</tr>
</tbody>
</table>
+----+---------------------+
1 row in set (0.00 sec)
```

```sql
-- the leap value with seconds=60 is invalid
SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
```

Empty set, 2 warnings (0.00 sec)

To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```sql
-- selecting using UNIX_TIMESTAMP value return leap value
SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
```

```
+----+---------------------+
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2008-12-31 23:59:59</td>
</tr>
</tbody>
</table>
+----+---------------------+
```
5.1.14 Server-Side Help Support

MySQL Server supports a HELP statement that returns information from the MySQL Reference Manual (see Section 13.8.3, “HELP Syntax”). This information is stored in several tables in the mysql schema (see Section 5.3, “The mysql System Schema”). Proper operation of the HELP statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see Section 2.10.1, “Initializing the Data Directory”). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is upgraded automatically by the server as of MySQL 8.0.16. Prior to MySQL 8.0.16, the content is not upgraded automatically, but you can upgrade it manually. Locate the fill_help_tables.sql file in the share or share/mysql directory. Change location into that directory and process the file with the mysql client as follows:

```
mysql -u root -p mysql < fill_help_tables.sql
```

The command shown here assumes that you connect to the server using an account such as root that has privileges for modifying tables in the mysql schema. Adjust the connection parameters as required.

Prior to MySQL 8.0.16, if you are working with Git and a MySQL development source tree, the source tree contains only a "stub" version of fill_help_tables.sql. To obtain a non-stub copy, use one from a source or binary distribution.

**Note**

Each MySQL series has its own series-specific reference manual, so help-table content is series specific as well. This has implications for replication because help-table content should match the MySQL series. If you load MySQL 8.0 help content into a MySQL 8.0 master server, it does not make sense to replicate that content to a slave server from a different MySQL series and for which that content is not appropriate. For this reason, as you upgrade individual servers in a replication scenario, you should upgrade each server's help tables, using the instructions given earlier. (Manual help-content upgrade is necessary only for replication servers from versions lower than 8.0.16. As mentioned in the preceding instructions, content upgrades occur automatically as of MySQL 8.0.16.)

5.1.15 Server Tracking of Client Session State Changes

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

One use for the tracker mechanism is to provide a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

Another use for the tracker mechanism is to permit applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-
balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:

- Immediately after `START TRANSACTION`
- After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

```
READ ONLY
READ WRITE
ISOLATION LEVEL
WITH CONSISTENT SNAPSHOT
```

To support the preceding session-switching activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
  - The default schema (database).
  - Session-specific values for system variables.
  - User-defined variables.
  - Temporary tables.
  - Prepared statements.

  The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.

- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker.

- Available GTIDs. The `session_track_gtids` system variable controls this tracker.

- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see Section 5.1.8, “Server System Variables”. Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected. To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:
• `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See Section 28.7.7.69, “mysql_session_track_get_first()”.

• `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See Section 28.7.7.70, “mysql_session_track_get_next()”.

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```sql
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
SET @@SESSION.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(1, RAND());
COMMIT;
```

Run the script as follows to see the information provided by the enabled trackers. For a description of the Tracker: information displayed by `mysqltest` for the various trackers, see Section 28.7.7.69, “mysql_session_track_get_first()”.

```
shell> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
SET @@SESSION.session_track_state_change=ON;
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_system_variables
-- *
SET @@SESSION.session_track_state_change=ON;
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_state_change
-- ON
USE information_schema;
-- Tracker : SESSION_TRACK_SCHEMA
-- information_schema
-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1
SET NAMES 'utf8mb4';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- character_set_client
-- utf8mb4
-- character_set_connection
-- utf8mb4
-- character_set_results
-- utf8mb4
```
Preceding the `START TRANSACTION` statement, two `SET TRANSACTION` statements execute that set the isolation level and access mode characteristics for the next transaction. The `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value indicates those next-transaction values that have been set.

Following the `COMMIT` statement that ends the transaction, the `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value is reported as empty. This indicates that the next-transaction characteristics that were set preceding the start of the transaction have been reset, and that the session defaults apply. To track changes to those session defaults, track the session values of the `transaction_isolation` and `transaction_read_only` system variables.
5.1.16 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- **SIGTERM** causes the server to shut down.
- **SIGHUP** causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:
Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:       8388600
Block_size:           1024
Division_limit:        100
Age_limit:             300
blocks used:            0
not flushed:            0
w_requests:             0
writes:                  0
r_requests:             0
reads:                   0

handler status:
read_key:            0
read_next:           0
read_rnd            0
read_first:          1
write:                0
delete:              0
update:               0

Table status:
Opened tables:          5
Open tables:            0
Open files:             7
Open streams:           0

Alarm status:
Active alarms:   1
Max used alarms: 2
Next alarm time: 67
```

5.1.17 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.
The Server Shutdown Process

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a SIGTERM signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.7.7.4, "KILL Syntax", in particular for the instructions about killed REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a KILL QUERY or KILL CONNECTION statement. See also Section 13.4.2.7, "STOP SLAVE Syntax". Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

```
Note
To guarantee crash safety on the slave, you must run the slave with --relay-log-recovery enabled.
```

See also Section 17.2.4, “Replication Relay and Status Logs”.

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. InnoDB flushes its buffer pool to disk (unless innodb_fast_shutdown is 2), writes the current LSN to the tablespace, and terminates its own internal threads. MyISAM flushes any pending index writes for a table.

6. The server exits.
To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by systemd in response to the code, for platforms on which systemd is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
  - The `mysql` directory corresponds to the `mysql` system schema, which contains information required by the MySQL server as it runs. This database contains data dictionary tables and system tables. See Section 5.3, “The mysql System Schema”.
  - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See Chapter 26, MySQL Performance Schema.
  - The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See Chapter 27, MySQL sys Schema.
  - The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

Other subdirectories correspond to databases created by users or applications.

**Note**

INFORMATION_SCHEMA is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See Section 5.4, “MySQL Server Logs”.
- InnoDB tablespace and log files. See Chapter 15, The InnoDB Storage Engine.
- Default/autogenerated SSL and RSA certificate and key files. See Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.
- The server process ID file (while the server is running).
- The `mysqld-auto.cnf` file that stores persisted global system variable settings. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.
5.3 The mysql System Schema

The mysql schema is the system schema. It contains tables that store information required by the MySQL server as it runs. A broad categorization is that the mysql schema contains data dictionary tables that store database object metadata, and system tables used for other operational purposes. The following discussion further subdivides the set of system tables into smaller categories.

- Data Dictionary Tables
- Grant System Tables
- Object Information System Tables
- Log System Tables
- Server-Side Help System Tables
- Time Zone System Tables
- Replication System Tables
- Optimizer System Tables
- Miscellaneous System Tables

The remainder of this section enumerates the tables in each category, with cross references for additional information. Data dictionary tables and system tables use the InnoDB storage engine unless otherwise indicated.

mysql system tables and data dictionary tables reside in a single InnoDB tablespace file named mysql.ibd in the MySQL data directory. Previously, these tables were created in individual tablespace files in the mysql database directory.

Data-at-rest encryption can be enabled for the mysql system schema tablespace. For more information, see Section 15.6.3.9, “InnoDB Data-at-Rest Encryption”.

Data Dictionary Tables

These tables comprise the data dictionary, which contains metadata about database objects. For additional information, see Chapter 14, MySQL Data Dictionary.

Important

The data dictionary is new in MySQL 8.0. A data dictionary-enabled server entails some general operational differences compared to previous MySQL releases. For details, see Section 14.7, “Data Dictionary Usage Differences”. Also, for upgrades to MySQL 8.0 from MySQL 5.7, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see Section 2.11, “Upgrading MySQL”, particularly Section 2.11.5, “Preparing Your Installation for Upgrade”.

- catalogs: Catalog information.
- character_sets: Information about available character sets.
- check_constraints: Information about CHECK constraints defined on tables. See Section 13.1.20.7, “CHECK Constraints”.
Data Dictionary Tables

- **collations**: Information about collations for each character set.
- **column_statistics**: Histogram statistics for column values. See Section 8.9.6, “Optimizer Statistics”.
- **column_type_elements**: Information about types used by columns.
- **columns**: Information about columns in tables.
- **dd_properties**: A table that identifies data dictionary properties, such as its version. The server uses this to determine whether the data dictionary must be upgraded to a newer version.
- **events**: Information about Event Scheduler events. See Section 24.4, “Using the Event Scheduler”. The server loads events listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- **foreign_keys, foreign_key_column_usage**: Information about foreign keys.
- **index_column_usage**: Information about columns used by indexes.
- **index_partitions**: Information about partitions used by indexes.
- **index_stats**: Used to store dynamic index statistics generated when `ANALYZE TABLE` is executed.
- **indexes**: Information about table indexes.
- **innodb_ddl_log**: Stores DDL logs for crash-safe DDL operations.
- **parameter_type_elements**: Information about stored procedure and function parameters, and about return values for stored functions.
- **parameters**: Information about stored procedures and functions. See Section 24.2, “Using Stored Routines”.
- **resource_groups**: Information about resource groups. See Section 8.12.5, “Resource Groups”
- **routines**: Information about stored procedures and functions. See Section 24.2, “Using Stored Routines”.
- **schemata**: Information about schemata. In MySQL, a schema is a database, so this table provides information about databases.
- **st_spatial_reference_systems**: Information about available spatial reference systems for spatial data.
- **table_partition_values**: Information about values used by table partitions.
- **table_partitions**: Information about partitions used by tables.
- **table_stats**: Information about dynamic table statistics generated when `ANALYZE TABLE` is executed.
- **tables**: Information about tables in databases.
- **tablespace_files**: Information about files used by tablespaces.
- **tablespaces**: Information about active tablespaces.
- **triggers**: Information about triggers.
Grant System Tables

- **view_routine_usage**: Information about dependencies between views and stored functions used by them.

- **view_table_usage**: Used to track dependencies between views and their underlying tables.

Data dictionary tables are invisible. They cannot be read with SELECT, do not appear in the output of SHOW TABLES, are not listed in the INFORMATION_SCHEMA.TABLES table, and so forth. However, in most cases there are corresponding INFORMATION_SCHEMA tables that can be queried. Conceptually, the INFORMATION_SCHEMA provides a view through which MySQL exposes data dictionary metadata. For example, you cannot select from the mysql.schemata table directly:

```sql
mysql> SELECT * FROM mysql.schemata;
ERROR 3554 (HY000): Access to data dictionary table 'mysql.schemata' is rejected.
```

Instead, select that information from the corresponding INFORMATION_SCHEMA table:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
```

```
*************************** 1. row ***************************
CATALOG_NAME: def
SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: utf8mb4
DEFAULT_COLLATION_NAME: utf8mb4_0900_ai_ci
SQL_PATH: NULL
DEFAULT_ENCRYPTION: NO
*************************** 2. row ***************************
CATALOG_NAME: def
SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
DEFAULT_COLLATION_NAME: utf8_general_ci
SQL_PATH: NULL
DEFAULT_ENCRYPTION: NO
```

There is no INFORMATION_SCHEMA table that corresponds exactly to mysql.indexes, but INFORMATION_SCHEMA.STATISTICS contains much of the same information.

As of yet, there are no INFORMATION_SCHEMA tables that correspond exactly to mysql.foreign_keys, mysql.foreign_key_column_usage. The standard SQL way to obtain foreign key information is by using the INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS and KEY_COLUMN_USAGE tables; these tables are now implemented as views on the foreign_keys, foreign_key_column_usage, and other data dictionary tables.

Some system tables from before MySQL 8.0 have been replaced by data dictionary tables and are no longer present in the mysql system schema:

- The **events** data dictionary table supersedes the **event** table from before MySQL 8.0.

- The **parameters** and **routines** data dictionary tables together supersed the **proc** table from before MySQL 8.0.

**Grant System Tables**

These system tables contain grant information about user accounts and the privileges held by them. For additional information about the structure, contents, and purpose of the these tables, see Section 6.2.3, “Grant Tables”.

As of MySQL 8.0, the grant tables are InnoDB (transactional) tables. Previously, these were MyISAM (nontransactional) tables. The change of grant-table storage engine underlies an accompanying change in MySQL 8.0 to the behavior of account-management statements such as CREATE USER and GRANT.
Previously, an account-management statement that named multiple users could succeed for some users and fail for others. The statements are now transactional and either succeed for all named users or roll back and have no effect if any error occurs.

Note
If MySQL is upgraded from an older version but the grant tables have not been upgraded from MyISAM to InnoDB, the server considers them read only and account-management statements produce an error. For upgrade instructions, see Section 2.11, “Upgrading MySQL”.

- **user**: User accounts, global privileges, and other nonprivilege columns.
- **global_grants**: Assignments of dynamic global privileges to users; see Static Versus Dynamic Privileges.
- **db**: Database-level privileges.
- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.
- **default_roles**: This table lists default roles to be activated after a user connects and authenticates, or executes `SET ROLE DEFAULT`.
- **role_edges**: This table lists edges for role subgraphs.

A given **user** table row might refer to a user account or a role. The server can distinguish whether a row represents a user account, a role, or both by consulting the **role_edges** table for information about relations between authentication IDs.

- **password_history**: Information about password changes.

## Object Information System Tables

These system tables contain information about stored programs, components, user-defined functions, and server-side plugins:

- **component**: The registry for server components. Any components listed in this table are installed by a loader service during the server startup sequence. See Section 5.5, “MySQL Server Components”.

- **func**: Information about user-defined functions (UDFs). See Section 29.4, “Adding New Functions to MySQL”. The server loads UDFs listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.

- **plugin**: Information about server-side plugins. See Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 29.2, “The MySQL Plugin API”. The server loads plugins listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.

## Log System Tables

The server uses these system tables for logging:

- **general_log**: The general query log table.
Server-Side Help System Tables

These system tables contain server-side help information:

• **help_category**: Information about help categories.
• **help_keyword**: Keywords associated with help topics.
• **help_relation**: Mappings between help keywords and topics.
• **help_topic**: Help topic contents.

For more information, see Section 5.1.14, “Server-Side Help Support”.

Time Zone System Tables

These system tables contain time zone information:

• **time_zone**: Time zone IDs and whether they use leap seconds.
• **time_zone_leap_second**: When leap seconds occur.
• **time_zone_name**: Mappings between time zone IDs and names.
• **time_zone_transition, time_zone_transition_type**: Time zone descriptions.

For more information, see Section 5.1.13, “MySQL Server Time Zone Support”.

Replication System Tables

The server uses these system tables to support replication:

• **gtid_executed**: Table for storing GTID values. See mysql.gtid_executed Table.
• **ndb_binlog_index**: Binary log information for NDB Cluster replication. This table is created only if the server is built with NDBCLUSTER support. See Section 22.6.4, “NDB Cluster Replication Schema and Tables”.
• **slave_master_info, slave_relay_log_info, slave_worker_info**: Used to store replication information on slave servers. See Section 17.2.4, “Replication Relay and Status Logs”.

All of the tables just listed use the InnoDB storage engine.

Optimizer System Tables

These system tables are for use by the optimizer:

• **innodb_index_stats, innodb_table_stats**: Used for InnoDB persistent optimizer statistics. See Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.
• **server_cost, engine_cost**: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. **server_cost** contains optimizer cost estimates for general server operations. **engine_cost** contains estimates for operations specific to particular storage engines. See Section 8.9.5, “The Optimizer Cost Model”.
Miscellaneous System Tables

Other system tables do not fit the preceding categories:

- **audit_log_filter, audit_log_user**: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See Audit Log Tables.

- **firewall_users, firewall_whitelist**: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See Section 6.4.7, “MySQL Enterprise Firewall”.

- **servers**: Used by the FEDERATED storage engine. See Section 16.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”.

- **innodb_dynamic_metadata**: Used by the InnoDB storage engine to store fast-changing table metadata such as auto-increment counter values and index tree corruption flags. Replaces the data dictionary buffer table that resided in the InnoDB system tablespace.

5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

<table>
<thead>
<tr>
<th>Log Type</th>
<th>Information Written to Log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error log</td>
<td>Problems encountered starting, running, or stopping mysqld</td>
</tr>
<tr>
<td>General query log</td>
<td>Established client connections and statements received from clients</td>
</tr>
<tr>
<td>Binary log</td>
<td>Statements that change data (also used for replication)</td>
</tr>
<tr>
<td>Relay log</td>
<td>Data changes received from a replication master server</td>
</tr>
<tr>
<td>Slow query log</td>
<td>Queries that took more than long_query_time seconds to execute</td>
</tr>
<tr>
<td>DDL log (metadata log)</td>
<td>Metadata operations performed by DDL statements</td>
</tr>
</tbody>
</table>

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see Section 5.4.6, “The DDL Log”.) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a FLUSH LOGS statement; execute mysqladmin with a flush-logs or refresh argument; or execute mysqldump with a --flush-logs or --master-data option. See Section 13.7.7.3, “FLUSH Syntax”, Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”, and Section 4.5.4, “mysqldump — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the max_binlog_size system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”, Section 5.4.3, “The General Query Log”, and Section 5.4.5, “The Slow Query Log”.

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see Section 17.2.4.1, “The Slave Relay Log”.

For information about log maintenance operations such as expiration of old log files, see Section 5.4.7, “Server Log Maintenance”.

954
For information about keeping logs secure, see Section 6.1.2.3, “Passwords and Logging”.

5.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the general_log and slow_log tables in the mysql system database. File output, table output, or both can be selected.

- **Log Control at Server Startup**
  
  - **Log Control at Runtime**
  
  - **Log Table Benefits and Characteristics**

**Log Control at Server Startup**

The log_output system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If log_output is not specified at startup, the default logging destination is FILE.

- If log_output is specified at startup, its value is a list one or more comma-separated words chosen from TABLE (log to tables), FILE (log to files), or NONE (do not log to tables or files). NONE, if present, takes precedence over any other specifiers.

The general_log system variable controls logging to the general query log for the selected log destinations. If specified at server startup, general_log takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the general_log_file variable. Similarly, the slow_query_log variable controls logging to the slow query log for the selected destinations and setting slow_query_log_file specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the FILE log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use --log_output=TABLE,FILE to select both log destinations and --general_log to enable the general query log.

- To write general and slow query log entries only to the log tables, use --log_output=TABLE to select tables as the log destination and --general_log and --slow_query_log to enable both logs.

- To write slow query log entries only to the log file, use --log_output=FILE to select files as the log destination and --slow_query_log to enable the slow query log. In this case, because the default log destination is FILE, you could omit the log_output setting.

**Log Control at Runtime**

The system variables associated with log tables and files enable runtime control over logging:

- The log_output variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The general_log and slow_query_log variables indicate whether the general query log and slow query log are enabled (ON) or disabled (OFF). You can set these variables at runtime to control whether the logs are enabled.
Selecting General Query Log and Slow Query Log Output Destinations

- The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.

- To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Log Table Benefits and Characteristics

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

  ```sql
  SHOW CREATE TABLE mysql.general_log;
  SHOW CREATE TABLE mysql.slow_log;
  ```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.

- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.

- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input. The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

Log Tables and “Too many open files” Errors. If you select `TABLE` as a log destination and the log tables use the `CSV` storage engine, you may find that disabling and enabling the general query log or slow query log repeatedly at runtime results in a number of open file descriptors for the `.CSV` file, possibly resulting in a “Too many open files” error. To work around this issue, execute `FLUSH TABLES` or ensure that the value of `open_files_limit` is greater than the value of `table_open_cache_instances`.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

  ```sql
  SET @old_log_state = @@GLOBAL.general_log;
  SET GLOBAL general_log = 'OFF';
  ALTER TABLE mysql.general_log ENGINE = MyISAM;
  ```
SET GLOBAL general_log = @old_log_state;

- **TRUNCATE TABLE** is a valid operation on a log table. It can be used to expire log entries.

- **RENAME TABLE** is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

  ```sql
  USE mysql;
  DROP TABLE IF EXISTS general_log2;
  CREATE TABLE general_log2 LIKE general_log;
  RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
  ```

- **CHECK TABLE** is a valid operation on a log table.

- **LOCK TABLES** cannot be used on a log table.

- **INSERT**, **DELETE**, and **UPDATE** cannot be used on a log table. These operations are permitted only internally to the server itself.

- **FLUSH TABLES WITH READ LOCK** and the state of the **read_only** system variable have no effect on log tables. The server can always write to the log tables.

- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.

- To flush the log tables or log files, use **FLUSH TABLES** or **FLUSH LOGS**, respectively.

- Partitioning of log tables is not permitted.

- A **mysqldump** dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

### 5.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set or language, see Section 10.6, “Error Message Character Set”, or Section 10.11, “Setting the Error Message Language”.

The error log contains a record of **mysqld** startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if **mysqld** notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if **mysqld** exits abnormally. The trace can be used to determine where **mysqld** exited. See Section 29.5, “Debugging and Porting MySQL”.

If used to start **mysqld**, **mysqld_safe** may write messages to the error log. For example, when **mysqld_safe** notices abnormal **mysqld** exits, it restarts **mysqld** and writes a **mysqld restarted** message to the error log.

The following sections discuss aspects of configuring error logging.

#### 5.4.2.1 Error Log Component Configuration

In MySQL 8.0, error logging uses the MySQL component architecture described at Section 5.5, “MySQL Server Components”. The error log subsystem consists of components that perform log event filtering and
Component-based error logging offers these features:

- Log events can be filtered by filter components to affect the information available for writing.
- Log events are output by sink (writer) components. Multiple sink components can be enabled, to write error log output to multiple destinations.
- Built-in filter and writer components combine to implement the default error log format.
- A loadable writer enables logging in JSON format.
- A loadable writer enables logging to the system log.
- System variables control which log components to enable and how each component operates.

The `log_error_services` system variable controls which log components to enable for error logging. The variable may contain a list with 0, 1, or many elements. In the latter case, elements may be delimited by semicolon or (as of MySQL 8.0.12) comma, optionally followed by space. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed.

By default, `log_error_services` has this value:

```
mysql> SELECT @@GLOBAL.log_error_services;
+----------------------------------------+
| @@GLOBAL.log_error_services            |
+----------------------------------------+
| log_filter_internal; log_sink_internal |
```

That value indicates that log events first pass through the built-in filter component, `log_filter_internal`, then through the built-in log writer component, `log_sink_internal`. A filter modifies log events seen by components named later in the `log_error_services` value. A sink is a destination for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log.

**Note**

Assigning `log_error_services` a value that contains no writer components causes no log output to be written from that point.

The final component in the `log_error_services` value should be a writer. If the final component is a filter, the component has no effect because the filtered events are not sent to any writer.

The combination of `log_filter_internal` and `log_sink_internal` implements the default error log filtering and output behavior. The action of these components is affected by other server options and system variables:
The output destination is determined by the `--log-error` option (and, on Windows, `--pid-file` and `--console`). These determine whether to write error messages to the console or a file and, if to a file, the error log file name. See Section 5.4.2.2, “Default Error Log Destination Configuration”.

The `log_error_verbosity` and `log_error_suppression_list` system variables affect which types of log events `log_filter_internal` permits or suppresses. See Section 5.4.2.4, “Priority-Based Error Log Filtering (log_filter_internal)”.

To change the set of log components used for error logging, load components as necessary and modify the `log_error_services` value. Adding or removing log components is subject to these constraints:

- To enable a log component, first load it using `INSTALL COMPONENT` (unless it is built in or already loaded), then list the component in the `log_error_services` value.

  For a component to be permitted in the `log_error_services` value, it must be known. A component is known if it is built in, or if it is loadable and has been loaded using `INSTALL COMPONENT`. Attempts to name an unknown component at server startup cause `log_error_services` to be set to its default value. Attempts to name an unknown component at runtime produce an error and the `log_error_services` value remains unchanged.

- To disable a log component, remove it from the `log_error_services` value. Then, if the component is loadable and you also want to unload it, use `UNINSTALL COMPONENT`.

  Attempts to use `UNINSTALL COMPONENT` to unload a loadable component that is still named in the `log_error_services` value produce an error.

For example, to use the system log writer (`log_sink_syseventlog`) instead of the default writer (`log_sink_internal`), first load the writer component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

Note

The URN to use for loading a log component with `INSTALL COMPONENT` is the component name prefixed with `file://component_`. For example, for the `log_sink_syseventlog` component, the corresponding URN is `file://component_log_sink_syseventlog`.

It is possible to configure multiple log writers, which enables sending output to multiple destinations. To enable the system log writer in addition to (rather than instead of) the default writer, set the `log_error_services` value like this:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal; log_sink_syseventlog';
```

To revert to using only the default writer and unload the system log writer, execute these statements:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
UNINSTALL COMPONENT 'file://component_log_sink_syseventlog';
```

To configure a log component to be enabled at each server startup, use this procedure:

1. If the component is loadable, load it at runtime using `INSTALL COMPONENT`. Loading the component registers it in the `mysql.component` system table so that the server loads it automatically for subsequent startups.
2. Set the `log_error_services` value at startup to include the component name. Set the value either in the server `my.cnf` file, or use `SET PERSIST`, which sets the value for the running MySQL instance and also saves the value to be used for subsequent server restarts; see Section 13.7.5.1, “SET Syntax for Variable Assignment”. A value set in `my.cnf` takes effect at the next restart. A value set using `SET PERSIST` takes effect immediately, and for subsequent restarts.

Suppose that you want to configure, for every server startup, use of the JSON log writer (`log_sink_json`) in addition to the built-in log filter and writer (`log_filter_internal, log_sink_internal`). First load the JSON writer if it is not loaded:

```
INSTALL COMPONENT 'file://component_log_sink_json';
```

Then set `log_error_services` to take effect at server startup. You can set it in `my.cnf`:

```
[mysqld]
log_error_services='log_filter_internal; log_sink_internal; log_sink_json'
```

Or you can set it using `SET PERSIST`:

```
SET PERSIST log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

The order of components named in `log_error_services` is significant, particularly with respect to the relative order of filters and writers. Consider this `log_error_services` value:

```
log_filter_internal; log_sink_1; log_sink_2
```

In this case, log events pass to the built-in filter, then to the first writer, then to the second writer. Both writers receive the filtered log events.

Compare that to this `log_error_services` value:

```
log_sink_1; log_filter_internal; log_sink_2
```

In this case, log events pass to the first writer, then to the built-in filter, then to the second writer. The first writer receives unfiltered events. The second writer receives filtered events. You might configure error logging this way if you want one log that contains messages for all log events, and another log that contains messages only for a subset of log events.

### 5.4.2.2 Default Error Log Destination Configuration

This section discusses which server options configure the default error log destination, which can be the console or a named file. It also indicates which log writer components base their own output destination on the default destination.

In this discussion, “console” means `stderr`, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine the default error log destination somewhat differently for Windows and Unix systems. Be sure to configure the destination using the information appropriate to your platform:

- For Windows, see Default Error Log Destination on Windows.
• For Unix and Unix-like systems, see Default Error Log Destination on Unix and Unix-Like Systems.

After the server interprets the default error log destination options, it sets the log_error system variable to indicate the default destination, which affects where several log writer components write error messages. See How the Default Error Log Destination Affects Log Writers.

• Default Error Log Destination on Windows

• Default Error Log Destination on Unix and Unix-Like Systems

• How the Default Error Log Destination Affects Log Writers

Default Error Log Destination on Windows

On Windows, mysqld uses the --log-error, --pid-file, and --console options to determine whether the default error log destination is the console or a file, and, if a file, the file name:

• If --console is given, the default destination is the console. (--console takes precedence over --log-error if both are given, and the following items regarding --log-error do not apply.)

• If --log-error is not given, or is given without naming a file, the default destination is a file named host_name.err in the data directory, unless the --pid-file option is specified. In that case, the file name is the PID file base name with a suffix of .err in the data directory.

• If --log-error is given to name a file, the default destination is that file (with an .err suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

If the default error log destination is the console, the server sets the log_error system variable to stderr. Otherwise, the default destination is a file and the server sets log_error to the file name.

Default Error Log Destination on Unix and Unix-Like Systems

On Unix and Unix-like systems, mysqld uses the --log-error option to determine whether the default error log destination is the console or a file, and, if a file, the file name:

• If --log-error is not given, the default destination is the console.

• If --log-error is given without naming a file, the default destination is a file named host_name.err in the data directory.

• If --log-error is given to name a file, the default destination is that file (with an .err suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

• If --log-error is given in an option file in a [mysqld], [server], or [mysqld_safe] section, mysqld_safe finds and uses the option, and passes it to mysqld.

Note

It is common for Yum or APT package installations to configure an error log file location under /var/log with an option like log-error=/var/log/mysqld.log in a server configuration file. Removing the file name from the option causes the host_name.err file in the data directory to be used.

If the default error log destination is the console, the server sets the log_error system variable to stderr. Otherwise, the default destination is a file and the server sets log_error to the file name.
How the Default Error Log Destination Affects Log Writers

After the server interprets the error log destination configuration options, it sets the `log_error` system variable to indicate the default error log destination. Log writer components may base their own output destination on the `log_error` value, or determine their destination independently of `log_error`.

If `log_error` is `stderr`, the default error log destination is the console, and log writers that base their output destination on the default destination also write to the console:

- `log_sink_internal, log_sink_json, log_sink_test`: These writers write to the console. This is true even for writers such as `log_sink_json` that can be enabled multiple times; all instances write to the console.
- `log_sink_syseventlog`: This writer writes to the system log, regardless of the `log_error` value.

If `log_error` is not `stderr`, the default error log destination is a file and `log_error` indicates the file name. Log writers that base their output destination on the default destination base output file naming on that file name. (A writer might use exactly that name, or it might use some variant thereof.) Suppose that the `log_error` value is `file_name`. Then log writers use the name like this:

- `log_sink_internal, log_sink_test`: These writers write to `file_name`.
- `log_sink_json`: Successive instances of this writer named in the `log_error_services` value write to files named `file_name` plus a numbered `.NN.json` suffix: `file_name.00.json`, `file_name.01.json`, and so forth.
- `log_sink_syseventlog`: This writer writes to the system log, regardless of the `log_error` value.

5.4.2.3 Types of Error Log Filtering

Error log configuration normally includes one log filter component and one or more log writer component. For error log filtering, MySQL offers a choice of components:

- `log_filter_internal`: This filter component provides error log filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. `log_filter_internal` is built in and enabled by default. See Section 5.4.2.4, “Priority-Based Error Log Filtering (log_filter_internal)”.

- `log_filter_dragnet`: This filter component provides error log filtering based on user-supplied rules, in combination with the `drgnet.log_error_filter_rules` system variable. See Section 5.4.2.5, “Rule-Based Error Log Filtering (log_filter_dragnet)”.

5.4.2.4 Priority-Based Error Log Filtering (log_filter_internal)

The `log_filter_internal` log filter component implements a simple form of log filtering based on event priority and error code. To affect how `log_filter_internal` permits or suppresses error, warning, and information events intended for the error log, set the `log_error_verbosity` and `log_error_suppression_list` system variables.

- `log_filter_internal` is built in and enabled by default. If this filter is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect, so filtering must be modeled using another filter service instead where desired (for example, with individual filter rules when using `log_filter_dragnet`). For information about filter configuration, see Section 5.4.2.1, “Error Log Component Configuration”.

- Verbosity Filtering
Suppression-List Filtering

Verbosity and Suppression-List Interaction

Verbosity Filtering

Events intended for the error log have a priority of \texttt{ERROR}, \texttt{WARNING}, or \texttt{INFORMATION}. The \texttt{log_error_verbosity} system variable controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

<table>
<thead>
<tr>
<th>Permitted Message Priorities</th>
<th>log_error_verbosity Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{ERROR}</td>
<td>1</td>
</tr>
<tr>
<td>\texttt{ERROR, WARNING}</td>
<td>2</td>
</tr>
<tr>
<td>\texttt{ERROR, WARNING, INFORMATION}</td>
<td>3</td>
</tr>
</tbody>
</table>

If \texttt{log_error_verbosity} is 2 or greater, the server logs messages about statements that are unsafe for statement-based logging. If the value is 3, the server logs aborted connections and access-denied errors for new connection attempts. See Section B.4.2.10, “Communication Errors and Aborted Connections”.

If you use replication, a \texttt{log_error_verbosity} value of 2 or greater is recommended, to obtain more information about what is happening, such as messages about network failures and reconnects.

If \texttt{log_error_verbosity} is 2 or greater on a slave server, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

There is also a priority of \texttt{SYSTEM}. System messages about non-error situations are printed to the error log regardless of the \texttt{log_error_verbosity} value. These messages include startup and shutdown messages, and some significant changes to settings.

In the MySQL error log, system messages are labeled as “System”. Other log writers might or might not follow the same convention, and in the resulting logs, system messages might be assigned the label used for the information priority level, such as “Note” or “Information”. If you apply any additional filtering or redirection for logging based on the labeling of messages, system messages do not override your filter, but are handled by it in the same way as other messages.

Suppression-List Filtering

The \texttt{log_error_suppression_list} system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of \texttt{WARNING} or \texttt{INFORMATION}. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed.

The \texttt{log_error_suppression_list} value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the \texttt{MY-} prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

\begin{verbatim}
ER\_SERVER\_SHUTDOWN\_COMPLETE
MY-000031
000031
MY-31
31
\end{verbatim}
Symbolic values are preferable to numeric values for readability and portability.

Although codes to be suppressed can be expressed in symbolic or numeric form, the numeric value of each code must be in a permitted range:

- 1 to 999: Global error codes that are used by the server as well as by clients.
- 10000 and higher: Server error codes intended to be written to the error log (not sent to clients).

In addition, each error code specified must actually be used by MySQL. Attempts to specify a code not within a permitted range or within a permitted range but not used by MySQL produce an error and the \texttt{log\_error\_suppression\_list} value remains unchanged.

For information about error code ranges and the error symbols and numbers defined within each range, see Appendix B, \textit{Errors, Error Codes, and Common Problems}.

The server can generate messages for a given error code at differing priorities, so suppression of a message associated with an error code listed in \texttt{log\_error\_suppression\_list} depends on its priority. Suppose that the variable has a value of '\texttt{ER\_PARSER\_TRACE,MY-010001,10002}'. Then \texttt{log\_error\_suppression\_list} has these effects:

- Messages for those codes are suppressed if generated with a priority of \texttt{WARNING} or \texttt{INFORMATION}.
- Messages generated with a priority of \texttt{ERROR} or \texttt{SYSTEM} are not suppressed.

\textbf{Verbosity and Suppression-List Interaction}

The effect of \texttt{log\_error\_verbosity} combines with that of \texttt{log\_error\_suppression\_list}. Consider a server started with these settings:

```
[mysqld]
log_error_verbosity=2     # error and warning messages only
log_error_suppression_list='ER\_PARSER\_TRACE,MY-010001,10002'
```

In this case, \texttt{log\_error\_verbosity} permits messages with \texttt{ERROR} or \texttt{WARNING} priority and discards messages with \texttt{INFORMATION} priority. Of the nondiscarded messages, \texttt{log\_error\_suppression\_list} discards messages with \texttt{WARNING} priority and any of the named error codes.

\textbf{Note}

The \texttt{log\_error\_verbosity} value of 2 shown in the example is also its default value, so the effect of this variable on \texttt{INFORMATION} messages is as just described by default, without an explicit setting. You must set \texttt{log\_error\_verbosity} to 3 if you want \texttt{log\_error\_suppression\_list} to affect messages with \texttt{INFORMATION} priority.

Consider a server started with this setting:

```
[mysqld]
log_error_verbosity=1     # error messages only
```

In this case, \texttt{log\_error\_verbosity} permits messages with \texttt{ERROR} priority and discards messages with \texttt{WARNING} or \texttt{INFORMATION} priority. Setting \texttt{log\_error\_suppression\_list} would have no effect because all error codes it might suppress are already discarded due to the \texttt{log\_error\_verbosity} setting.
The Error Log

5.4.2.5 Rule-Based Error Log Filtering (log_filter_dragnet)

The `log_filter_dragnet` log filter component enables log filtering based on user-defined rules. To define the applicable rules, set the `dragnet.log_error_filter_rules` system variable.

To enable the `log_filter_dragnet` filter, first load the filter component, then modify the `log_error_services` value. The following example enables `log_filter_dragnet` in combination with the built-in log writer:

```
INSTALL COMPONENT 'file://component_log_filter_dragnet';
SET GLOBAL log_error_services = 'log_filter_dragnet; log_sink_internal';
```

To set `log_error_services` to take effect at server startup, use the instructions at Section 5.4.2.1, "Error Log Component Configuration". Those instructions apply to other error-logging system variables as well.

With `log_filter_dragnet` enabled, define its filter rules by setting the `dragnet.log_error_filter_rules` system variable. A rule set consists of zero or more rules, where each rule is an `IF` statement terminated by a period (`.`) character. If the variable value is empty (zero rules), no filtering occurs.

Example 1. This rule set drops information events, and, for other events, removes the `source_line` field:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.';
```

The effect is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

Example 2: This rule limits information events to no more than one per 60 seconds:

```
SET GLOBAL dragnet.log_error_filter_rules =
  'IF prio>=INFORMATION THEN throttle 1/60.';
```

Once you have the filtering configuration set up as you desire, consider assigning `dragnet.log_error_filter_rules` using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts. Alternatively, add the setting to the server option file.

To stop using the filtering language, first remove it from the set of error logging components. Usually this means using a different filter component rather than no filter component. For example:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
```

Again, consider using using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts.

Then uninstall the filter `log_filter_dragnet` component:

```
UNINSTALL COMPONENT 'file://component_log_filter_dragnet';
```

The following sections describe aspects of `log_filter_dragnet` operation in more detail:

- `log_filter_dragnet` Rule Language
- `log_filter_dragnet` Rule Actions
• log_filter_dragnet Rule Fields

log_filter_dragnet Rule Language

The following grammar defines the language for log_filter_dragnet filter rules. Each rule is an IF statement terminated by a period (.) character. The language is not case sensitive.

```plaintext
rule:
   IF condition THEN action
   [ELSEIF condition THEN action] ...
   [ELSE action]
   .

condition: {
   field comparator value
   | [NOT] EXISTS field
   | condition {AND | OR} condition
}

action: {
   drop
   | throttle {count | count / window_size}
   | set field [:= | =] value
   | unset [field]
}

field: {
   core_field
   | optional_field
   | user_defined_field
}

core_field: {
   time
   | msg
   | prio
   | label
   | err_code
   | err_symbol
   | SQL_state
   | subsystem
}

optional_field: {
   OS_errno
   | OS_errmsg
   | user
   | host
   | thread
   | query_id
   | source_file
   | source_line
   | function
}

user_defined_field:
   sequence of characters in [a-zA-Z0-9_] class

comparator: {
   == | != | <> | >= | => | <= | <= | < | >}

value: {
   string_literal
   | integer_literal
   | float_literal
   | error_symbol
```
Simple conditions compare a field to a value or test field existence. To construct more complex conditions, use the **AND** and **OR** operators. Both operators have the same precedence and evaluate left to right.

To escape a character within a string, precede it by a backslash (\). A backslash is required to include backslash itself or the string-quoting character, optional for other characters.

For convenience, *log_filter_dragnet* supports symbolic names for comparisons to certain fields. Where applicable, symbolic values are preferable to numeric values for readability and portability.

- Event priority values 1, 2, and 3 can be specified as **ERROR**, **WARNING**, and **INFORMATION**. Priority symbols are recognized only in comparisons with the *prio* field. These comparisons are equivalent:

  ```sql
  IF prio == INFORMATION THEN ...  
  IF prio == 3 THEN ...  
  ```

- Error codes can be specified in numeric form or as the corresponding error symbol. For example, **ER_STARTUP** is the symbolic name for error 1408, so these comparisons are equivalent:

  ```sql
  IF err_code == ER_STARTUP THEN ...  
  IF err_code == 1408 THEN ...  
  ```

Error symbols are recognized only in comparisons with the *err_code* field and user-defined fields.

To find the error symbol corresponding to a given error code number, use one of these methods:

- Check the list of server errors at Section B.3.1, “Server Error Message Reference”.
- Use the *perror* command, which when given an error number argument, displays information about the error, including its symbol.

Suppose that a rule set with error numbers looks like this:

```sql
IF err_code == 10927 OR err_code == 10914 THEN drop.  
IF err_code == 1131 THEN drop.  
```

Using *perror*, determine the error symbols:
Substituting error symbols for numbers, the rule set becomes:

```plaintext
IF err_code == ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED
    OR err_code == ER_ABORTING_USER_CONNECTION THEN drop.
IF err_code == ER_PASSWORD_ANONYMOUS_USER THEN drop.
```

Symbolic names can be specified as quoted strings for comparison with string fields, but in such cases the names are strings that have no special meaning and `log_filter_dragnet` does not resolve them to the corresponding numeric value. Also, typos may go undetected, whereas an error is thrown immediately on `SET` for attempts to use an unquoted symbol unknown to the server.

**log_filter_dragnet Rule Actions**

`log_filter_dragnet` supports these actions in filter rules:

- **drop**: Drop the current log event (do not log it).
- **throttle**: Apply rate limiting to reduce log verbosity for events matching particular conditions. The argument indicates a rate, in the form `count` or `count/window_size`. The `count` value indicates the permitted number of events to log per time window. The `window_size` value is the time window in seconds; if omitted, the default window is 60 seconds. Both values must be integer literals.

This rule throttles plugin-shutdown messages to 5 per 60 seconds:

```plaintext
IF err_code == ER_PLUGIN_SHUTTING_DOWN_PLUGIN THEN throttle 5.
```

This rule throttles errors and warnings to 1000 per hour and information messages to 100 per hour:

```plaintext
IF prio <= INFORMATION THEN throttle 1000/3600 ELSE throttle 100/3600.
```

- **set**: Assign a value to a field (and cause the field to exist if it did not already). In subsequent rules, `EXISTS` tests against the field name are true, and the new value can be tested by comparison conditions.
- **unset**: Discard a field. In subsequent rules, `EXISTS` tests against the field name are false, and comparisons of the field against any value are false.

In the special case that the condition refers to exactly one field name, the field name following `unset` is optional and `unset` discards the named field. These rules are equivalent:

```plaintext
IF myfield == 2 THEN unset myfield.
IF myfield == 2 THEN unset.
```

**log_filter_dragnet Rule Fields**

`log_filter_dragnet` supports core, optional, and user-defined fields in rules:
• A core field is set up automatically for error events. However, its presence in the event is not guaranteed because a core field, like any type of field, may be unset by filter rules. If so, the field will be found missing by later rules within the rule set and by components that execute after the filter (such as log writers).

• An optional field is normally absent but may be present for certain event types. When present, an optional field provides additional event information as appropriate and available.

• A user-defined field is any field with a name that is not already defined as a core or optional field. A user-defined field does not exist until created with the `set` action.

As implied by the preceding description, any given field may be absent, either because it was not present in the first place, or was discarded by a filtering rule. For log writers, the effect of field absence is writer specific. For example, a writer might omit the field from the log message, indicate that the field is missing, or substitute a default. When in doubt, use a filter rule to unset the field, then check what the log writer does with it.

These fields are core fields:

• **time**
  
The event timestamp.

• **msg**
  
The event message string.

• **prio**
  
The event priority, to indicate error, warning, or note/information event. This field corresponds to severity in `syslog`.

  In comparisons, each priority can be specified as a symbolic priority name or an integer literal. Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

  ```
  IF prio == INFORMATION THEN ...
  IF prio == 3 THEN ...
  ```

  The following table shows the permitted priority levels.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Priority Symbol</th>
<th>Numeric Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error events</td>
<td>ERROR</td>
<td>1</td>
</tr>
<tr>
<td>Warning events</td>
<td>WARNING</td>
<td>2</td>
</tr>
<tr>
<td>Note/information events</td>
<td>INFORMATION</td>
<td>3</td>
</tr>
</tbody>
</table>

There is also a priority of `SYSTEM`, but system messages cannot be filtered and are always written to the error log.

In general, message priorities are determined as follows:

Is the situation or event actionable?

• Yes: Is the situation or event ignorable?

  • Yes: Priority is `WARNING`.  

  No: Priority is `ERROR` or `WARNING`.
The Error Log

- No: Priority is **ERROR**.
- No: Is the situation or event mandatory?
  - Yes: Priority is **SYSTEM**.
  - No: Priority is **INFORMATION**.

Priority values follow the principle that higher priorities have lower values, and vice versa. Priority values begin at 1 for the most severe events (errors) and increase for events with decreasing priority. For example, to discard events with lower priority than warnings, test for priority values higher than **WARNING**:

```sql
IF prio > WARNING THEN drop.
```

The following examples show the log_filter_dragnet rules to achieve an effect similar to each log_error_verbosity value permitted by the log_filter_internal filter:

- Errors only (log_error_verbosity=1):
  ```sql
  IF prio > ERROR THEN drop.
  ```

- Errors and warnings (log_error_verbosity=2):
  ```sql
  IF prio > WARNING THEN drop.
  ```

- Errors, warnings, and notes (log_error_verbosity=3):
  ```sql
  IF prio > INFORMATION THEN drop.
  ```

This rule can actually be omitted because there are no `prio` values greater than **INFORMATION**, so effectively it drops nothing.

- **err_code**

  The numeric event error code. In comparisons, the value to test can be specified as a symbolic error name or an integer literal. Error symbols are recognized only in comparisons with the `err_code` field and user-defined fields. These comparisons are equivalent:

  ```sql
  IF err_code == ER_ACCESS_DENIED_ERROR THEN ...
  IF err_code == 1045 THEN ...
  ```

- **err_symbol**

  The event error symbol, as a string (for example, 'ER_DUP_KEY'). `err_symbol` values are intended more for identifying particular lines in log output than for use in filter rule comparisons because log_filter_dragnet does not resolve comparison values specified as strings to the equivalent numeric error code.

- **SQL_state**

  The event SQLSTATE value, as a string (for example, '23000').

- **subsystem**
The subsystem in which the event occurred. Possible values are InnoDB (the InnoDB storage engine), Repl (the replication subsystem), Server (otherwise).

Optional fields fall into the following categories:

Additional information about the error, such as the error signaled by the operating system or the error label:

• OS_errno
  The operating system error number.

• OS_errmsg
  The operating system error message.

• label
  The label corresponding to the prio value, as a string. Filter rules can change the label for log writers that support custom labels. label values are intended more for identifying particular lines in log output than for use in filter rule comparisons because log_filter_dragonet does not resolve comparison values specified as strings to the equivalent numeric priority.

Identification of the client for which the event occurred:

• user
  The client user.

• host
  The client host.

• thread
  The thread ID.

• query_id
  The query ID.

Debugging information:

• source_file
  The source file in which the event occurred. The file name should omit any leading path. For example, to test for the sql/gis/distance.cc file, write the comparison like this:

  IF source_file == "distance.cc" THEN ...

• source_line
  The line within the source file at which the event occurred.

• function
  The function in which the event occurred.

• component
The component or plugin in which the event occurred.

5.4.2.6 Error Logging in JSON Format

This section describes how to configure error logging using the built-in filter, \texttt{log\_filter\_internal}, and the JSON writer, \texttt{log\_sink\_json}, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see Section 5.4.2.1, “Error Log Component Configuration”.

To enable the JSON writer, first load the writer component, then modify the \texttt{log\_error\_services} value:

\begin{verbatim}
INSTALL COMPONENT 'file://component_log_sink_json';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_json';
\end{verbatim}

To set \texttt{log\_error\_services} to take effect at server startup, use the instructions at Section 5.4.2.1, “Error Log Component Configuration”. Those instructions apply to other error-logging system variables as well.

It is permitted to name \texttt{log\_sink\_json} multiple times in the \texttt{log\_error\_services} value. For example, to write unfiltered events with one instance and filtered events with another instance, you could set \texttt{log\_error\_services} like this:

\begin{verbatim}
SET GLOBAL log_error_services = 'log_sink_json; log_filter_internal; log_sink_json';
\end{verbatim}

The JSON log writer determines its output destination based on the default error log destination, which is given by the \texttt{log\_error} system variable. If \texttt{log\_error} names a file, the JSON writer bases output file naming on that file name, plus a numbered \texttt{.NN.json} suffix, with \texttt{NN} starting at 00. For example, if \texttt{log\_error} is \texttt{file\_name}, successive instances of \texttt{log\_sink\_json} named in the \texttt{log\_error\_services} value write to \texttt{file\_name.00.json}, \texttt{file\_name.01.json}, and so forth.

If \texttt{log\_error} is \texttt{stderr}, the JSON writer writes to the console. If \texttt{log\_json\_writer} is named multiple times in the \texttt{log\_error\_services} value, they all write to the console, which is likely not useful.

5.4.2.7 Error Logging to the System Log

It is possible to have \texttt{mysqld} write the error log to the system log (the Event Log on Windows, and \texttt{syslog} on Unix and Unix-like systems).

This section describes how to configure error logging using the built-in filter, \texttt{log\_filter\_internal}, and the system log writer, \texttt{log\_sink\_syseventlog}, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see Section 5.4.2.1, “Error Log Component Configuration”.

To enable the system log writer, first load the writer component, then modify the \texttt{log\_error\_services} value:

\begin{verbatim}
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_syseventlog';
\end{verbatim}

To set \texttt{log\_error\_services} to take effect at server startup, use the instructions at Section 5.4.2.1, “Error Log Component Configuration”. Those instructions apply to other error-logging system variables as well.
For MySQL 8.0 configuration, you must enable error logging to the system log explicitly. This differs from MySQL 5.7 and earlier, for which error logging to the system log is enabled by default on Windows, and on all platforms requires no component loading.

Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

On Windows, error messages written to the Event Log within the Application log have these characteristics:

- Entries marked as Error, Warning, and Note are written to the Event Log, but not messages such as information statements from individual storage engines.
- Event Log entries have a source of MySQL (or MySQL-tag if syseventlog.tag is defined as tag).

On Unix and Unix-like systems, logging to the system log uses syslog. The following system variables affect syslog messages:

- syseventlog.facility: The default facility for syslog messages is daemon. Set this variable to specify a different facility.
- syseventlog.include_pid: Whether to include the server process ID in each line of syslog output.
- syseventlog.tag: This variable defines a tag to add to the server identifier (mysqld) in syslog messages. If defined, the tag is appended to the identifier with a leading hyphen.

Prior to MySQL 8.0.13, use the log_syslog_facility, log_syslog_include_pid, and log_syslog_tag system variables rather than the syseventlog.xxx variables.

MySQL uses the custom label “System” for important system messages about non-error situations, such as startup, shutdown, and some significant changes to settings. In logs that do not support custom labels, including the Event Log on Windows, and syslog on Unix and Unix-like systems, system messages are assigned the label used for the information priority level. However, these messages are printed to the log even if the MySQL log_error_verbosity setting normally excludes messages at the information level.

When a log writer must fall back to a label of “Information” instead of “System” in this way, and the log event is further processed outside of the MySQL server (for example, filtered or forwarded by a syslog configuration), these events may by default be processed by the secondary application as being of “Information” priority rather than “System” priority.

### 5.4.2.8 Error Log Message Format

Each error log sink (writer) component has a characteristic output format it uses to write messages to its destination, but other factors may influence the content of the messages:

- The information available to the log writer. If a log filter component executed prior to execution of the writer component removes a log event attribute, that attribute is not available for writing. For information about log filtering, see Section 5.4.2.3, “Types of Error Log Filtering”.
- System variables may affect log writers. See System Variables That Affect Error Log Format.

For all log writers, the ID included in error log messages is that of the thread within mysqld responsible for writing the message. This indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID.
The Error Log

- Output Format for log_sink_internal
- Output Format for log_sink_json
- Output Format for log_sink_syseventlog
- Output Format for Early-Startup Logging
- System Variables That Affect Error Log Format

Output Format for log_sink_internal

This log writer produces the traditional error log output. It writes messages using this format:

```
timestamp thread_id [priority] [err_code] [subsystem] message
```

The [ ] square bracket characters are literal characters in the message format. They do not indicate that fields are optional.

The [err_code] and [subsystem] fields were added in MySQL 8.0. They will be missing from logs generated by older servers. Log parsers can treat these fields as parts of the message text that will be present only for logs written by servers recent enough to include them. Parsers must treat the err_code part of [err_code] indicators as a string value.

Examples:

```
2018-03-22T12:35:47.538083Z 0 [Note] [MY-012487] [InnoDB] InnoDB: DDL log recovery : begin
2018-03-22T12:35:47.550565Z 0 [Warning] [MY-010068] [Server] CA certificate /var/mysql/sslinfo/cacert.pem is self signed.
2018-03-22T12:35:47.669397Z 4 [Note] [MY-010051] [Server] Event Scheduler: scheduler thread started with id 4
2018-03-22T12:35:47.550939Z 0 [Note] [MY-010253] [Server] IPv6 is available.
```

Output Format for log_sink_json

The JSON-format log writer produces messages as JSON objects that contain key-value pairs. For example:

```
```

Output Format for log_sink_syseventlog

The system log writer produces output that conforms to the system log format used on the local platform.

Output Format for Early-Startup Logging

The server generates some error log messages before startup options have been processed, and thus before it knows error log settings such as the log_error_verbosity and log_timestamps values, and which log components are to be used. The server handles error log messages that are generated early in the startup process as follows:

- Prior to MySQL 8.0.14, the server generates messages with the default timestamp, format, and verbosity level, and buffers them. After the startup options are processed and the error log configuration is known, the server flushes the buffered messages. Because these early messages use the default log configuration, they differ from what is specified by the startup options. Also, the early messages
are not flushed to log writers other than the default. For example, logging to the JSON writer does not include these early messages because they are not in JSON format.

• As of MySQL 8.0.14, the server buffers log events rather than formatted log messages. This enables it to retroactively apply configuration settings to those events after the settings are known, with the result that flushed messages use the configured settings, not the defaults. Also, messages are flushed to all configured writers, not just the default writer.

If a fatal error occurs before log configuration is known and the server must exit, the server so they are not lost. If no fatal error occurs but startup is excessively slow prior to processing startup options, the server periodically formats and flushes buffered messages using the logging defaults so as not to appear unresponsive. Although these behaviors are similar to pre-8.0.14 behavior in that the defaults are used, they are preferable to losing messages when exceptional conditions occur.

**System Variables That Affect Error Log Format**

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the error log (as well as to general query log and slow query log files). Permitted values are `UTC` (the default) and `SYSTEM` (local system time zone).

**5.4.2.9 Error Log File Flushing and Renaming**

If you flush the error log using `FLUSH ERROR LOGS`, `FLUSH LOGS`, or `mysqladmin flush-logs`, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of `host_name.err`, to rename the file and create a new one, use the following commands:

```
mv host_name.err host_name.err-old
mysqladmin flush-logs
mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the location of an error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the `/var/log/mysqld.log` file, where the `/var/log` directory is owned by `root` and is not writable by `mysqld`. For information about handling this case, see Section 5.4.7, “Server Log Maintenance”.

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

**5.4.3 The General Query Log**

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Each line that shows when a client connects also includes `using connection_type` to indicate the protocol used to establish the connection. `connection_type` is one of `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection established with SSL), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), or `Shared Memory` (Windows shared memory connection).

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which
The General Query Log

Statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication master server, statements received by its slaves are written to the query log of each slave. Statements are written to the query log of the master server if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log=[0|1]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

**Note**

If you specify the `TABLE` log destination, see Log Tables and “Too many open files” Errors.

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```
This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to **ON** or **OFF**. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also Section 6.1.2.3, “Passwords and Logging”.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

### 5.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a **DELETE** which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 17.2, “Replication Implementation”.

- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

The binary log is not used for statements such as **SELECT** or **SHOW** that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See Section 5.4.3, “The General Query Log”.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is resilient to unexpected halts. Only complete events or transactions are logged or read back.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also Section 6.1.2.3, “Passwords and Logging”.

---

977
From MySQL 8.0.14, binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see Section 17.1.6.4, “Binary Logging Options and Variables”.

Binary logging is enabled by default (the `log_bin` system variable is set to `ON`). The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default, but can be enabled by specifying the `--log-bin` option.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

The `--log-slave-updates` and `--slave-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--skip-log-slave-updates` and `--skip-slave-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-slave-updates` or `--slave-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

The `--log-bin[=base_name]` option is used to specify the base name for binary log files. If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine. It is recommended that you specify a base name, so that if the host name changes, you can easily continue to use the same binary log file names (see Section B.4.7, “Known Issues in MySQL”). If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log’s size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

The default location for binary log files and the binary log index file is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file...
must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

In MySQL 5.7, a server ID had to be specified when binary logging was enabled, or the server would not start. In MySQL 8.0, the `server_id` system variable is set to 1 by default. The server can be started with this default ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `--server-id` option. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

A client that has privileges sufficient to set restricted session system variables (see Section 5.1.9.1, “System Variable Privileges”) can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the master uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The slave I/O thread also verifies events received from the master. You can cause the slave SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported: row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see Section 5.4.4.1, “Binary Logging Formats”. For detailed information about the format of the binary log, see MySQL Internals: The Binary Log.

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

A replication slave server is started with the `--log-slave-updates` setting enabled by default, meaning that the slave writes to its own binary log any data modifications that are received from the replication master. The binary log must be enabled for this setting to work (see Section 17.1.6.3, “Replication Slave Options and Variables”). This setting enables the slave to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See Section 13.7.7.6, “RESET Syntax”, and Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use
it, see Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”. For more information about the binary log and recovery operations, see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (UPDATE, DELETE, or INSERT) that change transactional tables such as InnoDB tables are cached until a COMMIT statement is received by the server. At that point, mysqld writes the entire transaction to the binary log before the COMMIT is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of binlog_cache_size to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends. From MySQL 8.0.17, if binary log encryption is active on the server, the temporary file is encrypted.

The Binlog_cache_use status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The Binlog_cache_disk_use status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning binlog_cache_size to a large enough value that avoids the use of temporary files.

The max_binlog_cache_size system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for CREATE ... SELECT or INSERT ... SELECT statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See Section 17.4.1, “Replication Features and Issues”.

Binary logging for stored programs is done as described in Section 24.7, “Stored Program Binary Logging”.

Note that the binary log format differs in MySQL 8.0 from previous versions of MySQL, due to enhancements in replication. See Section 17.4.2, “Replication Compatibility Between MySQL Versions”.

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the replication master can become inconsistent and replication slaves can lose synchronization with the master. The binlog_error_action system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting, ABORT_SERVER, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”).

- The setting IGNORE_ERROR provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, log_bin must be enabled again, which requires a server restart. Only use this
option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

By default, the binary log is synchronized to disk at each write (sync_binlog=1). If sync_binlog was not enabled, and the operating system or machine (not only the MySQL server) crashed, there is a chance that the last statements of the binary log could be lost. To prevent this, enable the sync_binlog system variable to synchronize the binary log to disk after every N commit groups. See Section 5.1.8, “Server System Variables”. The safest value for sync_binlog is 1 (the default), but this is also the slowest.

In earlier MySQL releases, there was a chance of inconsistency between the table content and binary log content if a crash occurred, even with sync_binlog set to 1. For example, if you are using InnoDB tables and the MySQL server processes a COMMIT statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits the transaction into InnoDB. If the server crashed between those two operations, the transaction would be rolled back by InnoDB at restart but still exist in the binary log. Such an issue was resolved in previous releases by enabling InnoDB support for two-phase commit in XA transactions. In 5.8.0 and higher, the InnoDB support for two-phase commit in XA transactions is always enabled.

InnoDB support for two-phase commit in XA transactions ensures that the binary log and InnoDB data files are synchronized. However, the MySQL server should also be configured to synchronize the binary log and the InnoDB logs to disk before committing the transaction. The InnoDB logs are synchronized by default, and sync_binlog=1 ensures the binary log is synchronized. The effect of implicit InnoDB support for two-phase commit in XA transactions and sync_binlog=1 is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction xid values and calculate the last valid position in the binary log file. The MySQL server then tells InnoDB to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of InnoDB tables, and therefore the slave remains in synchrony with the master because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed InnoDB transaction. This should not happen if sync_binlog=1 and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message The binary log file_name is shorter than its expected size. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- sql_mode (except that the NO_DIR_IN_CREATE mode is not replicated; see Section 17.4.1.38, “Replication and Variables”)
- foreign_key_checks
- unique_checks
- character_set_client
- collation_connection
- collation_database
- collation_server
- sql_auto_is_null
5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called **statement-based logging**. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.

- In **row-based logging** (the default), the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.

- A third option is also available: **mixed logging**. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, **Statement may not be safe to log in statement format**.

You can avoid these issues by using MySQL’s row-based replication instead.

5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- **STATEMENT** causes logging to be statement based.
- **ROW** causes logging to be row based. This is the default.
- **MIXED** causes logging to use mixed format.

The logging format also can be switched at runtime, although note that there are a number of situations in which you cannot do this, as discussed later in this section. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

---

982
There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If the NDB storage engine is enabled.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@SESSION.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).
- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (`SET @@PERSIST_ONLY.binlog_format`) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication master does not cause a slave to change its logging format to match. When using STATEMENT mode, the `binlog_format` system variable is not replicated. When using MIXED or ROW logging mode, it is replicated but is ignored by the slave.

A replication slave is not able to convert binary log entries received in ROW logging format to STATEMENT format for use in its own binary log. The slave must therefore use ROW or MIXED format if the master does. Changing the binary logging format on the master from STATEMENT to ROW or MIXED while replication is ongoing to a slave with STATEMENT format can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'` Changing the binary logging format on the slave to STATEMENT format when the master is still using MIXED or ROW format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the master and the slave.

If you are using InnoDB tables and the transaction isolation level is READ COMMITTED or READ UNCOMMITTED, only row-based logging can be used. It is possible to change the logging format to STATEMENT, but doing so at runtime leads very rapidly to errors because InnoDB can no longer perform inserts.

With the binary log format set to ROW, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as CREATE TABLE, ALTER TABLE, or DROP TABLE.
When row-based binary logging is used, the `binlog_row_event_max_size` system variable and its corresponding startup option `--binlog-row-event-max-size` set a soft limit on the maximum size of row events. The default value is 8192 bytes, and the value can only be changed at server startup. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

**Warning**

When using statement-based logging for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Section B.4.7, “Known Issues in MySQL”.

For information about logs kept by replication slaves, see Section 17.2.4, “Replication Relay and Status Logs”.

### 5.4.4.3 Mixed Binary Logging Format

When running in *MIXED* logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)
- When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
The Binary Log

- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see Section 5.1.9, “Using System Variables”.

For information about how replication treats `sql_mode`, see Section 17.4.1.38, “Replication and Variables”.

In earlier releases, when mixed binary logging format was in use, if a statement was logged by row and the session that executed the statement had any temporary tables, all subsequent statements were treated as unsafe and logged in row-based format until all temporary tables in use by that session were dropped. As of MySQL 8.0, operations on temporary tables are not logged in mixed binary logging format, and the presence of temporary tables in the session has no impact on the logging mode used for each statement.

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be row-logging capable.
- If an engine supports statement-based logging, the engine is said to be statement-logging capable.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.
Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (**STATEMENT, ROW, or MIXED**), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using **ROW** format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. **Type**, **binlog_format**, **SLC**, and **RLC** columns outline the conditions, and **Error / Warning** and **Logged as** columns represent the corresponding actions. **SLC** stands for “statement-logging capable”, and **RLC** stands for “row-logging capable”.

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server has `log_error_verbosity` set to display warnings, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

#### 5.4.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).
CREATE TABLE ... SELECT is a combination of data definition and data manipulation. The CREATE TABLE part is logged using statement format and the SELECT part is logged according to the value of binlog_format.

5.4.5 The Slow Query Log

The slow query log consists of SQL statements that take more than long_query_time seconds to execute and require at least min_examined_row_limit rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the mysql慢查询命令 to process a slow query log file and summarize its contents. See Section 4.6.9, "mysqldumpslow — Summarize Slow Query Log Files".

The time to acquire the initial locks is not counted as execution time. mysqld writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

• Slow Query Log Parameters

Slow Query Log Parameters

The minimum and default values of long_query_time are 0 and 10, respectively. The value can be specified to a resolution of microseconds.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using log_slow_admin_statements and log_queries_not_using_indexes, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use --slow_query_log=0|1]. With no argument or an argument of 1, --slow_query_log enables the log. With an argument of 0, this option disables the log. To specify a log file name, use --slow_query_log_file=file_name. To specify the log destination, use the log_output system variable (as described in Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

Note

If you specify the TABLE log destination, see Log Tables and “Too many open files” Errors.

If you specify no name for the slow query log file, the default name is host_name-slow.log. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global slow_query_log and slow_query_log_file system variables. Set slow_query_log to 0 to disable the log or to 1 to enable it. Set slow_query_log_file to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the --log-short-format option.

To include slow administrative statements in the slow query log, enable the log_slow_admin_statements system variable. Administrative statements include ALTER TABLE, ANALYZE TABLE, CHECK TABLE, CREATE INDEX, DROP INDEX, OPTIMIZE TABLE, and REPAIR TABLE.
The Slow Query Log

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

By default, a replication slave does not write replicated queries to the slow query log. To change this, enable the `log_slow_slave_statements` system variable.

### Slow Query Log Contents

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

- **Query_time**: `duration`

  The statement execution time in seconds.

- **Lock_time**: `duration`

  The time to acquire locks in seconds.
The Slow Query Log

- **Rows_sent**: $N$
  The number of rows sent to the client.

- **Rows_examined**:
  The number of rows examined by the optimizer.

Enabling the `log_slow_extra` system variable (available as of MySQL 8.0.14) causes the server to write the following extra fields to `FILE` output in addition to those just listed (`TABLE` output is unaffected). Some field descriptions refer to status variable names. Consult the status variable descriptions for more information. However, in the slow query log, the counters are per-statement values, not cumulative per-session values.

- **Thread_id**: $ID$
  The statement thread identifier.

- **Errno**: `error_number`
  The statement error number, or 0 if no error occurred.

- **Killed**: $N$
  If the statement was terminated, the error number indicating why, or 0 if the statement terminated normally.

- **Bytes_received**: $N$
  The `Bytes_received` value for the statement.

- **Bytes_sent**: $N$
  The `Bytes_sent` value for the statement.

- **Read_first**: $N$
  The `Handler_read_first` value for the statement.

- **Read_last**: $N$
  The `Handler_read_last` value for the statement.

- **Read_key**: $N$
  The `Handler_read_key` value for the statement.

- **Read_next**: $N$
  The `Handler_read_next` value for the statement.

- **Read_prev**: $N$
  The `Handler_read_prev` value for the statement.

- **Read_rnd**: $N$
  The `Handler_read_rnd` value for the statement.

- **Read_rnd_next**: $N$
  The `Handler_read_rnd_next` value for the statement.
The Handler_read_rnd_next value for the statement.
• Sort_merge_passes: N
  The Sort_merge_passes value for the statement.
• Sort_range_count: N
  The Sort_range value for the statement.
• Sort_rows: N
  The Sort_rows value for the statement.
• Sort_scan_count: N
  The Sort_scan value for the statement.
• Created_tmp_disk_tables: N
  The Created_tmp_disk_tables value for the statement.
• Created_tmp_tables: N
  The Created_tmp_tables value for the statement.
• Start: timestamp
  The statement execution start time.
• End: timestamp
  The statement execution end time.

A given slow query log file may contain a mix of lines with and without the extra fields added by enabling log_slow_extra. Log file analyzers can determine whether a line contains the additional fields by the field count.

Each statement written to the slow query log file is preceded by a SET statement that includes a timestamp. As of MySQL 8.0.14, the timestamp indicates when the slow statement began executing. Prior to 8.0.14, the timestamp indicates when the slow statement was logged (which occurs after the statement finishes executing).

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See Section 6.1.2.3, “Passwords and Logging”.

5.4.6 The DDL Log

The DDL log, or metadata log, records metadata operations generated by data definition statements such as DROP TABLE and ALTER TABLE. MySQL uses this log to recover from crashes occurring in the middle of a metadata operation. When executing the statement DROP TABLE t1, t2, we need to ensure that both t1 and t2 are dropped, and that each table drop is complete. Another example of this type of SQL statement is ALTER TABLE t3 DROP PARTITION p2, where we must make certain that the partition is completely dropped and that its definition is removed from the list of partitions for table t3.

A record of metadata operations such as those just described are written to the file ddl_log.log, in the MySQL data directory. This is a binary file; it is not intended to be human-readable, and you should not attempt to modify its contents in any way.
**Server Log Maintenance**

`ddl_log.log` is not created until it is actually needed for recording metadata statements, and is removed following a successful start of `mysqld`. Thus, it is possible for this file not to be present on a MySQL server that is functioning in a completely normal manner.

Currently, `ddl_log.log` can hold up to 1048573 entries, equivalent to 4 GB in size. Once this limit is exceeded, you must rename or remove the file before it is possible to execute any additional DDL statements. This is a known issue which we are working to resolve (Bug #83708).

There are no user-configurable server options or variables associated with this file.

### 5.4.7 Server Log Maintenance

As described in Section 5.4, "MySQL Server Logs", MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 7.2, "Database Backup Methods".

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. You can specify an alternative expiration period using the `binlog_expire_logs_seconds` system variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see Section 13.4.1.1, “PURGE BINARY LOGS Syntax”).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqldump --flush-logs, mysqladmin flush-logs, mysqladmin refresh, mysqladmin --flush-logs, or mysqldump --master-data` command. See Section 13.7.7.3, “FLUSH Syntax”, Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”, and Section 4.5.4, “mysqldump — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.

- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files.
MySQL Server Components

Before flushing them, at flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one.

You can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

**Note**

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, the log-flushing operation will fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:

```
shell> mv /var/log/mysqld.log /var/log/mysqld.log.old
shell> install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

5.5 MySQL Server Components

MySQL Server includes a component-based infrastructure for extending server capabilities. A component provides services that are available to the server and other components. (With respect to service use, the server is a component, equal to other components.) Components interact with each other only through the services they provide.

MySQL distributions include several components that implement server extensions:

- Components for configuring error logging. See Section 5.4.2, “The Error Log”, and Section 5.5.3, “Error Log Components”.
• A component for checking passwords. See Section 6.4.3, “The Password Validation Component”.

• A component that enables applications to add their own message events to the audit log. See Section 6.4.6, “The Audit Message Component”.

System and status variables implemented by a server component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragon` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragon.log_error_filter_rules`. To refer to this variable, use the full name.

The following sections describe how to install and uninstall components, and how to determine at runtime which components are installed and obtain information about them.

For information about the internal implementation of components, see the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html. For example, if you intend to write your own components, this information is important for understanding how components work.

### 5.5.1 Installing and Uninstalling Components

Server components must be loaded into the server before they can be used. MySQL supports component loading at runtime.

The `INSTALL COMPONENT` and `UNINSTALL COMPONENT` SQL statements enable component loading and unloading. For example:

```
INSTALL COMPONENT 'file://component_validate_password';
UNINSTALL COMPONENT 'file://component_validate_password';
```

A loader service handles component loading and unloading, and also lists loaded components in the `component` table of the `mysql` system database that serves as a registry.

The SQL statements for component manipulation affect server operation and the `mysql.component` system table as follows:

- `INSTALL COMPONENT` loads components into the server. The components become active immediately. The loader service also registers loaded components in the `mysql.component` system table. For subsequent server restarts, the loader service loads any components listed in `mysql.component` during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.

- `UNINSTALL COMPONENT` deactivates components and unloads them from the server. The loader service also unregisters the components from the `mysql.component` system table so that they are no longer loaded during the startup sequence for subsequent server restarts.

Compared to the corresponding `INSTALL PLUGIN` statement for server plugins, the `INSTALL COMPONENT` statement for components offers the significant advantage that it is not necessary to know any platform-specific file name suffix for naming the component. This means that a given `INSTALL COMPONENT` statement can be executed uniformly across platforms.

### 5.5.2 Obtaining Server Component Information

The `component` table in the `mysql` system database contains information about currently loaded components and shows which components have been registered with `INSTALL COMPONENT`. To see which components are installed, use this statement:
5.5.3 Error Log Components

This section describes the characteristics of individual error log components. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

A log component can be a filter or a sink:

- A filter processes log events, to add, remove, or modify event fields, or to delete events entirely. The resulting events pass to the next log component named in the `log_error_services` system variable value.

- A sink is a destination (writer) for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log.

The server executes filters and sinks in the `log_error_services` value in the order they are named. The rightmost component should therefore be a sink. If the rightmost component is a filter, any changes it has on events have no effect on output.

The following sections describe individual log components, grouped by component type:

- **Error Log Filter Components**
- **Error Log Sink Components**

Component descriptions include these types of information:

- The component name and intended purpose.

- Whether the component is built in or must be loaded. For a loadable component, the description specifies the URN to use to load and unload the component with the `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements.

- Whether the component can be listed multiple times in the `log_error_services` value.

- For a sink component, the destination to which the component writes output.

### Error Log Filter Components

Error log filter components implement filtering of error log events:

- If no filter component is enabled, no filtering occurs.

- Any enabled filter component affects log events only for components listed later in the `log_error_services` value. In particular, for any log sink component listed in `log_error_services` earlier than any filter component, no log event filtering occurs.

### The log_filter_internal Component

- **Purpose:** Implements filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. See Section 5.4.2.4, “Priority-Based Error Log Filtering (log_filter_internal)”.

- **URN:** This component is built in and need not be loaded with `INSTALL COMPONENT` before use.
Error Log Components

- Multiple uses permitted: No.

If `log_filter_internal` is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect.

The log_filter_dragnet Component

- Purpose: Implements filtering based on the rules defined by the `dragnet.log_error_filter_rules` system variable setting. See Section 5.4.2.5, “Rule-Based Error Log Filtering (log_filter_dragnet)”.
- URN: `file://component_log_filter_dragnet`
- Multiple uses permitted: No.

Error Log Sink Components

Error log sink components are writers that implement error log output. If no sink component is enabled, no log output occurs.

Some sink component descriptions refer to the default error log destination. This is the console or a file and is indicated by the fault of the `log_error` system variable, determined as described in Section 5.4.2.2, “Default Error Log Destination Configuration”.

The log_sink_internal Component

- Purpose: Implements traditional error log message output format.
- URN: This component is built in and need not be loaded with INSTALL COMPONENT before use.
- Multiple uses permitted: No.
- Output destination: Writes to the default error log destination.

The log_sink_json Component

- Purpose: Implements JSON-format error logging. See Section 5.4.2.6, “Error Logging in JSON Format”.
- URN: `file://component_log_sink_json`
- Multiple uses permitted: Yes.
- Output destination: The JSON log writer determines its output destination based on the default error log destination, which is given by the `log_error` system variable:
  - If `log_error` names a file, the JSON writer bases output file naming on that file name, plus a numbered `NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.
  - If `log_error` is `stderr`, the JSON writer writes to the console. If `log_json_writer` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.

The log_sink_sysseventlog Component

- Purpose: Implements error logging to the system log. This is the Event Log on Windows, and `syslog` on Unix and Unix-like systems. See Section 5.4.2.7, “Error Logging to the System Log”. 

998
MySQL Server Plugins

• URN: file://component_log_sink_syseventlog

• Multiple uses permitted: No.

• Output destination: Writes to the system log. Does not use the default error log destination.

The log_sink_test Component

• Purpose: Intended for internal use in writing test cases. Not intended for production use.

• URN: file://component_log_sink_test

• Multiple uses permitted: Yes.

• Output destination: Writes to the default error log destination.

5.6 MySQL Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components supported by this interface include, but are not limited to, storage engines, INFORMATION_SCHEMA tables, full-text parser plugins, and server extensions.

MySQL distributions include several plugins that implement server extensions:

• Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See Section 6.2.17, “Pluggable Authentication”.

• A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See Section 6.4.2, “The Connection-Control Plugins”.

• A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See Section 6.4.3, “The Password Validation Component”.

• Semisynchronous replication plugins implement an interface to replication capabilities that permit the master to proceed as long as at least one slave has responded to each transaction. See Section 17.3.11, “Semisynchronous Replication”.

• Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See Chapter 18, Group Replication.

• MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.6.3, “MySQL Enterprise Thread Pool”.

• MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See Section 6.4.5, “MySQL Enterprise Audit”.

• MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. See Section 6.4.7, “MySQL Enterprise Firewall”.

• Query rewrite plugins examine statements received by MySQL Server and possibly rewrite them before the server executes them. See Section 5.6.4, “The Rewriter Query Rewrite Plugin”, and Section 5.6.5, “The ddl_rewriter Plugin”.
• Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a version_tokens plugin and a set of user-defined functions. See Section 5.6.6, “Version Tokens”.

• Keyring plugins provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

• X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. See Section 20.5, “X Plugin”.

• Test framework plugins test server services. For information about these plugins, see the Plugins for Testing Plugin Services section of the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see Section 29.2, “The MySQL Plugin API”.

5.6.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available from the INFORMATION_SCHEMA.PLUGINS table and the SHOW PLUGINS statement. See Section 5.6.2, “Obtaining Server Plugin Information”.

• Installing Plugins

• Controlling Plugin Activation State

• Uninstalling Plugins

Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, plugin_name stands for a plugin name such as innodb, csv, or validate_password.

Built-in plugins:

A built-in plugin is known by the server automatically. Normally, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the --plugin_name[=activation_state] option.

Plugins registered in the mysql.plugin system table:

The plugin table in the mysql system database serves as a registry of plugins (other than built-in plugins, which need not be registered). At startup, the server loads each plugin listed in the table. Normally, for a plugin loaded from the mysql.plugin table, the server also enables the plugin. This can be changed with the --plugin_name[=activation_state] option.

If the server is started with the --skip-grant-tables option, it does not consult the mysql.plugin table and does not load the plugins listed there.

Plugins named with command-line options:
Installing and Uninstalling Plugins

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one takes effect. With multiple instances of `--plugin-load-add`, all of them take effect.

- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load="y;x"
```
---

## Installing and Uninstalling Plugins

### --plugin-load=x

**Plugins installed with the `INSTALL PLUGIN` statement:**

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```plaintext
[mysqld]
plugin-load=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```plaintext
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```plaintext
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load`.

If a plugin is named both using a `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

### Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name=[activation_state]` startup option, where `plugin_name` is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores
are interchangeable in option names. Also, activation state values are not case-sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`
  Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`
  Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`
  Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`
  Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_xxx` options likely will need to be omitted at startup. In addition, because InnoDB is the default storage engine, it will not start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

### Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table.
Obtaining Server Plugin Information

With the plugin no longer registered in the table, the server does not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove any options related to the plugin from the `my.cnf` file.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

5.6.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS\G
*************************** 1. row ***************************
PLUGIN_NAME: binlog
PLUGIN_VERSION: 1.0
PLUGIN_STATUS: ACTIVE
PLUGIN_TYPE: STORAGE ENGINE
PLUGIN_TYPE_VERSION: 50158.0
PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
PLUGIN_AUTHOR: MySQL AB
PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
PLUGIN_LICENSE: GPL
LOAD_OPTION: FORCE
...
```

```sql
*************************** 10. row ***************************
PLUGIN_NAME: InnoDB
PLUGIN_VERSION: 1.0
PLUGIN_STATUS: ACTIVE
PLUGIN_TYPE: STORAGE ENGINE
PLUGIN_TYPE_VERSION: 50158.0
PLUGIN_LIBRARY: ha_innodb_plugin.so
PLUGIN_LIBRARY_VERSION: 1.0
PLUGIN_AUTHOR: Innobase Oy
PLUGIN_DESCRIPTION: Supports transactions, row-level locking, and foreign keys
PLUGIN_LICENSE: GPL
LOAD_OPTION: ON
...
```
The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
*************************** 1. row ****************************
    Name: binlog
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
    License: GPL
...
*************************** 10. row ****************************
    Name: InnoDB
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: ha_innodb_plugin.so
    License: GPL
...
```

The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

### 5.6.3 MySQL Enterprise Thread Pool

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, visit https://www.mysql.com/products/.

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.

- With too many threads executing in parallel, context switching overhead is high. This also presents a challenging task to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.

- Too many transactions executing in parallel increases resource contention. In InnoDB, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

### Additional Resources

Section A.14, "MySQL 8.0 FAQ: MySQL Enterprise Thread Pool"

### 5.6.3.1 Thread Pool Components
The thread pool feature comprises these components:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation:

  - As of MySQL 8.0.14, the monitoring tables are Performance Schema tables; see Section 26.12.15, “Performance Schema Thread Pool Tables”.

  - Prior to MySQL 8.0.14, the monitoring tables are INFORMATION_SCHEMA tables; see Section 25.40, “INFORMATION_SCHEMA Thread Pool Tables”.

The INFORMATION_SCHEMA tables now are deprecated and will be removed in a future MySQL version. Applications should transition away from the old tables to the new tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_state;
```

**Note**

If you do not load all the monitoring tables, some or all MySQL Enterprise Monitor thread pool graphs will be empty.

For a detailed description of how the thread pool works, see Section 5.6.3.3, “Thread Pool Operation”.

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

  The other related variables are implemented by the thread pool plugin; they are not available unless it is enabled:

  - `thread_pool_algorithm`: The concurrency algorithm to use for scheduling.

  - `thread_pool_high_priority_connection`: How to schedule statement execution for a session.

  - `thread_pool_prio_kickup_timer`: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.

  - `thread_pool_max_unused_threads`: How many sleeping threads to permit.

  - `thread_pool_size`: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.

  - `thread_pool_stall_limit`: The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see Section 5.6.3.4, “Thread Pool Tuning”.

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```
```
**5.6.3.2 Thread Pool Installation**

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

- Thread Pool Installation as of MySQL 8.0.14
- Thread Pool Installation Prior to MySQL 8.0.14

**Thread Pool Installation as of MySQL 8.0.14**

In MySQL 8.0.14 and higher, the thread pool monitoring tables are Performance Schema tables that are loaded and unloaded along with the thread pool plugin. The `INFORMATION_SCHEMA` versions of the tables are deprecated but still available; they are installed per the instructions in Thread Pool Installation Prior to MySQL 8.0.14.

To enable thread pool capability, load the plugin by starting the server with the `--plugin-load-add` option. To do this, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
     > FROM INFORMATION_SCHEMA.PLUGINS
     > WHERE PLUGIN_NAME LIKE 'thread%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_pool</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

To verify that the Performance Schema monitoring tables are available, examine the `INFORMATION_SCHEMA.TABLES` table or use the `SHOW TABLES` statement. For example:

```
mysql> SELECT TABLE_NAME
     > FROM INFORMATION_SCHEMA.TABLES
     > WHERE TABLE_SCHEMA = 'performance_schema'
     > AND TABLE_NAME LIKE 'tp%';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>tp_thread_group_state</td>
</tr>
</tbody>
</table>
If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If the plugin fails to initialize, check the server error log for diagnostic messages.

**Thread Pool Installation Prior to MySQL 8.0.14**

Prior to MySQL 8.0.14, the thread pool monitoring tables are plugins separate from the thread pool plugin and can be installed separately.

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load-add` option. For example, if you name only the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use options like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
+-----------------------+---------------+
| PLUGIN_NAME           | PLUGIN_STATUS |
+-----------------------+---------------+
| thread_pool           | ACTIVE        |
| TP_THREAD_STATE       | ACTIVE        |
| TP_THREAD_GROUP_STATE | ACTIVE        |
| TP_THREAD_GROUP_STATS | ACTIVE        |
+-----------------------+---------------+
```
If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If a plugin fails to initialize, check the server error log for diagnostic messages.

### 5.6.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The number of thread groups is configurable using the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see Section 5.6.3.4, “Thread Pool Tuning”.

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that the thread executes all statements from the connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance. The algorithm works in the following manner:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
  - Queuing occurs if the statement cannot begin executing immediately.

- If immediate execution occurs, execution is performed by the listener thread. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

  By using the listener thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

  When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute.
If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication master, a thread that is sending binary log events to a slave effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.

- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for InnoDB and MyISAM tables, the thread pool prioritizes those for InnoDB over those for MyISAM unless `autocommit` is enabled. With `autocommit` enabled, all statements will be low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.

- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms or 100 per second will be moved from the low-priority queue to the high-priority queue.

- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.

- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even through the first thread is still executing.

- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.

- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.
The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.

- Binary log dump threads that read the binary log and send it to slaves. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.

- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

### 5.6.3.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is InnoDB, the optimal `thread_pool_size` setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

  For workloads such as DBT2 and Sysbench, the optimum for InnoDB seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is MyISAM, the `thread_pool_size` setting should be fairly low. We tend to get optimal performance for values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit`, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout, the length of which can be tuned using the `thread_pool_stall_limit` system variable. This parameter ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group...
would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements will block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 (meaning 100ms). The default value of 60ms is okay for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `tp_thread_group_stats` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```sql
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM performance_schema.tp_thread_group_stats;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing?

Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).
- `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements will be moved to the high-priority queue because it will always already contain statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those will become stalled and it will take 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it will take 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

### 5.6.4 The Rewriter Query Rewrite Plugin

MySQL supports query rewrite plugins that can examine and possibly modify SQL statements received by the server before the server executes them. See [Query Rewrite Plugins](#).
MySQL distributions include a postparse query rewrite plugin named **Rewriter** and scripts for installing the plugin and its associated components. These components work together to provide statement-rewriting capability:

- A server-side plugin named **Rewriter** examines statements and may rewrite them, based on its in-memory cache of rewrite rules.

- These statements are subject to rewriting:
  - As of MySQL 8.0.12: SELECT, INSERT, REPLACE, UPDATE, and DELETE.
  - Prior to MySQL 8.0.12: SELECT only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- The **Rewriter** plugin uses a database named **query_rewrite** containing a table named **rewrite_rules**. The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the **message** column of table rows.

- The **query_rewrite** database contains a stored procedure named **flush_rewrite_rules()** that loads the contents of the rules table into the plugin.

- A user-defined function named **load_rewrite_rules()** is used by the **flush_rewrite_rules()** stored procedure.

- The **Rewriter** plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information.

The following sections describe how to install and use the **Rewriter** plugin, and provide reference information for its associated components.

### 5.6.4.1 Installing or Uninstalling the Rewriter Query Rewrite Plugin

**Note**

If installed, the **Rewriter** plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the **Rewriter** query rewrite plugin, choose the appropriate script located in the **share** directory of your MySQL installation:

- **install_rewriter.sql**: Choose this script to install the **Rewriter** plugin and its associated components.

- **uninstall_rewriter.sql**: Choose this script to uninstall the **Rewriter** plugin and its associated components.

Run the chosen script as follows:

```
shell> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)
```

The example here uses the **install_rewriter.sql** installation script. Substitute **uninstall_rewriter.sql** if you are uninstalling the plugin.
Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:

```sql
mysql> SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| rewriter_enabled | ON    |
+------------------+-------+
```

For usage instructions, see Section 5.6.4.2, “Using the Rewriter Query Rewrite Plugin”. For reference information, see Section 5.6.4.3, “Rewriter Query Rewrite Plugin Reference”.

### 5.6.4.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the `rewriter_enabled` system variable. By default, the Rewriter plugin is enabled when you install it (see Section 5.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```ini
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```sql
SET GLOBAL rewriter_enabled = ON;
SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the Rewriter plugin is enabled, it examines and possibly modifies each rewritable statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the `rewrite_rules` table in the `query_rewrite` database.

These statements are subject to rewriting:

- As of MySQL 8.0.12: `SELECT`, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE`.
- Prior to MySQL 8.0.12: `SELECT` only.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- Adding Rewrite Rules
- How Statement Matching Works
- Rewriting Prepared Statements
- Rewriter Plugin Operational Information
- Rewriter Plugin Use of Character Sets

### Adding Rewrite Rules

To add rules for the Rewriter plugin, add rows to the `rewrite_rules` table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement) VALUES('SELECT ?', 'SELECT ? + 1');

The resulting table contents look like this:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>id</th>
<th>pattern</th>
<th>pattern_database</th>
<th>replacement</th>
<th>enabled</th>
<th>message</th>
<th>pattern_digest</th>
<th>normalized_pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SELECT ?</td>
<td>NULL</td>
<td>SELECT ? + 1</td>
<td>YES</td>
<td>NULL</td>
<td>d1b44b0c19af710b5a679907e284acd2ddc285201794bc69a2389d77baeddda</td>
<td>select ?</td>
</tr>
</tbody>
</table>
```

The rule specifies a pattern template indicating which SELECT statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the rewrite_rules table is not sufficient to cause the Rewriter plugin to use the rule. You must invoke flush_rewrite_rules() to load the table contents into the plugin in-memory cache:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
```

**Tip**

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling flush_rewrite_rules().

When the plugin reads each rule from the rules table, it computes a normalized (statement digest) form from the pattern and a digest hash value, and uses them to update the normalized_pattern and pattern_digest columns:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>id</th>
<th>pattern</th>
<th>pattern_database</th>
<th>replacement</th>
<th>enabled</th>
<th>message</th>
<th>pattern_digest</th>
<th>normalized_pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SELECT ?</td>
<td>NULL</td>
<td>SELECT ? + 1</td>
<td>YES</td>
<td>NULL</td>
<td>d1b44b0c19af710b5a679907e284acd2ddc285201794bc69a2389d77baeddda</td>
<td>select ?</td>
</tr>
</tbody>
</table>
```

For information about statement digesting, normalized statements, and digest hash values, see Section 26.10, “Performance Schema Statement Digests and Sampling”.

If a rule cannot be loaded due to some error, calling flush_rewrite_rules() produces an error:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

When this occurs, the plugin writes an error message to the message column of the rule row to communicate the problem. Check the rewrite_rules table for rows with non-NULL message column values to see what problems exist.

Patterns use the same syntax as prepared statements (see Section 13.5.1, “PREPARE Syntax”). Within a pattern template, ? characters act as parameter markers that match data values. Parameter markers
The Rewriter Query Rewrite Plugin

can be used only where data values should appear, not for SQL keywords, identifiers, and so forth. The ? characters should not be enclosed within quotation marks.

Like the pattern, the replacement can contain ? characters. For a statement that matches a pattern template, the plugin rewrites it, replacing ? parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:

```
mysql> SELECT PI();
+----------+
| PI()     |
+----------+
| 3.141593 |
+----------+
1 row in set (0.01 sec)

mysql> SELECT 10;
+--------+
| 10 + 1  |
+--------+
|     11  |
+--------+
1 row in set, 1 warning (0.00 sec)
```

No rewriting occurs for the first SELECT statement, but does for the second. The second statement illustrates that when the Rewriter plugin rewrites a statement, it produces a warning message. To view the message, use SHOW WARNINGS:

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1105
Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

A statement need not be rewritten to a statement of the same type. The following example loads a rule that rewrites DELETE statements to UPDATE statements:

```
INSERT INTO query_rewrite_rewrite_rules (pattern, replacement)
VALUES('DELETE FROM db1.t1 WHERE col = ?',
       'UPDATE db1.t1 SET col = NULL WHERE col = ?');
CALL query_rewrite_rewrite_rules();
```

To enable or disable an existing rule, modify its enabled column and reload the table into the plugin. To disable rule 1:

```
UPDATE query_rewrite_rewrite_rules SET enabled = 'NO' WHERE id = 1;
CALL query_rewrite_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
UPDATE query_rewrite_rewrite_rules SET enabled = 'YES' WHERE id = 1;
CALL query_rewrite_rewrite_rules();
```
The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used only if `appdb` is the default database:

```sql
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```

Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause. But if there are old applications that cannot be written to change the `SELECT` queries they generate, they will no longer work properly. The `Rewriter` plugin can solve this problem. To match and rewrite statements whether or not they qualify the table name, add the following two rules and reload the rules table:

```sql
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement) VALUES(
'SELECT * FROM appdb.users WHERE id = ?',
'SELECT * FROM appdb.users WHERE user_id = ?'
);
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement, pattern_database) VALUES(
'SELECT * FROM users WHERE id = ?',
'SELECT * FROM users WHERE user_id = ?',
'appdb'
);
CALL query_rewrite.flush_rewrite_rules();
```

`Rewriter` uses the first rule to match statements that use the qualified table name. It uses the second to match statements that used the unqualified name, but only if the default database is `appdb` (the value in `pattern_database`).

How Statement Matching Works

The `Rewriter` plugin uses statement digests and digest hash values to match incoming statements against rewrite rules in stages. The `max_digest_length` system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.
2. If the statement digest hash value matches any pattern digest hash values, match the normalized (statement digest) form of the statement to the normalized form of the matching rule patterns.
3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A `?` character in the pattern matches any literal value in the statement. If the statement prepares a statement, `?` in the pattern also matches `?` in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is nondeterministic which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the `message` column of the rule row to communicate the problem, and sets the `Rewriter_reload_error` status variable to `ON`.

**Rewriting Prepared Statements**

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.

Prepared statements differ from nonprepared statements in that they may contain `?` characters as parameter markers. To match a `?` in a prepared statement, a Rewriter pattern must contain `?` in the same location. Suppose that a rewrite rule has this pattern:

```
SELECT ?, 3
```

The following table shows several prepared `SELECT` statements and whether the rule pattern matches them.

<table>
<thead>
<tr>
<th>Prepared Statement</th>
<th>Whether Pattern Matches Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREPARE s AS 'SELECT 3, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT 3, ?'</td>
<td>No</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, ?'</td>
<td>No</td>
</tr>
</tbody>
</table>

**Rewriter Plugin Operational Information**

The Rewriter plugin makes information available about its operation by means of several status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----------------------------------+-------+
| Variable_name                     | Value |
|-----------------------------------+-------|
| Rewriter_number_loaded_rules      | 1     |
| Rewriter_number_reloads           | 5     |
| Rewriter_number_rewritten_queries | 1     |
| Rewriter_reload_error             | ON    |
```

For descriptions of these variables, see Rewriter Query Rewrite Plugin Status Variables.

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the `CALL` statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to `ON`:
Rewriter Plugin Use of Character Sets

When the rewrite_rules table is loaded into the Rewriter plugin, the plugin interprets statements using the current global value of the character_set_client system variable. If the global character_set_client value is changed subsequently, the rules table must be reloaded.

A client must have a session character_set_client value identical to what the global value was when the rules table was loaded or rule matching will not work for that client.

5.6.4.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these components associated with the Rewriter query rewrite plugin:

- The Rewriter rules table in the query_rewrite database
- Rewriter procedures and functions
- Rewriter system and status variables

Rewriter Query Rewrite Plugin Rules Table

The rewrite_rules table in the query_rewrite database provides persistent storage for the rules that the Rewriter plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates information to users by setting the table's message column.

Note

The rules table is loaded into the plugin by the flush_rewrite_rules stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The rewrite_rules table has these columns:

- id
  
The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.

- pattern
  
The template that indicates the pattern for statements that the rule matches. Use ? to represent parameter markers that match data values.
The Rewriter Query Rewrite Plugin

- **pattern_database**
  The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

- **replacement**
  The template that indicates how to rewrite statements matching the `pattern` column value. Use `?` to represent parameter markers that match data values. In rewritten statements, the plugin replaces `?` parameter markers in `replacement` using data values matched by the corresponding markers in `pattern`.

- **enabled**
  Whether the rule is enabled. Load operations (performed by invoking the `flush_rewrite_rules()` stored procedure) load the rule from the table into the Rewriter in-memory cache only if this column is `YES`.
  
  This column makes it possible to deactivate a rule without removing it: Set the column to a value other than `YES` and reload the table into the plugin.

- **message**
  The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to `NULL`. A non-`NULL` value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

  - Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
  - The replacement contains more `?` parameter markers than the pattern.

  If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to `ON`.

- **pattern_digest**
  This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- **normalized_pattern**
  This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

**Rewriter Query Rewrite Plugin Procedures and Functions**

- **Rewriter plugin operation uses a stored procedure that loads the rules table into its in-memory cache, and a helper user-defined function (UDF). Under normal operation, users invoke only the stored procedure. The UDF is intended to be invoked by the stored procedure, not directly by users.**

- **flush_rewrite_rules()**
  This stored procedure uses the `load_rewrite_rules()` UDF to load the contents of the `rewrite_rules` table into the Rewriter in-memory cache.
Calling `flush_rewrite_rules()` implies COMMIT.

Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the message column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to ON.

- **load_rewrite_rules()**

  This UDF is a helper routine used by the `flush_rewrite_rules()` stored procedure.

### Rewriter Query Rewrite Plugin System Variables

The `Rewriter` query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see Section 5.6.4.1, "Installing or Uninstalling the Rewriter Query Rewrite Plugin").

- **rewriter_enabled**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>rewriter_enabled</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether the `Rewriter` query rewrite plugin is enabled.

- **rewriter_verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>rewriter_verbose</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

For internal use.

### Rewriter Query Rewrite Plugin Status Variables

The `Rewriter` query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see Section 5.6.4.1, "Installing or Uninstalling the Rewriter Query Rewrite Plugin").

- **Rewriter_number_loaded_rules**

  The number of rewrite plugin rewrite rules successfully loaded from the `rewrite_rules` table into memory for use by the `Rewriter` plugin.

- **Rewriter_number_reloads**
The number of times the `rewrite_rules` table has been loaded into the in-memory cache used by the `Rewriter` plugin.

- **Rewriter_number_rewritten_queries**

The number of queries rewritten by the `Rewriter` query rewrite plugin since it was loaded.

- **Rewriter_reload_error**

Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the `Rewriter` plugin. If the value is `OFF`, no error occurred. If the value is `ON`, an error occurred; check the `message` column of the `rewriter_rules` table for error messages.

### 5.6.5 The `ddl_rewriter` Plugin

MySQL 8.0.16 and higher includes a `ddl_rewriter` plugin that modifies `CREATE TABLE` statements received by the server before it parses and executes them. The plugin removes `ENCRYPTION`, `DATA DIRECTORY`, and `INDEX DIRECTORY` clauses, which may be helpful when restoring tables from SQL dump files created from databases that are encrypted or that have their tables stored outside the data directory. For example, the plugin may enable restoring such dump files into an unencrypted instance or in an environment where the paths outside the data directory are not accessible.

Before using the `ddl_rewriter` plugin, install it according to the instructions provided in Section 5.6.5.1, “Installing or Uninstalling `ddl_rewriter`”.

`ddl_rewriter` examines SQL statements received by the server prior to parsing, rewriting them according to these conditions:

- `ddl_rewriter` considers only `CREATE TABLE` statements, and only if they are standalone statements that occur at the beginning of an input line or at the beginning of prepared statement text. `ddl_rewriter` does not consider `CREATE TABLE` statements within stored program definitions. Statements can extend over multiple lines.

- Within statements considered for rewrite, instances of the following clauses are rewritten and each instance replaced by a single space:
  - `ENCRYPTION`
  - `DATA DIRECTORY` (at the table and partition levels)
  - `INDEX DIRECTORY` (at the table and partition levels)

- Rewriting does not depend on lettercase.

If `ddl_rewriter` rewrites a statement, it generates a warning:

```
mysql> CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data';
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
  Code: 1105
  Message: Query 'CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data''
    rewritten to 'CREATE TABLE t (i INT)' by a query rewrite plugin
1 row in set (0.00 sec)
```
If the general query log or binary log is enabled, the server writes to it statements as they appear after any rewriting by `ddl_rewriter`.

When installed, `ddl_rewriter` exposes the Performance Schema `memory/rewriter/ddl_rewriter` instrument for tracking plugin memory use. See Section 26.12.16.10, “Memory Summary Tables”.

### 5.6.5.1 Installing or Uninstalling `ddl_rewriter`

This section describes how to install or uninstall the `ddl_rewriter` plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

#### Note

If installed, the `ddl_rewriter` plugin involves some minimal overhead even when disabled. To avoid this overhead, install `ddl_rewriter` only for the period during which you intend to use it.

The primary use case is modification of statements restored from dump files, so the typical usage pattern is: 1) Install the plugin; 2) restore the dump file or files; 3) uninstall the plugin.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `ddl_rewriter`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `ddl_rewriter` plugin, use the `INSTALL PLUGIN` statement (adjust the `.so` suffix for your platform as necessary):

```sql
INSTALL PLUGIN ddl_rewriter SONAME 'ddl_rewriter.so';
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'ddl%';
+--------------+---------------+-------------+
| PLUGIN_NAME  | PLUGIN_STATUS | PLUGIN_TYPE |
|--------------+---------------+-------------+
|ddl_rewriter  | ACTIVE        | AUDIT       |
+--------------+---------------+-------------+
```

As the preceding result shows, `ddl_rewriter` is implemented as an audit plugin.

If the plugin fails to initialize, check the server error log for diagnostic messages.

Once installed as just described, `ddl_rewriter` remains installed until uninstalled. To remove it, use `UNINSTALL PLUGIN`:

```sql
UNINSTALL PLUGIN ddl_rewriter;
```

If `ddl_rewriter` is installed, you can use the `--ddl-rewriter` option for subsequent server startups to control `ddl_rewriter` plugin activation. For example, to prevent the plugin from being enabled at runtime, use this option:
5.6.5.2 ddl_rewriter Plugin Options

This section describes the command options that control operation of the `ddl_rewriter` plugin. If values specified at startup time are incorrect, the `ddl_rewriter` plugin may fail to initialize properly and the server does not load it.

To control activation of the `ddl_rewriter` plugin, use this option:

`--ddl-rewriter=[value]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ddl-rewriter=[value]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.16</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the `ddl_rewriter` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 5.6.5.1, “Installing or Uninstalling `ddl_rewriter`”.

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”. For example, `--ddl-rewriter=OFF` disables the plugin at server startup.

5.6.6 Version Tokens

MySQL includes Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

- Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.
- Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.
- Version token lists are established per server (for example, to specify the server assignment or operational state). In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the components of Version Tokens, discuss how to install and use it, and provide reference information for its components.
5.6.6.1 Version Tokens Components

Version Tokens is based on a plugin library that implements these components:

- A server-side plugin named version_tokens holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The version_tokens plugin uses the audit plugin API to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.

- A set of user-defined functions (UDFs) provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin. The VERSION_TOKEN_ADMIN or SUPER privilege is required to call any of the Version Token UDFs.

- When the version_tokens plugin loads, it defines the VERSION_TOKEN_ADMIN dynamic privilege. This privilege can be granted to users of the UDFs.

- A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

5.6.6.2 Installing or Uninstalling Version Tokens

Note

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is version_tokens. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To install the Version Tokens plugin and UDFs, use the INSTALL PLUGIN and CREATE FUNCTION statements (adjust the .so suffix for your platform as necessary):

```sql
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_unlock RETURNS INT
```
SONAME 'version_token.so';

You must install the UDFs to manage the server's version token list, but you must also install the plugin because the UDFs will not work correctly without it.

If the plugin and UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```sql
UNINSTALL PLUGIN version_tokens;
DROP FUNCTION version_tokens_set;
DROP FUNCTION version_tokens_show;
DROP FUNCTION version_tokens_edit;
DROP FUNCTION version_tokens_delete;
DROP FUNCTION version_tokens_lock_shared;
DROP FUNCTION version_tokens_lock_exclusive;
DROP FUNCTION version_tokens_unlock;
```

5.6.6.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at Section 5.6.6.2, “Installing or Uninstalling Version Tokens”.

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these components:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.

Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.

  If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it will issue (for example, reads versus writes), a client selects an appropriate server and connects to it.

- In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.
On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.
- The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server’s version token list is empty. Token list maintenance is performed by calling user-defined functions (UDFs). The `VERSION_TOKEN_ADMIN` or `SUPER` privilege is required to call any of the Version Token UDFs, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named `emp` and `prod`, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are `read` or `write` depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client sets its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the `version_tokens_set()` UDF. (There are also UDFs for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

Server 1:

```
mysql> SELECT version_tokens_set('emp=read;prod=read');
+------------------------------------------+
| version_tokens_set('emp=read;prod=read') |
| 2 version tokens set.                    |
+------------------------------------------+
```

Server 2:

```
mysql> SELECT version_tokens_set('emp=write;prod=read');
+-------------------------------------------+
| version_tokens_set('emp=write;prod=read') |
+-------------------------------------------+
```
The token list in each case is specified as a semicolon-separated list of `name=value` pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the `emp` database.
- Only server 3 accepts updates for the `prod` database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the `emp` database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its `version_tokens_session` system variable:

```
mysql> SET @@SESSION.version_tokens_session = 'emp=write';
```

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0
mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----------+------------+
| last_name | first_name |
+-----------+------------+
| Smith     | Abe        |
+-----------+------------+
1 row in set (0.01 sec)
```

Discrepancies between the server and client version token lists can occur two ways:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.

- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):
Server 1:

```sql
mysql> SELECT version_tokens_edit('emp=write');
+----------------------------------+
| version_tokens_edit('emp=write') |
| 1 version tokens updated.        |
+----------------------------------+
```

Server 2:

```sql
mysql> SELECT version_tokens_edit('emp=read');
+---------------------------------+
| version_tokens_edit('emp=read') |
| 1 version tokens updated.       |
+---------------------------------+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```sql
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

---

**Note**

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of `emp=read`, there is nothing in Version Tokens to prevent the client from sending updates for the `emp` database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
- Perform the comparison between the server and client token lists
- Execute the statement or produce an error depending on the comparison result
- Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the user-defined included in the Version Tokens plugin library, but there are others. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked.

These UDFs permit the server's list of version tokens to be created, changed, removed, and inspected:
Version Tokens

- `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of `name=value` pairs.

- `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of `name=value` pairs.

- `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.

- `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-------------------------------------+
| version_tokens_set('tok1=a;tok2=b') |
+-------------------------------------+
| 2 version tokens set.               |
+-------------------------------------+
mysql> SELECT version_tokens_edit('tok3=c');
+-------------------------------+
| version_tokens_edit('tok3=c')     |
+-------------------------------+
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_delete('tok2;tok1');
+------------------------------------+
| version_tokens_delete('tok2;tok1') |
+------------------------------------+
| 2 version tokens deleted.          |
+------------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show() |
+-----------------------+
| tok3=c;               |
+-----------------------+
```

Warnings occur if a token list is malformed:

```
mysql> SELECT version_tokens_set('tok1=a; =c');
+----------------------------------+
| version_tokens_set('tok1=a; =c') |
+----------------------------------+
| 1 version tokens set.            |
+----------------------------------+
1 row in set, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 42000
Message: Invalid version token pair encountered. The list provided is only partially updated.
1 row in set (0.00 sec)
```

As mentioned previously, version tokens are defined using a semicolon-separated list of `name=value` pairs. Consider this invocation of `version_tokens_set()`:

```
mysql> SELECT version_tokens_set('tok1=a; =c');
+----------------------------------+
| version_tokens_set('tok1=a; =c') |
+----------------------------------+
| 1 version tokens set.            |
+----------------------------------+
1 row in set, 1 warning (0.00 sec)
```
Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For `version_tokens_delete()`, which takes a list of names without values, whitespace around names is ignored.)

- There is no quoting mechanism.

- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding `version_tokens_set()` call results in a token list with two tokens: `tok1` has the value `1'2 3"4`, and `tok2` has the value `a = b`. To verify this, call `version_tokens_show()`:

If the token list contains two tokens, why did `version_tokens_set()` return the value `3 version tokens set`? That occurred because the original token list contained two definitions for `tok1`, and the second definition replaced the first.

The Version Tokens token-manipulation UDFs place these constraints on token names and values:

- Token names cannot contain `=` or `;` characters and have a maximum length of 64 characters.

- Token values cannot contain `;` characters. Length of values is constrained by the value of the `max_allowed_packet` system variable.

- Version Tokens treats token names and values as binary strings, so comparisons are case-sensitive.

Version Tokens also includes a set of UDFs enabling tokens to be locked and unlocked:

- `version_tokens_lock_exclusive()` acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.

- `version_tokens_lock_shared()` acquires shared version token locks. It takes a list of one or more lock names and a timeout value.

- `version_tokens_unlock()` releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:
Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexisting token names. This does not create the tokens.

**Note**

Version Tokens locking functions are based on the locking service described at Section 29.3.1, “The Locking Service”, and thus have the same semantics for shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service UDF interface, so those UDFs need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see [Locking Service Monitoring](#).

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and = and ; characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

### 5.6.6.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens components:

- **Version Tokens Functions**
- **Version Tokens System Variables**

#### Version Tokens Functions

The Version Tokens plugin library includes several user-defined functions. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked. The `VERSION_TOKEN_ADMIN` or `SUPER` privilege is required to invoke any Version Tokens UDF.

The following UDFs permit the server's list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in Section 5.6.6.3, “Using Version Tokens”, which provides details about the syntax for specifying tokens, as well as additional examples.

- `version_tokens_delete(name_list)`

  Deletes tokens from the server's list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.
An argument of **NULL** is treated as an empty string, which has no effect on the token list.

`version_tokens_delete()` deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexisting tokens.) To clear the token list entirely without knowing which tokens are in the list, pass **NULL** or a string containing no tokens to `version_tokens_set()`:

```
mysql> SELECT version_tokens_set(NULL);
+---------------------------+
| version_tokens_set(NULL)  |
| Version tokens list cleared. |
+---------------------------+
mysql> SELECT version_tokens_set('');
+---------------------------+
| version_tokens_set('')    |
| Version tokens list cleared. |
+---------------------------+
```

- **version_tokens_edit(token_list)**

  Modifies the server's list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is **NULL** or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_edit('tok1=value1;tok2=value2');
+-----------------------------------------------+
| version_tokens_edit('tok1=value1;tok2=value2') |
| 2 version tokens set.                         |
+-----------------------------------------------+
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
+--------------------------------------------------------+
| version_tokens_edit('tok2=new_value2;tok3=new_value3') |
| 2 version tokens updated.                        |
+--------------------------------------------------------+
```

- **version_tokens_set(token_list)**

  Replaces the server's list of version tokens with the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is **NULL** or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----------------------------------------------+
| version_tokens_set('tok1=value1;tok2=value2') |
| 2 version tokens set.                         |
+-----------------------------------------------+
```

- **version_tokens_show()**

  Returns the server's list of version tokens as a binary string containing a semicolon-separated list of `name=value` pairs.
The following UDFs permit version tokens to be locked and unlocked:

- **`version_tokens_lock_exclusive(token_name[, token_name] ... , timeout)`**
  
  Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.
  
  ```
  mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
  +-----------------------------------+
  | version_tokens_lock_exclusive('lock1', 'lock2', 10) |
  | 1 |
  +-----------------------------------+
  ```

- **`version_tokens_lock_shared(token_name[, token_name] ... , timeout)`**
  
  Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.
  
  ```
  mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
  +-----------------------------------+
  | version_tokens_lock_shared('lock1', 'lock2', 10) |
  | 1 |
  +-----------------------------------+
  ```

- **`version_tokens_unlock()`**
  
  Releases all locks that were acquired within the current session using `version_tokens_lock_exclusive()` and `version_tokens_lock_shared()`.
  
  ```
  mysql> SELECT version_tokens_unlock();
  +-------------------------+
  | version_tokens_unlock() |
  | 1 |
  +-------------------------+
  ```

The locking functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Token names are strings.
- In contrast to argument handling for the UDFs that manipulate the server token list, whitespace surrounding token name arguments is not ignored and = and ; characters are permitted.
- It is possible to lock nonexisting token names. This does not create the tokens.
- Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.
• Version Tokens locking functions are based on the locking service described at Section 29.3.1, “The Locking Service”.

Version Tokens System Variables

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see Section 5.6.6.2, “Installing or Uninstalling Version Tokens”).

System variables:

• \texttt{version\_tokens\_session}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--version_tokens_session=value}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{version_tokens_session}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\texttt{NULL}</td>
</tr>
</tbody>
</table>

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the \texttt{version\_tokens\_session} variable is \texttt{NULL} (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the \texttt{version\_tokens\_session} variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

• A token name in the \texttt{version\_tokens\_session} value is not present in the server token list. In this case, an \texttt{ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND} error occurs.

• A token value in the \texttt{version\_tokens\_session} value differs from the value of the corresponding token in the server token list. In this case, an \texttt{ER_VTOKEN_PLUGIN_TOKEN_MISMATCH} error occurs.

It is not a mismatch for the server version token list to include a token not named in the \texttt{version\_tokens\_session} value.

Suppose that a management application has set the server token list as follows:

```sql
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+--------------------------------------------+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
+--------------------------------------------+
| 3 version tokens set.                      |
+--------------------------------------------+
```

A client registers the tokens it requires the server to match by setting its \texttt{version\_tokens\_session} value. Then, for each subsequent statement sent by the client, the server checks its token list against the client \texttt{version\_tokens\_session} value and produces an error if there is a mismatch:
The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```
mysql> SELECT version_tokens_edit('tok1=b');
+-------------------------------+
| version_tokens_edit('tok1=b') |
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show() |
| tok3=c;tok1=b;tok2=b;   |
+-----------------------+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```
mysql> SELECT 1;
+---+
| 1 |
+---+
```

• `version_tokens_session_number`

5.7 MySQL Server User-Defined Functions
MySQL Server enables user-defined functions (UDFs) to be created and loaded into the server to extend server capabilities. Server capabilities can be implemented in whole or in part using UDFs. In addition, you can write your own UDFs.

The following sections describe how to install and uninstall UDFs, and how to determine at runtime which UDFs are installed and obtain information about them. For information about writing UDFs, see Section 29.4, “Adding New Functions to MySQL”.

5.7.1 Installing and Uninstalling User-Defined Functions

User-defined functions (UDFs) must be loaded into the server before they can be used. MySQL supports UDF loading at runtime.

To load a UDF, use the `CREATE FUNCTION` statement. For example:

```sql
CREATE FUNCTION metaphon
    RETURNS STRING
    SONAME 'udf_example.so';
```

The UDF file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

While a UDF is loaded, information about it is available from the Performance Schema `user_defined_functions` table. See Section 5.7.2, “Obtaining User-Defined Function Information”.

The statement also registers the UDF in the `mysql.func` system table to cause the server to load it on subsequent restarts. For this reason, `CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` database.

To remove a UDF, use the `DROP FUNCTION` statement. For example:

```sql
DROP FUNCTION metaphon;
```

`CREATE FUNCTION` unloads the UDF and removes it from the `mysql.func` system table. For this reason, `DROP FUNCTION` statement requires the `DELETE` privilege for the `mysql` database. With the UDF no longer registered in the table, the server does not load the UDF automatically for subsequent restarts.

You cannot use `CREATE FUNCTION` to reinstall a function that has previously been installed. To reinstall a function, first remove it with `DROP FUNCTION`, then install it again with `CREATE FUNCTION`. You would need to do this, for example, if you upgrade to a new version of MySQL that provides an updated implementation of the function, or you recompile a new version of a function that you have written. Otherwise, the server continues to use the old version.

If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.func` table and does not load the UDFs listed there.

5.7.2 Obtaining User-Defined Function Information

The Performance Schema `user_defined_functions` table contains information about the currently loaded user-defined functions:

```sql
SELECT * FROM performance_schema.user_defined_functions;
```

For more information, see Section 26.12.17.6, “The user_defined_functions Table”.

5.8 Running Multiple MySQL Instances on One Machine
In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.7 and one from MySQL 8.0, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See Section 4.2.2, “Specifying Program Options”. To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see Section 5.8.1, “Setting Up Multiple Data Directories”.

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`
  
  `--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause each server to listen to a different address.

- `--socket={file_name|pipe_name}`
  
  `--socket` controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`
  
  This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`
  
  This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`

- `--log-bin [=file_name]`

- `--slow_query_log_file=file_name`

- `--log-error [=file_name]`
For further discussion of log file options, see Section 5.4, “MySQL Server Logs”.

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using tar file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

### 5.8.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

#### Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with MyISAM and MERGE tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a very bad idea. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.
Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See Section 2.10, “Postinstallation Setup and Testing”.

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it to where you are setting up the new instance.

- Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.

2. Copy the data directory to the location where the new data directory should be.

3. Copy the my.cnf or my.ini option file used by the existing instance. This serves as a basis for the new instance.

4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see Section 5.8, “Running Multiple MySQL Instances on One Machine”.

5. Start the new instance, telling it to use the new option file.

5.8.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in Section 2.3, “Installing MySQL on Microsoft Windows”. The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in Section 5.8, “Running Multiple MySQL Instances on One Machine”.

5.8.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in Section 2.3.5.6, “Starting MySQL from the Windows Command Line”. To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a --defaults-file option when you run it.
Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.

2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata1
   port = 3307
   ```

   Create a second file named `C:\my-opts2.cnf` that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata2
   port = 3308
   ```

3. Use the `--defaults-file` option to start each server with its own option file:

   ```
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
   ```

   Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```  

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```  

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

### 5.8.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.5.8, “Starting MySQL as a Windows Service”.

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.
For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-8.0.18`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 8.0.18.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1**: Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 8.0.18 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 8.0.18. For example, you can set up `C:\my.cnf` like this:

```plaintext
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-8.0.18
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-8.0.18\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:

```
C:\> SC START mysqld1
C:\> SC START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` or `SC STOP` with the appropriate service names:

```
C:\> SC STOP mysqld1
C:\> SC STOP mysqld2
```

- **Approach 2**: Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```plaintext
# options for mysqld service
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1
```

Install the services as follows:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install --defaults-file C:\my-opts1.cnf
C:\> C:\mysql-8.0.18\bin\mysqld --install --defaults-file C:\my-opts2.cnf
```

To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:

```
C:\> SC START mysqld1
C:\> SC START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` or `SC STOP` with the appropriate service names:

```
C:\> SC STOP mysqld1
C:\> SC STOP mysqld2
```
Running Multiple MySQL Instances on Unix

For the 8.0.18 mysqld, create a file C:\my-opts2.cnf that looks like this:

```
[mysqld]
basedir = C:/mysql-8.0.18
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1 --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-8.0.18\bin\mysqld --install mysqld2 --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a --defaults-file option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use SC DELETE mysqld_service_name for each one. Alternatively, use mysqld --remove for each one, specifying a service name following the --remove option. If the service name is the default (MySQL), you can omit it when using mysqld --remove.

5.8.3 Running Multiple MySQL Instances on Unix

Note

The discussion here uses mysqld_safe to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by systemd on several Linux platforms. On these platforms, mysqld_safe is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see Section 2.5.9, "Managing MySQL Server with systemd".

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.7 server is configured for the default TCP/IP port number (3306) and Unix socket file (/tmp/mysql.sock). To configure a new 8.0.18 server to have different operating parameters, use a CMake command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
    -DMYSQL_UNIX_ADDR=file_name \
    -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-8.0.18
```

Here, port_number and file_name must be different from the default TCP/IP port number and Unix socket file path name, and the CMAKE_INSTALL_PREFIX value should specify an installation directory different from the one under which the existing MySQL installation is located.
If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> bin/mysqld --initialize --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

*Section 4.9, “MySQL Environment Variables”, includes a list of other environment variables you can use to affect MySQL programs.*

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See *Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”.*

### 5.8.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=localhost --port=port_number` to connect using TCP/IP to a local server, or
with --host=localhost --socket=file_name to connect to a local server using a Unix socket file or a Windows named pipe.

• Start the client with --protocol=TCP to connect using TCP/IP, --protocol=SOCKET to connect using a Unix socket file, --protocol=PIPE to connect using a named pipe, or --protocol=MEMORY to connect using shared memory. For TCP/IP connections, you may also need to specify --host and --port options. For the other types of connections, you may need to specify a --socket option to specify a Unix socket file or Windows named-pipe name, or a --shared-memory-base-name option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

• On Unix, set the MYSQL_UNIX_PORT and MYSQL_TCP_PORT environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your .login file so that they apply each time you log in. See Section 4.9, “MySQL Environment Variables”.

• Specify the default Unix socket file and TCP/IP port number in the [client] group of an option file. For example, you can use C:\my.cnf on Windows, or the .my.cnf file in your home directory on Unix. See Section 4.2.2.2, “Using Option Files”.

• In a C program, you can specify the socket file or port number arguments in the mysql_real_connect() call. You can also have the program read option files by calling mysql_options(). See Section 28.7.7, “C API Function Descriptions”.

• If you are using the Perl DBD::mysql module, you can read options from MySQL option files. For example:

```perl
$dsn = "DBI:mysql:test;mysql_read_default_group=client;" . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 28.9, “MySQL Perl API”.

Other programming interfaces may provide similar capabilities for reading option files.

  6.4.8 MySQL Enterprise Data Masking and De-Identification .................... 1370

6.5 FIPS Support ............................................................................. 1387
When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See Section 6.1, “General Security Issues”.

- Security of the installation itself. The data files, log files, and all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see Section 2.10, “Postinstallation Setup and Testing”.

- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see Section 6.2, “Access Control and Account Management”.

- The features offered by security-related plugins. See Section 6.4, “Security Components and Plugins”.

- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.

- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See Chapter 7, Backup and Recovery.

### 6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 2.10, “Postinstallation Setup and Testing”.

For answers to some questions that are often asked about MySQL Server security issues, see Section A.9, “MySQL 8.0 FAQ: Security”.

#### 6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql system database!** This is critical.

- Learn how the MySQL access privilege system works (see Section 6.2, “Access Control and Account Management”). Use the GRANT and REVOKE statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.
Checklist:

• Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL root user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a root password. See Section 2.10.4, “Securing the Initial MySQL Account”.

• Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

• Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()` or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

• Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

• Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

• Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

  ```bash
  shell> telnet server_host 3306
  ```

  If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

• Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See Section 6.1.7, “Client Programming Security Guidelines”.

• Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

• Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

  ```bash
  shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
  ```
This works under Linux and should work with small modifications under other systems.

Warning
If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. In addition, the validate_password plugin can be used to enforce a policy on acceptable password. See Section 6.4.3, “The Password Validation Component”.

6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

• Use the mysql_config_editor utility, which enables you to store authentication credentials in an encrypted login path file named .mylogin.cnf. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

• Use a --password=password or -p password option on the command line. For example:

```
shell> mysql --password=frank -u francis db_name
```

Warning
This is convenient but insecure. On some systems, your password becomes visible to system status programs such as ps that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to ps. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

• Use the --password or -p option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: ********
```

The * characters indicate where you enter your password. The password is not displayed as you enter it.
Keeping Passwords Secure

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the [client] section of the .my.cnf file in your home directory:

  ```
  [client]
  password=password
  ```

  To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to 400 or 600. For example:

  ```
  shell> chmod 600 .my.cnf
  ```

  To name from the command line a specific option file containing the password, use the --defaults-file=file_name option, where file_name is the full path name to the file. For example:

  ```
  shell> mysql --defaults-file=/home/francis/mysql-opts
  ```

  Section 4.2.2.2, “Using Option Files”, discusses option files in more detail.

- Store your password in the MYSQL_PWD environment variable. See Section 4.9, “MySQL Environment Variables”.

  This method of specifying your MySQL password must be considered extremely insecure and should not be used. Some versions of ps include an option to display the environment of running processes. On some systems, if you set MYSQL_PWD, your password is exposed to any other user who runs ps. Even on systems without such a version of ps, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the mysql client writes a record of executed statements to a history file (see Section 4.5.1.3, “mysql Client Logging”). By default, this file is named .mysql_history and is created in your home directory. Passwords can be written as plain text in SQL statements such as CREATE USER and ALTER USER, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the .my.cnf file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, bash uses ~/.bash_history. Any such file should have a restrictive access mode.

6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the mysql.user system table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See Section 6.2.15, “Password Management”, and Section 6.2.16, “Server Handling of Expired Passwords”.
The `validate_password` plugin can be used to enforce a policy on acceptable password. See Section 6.4.3, "The Password Validation Component".

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 6.1.2.3, "Passwords and Logging".

### 6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT` and `SET PASSWORD`. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Statement logging avoids writing passwords as cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
SET PASSWORD ...
SLAVE START ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...) ...
ALTER SERVER ... OPTIONS(... PASSWORD ...) ...
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` system table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. See Section 6.4.5.3, "MySQL Enterprise Audit Security Considerations".

Statements received by the server may be rewritten if a query rewrite plugin is installed (see Query Rewrite Plugins). In this case, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.
To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replication slaves store the password for the replication master in the master info repository, which by default is a table in the `mysql` database named `slave_master_info`. The use of a file in the data directory for the master info repository is now deprecated, but still possible (see Section 17.2.4, “Replication Relay and Status Logs”). Ensure that the master info repository can be accessed only by the database administrator. An alternative to storing the password in the master info repository is to use the `START SLAVE` statement to specify credentials for connecting to the master.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

### 6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection.

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Section 6.3, “Using Encrypted Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at [http://www.openssh.org/](http://www.openssh.org/), and a comparison of both Open Source and Commercial SSH clients at [http://en.wikipedia.org/wiki/Comparison_of_SSH_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).

To make a MySQL system secure, you should strongly consider the following suggestions:

- **Require all MySQL accounts to have a password.** A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 6.2.14, “Assigning Account Passwords”.

- **Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`**.

- **Never run the MySQL server as the Unix `root` user.** This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

  `mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

  ```
  [mysqld]
  user=mysql
  ```
This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section 6.1.5, “How to Run MySQL as a Normal User”.

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. User names for MySQL accounts have nothing to do with user names for Unix accounts.

• Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server’s data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See Section 5.1.8, “Server System Variables”.

• Encrypt binary log files and relay log files. Encryption helps to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

• Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users.

  `mysqld` reserves an extra connection for users who have the `CONNECTION_ADMIN` or `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

• Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”.

• Stored programs and views should be written using the security guidelines discussed in Section 24.6, “Stored Object Access Control”.

• If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.

• If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `CREATE USER` and `ALTER USER` statements also support resource control options for limiting the extent of server use permitted to an account. See Section 13.7.1.3, “CREATE USER Syntax”, and Section 13.7.1.1, “ALTER USER Syntax”.
6.1.4 Security-Related mysqld Options and Variables

The following table shows mysqld options and system variables that affect security. For descriptions of each of these, see Section 5.1.7, “Server Command Options”, and Section 5.1.8, “Server System Variables”.

6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository or RPM packages, the MySQL server mysqld should be started by the local mysql operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the MySQL repositories.

On Unix (or Linux for installations performed using tar.gz packages), the MySQL server mysqld can be started and run by any user. However, you should avoid running the server as the Unix root user for...
security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).

2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.

4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10.4, “Securing the Initial MySQL Account”.

### 6.1.6 Security Issues with LOAD DATA LOCAL

The `LOAD DATA` statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

There are two potential security issues with the `LOCAL` version of `LOAD DATA`:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.
Security Issues with LOAD DATA LOCAL

To avoid LOAD DATA issues, clients should avoid using LOCAL. To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the --ssl-mode=VERIFY_IDENTITY option and the appropriate CA certificate.

To enable administrators and applications to manage the local data loading capability, LOCAL configuration works like this:

• On the server side:
  • The local_infile system variable controls server-side LOCAL capability. Depending on the local_infile setting, the server refuses or permits local data loading by clients that have LOCAL enabled on the client side. By default, local_infile is disabled.
  • To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled, respectively. local_infile can also be set at runtime.

• On the client side:
  • The ENABLED_LOCAL_INFILE CMake option controls the compiled-in default LOCAL capability for the MySQL client library. Clients that make no explicit arrangements therefore have LOCAL capability disabled or enabled according to the ENABLED_LOCAL_INFILE setting specified at MySQL build time.
  
  By default, the client library in MySQL binary distributions is compiled with ENABLED_LOCAL_INFILE disabled. If you compile MySQL from source, configure it with ENABLED_LOCAL_INFILE disabled or enabled based on whether clients that make no explicit arrangements should have LOCAL capability disabled or enabled, respectively.

  • Client programs that use the C API can control load data loading explicitly by invoking mysql_options() to disable or enable the MYSQL_OPT_LOCAL_INFILE option. See Section 28.7.7.50, “mysql_options()”.

• For the mysql client, local data loading is disabled by default. To disable or enable it explicitly, use the --local-infile=0 or --local-infile=1 option.

• For the mysqlimport client, local data loading is disabled by default. To disable or enable it explicitly, use the --local=0 or --local=1 option.

• If you use LOAD DATA LOCAL in Perl scripts or other programs that read the [client] group from option files, you can add an local-infile option setting to that group. To prevent problems for programs that do not understand this option, specify it using the loose- prefix:

```
[client]
loose-local-infile=0
```

or:

```
[client]
loose-local-infile=1
```

• In all cases, successful use of a LOCAL load operation by a client also requires that the server permits it.

If LOCAL capability is disabled, on either the server or client side, a client that attempts to issue a LOAD DATA LOCAL statement receives the following error message:
6.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like `DROP DATABASE mysql;`. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value 234, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See Section 5.1.11, “Server SQL Modes”.
- Try to enter single and double quotation marks (‘ and ”) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22 ("), %23 (#), and %27 (‘) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string_quote()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
Access Control and Account Management

- PHP: Use either the mysqli or pdo_mysql extensions, and not the older ext/mysql extension. The preferred API’s support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also Choosing an API.

If the older ext/mysql extension must be used, then for escaping use the mysql_real_escape_string_quote() function and not mysql_escape_string() or addslashes() because only mysql_real_escape_string_quote() is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

- Perl DBI: Use placeholders or the quote() method.
- Ruby DBI: Use placeholders or the quote() method.
- Java JDBC: Use a PreparedStatement object and placeholders.

Other programming interfaces might have similar capabilities.

6.2 Access Control and Account Management

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as SELECT, INSERT, UPDATE, and DELETE. Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as CREATE USER, GRANT, and REVOKE. See Section 13.7.1, “Account Management Statements”.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by the host from which you connect and the user name you specify. When you issue requests after connecting, the system grants privileges according to your identity and what you want to do.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user joe who connects from office.example.com need not be the same person as the user joe who connects from home.example.com. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by joe from office.example.com, and a different set of privileges for connections by joe from home.example.com. To see what privileges a given account has, use the SHOW GRANTS statement. For example:

```sql
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the mysql system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.
Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the **SELECT** privilege for the table or the **DROP** privilege for the database.

For a more detailed description of what happens during each stage, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”, and Section 6.2.7, “Access Control, Stage 2: Request Verification”. For help in diagnosing privilege-related problems, see Section 6.2.21, “Troubleshooting Problems Connecting to MySQL”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 6.2.13, “When Privilege Changes Take Effect”.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.

- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.

- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

### 6.2.1 Account User Names and Passwords

MySQL stores accounts in the **user** table of the **mysql** system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the **user** table, see Section 6.2.3, “Grant Tables”.

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See Section 6.2.17, “Pluggable Authentication”.

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a **-u** or **--user** option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.

- MySQL user names are up to 32 characters long. Operating system user names may have a different maximum length.

**Warning**

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the **mysql** database **does not work**.
You should never alter the structure of tables in the \texttt{mysql} database in any manner whatsoever except by means of the procedure that is described in Section 2.11, “Upgrading MySQL”. Attempting to redefine MySQL’s system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.

- To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the \texttt{user} table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

  If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the \texttt{user} table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the \texttt{user} table are encrypted using plugin-specific algorithms.

- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the \texttt{mysql_options()} C API function with the \texttt{MYSQL_SET_CHARSET_NAME} option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

  Standard MySQL client programs support a \texttt{--default-character-set} option that causes \texttt{mysql_options()} to be called as just described. In addition, character set autodetection is supported as described in Section 10.4, “Connection Character Sets and Collations”. For programs that use a connector that is not based on the C API, the connector may provide an equivalent to \texttt{mysql_options()} that can be used instead. Check the connector documentation.

  The preceding notes do not apply for \texttt{ucs2}, \texttt{utf16}, and \texttt{utf32}, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial \texttt{root} account, as described in Section 2.10.4, “Securing the Initial MySQL Account”, which also discusses how to assign a password to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as \texttt{CREATE USER}, \texttt{DROP USER}, \texttt{GRANT}, and \texttt{REVOKE}. See Section 6.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”, and Section 13.7.1, “Account Management Statements”.

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u finley -p db_name
```

If you omit the password value following the \texttt{--password} or \texttt{-p} option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -ppassword db_name
```
If you use the `-p` option, there must be no space between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. To avoid giving the password on the command line, use an option file or a login path file. See Section 4.2.2.2, “Using Option Files”, and Section 4.6.7, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

6.2.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.

- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.

- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Privileges also differ in terms of whether they are static (built in to the server) or dynamic (defined at runtime). Whether a privilege is static or dynamic affects its availability to be granted to user accounts and roles. For information about the differences between static and dynamic privileges, see Static Versus Dynamic Privileges.

Information about account privileges is stored in the grant tables in the `mysql` system database. For a description of the structure and contents of these tables, see Section 6.2.3, “Grant Tables”. The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in Section 6.2.13, “When Privilege Changes Take Effect”. The server bases access-control decisions on the in-memory copies of the grant tables.

**Important**

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

- Summary of Available Privileges
- Static Privilege Descriptions
- Dynamic Privilege Descriptions
- Privilege-Granting Guidelines
- Static Versus Dynamic Privileges
- Migrating Accounts from SUPER to Dynamic Privileges
## Summary of Available Privileges

The following table shows the static privilege names used in `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

### Table 6.2 Permissible Static Privileges for GRANT and REVOKE

<table>
<thead>

</tbody>
</table>

Static Privilege Descriptions

Static privileges are built in to the server, in contrast to dynamic privileges, which are defined at runtime. The following list describes each static privilege available in MySQL.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- `ALL`, `ALL PRIVILEGES`
Privileges Provided by MySQL

These privilege specifiers are shorthand for “all privileges available at a given privilege level” (except `GRANT OPTION`). For example, granting `ALL` at the global or table level grants all global privileges or all table-level privileges, respectively.

- **ALTER**
  Enables use of the `ALTER TABLE` statement to change the structure of tables. `ALTER TABLE` also requires the `CREATE` and `INSERT` privileges. Renaming a table requires `ALTER` and `DROP` on the old table, `CREATE`, and `INSERT` on the new table.

- **ALTER ROUTINE**
  Enables use of statements that alter or drop stored routines (stored procedures and functions).

- **CREATE**
  Enables use of statements that create new databases and tables.

- **CREATE ROLE**
  Enables use of the `CREATE ROLE` statement. (The `CREATE USER` privilege also enables use of the `CREATE ROLE` statement.) See Section 6.2.10, “Using Roles”.

  The `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` because they can be used only to create and drop accounts. They cannot be used as `CREATE USER` can be modify account attributes or rename accounts. See User and Role Interchangeability.

- **CREATE ROUTINE**
  Enables use of statements that create stored routines (stored procedures and functions).

- **CREATE TABLESPACE**
  Enables use of statements that create, alter, or drop tablespaces and log file groups.

- **CREATE TEMPORARY TABLES**
  Enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

  After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`. For more information, see Section 13.1.20.3, “CREATE TEMPORARY TABLE Syntax”.

- **CREATE USER**
  Enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

- **CREATE VIEW**
  Enables use of the `CREATE VIEW` statement.

- **DELETE**
  Enables rows to be deleted from tables in a database.

- **DROP**
Privileges Provided by MySQL

Enables use of statements that drop (remove) existing databases, tables, and views. The DROP privilege is required to use the ALTER TABLE ... DROP PARTITION statement on a partitioned table. The DROP privilege is also required for TRUNCATE TABLE.

- **DROP ROLE**

  Enables use of the DROP ROLE statement. (The CREATE USER privilege also enables use of the DROP ROLE statement.) See Section 6.2.10, “Using Roles”.

  The CREATE ROLE and DROP ROLE privileges are not as powerful as CREATE USER because they can be used only to create and drop accounts. They cannot be used as CREATE USER can be modify account attributes or rename accounts. See User and Role Interchangeability.

- **EVENT**

  Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

- **EXECUTE**

  Enables use of statements that execute stored routines (stored procedures and functions).

- **FILE**

  Affects the following operations and server behaviors:

  - Enables reading and writing files on the server host using the LOAD DATA and SELECT ... INTO OUTFILE statements and the LOAD_FILE() function. A user who has the FILE privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.)

  - Enables creating new files in any directory where the MySQL server has write access. This includes the server’s data directory containing the files that implement the privilege tables.

  - Enables use of the DATA DIRECTORY or INDEX DIRECTORY table option for the CREATE TABLE statement.

    As a security measure, the server does not overwrite existing files.

    To limit the location in which files can be read and written, set the secure_file_priv system variable to a specific directory. See Section 5.1.8, “Server System Variables”.

- **GRANT OPTION**

  Enables you to grant to or revoke from other users those privileges that you yourself possess.

- **INDEX**

  Enables use of statements that create or drop (remove) indexes. INDEX applies to existing tables. If you have the CREATE privilege for a table, you can include index definitions in the CREATE TABLE statement.

- **INSERT**

  Enables rows to be inserted into tables in a database. INSERT is also required for the ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE table-maintenance statements.

- **LOCK TABLES**
Enables use of explicit LOCK TABLES statements to lock tables for which you have the SELECT privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

- **PROCESS**

   Enables display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of SHOW PROCESSLIST or mysqladmin processlist to see threads belonging to other accounts; you can always see your own threads. The PROCESS privilege also enables use of SHOW ENGINE.

- **PROXY**

   Enables one user to impersonate or become known as another user. See Section 6.2.18, “Proxy Users”.

- **REFERENCES**

   Creation of a foreign key constraint requires the REFERENCES privilege for the parent table.

- **RELOAD**

   Enables use of the FLUSH statement. It also enables mysqladmin commands that are equivalent to FLUSH operations: flush-hosts, flush-logs, flush-privileges, flush-status, flush-tables, flush-threads, refresh, and reload.

   The reload command tells the server to reload the grant tables into memory. flush-privileges is a synonym for reload. The refresh command closes and reopens the log files and flushes all tables. The other flush-xxx commands perform functions similar to refresh, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, flush-logs is a better choice than refresh.

   The RELOAD privilege also enables use of the RESET MASTER and RESET SLAVE statements.

- **REPLICATION CLIENT**

   Enables use of the SHOW MASTER STATUS, SHOW SLAVE STATUS, and SHOW BINARY LOGS statements. Grant this privilege to accounts that are used by slave servers to connect to the current server as their master.

- **REPLICATION SLAVE**

   Enables the account to request updates that have been made to databases on the master server, using the SHOW SLAVE HOSTS, SHOW RELAYLOG EVENTS, and SHOW BINLOG EVENTS statements. This privilege is also required to use the mysqlbinlog options --read-from-remote-server (-R) and --read-from-remote-master. Grant this privilege to accounts that are used by slave servers to connect to the current server as their master.

- **SELECT**

   Enables rows to be selected from tables in a database. SELECT statements require the SELECT privilege only if they actually access tables. Some SELECT statements do not access tables and can be executed without permission for any database. For example, you can use SELECT as a simple calculator to evaluate expressions that make no reference to tables:

   ```sql
   SELECT 1+1;
   SELECT PI()*2;
   ```
The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

The `SELECT` privilege is needed for tables or views used with `EXPLAIN`, including any underlying tables in view definitions.

- **SHOW DATABASES**

  Enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

  **Caution**

  Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- **SHOW VIEW**

  Enables use of the `SHOW CREATE VIEW` statement. This privilege is also needed for views used with `EXPLAIN`.

- **SHUTDOWN**

  Enables use of the `SHUTDOWN` and `RESTART` statements, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.

- **SUPER**

  `SUPER` is a powerful and far-reaching privilege and should not be granted lightly. If an account needs to perform only a subset of `SUPER` operations, it may be possible to achieve the desired privilege set by instead granting one or more dynamic privileges, each of which confers more limited capabilities. See Dynamic Privilege Descriptions.

  **Note**

  `SUPER` is deprecated and will be removed in a future version of MySQL. See Migrating Accounts from SUPER to Dynamic Privileges.

  `SUPER` affects the following operations and server behaviors:

  - Enables system variable changes at runtime:
    - Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`.
      - The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.
    - Enables setting restricted session system variables that require a special privilege.
      - The corresponding dynamic privilege is `SESSION_VARIABLES_ADMIN`.

  See also Section 5.1.9.1, “System Variable Privileges”.
• Enables changes to global transaction characteristics (see Section 13.3.7, “SET TRANSACTION Syntax”).

The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.

• Enables the account to start and stop replication, including Group Replication.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN` for regular replication, `GROUP_REPLICATION_ADMIN` for Group Replication.

• Enables use of the `CHANGE MASTER TO` and `CHANGE_REPLICATION FILTER` statements.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN`.

• Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

The corresponding dynamic privilege is `BINLOG_ADMIN`.

• Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.

The corresponding dynamic privilege is `SET_USER_ID`.

• Enables use of the `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.

• Enables use of the `mysqladmin debug` command.

• Enables InnoDB encryption key rotation.

The corresponding dynamic privilege is `ENCRYPTION_KEY_ADMIN`.

• Enables execution of Version Tokens user-defined functions.

The corresponding dynamic privilege is `VERSION_TOKEN_ADMIN`.

• Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function.

The corresponding dynamic privilege is `ROLE_ADMIN`.

• Enables control over client connections not permitted to non-SUPER accounts:

  • Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

  • The server does not execute `init_connect` system variable content when SUPER clients connect.

  • The server accepts one connection from a SUPER client even if the connection limit configured by the `max_connections` system variable is reached.

  • A server in offline mode (offline_mode enabled) does not terminate SUPER client connections at the next client request, and accepts new connections from SUPER clients.

  • Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.
The corresponding dynamic privilege for the preceding connection-control operations is `CONNECTION_ADMIN`.

You may also need the `SUPER` privilege to create or alter stored functions if binary logging is enabled, as described in Section 24.7, “Stored Program Binary Logging”.

- `TRIGGER`

  Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

  When a trigger is activated (by a user who has privileges to execute `INSERT`, `UPDATE`, or `DELETE` statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the `TRIGGER` privilege for the table.

- `UPDATE`

  Enables rows to be updated in tables in a database.

- `USAGE`

  This privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to specify clauses such as `WITH GRANT OPTION` without naming specific account privileges in the privilege list. `SHOW GRANTS` displays `USAGE` to indicate that an account has no privileges at a privilege level.

**Dynamic Privilege Descriptions**

Dynamic privileges are defined at runtime, in contrast to static privileges, which are built in to the server. The following list describes each dynamic privilege available in MySQL.

Most dynamic privileges are defined at server startup. Others are defined by a particular server component or plugin, as indicated in the privilege descriptions. In such cases, the privilege is unavailable unless the component or plugin that defines it is enabled.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- `APPLICATION_PASSWORD_ADMIN` (added in MySQL 8.0.14)

  For dual-password capability, this privilege enables use of the `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses for `ALTER USER` and `SET PASSWORD` statements that apply to your own account. This privilege is required to manipulate your own secondary password because most users require only one password.

  If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

  For more information about use of dual passwords, see Section 6.2.15, “Password Management”.

- `AUDIT_ADMIN`

  Enables audit log configuration. This privilege is defined by the `audit_log` plugin; see Section 6.4.5, “MySQL Enterprise Audit”.

- `BACKUP_ADMIN`
Privileges Provided by MySQL

Enables execution of the `LOCK INSTANCE FOR BACKUP` statement and access to the Performance Schema `log_status` table.

The `BACKUP_ADMIN` privilege is automatically granted to users with the `RELOAD` privilege when performing an in-place upgrade to MySQL 8.0 from an earlier version.

- **BINLOG_ADMIN**
  Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

- **BINLOG_ENCRYPTION_ADMIN**
  Enables setting the system variable `binlog_encryption`, which activates or deactivates encryption for binary log files and relay log files. This ability is not provided by the `BINLOG_ADMIN`, `SYSTEM_VARIABLES_ADMIN`, or `SESSION_VARIABLES_ADMIN` privileges. The related system variable `binlog_rotate_encryption_master_key_at_startup`, which rotates the binary log master key automatically when the server is restarted, does not require this privilege.

- **CLONE_ADMIN**
  Enables execution of the `CLONE` statements. Includes `BACKUP_ADMIN` and `SHUTDOWN` privileges.

- **CONNECTION_ADMIN**
  Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

  Enables setting system variables related to client connections, or circumventing restrictions related to client connections. `CONNECTION_ADMIN` applies to the effects of these system variables:

  - `init_connect`: The server does not execute `init_connect` system variable content when `CONNECTION_ADMIN` clients connect.

  - `max_connections`: The server accepts one connection from a `CONNECTION_ADMIN` client even if the connection limit configured by the `max_connections` system variable is reached.

  - `offline_mode`: A server in offline mode (`offline_mode` enabled) does not terminate `CONNECTION_ADMIN` client connections at the next client request, and accepts new connections from `CONNECTION_ADMIN` clients.

  - `read_only`: Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

- **ENCRYPTION_KEY_ADMIN**
  Enables InnoDB encryption key rotation.

- **FIREWALL_ADMIN**
  Enables a user to administer firewall rules for any user. This privilege is defined by the `MYSQL_FIREWALL` plugin; see Section 6.4.7, “MySQL Enterprise Firewall”.

- **FIREWALL_USER**
  Enables users to update their own firewall rules. This privilege is defined by the `MYSQL_FIREWALL` plugin; see Section 6.4.7, “MySQL Enterprise Firewall”.

Privileges Provided by MySQL

- **GROUP_REPLICATION_ADMIN**
  Enables the account to start and stop Group Replication using the `START GROUP REPLICATION` and `STOP GROUP REPLICATION` statements, to change the global setting for the `group_replication_consistency` system variable, and to use the `group_replication_set_write_concurrency()` and `group_replication_set_communication_protocol()` UDFs. Grant this privilege to accounts that are used to administrate servers that are members of a replication group.

- **INNODB_REDO_LOG_ARCHIVE**
  Enables the account to activate and deactivate redo log archiving.

- **PERSIST_RO_VARIABLES_ADMIN**
  For users who also have `SYSTEM_VARIABLES_ADMIN`, `PERSIST_RO_VARIABLES_ADMIN` enables use of `SET PERSIST ONLY` to persist global system variables to the `mysql_binlog.auto.cnf` option file in the data directory. This statement is similar to `SET PERSIST` but does not modify the runtime global system variable value. This makes `SET PERSIST ONLY` suitable for configuring read-only system variables that can be set only at server startup.
  
  See also Section 5.1.9.1, “System Variable Privileges”.

- **REPLICATION_SLAVE_ADMIN**
  Enables the account to connect to the master server, start and stop replication using the `START SLAVE` and `STOP SLAVE` statements, and use the `CHANGE MASTER TO` and `CHANGE REPLICATION FILTER` statements. Grant this privilege to accounts that are used by slave servers to connect to the current server as their master. This privilege does not apply to Group Replication; use `GROUP_REPLICATION_ADMIN` for that.

- **RESOURCE_GROUP_ADMIN**
  Enables resource group management, consisting of creating, altering, and dropping resource groups, and assignment of threads and statements to resource groups. A user with this privilege can perform any operation relating to resource groups.

- **RESOURCE_GROUP_USER**
  Enables assigning threads and statements to resource groups. A user with this privilege can use the `SET RESOURCE GROUP` statement and the `RESOURCE_GROUP` optimizer hint.

- **ROLE_ADMIN**
  Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function. Required to set the value of the `mandatory_roles` system variable.

- **SERVICE_CONNECTION_ADMIN**
  Enables connections to the network interface that permits only administrative connections (see Section 8.12.4.1, “How MySQL Handles Client Connections”).

- **SESSION_VARIABLES_ADMIN** (added in MySQL 8.0.14)
  For most system variables, setting the session value requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session
value can have effects outside the current session and thus is a restricted operation. For these, the `SESSION_VARIABLES_ADMIN` privilege enables the user to set the session value.

If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include `binlog_format`, `sql_log_bin`, and `sql_log_off`.

Prior to MySQL 8.0.14 when `SESSION_VARIABLES_ADMIN` was added, restricted session system variables can be set only by users who have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

The `SESSION_VARIABLES_ADMIN` privilege is a subset of the `SYSTEM_VARIABLES_ADMIN` and `SUPER` privileges. A user who has either of those privileges is also permitted to set restricted session variables and effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

See also Section 5.1.9.1, “System Variable Privileges”.

• **SET_USER_ID**

  Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.

• **SYSTEM_USER** (added in MySQL 8.0.16)

  The `SYSTEM_USER` privilege distinguishes system users from regular users:

  • A user with the `SYSTEM_USER` privilege is a system user.

  • A user without the `SYSTEM_USER` privilege is a regular user.

  The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

  • A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER` to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.

  • A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

  For more information, see Section 6.2.11, “Account Categories”.

  The protection against modification by regular accounts that is afforded to system accounts by the `SYSTEM_USER` privilege does not apply to regular accounts that have privileges on the `mysql` system schema and thus can directly modify the grant tables in that schema. For full protection, do not grant `mysql` schema privileges to regular accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.

• **SYSTEM_VARIABLES_ADMIN**

  Affects the following operations and server behaviors:

  • Enables system variable changes at runtime:

    • Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`. 
Privileges Provided by MySQL

• Enables server configuration changes to global system variables with `SET PERSIST_ONLY`, if the user also has `PERSIST_RO_VARIABLES_ADMIN`.

• Enables setting restricted session system variables that require a special privilege. In effect, `SYSTEM_VARIABLES_ADMIN` implies `SESSION_VARIABLES_ADMIN` without explicitly granting `SESSION_VARIABLES_ADMIN`.

See also Section 5.1.9.1, “System Variable Privileges”.

• Enables changes to global transaction characteristics (see Section 13.3.7, “SET TRANSACTION Syntax”).

• `TABLE_ENCRYPTION_ADMIN` (added in MySQL 8.0.16)

  Enables a user to override default encryption settings when `table_encryption_privilege_check` is enabled; see Defining an Encryption Default for Schemas and General Tablespaces.

• `VERSION_TOKEN_ADMIN`

  Enables execution of Version Tokens user-defined functions. This privilege is defined by the `version_tokens` plugin; see Section 5.6.6, “Version Tokens”.

• `XA_RECOVER_ADMIN`

  Enables execution of the `XA RECOVER` statement; see Section 13.3.8.1, “XA Transaction SQL Syntax”.

Prior to MySQL 8.0, any user could execute the `XA RECOVER` statement to discover the XID values for outstanding prepared XA transactions, possibly leading to commit or rollback of an XA transaction by a user other than the one who started it. In MySQL 8.0, `XA RECOVER` is permitted only to users who have the `XA_RECOVER_ADMIN` privilege, which is expected to be granted only to administrative users who have need for it. This might be the case, for example, for administrators of an XA application if it has crashed and it is necessary to find outstanding transactions started by the application so they can be rolled back. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

Privilege-Granting Guidelines

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

• `FILE` can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server’s data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.

• `GRANT OPTION` enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.

• `ALTER` may be used to subvert the privilege system by renaming tables.

• `SHUTDOWN` can be abused to deny service to other users entirely by terminating the server.

• `PROCESS` can be used to view the plain text of currently executing statements, including statements that set or change passwords.

• `SUPER` can be used to terminate other sessions or change how the server operates.
Privileges Provided by MySQL

- Privileges granted for the `mysql` system database itself can be used to change passwords and other access privilege information:

- Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `mysql.user` system table `authentication_string` column can change an account's password, and then connect to the MySQL server using that account.

- `INSERT` or `UPDATE` granted for the `mysql` system database enable a user to add privileges or modify existing privileges, respectively.

- `DROP` for the `mysql` system database enables a user to remote privilege tables, or even the database itself.

Static Versus Dynamic Privileges

MySQL supports static and dynamic privileges:

- Static privileges are built in to the server. They are always available to be granted to user accounts and cannot be unregistered.

- Dynamic privileges can be registered and unregistered at runtime. This affects their availability: A dynamic privilege that has not been registered cannot be granted.

For example, the `SELECT` and `INSERT` privileges are static and always available, whereas a dynamic privilege becomes available only if the server component that implements it has been enabled.

The remainder of this section describes how dynamic privileges work in MySQL. The discussion uses the term “components” but applies equally to plugins.

Note

Server administrators should be aware of which server components define dynamic privileges. For MySQL distributions, documentation of components that define dynamic privileges describes those privileges.

Third-party components may also define dynamic privileges; an administrator should understand those privileges and not install components that might conflict or compromise server operation. For example, one component conflicts with another if both define a privilege with the same name. Component developers can reduce the likelihood of this occurrence by choosing privilege names having a prefix based on the component name.

The server maintains the set of registered dynamic privileges internally in memory. Unregistration occurs at server shutdown.

Normally, a server component that defines dynamic privileges registers them when it is installed, during its initialization sequence. When uninstalled, a server component does not unregister its registered dynamic privileges. (This is current practice, not a requirement. That is, components could, but do not, unregister at any time privileges they register.)

No warning or error occurs for attempts to register an already registered dynamic privilege. Consider the following sequence of statements:

```
INSTALL COMPONENT 'my_component';
```
UNINSTALL COMPONENT 'my_component';
INSTALL COMPONENT 'my_component';

The first INSTALL COMPONENT statement registers any privileges defined by server component my_component, but UNINSTALL COMPONENT does not unregister them. For the second INSTALL COMPONENT statement, the component privileges it registers are found to be already registered, but no warnings or errors occur.

Dynamic privileges apply only at the global level. The server stores information about current assignments of dynamic privileges to user accounts in the mysql.global_grants system table:

- The server automatically registers privileges named in global_grants during server startup (unless the --skip-grant-tables option is given).
- The GRANT and REVOKE statements modify the contents of global_grants.
- Dynamic privilege assignments listed in global_grants are persistent. They are not removed at server shutdown.

Example: The following statement grants to user u1 the privileges required to control replication (including Group Replication) on a slave server, and to modify system variables:

```
GRANT REPLICATION_SLAVE_ADMIN, GROUP_REPLICATION_ADMIN, BINLOG_ADMIN ON *.* TO 'u1'@'localhost';
```

Granted dynamic privileges appear in the output from the SHOW GRANTS statement and the INFORMATION_SCHEMA USER_PRIVILEGES table.

For GRANT and REVOKE at the global level, any named privileges not recognized as static are checked against the current set of registered dynamic privileges and granted if found. Otherwise, an error occurs to indicate an unknown privilege identifier.

For GRANT and REVOKE the meaning of ALL [PRIVILEGES] at the global level includes all static global privileges, as well as all currently registered dynamic privileges:

- GRANT ALL at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the GRANT statement is not granted retroactively to any account.
- REVOKE ALL at the global level revokes all granted static global privileges and all granted dynamic privileges.

The FLUSH PRIVILEGES statement reads the global_grants table for dynamic privilege assignments and registers any unregistered privileges found there.

For descriptions of the dynamic privileges provided by MySQL Server and server components included in MySQL distributions, see Section 6.2.2, “Privileges Provided by MySQL”.

**Migrating Accounts from SUPER to Dynamic Privileges**

In MySQL 8.0, many operations that previously required the SUPER privilege are also associated with a dynamic privilege of more limited scope. (For descriptions of these privileges, see Section 6.2.2, “Privileges Provided by MySQL”.) Each such operation can be permitted to an account by granting the associated dynamic privilege rather than SUPER. This change improves security by enabling DBAs to avoid granting SUPER and tailor user privileges more closely to the operations permitted. SUPER is now deprecated and will be removed in a future version of MySQL.
When removal of \texttt{SUPER} occurs, operations that formerly required \texttt{SUPER} will fail unless accounts granted \texttt{SUPER} are migrated to the appropriate dynamic privileges. Use the following instructions to accomplish that goal so that accounts are ready prior to \texttt{SUPER} removal:

1. Execute this query to identify accounts that are granted \texttt{SUPER}:

   ```sql
   SELECT GRANTEE FROM INFORMATION_SCHEMA.USER_PRIVILEGES
   WHERE PRIVILEGE_TYPE = 'SUPER';
   ```

2. For each account identified by the preceding query, determine the operations for which it needs \texttt{SUPER}. Then grant the dynamic privileges corresponding to those operations, and revoke \texttt{SUPER}.

   For example, if 'u1'@'localhost' requires \texttt{SUPER} for binary log purging and system variable modification, these statements make the required changes to the account:

   ```sql
   GRANT BINLOG_ADMIN, SYSTEM_VARIABLES_ADMIN ON *.* TO 'u1'@'localhost';
   REVOKE SUPER ON *.* FROM 'u1'@'localhost';
   ```

   After you have modified all applicable accounts, the \texttt{INFORMATION_SCHEMA} query in the first step should produce an empty result set.

### 6.2.3 Grant Tables

The \texttt{mysql} system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see Section 5.3, “The \texttt{mysql} System Schema”.

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables directly. Modifications occur indirectly when you use account-management statements such as \texttt{CREATE USER}, \texttt{GRANT}, and \texttt{REVOKE} to set up accounts and control the privileges available to each one. See Section 13.7.1, “Account Management Statements”. When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

#### Note

Direct modification of grant tables using statements such as \texttt{INSERT}, \texttt{UPDATE}, or \texttt{DELETE} is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”.

- Grant Table Overview
- The user and db Tables
- The tables\_priv and columns\_priv Tables
- The procs\_priv Table
- The proxies\_priv Table
- The global\_grants Table
Grant Table Overview

These MySQL database tables contain grant information:

- **user**: User accounts, static global privileges, and other non-privilege columns.
- **global_grants**: Dynamic global privileges.
- **db**: Database-level privileges.
- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.
- **default_roles**: Default user roles.
- **role_edges**: Edges for role subgraphs.
- **password_history**: Password change history.

For information about the differences between static and dynamic global privileges, see [Static Versus Dynamic Privileges](https://dev.mysql.com/doc/refman/8.0/en/static-versus-dynamic-privileges.html).

In MySQL 8.0, grant tables use the InnoDB storage engine and are transactional. Before MySQL 8.0, grant tables used the MyISAM storage engine and were nontransactional. This change of grant table storage engine enables an accompanying change to the behavior of account-management statements such as `CREATE USER` or `GRANT`. Previously, an account-management statement that named multiple users could succeed for some users and fail for others. Now, each statement is transactional and either succeeds for all named users or rolls back and has no effect if any error occurs.

Each grant table contains scope columns and privilege columns:

- **Scope columns** determine the scope of each row in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of 'h1.example.net' and 'bob' applies to authenticating connections made to the server from the host `h1.example.net` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of 'h1.example.net', 'bob' and 'reports' applies when bob connects from the host `h1.example.net` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.

- **Privilege columns** indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 6.2.7, “Access Control, Stage 2: Request Verification”](https://dev.mysql.com/doc/refman/8.0/en/security-access-control.html), describes the rules for this.
In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user’s static global privileges. Any privileges granted in this table apply to all databases on the server.

  **Caution**

  Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- The `global_grants` table lists current assignments of dynamic global privileges to user accounts. For each row, the scope columns determine which user has the privilege named in the privilege column.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The `procs_priv` table applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.

- The `proxies_priv` table indicates which users can act as proxies for other users and whether a user can grant the `PROXY` privilege to other users.

- The `default_roles` and `role_edges` tables contain information about role relationships.

- The `password_history` table retains previously chosen passwords to enable restrictions on password reuse. See Section 6.2.15, “Password Management”.

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in Section 6.2.13, “When Privilege Changes Take Effect”.

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the `SHOW GRANTS` statement. For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

To display nonprivilege properties of an account, use `SHOW CREATE USER`:

```
SHOW CREATE USER 'bob'@'pc84.example.com';
```
The user and db Tables

The server uses the user and db tables in the mysql database at both the first and second stages of access control (see Section 6.2, “Access Control and Account Management”). The columns in the user and db tables are shown here.

</tbody>
</table>
The `user` table `plugin` and `authentication_string` columns store authentication plugin and credential information.

The server uses the plugin named in the `plugin` column of an account row to authenticate connection attempts for the account.

The `plugin` column must be nonempty. At startup, and at runtime when `FLUSH PRIVILEGES` is executed, the server checks `user` table rows. For any row with an empty `plugin` column, the server writes a warning to the error log of this form:

```
[Warning] User entry 'user_name'@'host_name' has an empty plugin value. The user will be ignored and no one can login with this user anymore.
```

To assign a plugin to an account that is missing one, use the `ALTER USER` statement.

The `password_expired` column permits DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is 'N', but can be set to 'Y' with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an `ALTER USER` statement to establish a new account password.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.
DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

`password_last_changed` is a TIMESTAMP column indicating when the password was last changed. The value is non-NULL only for accounts that use a MySQL built-in authentication plugin (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). The value is NULL for other accounts, such as those authenticated using an external authentication system.

`password_last_changed` is updated by the CREATE USER, ALTER USER, and SET PASSWORD statements, and by GRANT statements that create an account or change an account password.

`password_lifetime` indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the `password_last_changed` column), the server considers the password expired when clients connect using the account. A value of \( N \) greater than zero means that the password must be changed every \( N \) days. A value of 0 disables automatic password expiration. If the value is NULL (the default), the global expiration policy applies, as defined by the `default_password_lifetime` system variable.

`account_locked` indicates whether the account is locked (see Section 6.2.19, “Account Locking”).

`Password_reuse_history` is the value of the PASSWORD_HISTORY option for the account, or NULL for the default history.

`Password_reuse_time` is the value of the PASSWORD_REUSE_INTERVAL option for the account, or NULL for the default interval.

`Password_require_current` (added in MySQL 8.0.13) corresponds to the value of the PASSWORD_REQUIRE option for the account, as shown by the following table.

**Table 6.5 Permitted Password_require_current Values**

<table>
<thead>
<tr>
<th>Password_require_current Value</th>
<th>Corresponding PASSWORD REQUIRE Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Y'</td>
<td>PASSWORD REQUIRE CURRENT</td>
</tr>
<tr>
<td>'N'</td>
<td>PASSWORD REQUIRE CURRENT OPTIONAL</td>
</tr>
<tr>
<td>NULL</td>
<td>PASSWORD REQUIRE CURRENT DEFAULT</td>
</tr>
</tbody>
</table>

`User_attributes` (added in MySQL 8.0.14) stores account attributes not stored in other columns:

- **additional_password**: The secondary password, if any. See Dual Password Support.
- **Restrictions**: Restriction lists, if any. Restrictions are added by partial-revoke operations. The attribute value is an array of elements that each have Database and Restrictions keys indicating the name of a restricted database and the applicable restrictions on it (see Section 6.2.12, “Privilege Restriction Using Partial Revokes”).

If no attributes apply, `User_attributes` is NULL.

Example: An account that has a secondary password and partially revoked database privileges has `additional_password` and `Restrictions` attributes in the column value:

```sql
mysql> SELECT User_attributes FROM mysql.User WHERE User = 'u'\G
*************************** 1. row ***************************
User_attributes: {"Restrictions":
                    ["Database": "mysql", "Privileges": ["SELECT"]],
                    "additional_password": "secondary_password"},
```

1082
Grant Tables

"additional_password": "hashed_credentials"

To determine which attributes are present, use the JSON_KEYS() function:

```
SELECT User, Host, JSON_KEYS(User_attributes)
FROM mysql.user WHERE User_attributes IS NOT NULL;
```

To extract a particular attribute, such as Restrictions, do this:

```
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> ';
```

The tables_priv and columns_priv Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the user and db grant tables, the server may also consult the tables_priv and columns_priv tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table 6.6 tables_priv and columns_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>tables_priv</th>
<th>columns_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>Host</td>
<td>Host</td>
</tr>
<tr>
<td>Db</td>
<td>Db</td>
<td></td>
</tr>
<tr>
<td>User</td>
<td>User</td>
<td></td>
</tr>
<tr>
<td>Table_name</td>
<td>Table_name</td>
<td>Column_name</td>
</tr>
<tr>
<td>Privilege columns</td>
<td>Table_priv</td>
<td>Column_priv</td>
</tr>
<tr>
<td>Other columns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Timestamp</td>
<td>Timestamp</td>
<td></td>
</tr>
<tr>
<td>Grantor</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Timestamp and Grantor columns are set to the current timestamp and the CURRENT_USER value, respectively, but are otherwise unused.

The procs_priv Table

For verification of requests that involve stored routines, the server may consult the procs_priv table, which has the columns shown in the following table.

Table 6.7 procs_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>procs_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td></td>
</tr>
<tr>
<td>Db</td>
<td></td>
</tr>
<tr>
<td>User</td>
<td></td>
</tr>
<tr>
<td>Routine_name</td>
<td></td>
</tr>
</tbody>
</table>
The `Routine_type` column is an `ENUM` column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

**The proxies_priv Table**

The `proxies_priv` table records information about proxy accounts. It has these columns:

- **Host, User**: The proxy account; that is, the account that has the `PROXY` privilege for the proxied account.
- **Proxied_host, Proxied_user**: The proxied account.
- **Grantor, Timestamp**: Unused.
- **With_grant**: Whether the proxy account can grant the `PROXY` privilege to other accounts.

For an account to be able to grant the `PROXY` privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the 'root'@'localhost' account created during MySQL installation has a row in the `proxies_priv` table that enables granting the `PROXY` privilege for '[@]', that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.18, "Proxy Users".

**The global_grants Table**

The `global_grants` table lists current assignments of dynamic global privileges to user accounts. The table has these columns:

- **USER, HOST**: The user name and host name of the account to which the privilege is granted.
- **PRIV**: The privilege name.
- **WITH_GRANT_OPTION**: Whether the account can grant the privilege to other accounts.

**The default_roles Table**

The `default_roles` table lists default user roles. It has these columns:

- **HOST, USER**: The account or role to which the default role applies.
- **DEFAULT_ROLE_HOST, DEFAULT_ROLE_USER**: The default role.

**The role_edges Table**

The `role_edges` table lists edges for role subgraphs. It has these columns:
Grant Tables

- **FROM_HOST, FROM_USER**: The account that is granted a role.
- **TO_HOST, TO_USER**: The role that is granted to the account.
- **WITH_ADMIN_OPTION**: Whether the account can grant the role to and revoke it from other accounts by using WITH ADMIN OPTION.

The password_history Table

The `password_history` table contains information about password changes. It has these columns:

- **Host, User**: The account for which the password change occurred.
- **Password_timestamp**: The time when the password change occurred.
- **Password**: The new password hash value.

The `password_history` table accumulates a sufficient number of nonempty passwords per account to enable MySQL to perform checks against both the account password history length and reuse interval. Automatic pruning of entries that are outside both limits occurs when password-change attempts occur.

**Note**

The empty password does not count in the password history and is subject to reuse at any time.

If an account is renamed, its entries are renamed to match. If an account is dropped or its authentication plugin is changed, its entries are removed.

Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Maximum Permitted Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host, Proxied_host</td>
<td>255 (60 prior to MySQL 8.0.17)</td>
</tr>
<tr>
<td>User, Proxied_user</td>
<td>32</td>
</tr>
<tr>
<td>Db</td>
<td>64</td>
</tr>
<tr>
<td>Table_name</td>
<td>64</td>
</tr>
<tr>
<td>Column_name</td>
<td>64</td>
</tr>
<tr>
<td>Routine_name</td>
<td>64</td>
</tr>
</tbody>
</table>

For access-checking purposes, comparisons of `User, Proxied_user, authentication_string, Db, and Table_name` values are case-sensitive. Comparisons of `Host, Proxied_host, Column_name, and Routine_name` values are not case-sensitive.

Privilege Column Properties

The `user` and `db` tables list each privilege in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.
The `tables_priv`, `columns_priv`, and `procs_priv` tables declare the privilege columns as SET columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

### Table 6.9 Set-Type Privilege Column Values

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Column Name</th>
<th>Possible Set Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tables_priv</code></td>
<td>Table_priv</td>
<td>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</td>
</tr>
<tr>
<td><code>tables_priv</code></td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td><code>columns_priv</code></td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td><code>procs_priv</code></td>
<td>Proc_priv</td>
<td>'Execute', 'Alter Routine', 'Grant'</td>
</tr>
</tbody>
</table>

Only the `user` and `global_grants` tables specify administrative privileges, such as `RELOAD`, `SHUTDOWN`, and `SYSTEM_VARIABLES_ADMIN`. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the `user` and `global_grants` tables to determine whether a user can perform an administrative operation.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but a user’s ability to read or write files on the server host is independent of the database being accessed.

### 6.2.4 Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

MySQL role names are similar to account names, with some differences described at Section 6.2.5, “Specifying Role Names”.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names follow these rules:

- Account name syntax is `'user_name'@'host_name'`.

- An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.

- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as space or `-`), or a `host_name` string containing special characters or wildcard characters (such as . or `%`) (for example, `'test-user'@'%.com'`).

- Quote user names and host names as identifiers or as strings, using either backticks (``), single quotation marks (`'`), or double quotation marks (``). For string-quoting and identifier-quoting guidelines, see Section 9.1.1, “String Literals”, and Section 9.2, “Schema Object Names”.

1086
Specifying Account Names

- The user name and host name parts, if quoted, must be quoted separately. That is, write 'me'@'localhost', not 'me@localhost'; the latter is actually equivalent to 'me@localhost'@'%'.

- A reference to the CURRENT_USER or CURRENT_USER() function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the mysql system database using separate columns for the user name and host name parts:

- The user table contains one row for each account. The User and Host columns store the user name and host name. This table also indicates which global privileges the account has.

- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have User and Host columns to store the account name. Each row in these tables associates with the account in the user table that has the same User and Host values.

- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case sensitive.

For additional detail about grant table structure, see Section 6.2.3, "Grant Tables".

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as ''@'localhost'.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name 'localhost' indicates the local host. The IP address '127.0.0.1' indicates the IPv4 loopback interface. The IP address '::1' indicates the IPv6 loopback interface.

- The % and _ wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, a host value of '%.' matches any host name, whereas a value of '%.mysql.com' matches any host in the mysql.com domain. '198.51.100.%' matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, '198.51.100.%' to match every host on a subnet), someone could try to exploit this capability by naming a host 198.51.100.somewhere.com. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named 1.2.example.com, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is host_ip/netmask. For example:

```sql
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables david to connect from any client host having an IP address client_ip for which the following condition is true:
Specifying Role Names

**client_ip & netmask = host_ip**

That is, for the `CREATE USER` statement just shown:

**client_ip & 255.255.255.0 = 198.51.100.0**

IP addresses that satisfy this condition range from \( 198.51.100.0 \) to \( 198.51.100.255 \).

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- \( 198.0.0.0/255.0.0.0 \): Any host on the 198 class A network
- \( 198.51.100.0/255.255.0.0 \): Any host on the 198.51 class B network
- \( 198.51.100.0/255.255.255.0 \): Any host on the 198.51.100 class C network
- \( 198.51.100.1 \): Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.

- If DNS returns the IP address for a given host as `198.51.100.2`, that will match an account host value of `198.51.100.2` but not `198.051.100.2`. Similarly, it will match an account host pattern like `198.51.100.%` but not `198.051.100.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

### 6.2.5 Specifying Role Names

MySQL role names refer to roles, which are named collections of privileges. For role usage examples, see Section 6.2.10, "Using Roles".

Role names have syntax and semantics similar to account names (Section 6.2.4, “Specifying Account Names”). Role names differ from account names in these respects:

- The user part of role names cannot be blank. Thus, there is no “anonymous role” analogous to the concept of “anonymous user.”

- As for an account name, omitting the host part of a role name results in a host part of `'%'`. But unlike `'%'` in an account name, a host part of `'%'` in a role name has no wildcard properties. For example, for a name `me@'%'` used as a role name, the host part (`'%'`) is just a literal value; it has no “any host” matching property.

- Netmask notation in the host part of a role name has no significance.

- An account name is permitted to be `CURRENT_USER()` in several contexts. A role name is not.

It is possible for a row in the `mysql.user` system table to serve as both an account and a role. In this case, any special user or host name matching properties do not apply in contexts for which the name is
used as a role name. For example, you cannot execute the following statement with the expectation that it will set the current session roles using all roles that have a user part of `myrole` and any host name:

```sql
SET ROLE 'myrole'@'%';
```

Instead, the statement sets the active role for the session to the role with exactly the name `myrole'@'%'.

For this reason, role names are often specified using only the user name part and letting the host name part implicitly be `'%'. Specifying a role with a non-`%' host part can be useful if you intend to create a name that works both as a role an as a user account that is permitted to connect from the given host.

### 6.2.6 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify your identity by supplying the correct password
- Whether your account is locked or unlocked

The server checks credentials first, then account locking state. A failure for either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Credential checking is performed using the three `user` table scope columns (`Host`, `User`, and `authentication_string`). Locking state is recorded in the `user` table `account_locked` column. The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name, the client supplies the password specified in that row, and the `account_locked` value is `'N'`. The rules for permissible `Host` and `User` values are given in Section 6.2.4, "Specifying Account Names". Account locking can be changed with the `ALTER USER` statement.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `authentication_string` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `authentication_string` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank `authentication_string` values in the `user` table represent encrypted passwords. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented by the account authentication plugin). The encrypted password then is used during the connection process when checking
whether the password is correct. This is done without the encrypted password ever traveling over the connection. See Section 6.2.1, “Account User Names and Passwords”.

From MySQL's point of view, the encrypted password is the real password, so you should never give anyone access to it. In particular, do not give nonadministrative users read access to tables in the `mysql` system database.

The following table shows how various combinations of `User` and `Host` values in the `user` table apply to incoming connections.

<table>
<thead>
<tr>
<th>User Value</th>
<th>Host Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'h1.example.net'</td>
<td>fred, connecting from h1.example.net</td>
</tr>
<tr>
<td>''</td>
<td>'h1.example.net'</td>
<td>Any user, connecting from h1.example.net</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%'</td>
<td>fred, connecting from any host</td>
</tr>
<tr>
<td>''</td>
<td>'%'</td>
<td>Any user, connecting from any host</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%.example.net'</td>
<td>fred, connecting from any host in the example.net domain</td>
</tr>
<tr>
<td>'fred'</td>
<td>'x.example.%'</td>
<td>fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.177'</td>
<td>fred, connecting from the host with IP address 198.51.100.177</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.%'</td>
<td>fred, connecting from any host in the 198.51.100 class C subnet</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.0/255.255.255.0'</td>
<td>Same as previous example</td>
</tr>
</tbody>
</table>

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `h1.example.net` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so `198.51.100.13` and `198.51.100.0/255.255.255.0` are considered equally specific.) The pattern `'%'` means “any host” and is least specific. The empty string `''` also means “any host” but sorts after `'%'`. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific). For rows with equally-specific `Host` and `User` values, the order is nondeterministic.

To see how this works, suppose that the `user` table looks like this:

```
+---------+--------+---+
| Host    | User   | ... |
+---------+--------+---+---+
| %       | root   | ... |
```
When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost</td>
<td>root</td>
<td>...</td>
</tr>
<tr>
<td>localhost</td>
<td></td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>root</td>
<td>...</td>
</tr>
</tbody>
</table>

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of 'localhost' and '', and the one with values of '%' and 'jeffrey'. The 'localhost' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
<tr>
<td>h1.example.net</td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>

The sorted table looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>h1.example.net</td>
<td></td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
</tbody>
</table>

A connection by `jeffrey` from `h1.example.net` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

**Note**

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `h1.example.net` by `jeffrey` is first matched not by the row containing 'jeffrey' as the User column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Section 12.15, "Information Functions"). It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:
The result shown here indicates that the matching \texttt{user} table row had a blank \texttt{User} column value. In other words, the server is treating \texttt{jeffrey} as an anonymous user.

Another way to diagnose authentication problems is to print out the \texttt{user} table and sort it by hand to see where the first match is being made.

### 6.2.7 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the \texttt{user}, \texttt{global_grants}, \texttt{db}, \texttt{tables_priv}, \texttt{columns_priv}, or \texttt{procs_priv} tables. (You may find it helpful to refer to Section 6.2.3, “Grant Tables”, which lists the columns present in each grant table.)

The \texttt{user} and \texttt{global_grants} tables grant global privileges. The rows in these tables for a given account indicate the account privileges that apply on a global basis no matter what the default database is. For example, if the \texttt{user} table grants you the \texttt{DELETE} privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the \texttt{user} table only to people who need them, such as database administrators. For other users, leave all privileges in the \texttt{user} table set to 'N' and grant privileges at more specific levels only (for particular databases, tables, columns, or routines). It is also possible to grant database privileges globally but use partial revokes to restrict them from being exercised on specific databases (see Section 6.2.12, “Privilege Restriction Using Partial Revokes”).

The \texttt{db} table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank \texttt{User} value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.

- The wildcard characters % and \_ can be used in the \texttt{Host} and \texttt{Db} columns. These have the same meaning as for pattern-matching operations performed with the \texttt{LIKE} operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (\_) as part of a database name, specify it as \_\_ in the \texttt{GRANT} statement.

- A '%%' or blank \texttt{Host} value means "any host."

- A '%%' or blank \texttt{Db} value means "any database."

The server reads the \texttt{db} table into memory and sorts it at the same time that it reads the \texttt{user} table. The server sorts the \texttt{db} table based on the \texttt{Host}, \texttt{Db}, and \texttt{User} scope columns. As with the \texttt{user} table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The \texttt{tables_priv}, \texttt{columns_priv}, and \texttt{procs_priv} tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters % and \_ can be used in the \texttt{Host} column. These have the same meaning as for pattern-matching operations performed with the \texttt{LIKE} operator.
• A '%' or blank Host value means “any host.”

• The Db, Table_name, Column_name, and Routine_name columns cannot contain wildcards or be blank.

The server sorts the tables_priv, columns_priv, and procs_priv tables based on the Host, Db, and User columns. This is similar to db table sorting, but simpler because only the Host column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as SHUTDOWN or RELOAD, the server checks only the user and global_privilege tables because those are the only tables that specify administrative privileges. The server grants access if a row for the account in those tables permits the requested operation and denies access otherwise. For example, if you want to execute mysqladmin shutdown but your user table row does not grant the SHUTDOWN privilege to you, the server denies access without even checking the db table. (The latter table contains no Shutdown_priv column, so there is no need to check it.)

For database-related requests (INSERT, UPDATE, and so on), the server first checks the user’s global privileges in the user table row (less any privilege restrictions imposed by partial revokes). If the row permits the requested operation, access is granted. If the global privileges in the user table are insufficient, the server determines the user's database-specific privileges from the db table:

The server looks in the db table for a match on the Host, Db, and User columns. The Host and User columns are matched to the connecting user's host name and MySQL user name. The Db column is matched to the database that the user wants to access. If there is no row for the Host and User, access is denied.

After determining the database-specific privileges granted by the db table rows, the server adds them to the global privileges granted by the user table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the tables_priv and columns_priv tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the procs_priv table rather than tables_priv and columns_priv.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an INSERT INTO ... SELECT statement, you need both the INSERT and the SELECT privileges. Your privileges might be such that the user table row grants one privilege global and the db table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

### 6.2.8 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:
Adding Accounts, Assigning Privileges, and Dropping Accounts

- **CREATE USER** and **DROP USER** create and remove accounts.
- **GRANT** and **REVOKE** assign privileges to and revoke privileges from accounts.
- **SHOW GRANTS** displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in Section 6.2.3, "Grant Tables".

**Note**

Direct modification of grant tables using statements such as **INSERT**, **UPDATE**, or **DELETE** is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See Section 2.11, "Upgrading MySQL".

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. **phpMyAdmin** is one such program.

This section discusses the following topics:

- Creating Accounts and Granting Privileges
- Checking Account Privileges and Properties
- Revoking Account Privileges
- Dropping Accounts

For additional information about the statements discussed here, see Section 13.7.1, "Account Management Statements".

**Creating Accounts and Granting Privileges**

The following examples show how to use the **mysql** client program to set up new accounts. These examples assume that the MySQL **root** account has the **CREATE USER** privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL **root** user, supplying the appropriate password at the password prompt:

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
```

After connecting to the server, you can add new accounts. The following example uses **CREATE USER** and **GRANT** statements to set up four accounts (where you see 'password', substitute an appropriate password):

```sql
CREATE USER 'finley'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON '.*'
    TO 'finley'@'localhost'
    WITH GRANT OPTION;
```
Adding Accounts, Assigning Privileges, and Dropping Accounts

CREATE USER 'finley'@'%.example.com'
IDENTIFIED BY 'password';
GRANT ALL
ON *.*
TO 'finley'@'%.example.com'
WITH GRANT OPTION;

CREATE USER 'admin'@'localhost'
IDENTIFIED BY 'password';
GRANT RELOAD,PROCESS
ON *.*
TO 'admin'@'localhost';

CREATE USER 'dummy'@'localhost';

The accounts created by those statements have the following properties:

- Two accounts have a user name of finley. Both are superuser accounts with full global privileges to do anything. The finley@localhost account can be used only when connecting from the local host. The finley@%.example.com account uses the % wildcard in the host part, so it can be used to connect from any host in the example.com domain.

  The finley@localhost account is necessary if there is an anonymous-user account for localhost. Without the finley@localhost account, that anonymous-user account takes precedence when finley connects from the local host and finley is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific Host column value than the finley@% account and thus comes earlier in the user table sort order. (For information about user table sorting, see Section 6.2.6, “Access Control, Stage 1: Connection Verification”.)

- The admin@localhost account can be used only by admin to connect from the local host. It is granted the global RELOAD and PROCESS administrative privileges. These privileges enable the admin user to execute the mysqladmin reload, mysqladmin refresh, and mysqladmin flush-xxx commands, as well as mysqladmin processlist. No privileges are granted for accessing any databases. You could add such privileges using GRANT statements.

- The dummy@localhost account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account using GRANT statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of custom, but the host name parts differ:

CREATE USER 'custom'@'localhost'
IDENTIFIED BY 'password';
GRANT ALL
ON bankaccount.*
TO 'custom'@'localhost';

CREATE USER 'custom'@'host47.example.com'
IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
ON expenses.*
TO 'custom'@'host47.example.com';

CREATE USER 'custom'@'%.example.com'
IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
ON customer.addresses
TO 'custom'@'%.example.com';
Adding Accounts, Assigning Privileges, and Dropping Accounts

The three accounts can be used as follows:

- The 'custom'@'localhost' account has all database-level privileges to access the bankaccount database. The account can be used to connect to the server only from the local host.

- The 'custom'@'host47.example.com' account has specific database-level privileges to access the expenses database. The account can be used to connect to the server only from the host host47.example.com.

- The 'custom'@'%.example.com' account has specific table-level privileges to access the addresses table in the customer database, from any host in the example.com domain. The account can be used to connect to the server from all machines in the domain due to use of the % wildcard character in the host part of the account name.

Checking Account Privileges and Properties

To see the privileges for an account, use **SHOW GRANTS**:

```sql
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----------------------------------------------------+
| Grants for admin@localhost                          |
+-----------------------------------------------------+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

To see nonprivilege properties for an account, use **SHOW CREATE USER**:

```sql
mysql> SET print_identified_with_as_hex = ON;
mysql> SHOW CREATE USER 'admin'@'localhost'
```

Enabling the `print_identified_with_as_hex` system variable (available as of MySQL 8.0.17) causes **SHOW CREATE USER** to display hash values that contain unprintable characters as hexadecimal strings rather than as regular string literals.

Revoking Account Privileges

To revoke account privileges, use the **REVOKE** statement. Privileges can be revoked at different levels, just as they can be granted at different levels.

Revoke global privileges:

```sql
REVOKE ALL ON *.* FROM 'finley'@'%.example.com';
REVOKE RELOAD ON *.* FROM 'admin'@'localhost';
```

Revoke database-level privileges:
Reserved Accounts

Revoke table-level privileges:

```sql
REVOKE INSERT,UPDATE,DELETE
ON customer.addresses
FROM 'custom'@'%.example.com';
```

To check the effect of privilege revocation, use `SHOW GRANTS`:

```sql
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+---------------------------------------------+
| Grants for admin@localhost                  |
+---------------------------------------------+
```

Dropping Accounts

To remove an account, use the `DROP USER` statement. For example, to drop some of the accounts created previously:

```sql
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%.example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

6.2.9 Reserved Accounts

One part of the MySQL installation process is data directory initialization (see Section 2.10.1, “Initializing the Data Directory”). During data directory initialization, MySQL creates user accounts that should be considered reserved:

- `'root'@'localhost'`: Used for administrative purposes. This account has all privileges, is a system account, and can perform any operation.

  Strictly speaking, this account name is not reserved, in the sense that some installations rename the `root` account to something else to avoid exposing a highly privileged account with a well-known name.

- `'mysql.sys'@'localhost'`: Used as the `DEFINER` for `sys` schema objects. Use of the `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account. This account is locked so that it cannot be used for client connections.

- `'mysql.session'@'localhost'`: Used internally by plugins to access the server. This account is locked so that it cannot be used for client connections. The account is a system account.

- `'mysql.infoschema'@'localhost'`: Used as the `DEFINER` for `INFORMATION_SCHEMA` views. Use of the `mysql.infoschema` account avoids problems that occur if a DBA renames or removes the root account. This account is locked so that it cannot be used for client connections.

6.2.10 Using Roles

A MySQL role is a named collection of privileges. Like user accounts, roles can have privileges granted to and revoked from them.
A user account can be granted roles, which grants to the account the privileges associated with each role. This enables assignment of sets of privileges to accounts and provides a convenient alternative to granting individual privileges, both for conceptualizing desired privilege assignments and implementing them.

The following list summarizes role-management capabilities provided by MySQL:

- **CREATE ROLE** and **DROP ROLE** create and remove roles.
- **GRANT** and **REVOKE** assign privileges to revoke privileges from user accounts and roles.
- **SHOW GRANTS** displays privilege and role assignments for user accounts and roles.
- **SET DEFAULT ROLE** specifies which account roles are active by default.
- **SET ROLE** changes the active roles within the current session.
- The **CURRENT_ROLE()** function displays the active roles within the current session.
- The **mandatory_roles** and **activate_all_roles_on_login** system variables enable defining mandatory roles and automatic activation of granted roles when users log in to the server.

For descriptions of individual role-manipulation statements (including the privileges required to use them), see Section 13.7.1, “Account Management Statements”. The following discussion provides examples of role usage. Unless otherwise specified, SQL statements shown here should be executed using a MySQL account with sufficient administrative privileges, such as the root account.

- **Creating Roles and Granting Privileges to Them**
- **Defining Mandatory Roles**
- **Checking Role Privileges**
- **Activating Roles**
- **Revoking Roles or Role Privileges**
- **Dropping Roles**
- **User and Role Interchangeability**

### Creating Roles and Granting Privileges to Them

Consider this scenario:

- An application uses a database named **app_db**.
- Associated with the application, there can be accounts for developers who create and maintain the application, and for users who interact with it.
- Developers need full access to the database. Some users need only read access, others need read/write access.

To avoid granting privileges individually to possibly many user accounts, create roles as names for the required privilege sets. This makes it easy to grant the required privileges to user accounts, by granting the appropriate roles.

To create the roles, use the **CREATE ROLE** statement:

```sql
CREATE ROLE 'app_developer', 'app_read', 'app_write';
```
### Using Roles

Role names are much like user account names and consist of a user part and host part in `'user_name'@'host_name'` format. The host part, if omitted, defaults to `'%'`. The user and host parts can be unquoted unless they contain special characters such as `–` or `%`. Unlike account names, the user part of role names cannot be blank. For additional information, see Section 6.2.5, “Specifying Role Names”.

To assign privileges to the roles, execute `GRANT` statements using the same syntax as for assigning privileges to user accounts:

```sql
GRANT ALL ON app_db.* TO 'app_developer';
GRANT SELECT ON app_db.* TO 'app_read';
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now suppose that initially you require one developer account, two user accounts that need read-only access, and one user account that needs read/write access. Use `CREATE USER` to create the accounts:

```sql
CREATE USER 'dev1'@'localhost' IDENTIFIED BY 'dev1pass';
CREATE USER 'read_user1'@'localhost' IDENTIFIED BY 'read_user1pass';
CREATE USER 'read_user2'@'localhost' IDENTIFIED BY 'read_user2pass';
CREATE USER 'rw_user1'@'localhost' IDENTIFIED BY 'rw_user1pass';
```

To assign each user account its required privileges, you could use `GRANT` statements of the same form as just shown, but that requires enumerating individual privileges for each user. Instead, use an alternative `GRANT` syntax that permits granting roles rather than privileges:

```sql
GRANT 'app_developer' TO 'dev1'@'localhost';
GRANT 'app_read' TO 'read_user1'@'localhost', 'read_user2'@'localhost';
GRANT 'app_read', 'app_write' TO 'rw_user1'@'localhost';
```

The `GRANT` statement for the `rw_user1` account grants the read and write roles, which combine to provide the required read and write privileges.

The `GRANT` syntax for granting roles to an account differs from the syntax for granting privileges: There is an `ON` clause to assign privileges, whereas there is no `ON` clause to assign roles. Because the syntaxes are distinct, you cannot mix assigning privileges and roles in the same statement. (It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.) As of MySQL 8.0.16, roles cannot be granted to anonymous users.

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the `ALTER USER` statement, by users who have the global `CREATE USER` privilege.)

While locked, a role cannot be used to authenticate to the server. If unlocked, a role can be used to authenticate. This is because roles and users are both authorization identifiers with much in common and little to distinguish them. See also User and Role Interchangeability.

### Defining Mandatory Roles

It is possible to specify roles as mandatory by naming them in the value of the `mandatory_roles` system variable. The server treats a mandatory role as granted to all users, so that it need not be granted explicitly to any account.

To specify mandatory roles at server startup, define `mandatory_roles` in your server `my.cnf` file:

```ini
[mysqld]
mandatory_roles='role1,role2@localhost,r3@%.example.com'
```
To set and persist `mandatory_roles` at runtime, use a statement like this:

```
SET PERSIST mandatory_roles = 'role1,role2@localhost,r3@%.example.com';
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. To change the value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

Setting `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege normally required to set a global system variable.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see Activating Roles). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

If a role named in `mandatory_roles` is not present in the `mysql.user` system table, the role is not granted to users. When the server attempts role activation for a user, it does not treat the nonexistent role as mandatory and writes a warning to the error log. If the role is created later and thus becomes valid, `FLUSH PRIVILEGES` may be necessary to cause the server to treat it as mandatory.

`SHOW GRANTS` displays mandatory roles according to the rules described in Section 13.7.6.21, “SHOW GRANTS Syntax”.

### Checking Role Privileges

To verify the privileges assigned to an account, use `SHOW GRANTS`. For example:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost';
+-------------------------------------------------+
| Grants for dev1@localhost                       |
| Grants for dev1@localhost                       |
| GRANT USAGE ON *.* TO `dev1`@`localhost`         |
| GRANT `app_developer`@`%` TO `dev1`@`localhost`  |
+-------------------------------------------------+
```

However, that shows each granted role without “expanding” it to the privileges the role represents. To show role privileges as well, add a `USING` clause naming the granted roles for which to display privileges:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost' USING 'app_developer';
+-------------------------------------------------+
| Grants for dev1@localhost                       |
| Grants for dev1@localhost                       |
| GRANT USAGE ON *.* TO `dev1`@`localhost`         |
| GRANT ALL PRIVILEGES ON `app_db`.* TO `dev1`@`localhost` |
+-------------------------------------------------+
```
Using Roles

|
---
| GRANT `app_developer`@`%` TO `dev1`@`localhost`

---

Verify each other type of user similarly:

```
mysql> SHOW GRANTS FOR 'read_user1'@'localhost' USING 'app_read';
+--------------------------------------------------------+
| Grants for read_user1@localhost                        |
+--------------------------------------------------------+
| GRANT USAGE ON *.* TO `read_user1`@`localhost`         |
| GRANT SELECT ON `app_db`.* TO `read_user1`@`localhost` |
| GRANT `app_read`@`%` TO `read_user1`@`localhost`       |
+--------------------------------------------------------+
```

```
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
+------------------------------------------------------------------------------+
| Grants for rw_user1@localhost                                                |
+------------------------------------------------------------------------------+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost`                                 |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost`               |
+------------------------------------------------------------------------------+
```

SHOW GRANTS displays mandatory roles according to the rules described in Section 13.7.6.21, “SHOW GRANTS Syntax”.

Activating Roles

Roles granted to a user account can be active or inactive within account sessions. If a granted role is active within a session, its privileges apply; otherwise, they do not. To determine which roles are active within the current session, use the CURRENT_ROLE() function.

By default, granting a role to an account or naming it in the mandatory_roles system variable value does not automatically cause the role to become active within account sessions. For example, because thus far in the preceding discussion no rw_user1 roles have been activated, if you connect to the server as rw_user1 and invoke the CURRENT_ROLE() function, the result is NONE (no active roles):

```
mysql> SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| NONE           |
+----------------+
```

To specify which roles should become active each time a user connects to the server and authenticates, use SET DEFAULT ROLE. To set the default to all assigned roles for each account created earlier, use this statement:

```
SET DEFAULT ROLE ALL TO
  'dev1'@'localhost',
  'read_user1'@'localhost',
  'read_user2'@'localhost',
  'rw_user1'@'localhost';
```

Now if you connect as rw_user1, the initial value of CURRENT_ROLE() reflects the new default role assignments:

```
mysql> SELECT CURRENT_ROLE();
+-----------------------------+
| CURRENT_ROLE() |             |
+-----------------------------+
```
Using Roles

To cause all explicitly granted and mandatory roles to be automatically activated when users connect to the server, enable the `activate_all_roles_on_login` system variable. By default, automatic role activation is disabled.

Within a session, a user can execute `SET ROLE` to change the set of active roles. For example, for `rw_user1`:

```sql
mysql> SET ROLE NONE; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| NONE           |
+----------------+
mysql> SET ROLE ALL EXCEPT 'app_write'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%` |
+----------------+
mysql> SET ROLE DEFAULT; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%`, `app_write`@`%` |
+----------------+
```

The first `SET ROLE` statement deactivates all roles. The second makes `rw_user1` effectively read only. The third restores the default roles.

The effective user for stored program and view objects is subject to the `DEFINER` and `SQL SECURITY` attributes, which determine whether execution occurs in invoker or definer context (see Section 24.6, “Stored Object Access Control”):

- Stored program and view objects that execute in invoker context execute with the roles that are active within the current session.
- Stored program and view objects that execute in definer context execute with the default roles of the user named in their `DEFINER` attribute. If `activate_all_roles_on_login` is enabled, such objects execute with all roles granted to the `DEFINER` user, including mandatory roles. For stored programs, if execution should occur with roles different from the default, the program body should execute `SET ROLE` to activate the required roles.

Revoking Roles or Role Privileges

Just as roles can be granted to an account, they can be revoked from an account:

```sql
REVOKE role FROM user;
```

Roles named in the `mandatory_roles` system variable value cannot be revoked.

`REVOKE` can also be applied to a role to modify the privileges granted to it. This affects not only the role itself, but any account granted that role. Suppose that you want to temporarily make all application users read only. To do this, use `REVOKE` to revoke the modification privileges from the `app_write` role:

```sql
REVOKE INSERT, UPDATE, DELETE ON app_db.* FROM 'app_write';
```
As it happens, that leaves the role with no privileges at all, as can be seen using `SHOW GRANTS` (which demonstrates that this statement can be used with roles, not just users):

```sql
mysql> SHOW GRANTS FOR 'app_write';
+---------------------------------------+
| Grants for app_write@%               |
| GRANT USAGE ON *.* TO `app_write`@`%` |
+---------------------------------------+
```

Because revoking privileges from a role affects the privileges for any user who is assigned the modified role, `rw_user1` now has no table modification privileges (`INSERT`, `UPDATE`, and `DELETE` are no longer present):

```sql
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
+----------------------------------------------------------------+
| Grants for rw_user1@localhost                                      |
| GRANT USAGE ON *.* TO `rw_user1`@`localhost`                      |
| GRANT SELECT ON `app_db`.* TO `rw_user1`@`localhost`              |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost`     |
+----------------------------------------------------------------+
```

In effect, the `rw_user1` read/write user has become a read-only user. This also occurs for any other accounts that are granted the `app_write` role, illustrating how use of roles makes it unnecessary to modify privileges for individual accounts.

To restore modification privileges to the role, simply re-grant them:

```sql
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now `rw_user1` again has modification privileges, as do any other accounts granted the `app_write` role.

**Dropping Roles**

To drop roles, use `DROP ROLE`:

```sql
DROP ROLE 'app_read', 'app_write';
```

Dropping a role revokes it from every account to which it was granted.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

**User and Role Interchangeability**

As has been hinted at earlier for `SHOW GRANTS`, which displays grants for user accounts or roles, accounts and roles can be used interchangeably.

One difference between roles and users is that `CREATE ROLE` creates an authorization identifier that is locked by default, whereas `CREATE USER` creates an authorization identifier that is unlocked by default. However, distinction is not immutable because a user with appropriate privileges can lock or unlock roles or users after they have been created.

If a database administrator has a preference that a specific authorization identifier must be a role, a name scheme can be used to communicate this intention. For example, you could use a `r_` prefix for all authorization identifiers that you intend to be roles and nothing else.
Another difference between roles and users lies in the privileges available for administering them:

- The `CREATE ROLE` and `DROP ROLE` privileges enable only use of the `CREATE ROLE` and `DROP ROLE` statements, respectively.

- The `CREATE USER` privilege enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

Thus, the `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` and may be granted to users who should only be permitted to create and drop roles, and not perform more general account manipulation.

With regard to privileges and interchangeability of users and roles, you can treat a user account like a role and grant that account to another user or a role. The effect is to grant the account's privileges and roles to the other user or role.

This set of statements demonstrates that you can grant a user to a user, a role to a user, a user to a role, or a role to a role:

```
CREATE USER 'u1';
CREATE ROLE 'r1';
GRANT SELECT ON db1.* TO 'u1';
GRANT SELECT ON db2.* TO 'r1';
CREATE USER 'u2';
CREATE ROLE 'r2';
GRANT 'u1', 'r1' TO 'u2';
GRANT 'u1', 'r1' TO 'r2';
```

The result in each case is to grant to the grantee object the privileges associated with the granted object. After executing those statements, each of `u2` and `r2` have been granted privileges from a user (`u1`) and a role (`r1`):

```
mysql> SHOW GRANTS FOR 'u2' USING 'u1', 'r1';
+-------------------------------------+
| Grants for u2@%                     |
+-------------------------------------+
| GRANT USAGE ON *.* TO `u2`@`%`      |
| GRANT SELECT ON `db1`.* TO `u2`@`%` |
| GRANT SELECT ON `db2`.* TO `u2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `u2`@`%` |
+-------------------------------------+
mysql> SHOW GRANTS FOR 'r2' USING 'u1', 'r1';
+-------------------------------------+
| Grants for r2@%                     |
+-------------------------------------+
| GRANT USAGE ON *.* TO `r2`@`%`      |
| GRANT SELECT ON `db1`.* TO `r2`@`%` |
| GRANT SELECT ON `db2`.* TO `r2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `r2`@`%` |
+-------------------------------------+
```

The preceding example is illustrative only, but interchangeability of user accounts and roles has practical application, such as in the following situation: Suppose that a legacy application development project began before the advent of roles in MySQL, so all user accounts associated with the project are granted privileges directly (rather than granted privileges by virtue of being granted roles). One of these accounts is a developer account that was originally granted privileges as follows:

```
CREATE USER 'old_app_dev'@'localhost' IDENTIFIED BY 'old_app_devpass';
GRANT ALL ON old_app.* TO 'old_app_dev'@'localhost';
```
If this developer leaves the project, it becomes necessary to assign the privileges to another user, or perhaps multiple users if development activities have expanded. Here are some ways to deal with the issue:

- Without using roles: Change the account password so the original developer cannot use it, and have a new developer use the account instead:

  ```sql
  ALTER USER 'old_app_dev'@'localhost' IDENTIFIED BY 'new_password';
  ```

- Using roles: Lock the account to prevent anyone from using it to connect to the server:

  ```sql
  ALTER USER 'old_app_dev'@'localhost' ACCOUNT LOCK;
  ```

  Then treat the account as a role. For each developer new to the project, create a new account and grant to it the original developer account:

  ```sql
  CREATE USER 'new_app_dev1'@'localhost' IDENTIFIED BY 'new_password';
  GRANT 'old_app_dev'@'localhost' TO 'new_app_dev1'@'localhost';
  ```

  The effect is to assign the original developer account privileges to the new account.

### 6.2.11 Account Categories

As of MySQL 8.0.16, MySQL incorporates the concept of user account categories, based on the `SYSTEM_USER` privilege.

- **System and Regular Accounts**
- **Operations Affected by the SYSTEM_USER Privilege**
- **System and Regular Sessions**
- **Protecting System Accounts Against Manipulation by Regular Accounts**

#### System and Regular Accounts

MySQL incorporates the concept of user account categories, with system and regular users distinguished according to whether they have the `SYSTEM_USER` privilege:

- A user with the `SYSTEM_USER` privilege is a system user.
- A user without the `SYSTEM_USER` privilege is a regular user.

The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER` to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.

- A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

If a user has the appropriate privileges to perform a given operation on regular accounts, `SYSTEM_USER` enables the user to also perform the operation on system accounts. `SYSTEM_USER` does not imply any other privilege, so the ability to perform a given account operation remains predicated on possession of any other required privileges. For example, if a user can grant the `SELECT` and `UPDATE` privileges...
to regular accounts, then with SYSTEM_USER the user can also grant SELECT and UPDATE to system accounts.

The distinction between system and regular accounts enables better control over certain account administration issues by protecting accounts that have the SYSTEM_USER privilege from accounts that do not have the privilege. For example, the CREATE_USER privilege enables not only creation of new accounts, but modification and removal of existing accounts. Without the system user concept, a user who has the CREATE_USER privilege can modify or drop any existing account, including the root account. The concept of system user enables restricting modifications to the root account (itself a system account) so they can be made only by system users. Regular users with the CREATE_USER privilege can still modify or drop existing accounts, but only regular accounts.

Operations Affected by the SYSTEM_USER Privilege

The SYSTEM_USER privilege affects these operations:

• Account manipulation.

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

The SYSTEM_USER privilege is required to manipulate system accounts using account-management statements such as CREATE_USER and GRANT. To prevent an account from modifying system accounts this way, make it a regular account by not granting it the SYSTEM_USER privilege. (However, to fully protect system accounts against regular accounts, you must also withhold modification privileges for the mysql system schema from regular accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.)

• Killing current sessions and statements executing within them.

To kill a session or statement that is executing with the SYSTEM_USER privilege, your own session must have the SYSTEM_USER privilege, in addition to any other required privilege (CONNECTION_ADMIN or SUPER).

Prior to MySQL 8.0.16, CONNECTION_ADMIN or SUPER are sufficient to kill any session or statement.

• Setting the DEFINER for stored objects.

To set the DEFINER attribute for a stored object to an account that has the SYSTEM_USER privilege, you must have the SYSTEM_USER privilege, in addition to any other required privilege (SET_USER_ID or SUPER).

Prior to MySQL 8.0.16, SET_USER_ID or SUPER are sufficient to specify any DEFINER value for stored objects.

• Specifying mandatory roles.

A role that has the SYSTEM_USER privilege cannot be listed in the value of the mandatory_roles system variable.

Prior to MySQL 8.0.16, any role can be listed in mandatory_roles.

System and Regular Sessions

Sessions executing within the server are distinguished as system or regular sessions, similar to the distinction between system and regular users:
Account Categories

- A session that possesses the `SYSTEM_USER` privilege is a system session.
- A session that does not possess the `SYSTEM_USER` privilege is a regular session.

A regular session is able to perform only operations permitted to regular users. A system session is additionally able to perform operations permitted only to system users.

The privileges possessed by a session are those granted directly to its underlying account, plus those granted to all roles currently active within the session. Thus, a session may be a system session because its account has been granted the `SYSTEM_USER` privilege directly, or because the session has activated a role that has the `SYSTEM_USER` privilege. Roles granted to an account that are not active within the session do not affect session privileges.

Because activating and deactivating roles can change the privileges possessed by sessions, a session may change from a regular session to a system session or vice versa. If a session activates or deactivates a role that has the `SYSTEM_USER` privilege, the appropriate change between regular and system session takes place immediately, for that session only:

- If a regular session activates a role with the `SYSTEM_USER` privilege, the session becomes a system session.
- If a system session deactivates a role with the `SYSTEM_USER` privilege, the session becomes a regular session, unless some other role with the `SYSTEM_USER` privilege remains active.

These operations have no effect on existing sessions:

- If the `SYSTEM_USER` privilege is granted to or revoked from an account, existing sessions for the account do not change between regular and system sessions. The grant or revoke operation affects only sessions for subsequent connections by the account.
- Statements executed by a stored object invoked within a session execute with the system or regular status of the parent session, even if the object `DEFINER` attribute names a system account.

Because role activation affects only sessions and not accounts, granting a role that has the `SYSTEM_USER` privilege to a regular account does not protect that account against regular users. The role protects only sessions for the account in which the role has been activated, and protects the session only against being killed by regular sessions.

Protecting System Accounts Against Manipulation by Regular Accounts

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

Account manipulation can be done two ways:

- By using account-management statements such as `CREATE USER` and `GRANT`. This is the preferred method.
- By direct grant-table modification using statements such as `INSERT` and `UPDATE`. This method is discouraged but possible for users with the appropriate privileges on the `mysql` system schema that contains the grant tables.

To fully protect system accounts against modification by a given account, make it a regular account and do not grant it modification privileges for the `mysql` schema:

- The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements. To prevent an account from modifying system accounts this way, make it a regular account.
by not granting `SYSTEM_USER` to it. This includes not granting `SYSTEM_USER` to any roles granted to the account.

- Privileges for the `mysql` schema enable manipulation of system accounts through direct modification of the grant tables, even if the modifying account is a regular account. To restrict unauthorized direct modification of system accounts by a regular account, do not grant modification privileges for the `mysql` schema to the account (or any roles granted to the account). If a regular account must have global privileges that apply to all schemas, `mysql` schema modifications can be prevented using privilege restrictions imposed using partial revokes. See Section 6.2.12, “Privilege Restriction Using Partial Revokes”.

**Note**

Unlike withholding the `SYSTEM_USER` privilege, which prevents an account from modifying system accounts but not regular accounts, withholding `mysql` schema privileges prevents an account from modifying system accounts as well as regular accounts. This should not be an issue because, as mentioned, direct grant-table modification is discouraged.

Suppose that you want to create a user `u1` who has all privileges on all schemas, except that `u1` should be a regular user without the ability to modify system accounts. Assuming that the `partial_revokes` system variable is enabled, configure `u1` as follows:

```sql
CREATE USER u1 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u1 WITH GRANT OPTION;
-- u1 can manipulate system or regular accounts
REVOKE SYSTEM_USER ON *.* FROM u1;
-- u1 is now a regular user; can use account-management statements
REVOKE ALL ON mysql.* FROM u1;
-- This partial revoke prevents u1 from directly modifying grant tables to manipulate accounts
```

To prevent all `mysql` system schema access by an account, revoke all its privileges on the `mysql` schema, as just shown. It is also possible to permit partial `mysql` schema access, such as read-only access. The following example creates an account that has `SELECT`, `INSERT`, `UPDATE`, and `DELETE` privileges globally for all schemas, but only `SELECT` for the `mysql` schema:

```sql
CREATE USER u2 IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u2;
REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u2;
```

Another possibility is to revoke all `mysql` schema privileges but grant access to specific `mysql` tables or columns. This can be done even with a partial revoke on `mysql`. The following statements enable read-only access to `u1` within the `mysql` schema, but only for the `db` table and the `Host` and `User` columns of the `user` table:

```sql
CREATE USER u3 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u3;
REVOKE ALL ON mysql.* FROM u3;
GRANT SELECT ON mysql.db TO u3;
GRANT SELECT(Host,User) ON mysql.user TO u3;
```
6.2.12 Privilege Restriction Using Partial Revokes

Prior to MySQL 8.0.16, it is not possible to grant privileges that apply globally except for certain schemas. As of MySQL 8.0.16, that is possible if the `partial_revokes` system variable is enabled. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. Privilege restrictions thus imposed may be useful for administration of accounts that have global privileges but should not be permitted to access certain schemas. For example, it is possible to permit an account to modify any table except those in the `mysql` system schema.

- Using Partial Revokes
- Partial Revokes Versus Explicit Schema Grants
- Disabling Partial Revokes
- Partial Revokes and Replication

**Note**

For brevity, `CREATE USER` statements shown here do not include passwords. For production use, always assign account passwords.

### Using Partial Revokes

The `partial_revokes` system variable controls whether privilege restrictions can be placed on accounts. By default, `partial_revokes` is disabled and attempts to partially revoke global privileges produce an error:

```sql
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> REVOKE INSERT ON world.* FROM u1;
ERROR 1141 (42000): There is no such grant defined for user 'u1' on host '%'
```

To permit the `REVOKE` operation, enable `partial_revokes`:

```sql
SET PERSIST partial_revokes = ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. To change the value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

With `partial_revokes` enabled, the partial revoke succeeds:

```sql
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u1@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT ON <em>.</em> TO <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE INSERT ON <code>world</code>.* FROM <code>u1</code>@<code>%</code></td>
</tr>
</tbody>
</table>
+------------------------------------------+
```

`SHOW GRANTS` lists partial revokes as `REVOKE` statements in its output. The result indicates that `u1` has global `SELECT` and `INSERT` privileges, except that `INSERT` cannot be exercised for tables in the `world` schema. That is, access by `u1` to `world` tables is read only.
Privilege Restriction Using Partial Revokes

The server records privilege restrictions implemented through partial revokes in the `mysql.user` system table. If an account has partial revokes, its `User_attributes` column value has a `Restrictions` attribute:

```sql
mysql> SELECT User, Host, User_attributes->>'$.Restrictions'
    -> FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> ''
+------+-----------------------------+
<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>User_attributes-&gt;&gt;'$.Restrictions'</th>
</tr>
</thead>
<tbody>
<tr>
<td>u1</td>
<td>%</td>
<td>[&quot;Database&quot;: &quot;world&quot;, &quot;Privileges&quot;: [&quot;INSERT&quot;]]</td>
</tr>
</tbody>
</table>
```

Note

Although partial revokes can be imposed for any schema, privilege restrictions on the `mysql` system schema in particular are useful as part of a strategy for preventing regular accounts from modifying system accounts. See Protecting System Accounts Against Manipulation by Regular Accounts.

Partial revoke operations are subject to these conditions:

- Partial revokes must name the schema literally. Schema names that contain the `%` or `_` SQL wildcard characters (for example, `myschema%`) are not permitted.

- It is possible to use partial revokes to place restrictions on nonexistent schemas, but only if the revoked privilege is granted globally. If a privilege is not granted globally, revoking it for a nonexistent schema produces an error.

- Partial revokes apply at the schema level only. You cannot use partial revokes for privileges that apply only globally (such as `FILE` or `BINLOG_ADMIN`), or for table, column, or routine privileges.

As mentioned previously, partial revokes of schema-level privileges appear in `SHOW GRANTS` output as `REVOKE` statements. This differs from how `SHOW GRANTS` represents "plain" schema-level privileges:

- When granted, schema-level privileges are represented by their own `GRANT` statements in the output:

```sql
mysql> CREATE USER u1;
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> GRANT DELETE ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

```
+---------------------------------------+
| Grants for u1@%                       |
+---------------------------------------+
| GRANT USAGE ON *.* TO `u1`@`%`        |
| GRANT UPDATE ON `mysql`.* TO `u1`@`%` |
| GRANT DELETE ON `world`.* TO `u1`@`%` |
+---------------------------------------+
```

- When revoked, schema-level privileges simply disappear from the output. They do not appear as `REVOKE` statements:

```sql
mysql> REVOKE UPDATE ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

```
+----------------------------------+
| Grants for u1@%                  |
+----------------------------------+
| GRANT USAGE ON *.* TO `u1`@`%`   |
+----------------------------------+
```
When a user grants a privilege, any restriction the grantor has on the privilege is inherited by the grantee, unless the grantee already has the privilege without the restriction. Consider the following two users, one of whom has the global `SELECT` privilege:

```
CREATE USER u1, u2;
GRANT SELECT ON *.* TO u2;
```

Suppose that an administrative user `admin` has a global but partially revoked `SELECT` privilege:

```
mysql> CREATE USER admin;
mysql> GRANT SELECT ON *.* TO admin WITH GRANT OPTION;
mysql> REVOKE SELECT ON mysql.* FROM admin;
mysql> SHOW GRANTS FOR admin;

+------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for admin@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT ON <em>.</em> TO <code>admin</code>@<code>%</code> WITH GRANT OPTION</td>
</tr>
<tr>
<td>REVOKE SELECT ON <code>mysql</code>.* FROM <code>admin</code>@<code>%</code></td>
</tr>
</tbody>
</table>
+------------------------------------------------------+
```

If `admin` grants `SELECT` globally to `u1` and `u2`, the result differs for each user:

- If `admin` grants `SELECT` globally to `u1`, who has no `SELECT` privilege to begin with, `u1` inherits the `admin` privilege restriction:

```
mysql> GRANT SELECT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

```
+------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u1@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT ON <em>.</em> TO <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE SELECT ON <code>mysql</code>.* FROM <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>------------------------------------------</td>
</tr>
</tbody>
</table>
```

- On the other hand, `u2` already holds a global `SELECT` privilege without restriction. `GRANT` can only add to a grantee’s existing privileges, not reduce them, so if `admin` grants `SELECT` globally to `u2`, `u2` does not inherit the `admin` restriction:

```
mysql> GRANT SELECT ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
```

```
+---------------------------------+
<table>
<thead>
<tr>
<th>Grants for u2@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT ON <em>.</em> TO <code>u2</code>@<code>%</code></td>
</tr>
<tr>
<td>---------------------------------</td>
</tr>
</tbody>
</table>
```

If a `GRANT` statement includes an `AS user` clause, the privilege restrictions applied are those on the user/role combination specified by the clause, rather than those on the user who executes the statement. For information about the `AS` clause, see Section 13.7.1.6, “GRANT Syntax”.

Restrictions on new privileges granted to an account are added to any existing restrictions for that account:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

```
+---------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u1@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT ON <em>.</em> TO <code>u1</code>@<code>%</code></td>
</tr>
</tbody>
</table>
+---------------------------------------------------------|
```
Privilege Restriction Using Partial Revokes

Aggregation of privilege restrictions applies both when privileges are partially revoked explicitly (as just shown) and when restrictions are inherited implicitly from the user who executes the statement or the user mentioned in an `AS user` clause.

If an account has a privilege restriction on a schema:

- The account cannot grant to other accounts a privilege on the restricted schema or any object within it.
- Another account that does not have the restriction can grant privileges to the restricted account for the restricted schema or objects within it. Suppose that an unrestricted user executes these statements:

```sql
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
REVOKE SELECT, INSERT, UPDATE ON mysql.* FROM u1;
GRANT SELECT ON mysql.user TO u1;  -- grant table privilege
GRANT SELECT(Host,User) ON mysql.db TO u1;  -- grant column privileges
```

The resulting account has these privileges, with the ability to perform limited operations within the restricted schema:

```sql
mysql> SHOW GRANTS FOR u1;
+----------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for u1@%</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT SELECT, INSERT, UPDATE, DELETE ON <em>.</em> TO <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>REVOKE SELECT, INSERT, UPDATE ON <code>mysql</code>.* FROM <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>GRANT SELECT (<code>Host</code>, <code>User</code>) ON <code>mysql</code>.<code>db</code> TO <code>u1</code>@<code>%</code></td>
</tr>
<tr>
<td>GRANT SELECT ON <code>mysql</code>.* TO <code>u1</code>@<code>%</code></td>
</tr>
</tbody>
</table>
+----------------------------------------------------------+
```

If an account has a restriction on a global privilege, the restriction is removed by any of these actions:

- Granting the privilege globally to the account by an account that has no restriction on the privilege.
- Granting the privilege at the schema level.
- Revoking the privilege globally.

Consider a user `u1` who holds several privileges globally, but with restrictions on `INSERT`, `UPDATE` and `DELETE`:

```sql
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+----------------------------------------------------------+
| Grants for u1@%                                          |
+----------------------------------------------------------+
```
Privilege Restriction Using Partial Revokes

Granting a privilege globally to `u1` from an account with no restriction removes the privilege restriction. For example, to remove the `INSERT` restriction:

```
mysql> GRANT INSERT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

Granting a privilege at the schema level to `u1` removes the privilege restriction. For example, to remove the `UPDATE` restriction:

```
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

Revoking a global privilege removes the privilege, including any restrictions on it. For example, to remove the `DELETE` restriction (at the cost of removing all `DELETE` access):

```
mysql> REVOKE DELETE ON *.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

If an account has a privilege at both the global and schema levels, you must revoke it at the schema level twice to effect a partial revoke. Suppose that `u1` has these privileges, where `INSERT` is held both globally and on the `world` schema:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> GRANT INSERT ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
```

Revoking `INSERT` on `world` revokes the schema-level privilege (`SHOW GRANTS` no longer displays the schema-level `GRANT` statement):

```
mysql> REVOKE INSERT ON world.* FROM u1;
```
Revoking `INSERT` on `world` again performs a partial revoke of the global privilege (`SHOW GRANTS` now includes a schema-level `REVOKE` statement):

```sql
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
```

### Partial Revokes Versus Explicit Schema Grants

To provide access to accounts for some schemas but not others, partial revokes provide an alternative to the approach of explicitly granting schema-level access without granting global privileges. The two approaches have different advantages and disadvantages.

Granting schema-level privileges and not global privileges:

- Adding a new schema: The schema is inaccessible to existing accounts by default. For any account to which the schema should be accessible, the DBA must grant schema-level access.
- Adding a new account: The DBA must grant schema-level access for each schema to which the account should have access.

Granting global privileges in conjunction with partial revokes:

- Adding a new schema: The schema is accessible to existing accounts that have global privileges. For any such account to which the schema should be inaccessible, the DBA must add a partial revoke.
- Adding a new account: The DBA must grant the global privileges, plus a partial revoke on each restricted schema.

The approach that uses explicit schema-level grant is more convenient for accounts for which access is limited to a few schemas. The approach that uses partial revokes is more convenient for accounts with broad access to all schemas except a few.

### Disabling Partial Revokes

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.
- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` when restrictions exist, the restrictions first must be removed:

1. Determine which accounts have partial revokes:
When Privilege Changes Take Effect

2. For each such account, remove its privilege restrictions. Suppose that the previous step shows account `u1` to have these restrictions:

```json
[{
"Database": "world",
"Privileges": ["INSERT", "DELETE"]
}
```

Restriction removal can be done various ways:

- Grant the privileges globally, without restrictions:
  ```sql
  GRANT INSERT, DELETE ON *.* TO u1;
  ```

- Grant the privileges at the schema level:
  ```sql
  GRANT INSERT, DELETE ON world.* TO u1;
  ```

- Revoke the privileges globally (assuming that they are no longer needed):
  ```sql
  REVOKE INSERT, DELETE ON *.* FROM u1;
  ```

- Remove the account itself (assuming that it is no longer needed):
  ```sql
  DROP USER u1;
  ```

After all privilege restrictions are removed, it is possible to disable partial revokes:

```sql
SET PERSIST partial_revokes = OFF;
```

Partial Revokes and Replication

In replication scenarios, if `partial_revokes` is enabled on any host, it must be enabled on all hosts. Otherwise, `REVOKE` statements to partially revoke a global privilege do not have the same effect for all hosts on which replication occurs, potentially resulting in replication inconsistencies or errors.

6.2.13 When Privilege Changes Take Effect

If the `mysqld` server is started without the `--skip-grant-tables` option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are described in Section 13.7.1, “Account Management Statements”. Examples include `GRANT`, `REVOKE`, `SET PASSWORD`, and `RENAME USER`.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE` (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have no effect until you restart the server. This may leave you wondering why your changes seem to make no difference!
To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections.

Changes to the set of active roles within a session take effect immediately, for that session only. The `SET ROLE` statement performs session role activation and deactivation (see Section 13.7.1.11, “SET ROLE Syntax”).

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, which is insecure. To cause a server thus started to read the tables and enable access checking, flush the privileges.

### 6.2.14 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `ALTER USER` additionally requires the `CONNECTION_ADMIN` or `SUPER` privilege.

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see Section 13.7.1.3, “CREATE USER Syntax”, Section 13.7.1.1, “ALTER USER Syntax”, and Section 13.7.1.10, “SET PASSWORD Syntax”.

MySQL uses plugins to perform client authentication; see Section 6.2.17, “Pluggable Authentication”. In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to storing them in the `mysql.user` system table. For the statements described here, MySQL automatically hashes the password specified. There are also syntaxes for `CREATE USER` and `ALTER USER` that permit hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

`CREATE USER` also supports syntax for specifying the account authentication plugin. See Section 13.7.1.3, “CREATE USER Syntax”.

1116
To assign or change a password for an existing account, use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```
ALTER USER USER() IDENTIFIED BY 'password';
```

To change an account password from the command line, use the `mysqladmin` command:

```
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the `mysql.user` system table that matches `user_name` in the `User` column and the client host `from which you connect` in the `Host` column.

**Warning**

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

### 6.2.15 Password Management

MySQL supports these password-management capabilities:

- **Password Expiration Policy**
- **Password Reuse Policy**
- **Password Verification**
- **Dual Passwords**
- **Password Strength Assessment**

The following sections these capabilities, except password strength assessment, which is implemented using the `validate_password` plugin and is described in Section 6.4.3, “The Password Validation Component”.

- **Password Expiration Policy**
- **Password Reuse Policy**
Password Management

- **Password Verification-Required Policy**
- **Dual Password Support**

---

**Important**

MySQL implements password-management capabilities using tables in the `mysql` system database. If you upgrade MySQL from an earlier version, your system tables might not be up to date. In that case, the server writes messages similar to these to the error log during the startup process (the exact numbers may vary):

```
[ERROR] Column count of mysql.user is wrong. Expected 49, found 47. The table is probably corrupted
[Warning] ACL table mysql.password_history missing. Some operations may fail.
```

To correct the issue, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”. Until this is done, **password changes are not possible**.

---

**Note**

The password-management capabilities described here apply only to accounts that store credentials internally in the `mysql.user` system table (`mysql_native_password`, `sha256_password`, or `caching_sha2_password`). For accounts that use plugins that perform authentication against an external credential system, password management must be handled externally against that system as well.

---

**Password Expiration Policy**

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration. Expiration policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

To expire an account password manually, use the `ALTER USER` statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding row in the `mysql.user` system table.

Password expiration according to policy is automatic and is based on password age, which for a given account is assessed from the date and time of its most recent password change. The `mysql.user` system table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if its age is greater than its permitted lifetime. This works with no explicit manual password expiration.

To establish automatic password-expiration policy globally, use the `default_password_lifetime` system variable. Its default value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer $N$, it indicates the permitted password lifetime, such that passwords must be changed every $N$ days.

Examples:

- To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in a server `my.cnf` file:
Password Management

```
[mysqld]
default_password_lifetime=180
```

- To establish a global policy such that passwords never expire, set `default_password_lifetime` to 0:

```
[mysqld]
default_password_lifetime=0
```

- `default_password_lifetime` can also be set and persisted at runtime:

```
SET PERSIST default_password_lifetime = 180;
SET PERSIST default_password_lifetime = 0;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value to be used for subsequent server restarts; see Section 13.7.5.1, “SET Syntax for Variable Assignment”. To change the value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-expiration policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD EXPIRE` option of the `CREATE USER` and `ALTER USER` statements. See Section 13.7.1.3, “CREATE USER Syntax”, and Section 13.7.1.1, “ALTER USER Syntax”.

Example account-specific statements:

- Require the password to be changed every 90 days:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
  ```

  This expiration option overrides the global policy for all accounts named by the statement.

- Disable password expiration:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

  This expiration option overrides the global policy for all accounts named by the statement.

- Defer to the global expiration policy for all accounts named by the statement:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

  When a client successfully connects, the server determines whether the account password has expired:

  - The server checks whether the password has been manually expired.

  - Otherwise, the server checks whether the password age is greater than its permitted lifetime according to the automatic password expiration policy. If so, the server considers the password expired.

  If the password is expired (whether manually or automatically), the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.16, “Server Handling of Expired Passwords”).
Operations performed by a restricted client result in an error until the user establishes a new account password:

```sql
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.
```

```sql
mysql> ALTER USER USER() IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.01 sec)
```

```sql
mysql> SELECT 1;
+---+
| 1 |
+---+
1 row in set (0.00 sec)
```

After the client resets the password, the server restores normal access for the session, as well as for subsequent connections that use the account. It is also possible for an administrative user to reset the account password, but any existing restricted sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

### Password Reuse Policy

MySQL enables restrictions to be placed on reuse of previous passwords. Reuse restrictions can be established based on number of password changes, time elapsed, or both. Reuse policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

The password history for an account consists of passwords it has been assigned in the past. MySQL can restrict new passwords from being chosen from this history:

- If an account is restricted on the basis of number of password changes, a new password cannot be chosen from a specified number of the most recent passwords. For example, if the minimum number of password changes is set to 3, a new password cannot be the same as any of the most recent 3 passwords.

- If an account is restricted based on time elapsed, a new password cannot be chosen from passwords in the history that are newer than a specified number of days. For example, if the password reuse interval is set to 60, a new password must not be among those previously chosen within the last 60 days.

**Note**

The empty password does not count in the password history and is subject to reuse at any time.

To establish password-reuse policy globally, use the `password_history` and `password_reuse_interval` system variables.

Examples:
Password Management

• To prohibit reusing any of the last 6 passwords or passwords newer than 365 days, put these lines in the server `my.cnf` file:

```
[mysqld]
password_history=6
password_reuse_interval=365
```

• To set and persist the variables at runtime, use statements like this:

```
SET PERSIST password_history = 6;
SET PERSIST password_reuse_interval = 365;
```

The global password-reuse policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options of the `CREATE USER` and `ALTER USER` statements. See Section 13.7.1.3, “CREATE USER Syntax”, and Section 13.7.1.1, “ALTER USER Syntax”.

Example account-specific statements:

• Require a minimum of 5 password changes before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
```

This history-length option overrides the global policy for all accounts named by the statement.

• Require a minimum of 365 days elapsed before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
```

This time-elapsed option overrides the global policy for all accounts named by the statement.

• To combine both types of reuse restrictions, use `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` together:

```
CREATE USER 'jeffrey'@'localhost'
    PASSWORD HISTORY 5
    PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'jeffrey'@'localhost'
    PASSWORD HISTORY 5
    PASSWORD REUSE INTERVAL 365 DAY;
```

These options override both global policy reuse restrictions for all accounts named by the statement.

• Defer to the global policy for both types of reuse restrictions:

```
CREATE USER 'jeffrey'@'localhost'
    PASSWORD HISTORY DEFAULT
    PASSWORD REUSE INTERVAL DEFAULT;
ALTER USER 'jeffrey'@'localhost'
```
Password Verification-Required Policy

As of MySQL 8.0.13, it is possible to require that attempts to change an account password be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing a password without proving that they know the current password. Such changes could otherwise occur, for example, if one user walks away from a terminal session temporarily without logging out, and a malicious user uses the session to change the original user's MySQL password. This can have unfortunate consequences:

- The original user becomes unable to access MySQL until the account password is reset by an administrator.
- Until the password reset occurs, the malicious user can access MySQL with the benign user's changed credentials.

Password-verification policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

For each account, its `mysql.user` row indicates whether there is an account-specific setting requiring verification of the current password for password change attempts. The setting is established by the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements:

- If the account setting is `PASSWORD REQUIRE CURRENT`, password changes must specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT OPTIONAL`, password changes may but need not specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT DEFAULT`, the `password_require_current` system variable determines the verification-required policy for the account:
  - If `password_require_current` is enabled, password changes must specify the current password.
  - If `password_require_current` is disabled, password changes may but need not specify the current password.

In other words, if the account setting is not `PASSWORD REQUIRE CURRENT DEFAULT`, the account setting takes precedence over the global policy established by the `password_require_current` system variable. Otherwise, the account defers to the `password_require_current` setting.

By default, password verification is optional: `password_require_current` is disabled and accounts created with no `PASSWORD REQUIRE` option default to `PASSWORD REQUIRE CURRENT DEFAULT`.

The following table shows how per-account settings interact with `password_require_current` system variable values to determine account password verification-required policy.

### Table 6.10 Password-Verification Policy

<table>
<thead>
<tr>
<th>Per-Account Setting</th>
<th><code>password_require_current</code> System Variable</th>
<th>Password Changes Require Current Password?</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>PASSWORD REQUIRE CURRENT</code></td>
<td>OFF</td>
<td>Yes</td>
</tr>
<tr>
<td><code>PASSWORD REQUIRE CURRENT</code></td>
<td>ON</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Password Management

<table>
<thead>
<tr>
<th>Per-Account Setting</th>
<th>password_require_current System Variable</th>
<th>Password Changes Require Current Password?</th>
</tr>
</thead>
<tbody>
<tr>
<td>PASSWORD REQUIRE CURRENT</td>
<td>OFF</td>
<td>No</td>
</tr>
<tr>
<td>OPTIONAL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PASSWORD REQUIRE CURRENT</td>
<td>ON</td>
<td>No</td>
</tr>
<tr>
<td>OPTIONAL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PASSWORD REQUIRE CURRENT</td>
<td>OFF</td>
<td>No</td>
</tr>
<tr>
<td>DEFAULT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PASSWORD REQUIRE CURRENT</td>
<td>ON</td>
<td>Yes</td>
</tr>
<tr>
<td>DEFAULT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

Privileged users can change any account password without specifying the current password, regardless of the verification-required policy. A privileged user is one who has the global CREATE USER privilege or the UPDATE privilege for the mysql system database.

To establish password-verification policy globally, use the `password_require_current` system variable. Its default value is OFF, so it is not required that account password changes specify the current password.

Examples:

- To establish a global policy that password changes must specify the current password, start the server with these lines in a server `my.cnf` file:

  ```
  [mysqld]
  password_require_current=ON
  ```

- To set and persist `password_require_current` at runtime, use a statement such as one of these:

  ```
  SET PERSIST password_require_current = ON;
  SET PERSIST password_require_current = OFF;
  ```

  `SET PERSIST` sets the value for the running MySQL instance. It also saves the value to be used for subsequent server restarts; see Section 13.7.5.1, “SET Syntax for Variable Assignment”. To change the value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password verification-required policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD REQUIRE` options of the CREATE USER and ALTER USER statements. See Section 13.7.1.3, “CREATE USER Syntax”, and Section 13.7.1.1, “ALTER USER Syntax”.

Example account-specific statements:

- Require that password changes specify the current password:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
  ```

  This verification option overrides the global policy for all accounts named by the statement.
Password Management

- Do not require that password changes specify the current password (the current password may but need not be given):

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

This verification option overrides the global policy for all accounts named by the statement.

- Defer to the global password verification-required policy for all accounts named by the statement:

```sql
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

Verification of the current password comes into play when a user changes a password using the `ALTER USER` or `SET PASSWORD` statement. The examples use `ALTER USER`, which is preferred over `SET PASSWORD`, but the principles described here are the same for both statements.

In password-change statements, a `REPLACE` clause specifies the current password to be replaced. Examples:

- Change the current user's password:

  ```sql
  ALTER USER USER() IDENTIFIED BY 'auth_string' REPLACE 'current_auth_string';
  ```

- Change a named user's password:

  ```sql
  ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'auth_string'
  REPLACE 'current_auth_string';
  ```

- Change a named user's authentication plugin and password:

  ```sql
  ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH caching_sha2_password BY 'auth_string'
  REPLACE 'current_auth_string';
  ```

The `REPLACE` clause works like this:

- `REPLACE` must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.

- `REPLACE` is optional if password changes for the account may but need not specify the current password.

- If `REPLACE` is specified, it must specify the correct current password, or an error occurs. This is true even if `REPLACE` is optional.

- `REPLACE` can be specified only when changing the account password for the current user. (This means that in the examples just shown, the statements that explicitly name the account for `jeffrey` fail unless the current user is `jeffrey`.) This is true even if the change is attempted for another user by a privileged user; however, such a user can change any password without specifying `REPLACE`.

- `REPLACE` is omitted from the binary log to avoid writing cleartext passwords to it.

Dual Password Support
As of MySQL 8.0.14, user accounts are permitted to have dual passwords, designated as primary and secondary passwords. Dual-password capability makes it possible to seamlessly perform credential changes in scenarios like this:

- A system has a large number of MySQL servers, possibly involving replication.
- Multiple applications connect to different MySQL servers.
- Periodic credential changes must be made to the account or accounts used by the applications to connect to the servers.

Consider how a credential change must be performed in the preceding type of scenario when an account is permitted only a single password. In this case, there must be close cooperation in the timing of when the account password change is made and propagated throughout all servers, and when all applications that use the account are updated to use the new password. This process may involve downtime during which servers or applications are unavailable.

With dual passwords, credential changes can be made more easily, in phases, without requiring close cooperation, and without downtime:

1. For each affected account, establish a new primary password on the servers, retaining the current password as the secondary password. This enables servers to recognize either the primary or secondary password for each account, while applications can continue to connect to the servers using the same password as previously (which is now the secondary password).

2. After the password change has propagated to all servers, modify applications that use any affected account to connect using the account primary password.

3. After all applications have been migrated from the secondary passwords to the primary passwords, the secondary passwords are no longer needed and can be discarded. After this change has propagated to all servers, only the primary password for each account can be used to connect. The credential change is now complete.

MySQL implements dual-password capability with syntax that saves and discards secondary passwords:

- The `RETAIN CURRENT PASSWORD` clause for the `ALTER USER` and `SET PASSWORD` statements saves an account current password as its secondary password when you assign a new primary password.

- The `DISCARD OLD PASSWORD` clause for `ALTER USER` discards an account secondary password, leaving only the primary password.

Suppose that, for the previously described credential-change scenario, an account named 'appuser1 '@'host1.example.com' is used by applications to connect to servers, and that the account password is to be changed from 'password_a' to 'password_b'.

To perform this change of credentials, use `ALTER USER` as follows:

1. On each server that is not a replication slave, establish 'password_b' as the new appuser1 primary password, retaining the current password as the secondary password:

   ```
   ALTER USER 'appuser1 '@'host1.example.com' 
   IDENTIFIED BY 'password_b'
   RETAIN CURRENT PASSWORD;
   ```

2. Wait for the password change to replicate throughout the system to all slave servers.

3. Modify each application that uses the appuser1 account so that it connects to the servers using a password of 'password_b' rather than 'password_a'.
4. At this point, the secondary password is no longer needed. On each server that is not a replication slave, discard the secondary password:

```sql
ALTER USER 'appuser1'@'host1.example.com'
DISCARD OLD PASSWORD;
```

5. After the discard-password change has replicated to all slave servers, the credential change is complete.

The `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses have the following effects:

- `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `ALTER USER` or `SET PASSWORD` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)

- If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.

- If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.

- For `ALTER USER`, if you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify `RETAIN CURRENT PASSWORD`, the statement fails.

- For `ALTER USER, DISCARD OLD PASSWORD` discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

Statements that modify secondary passwords require these privileges:

- The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` and `SET PASSWORD` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.

- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE_USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

### 6.2.16 Server Handling of Expired Passwords

MySQL provides password-expiration capability, which enables database administrators to require that users reset their password. Passwords can be expired manually, and on the basis of a policy for automatic expiration (see Section 6.2.15, “Password Management”).

The `ALTER USER` statement enables account password expiration. For example:

```sql
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:
Server Handling of Expired Passwords

shell> mysql -u myuser -p
Password: ******
ERROR 1862 (HY000): Your password has expired. To log in you must change it using a client that supports expired passwords.

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

  **Note**

  Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See Password Reuse Policy.

- The client can use the `SET` statement.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```sql
mysql> USE performance_schema;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.
```

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

**Note**

This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

```c
bool arg = 1;
mysql_options(mysql,
    MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
    &arg);
```
This is the technique used within the mysql client, which enables
MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS if invoked interactively or with the --connect-expired-password option.

- Pass the CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS flag to mysql_real_connect() at connect time:

```c
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql,
    host, user, password, db,
    port, unix_socket,
    CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
{
    ... handle error ... 
}
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the disconnect_on_expired_password system variable:

- If `disconnect_on_expired_password` is enabled (the default), the server disconnects the client with an ER_MUST_CHANGE_PASSWORD_LOGIN error.
- If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

### 6.2.17 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

- If the server cannot find the plugin, an error occurs and the connection attempt is rejected.
- Otherwise, the server invokes the plugin to authenticate the user, and the plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:

- **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.

- **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.

- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see Section 6.2.18, “Proxy Users”. 
Pluggable Authentication

Note
If you start the server with the --skip-grant-tables option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, if the server is started with the --skip-grant-tables option, it enables --skip-networking automatically to prevent remote connections.

- Available Authentication Plugins
- Authentication Plugin Usage
- Authentication Plugin Client/Server Compatibility
- Authentication Plugin Connector-Writing Considerations

Available Authentication Plugins

MySQL 8.0 provides these authentication plugins:

- A plugin that performs native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication in MySQL. The mysql_native_password plugin implements authentication based on this native password hashing method. See Section 6.4.1.1, “Native Pluggable Authentication”.

- Plugins that perform authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”.

- A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See Section 6.4.1.5, “PAM Pluggable Authentication”.

- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See Section 6.4.1.6, “Windows Pluggable Authentication”.

- Plugins that perform authentication using LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. These plugins support proxy users as well. See Section 6.4.1.7, “LDAP Pluggable Authentication”.

- A plugin that prevents all client connections to any account that uses it. Use cases for this plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users. See Section 6.4.1.8, “No-Login Pluggable Authentication”.

- A plugin that authenticates clients that connect from the local host through the Unix socket file. See Section 6.4.1.9, “Socket Peer-Credential Pluggable Authentication”.

- A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See Section 6.4.1.10, “Test Pluggable Authentication”.

1129
Note

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see Section C.9, “Restrictions on Pluggable Authentication”.

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see Section 29.2.4.9, “Writing Authentication Plugins”.

Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under Section 6.4.1, “Authentication Plugins”.

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

- If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.

- For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The `default_authentication_plugin` system variable configures the default authentication plugin.

- When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.

In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided.

For standard MySQL clients such as `mysql` and `mysqladmin`, the `--default-auth=plugin_name` option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server will override this if the server-side plugin associated with the user account requires a different client-side plugin.

If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

Authentication Plugin Client/Server Compatibility

Pluggable authentication enables flexibility in the choice of authentication methods for MySQL accounts, but in some cases client connections cannot be established due to authentication plugin incompatibility between the client and server.

The general compatibility principle for a successful client connection to a given account on a given server is that the client and server both must support the authentication method required by the account. Because authentication methods are implemented by authentication plugins, the client and server both must support the authentication plugin required by the account.
Authentication plugin incompatibilities can arise in various ways. Examples:

- Connect using a MySQL 5.7 client from 5.7.22 or lower to a MySQL 8.0 server account that authenticates with `caching_sha2_password`. This fails because the 5.7 client does not recognize the plugin, which was introduced in MySQL 8.0. (This issue is addressed in MySQL 5.7 as of 5.7.23, when `caching_sha2_password` client-side support was added to the MySQL client library and client programs.)

- Connect using a MySQL 5.5 client to a MySQL 5.6 server account that authenticates with `sha256_password`. This fails because the 5.5 client does not recognize the plugin, which was introduced in MySQL 5.6.

- Connect using a MySQL 5.7 client to a pre-5.7 server account that authenticates with `mysql_old_password`. This fails for multiple reasons. First, such a connection requires `--secure-auth=0`, which is no longer a supported option. Even were it supported, the 5.7 client does not recognize the plugin because it was removed in MySQL 5.7.

- Connect using a MySQL 5.7 client from a Community distribution to a MySQL 5.7 Enterprise server account that authenticates using one of the Enterprise-only LDAP authentication plugins. This fails because the Community client does not have access to the Enterprise plugin.

In general, these compatibility issues do not arise when connections are made between a client and server from the same MySQL distribution. When connections are made between a client and server from different MySQL series, issues can arise. These issues are inherent in the development process when MySQL introduces new authentication plugins or removes old ones. To minimize the potential for incompatibilities, regularly upgrade the server, clients, and connectors on a timely basis.

**Authentication Plugin Connector-Writing Considerations**

Various implementations of the MySQL client/server protocol exist. The `libmysqlclient` C API client library is one implementation. Some MySQL connectors (typically those not written in C) provide their own implementation. However, not all protocol implementations handle plugin authentication the same way. This section describes an authentication issue that protocol implementors should take into account.

In the client/server protocol, the server tells connecting clients which authentication plugin it considers the default. If the protocol implementation used by the client tries to load the default plugin and that plugin does not exist on the client side, the load operation fails. This is an unnecessary failure if the default plugin is not the plugin actually required by the account to which the client is trying to connect.

If a client/server protocol implementation does not have its own notion of default authentication plugin and always tries to load the default plugin specified by the server, it will fail with an error if that plugin is not available.

To avoid this problem, the protocol implementation used by the client should have its own default plugin and should use it as its first choice (or, alternatively, fall back to this default in case of failure to load the default plugin specified by the server). Example:

- In MySQL 5.7, `libmysqlclient` uses as its default choice either `mysql_native_password` or the plugin specified through the `MYSQL_DEFAULT_AUTH` option for `mysql_options()`.

- When a 5.7 client tries to connect to an 8.0 server, the server specifies `caching_sha2_password` as its default authentication plugin, but the client still sends credential details per either `mysql_native_password` or whatever is specified through `MYSQL_DEFAULT_AUTH`.

- The only time the client loads the plugin specified by the server is for a change-plugin request, but in that case it can be any plugin depending on the user account. In this case, the client must try to load the plugin, and if that plugin is not available, an error is not optional.
Proxy Users

6.2.18 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see Section 6.2.17, “Pluggable Authentication”. For information about specific plugins, see Section 6.4.1, “Authentication Plugins”. For information about writing authentication plugins that support proxy users, see Implementing Proxy User Support in Authentication Plugins.

- Requirements for Proxy User Support
- Granting and Revoking the PROXY Privilege
- Default Proxy Users
- Default Proxy User and Anonymous User Conflicts
- Server Support for Proxy User Mapping
- Proxy User System Variables

**Note**

As an alternative to proxy users, you may find that roles provide a suitable way to map users onto specific sets of named privileges. See Section 6.2.10, “Using Roles”.

### Requirements for Proxy User Support

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- Proxying must be supported, either by the plugin itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see Server Support for Proxy User Mapping.

- The account for the external proxy user must be set up to be authenticated by the plugin. Use the CREATE_USER statement to associate an account with an authentication plugin, or ALTER_USER to change its plugin.

- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the CREATE_USER and GRANT statements for this.

- The proxy user account must have the PROXY privilege for the proxied account. Use the GRANT statement for this.

- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.
Alternatively, for plugins that are provided proxy mapping by the server, the proxied user is determined from the PROXY privilege held by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

• When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.

• If that account is a proxy account, the server attempts to find a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

Consider the following account definitions:

```
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
  IDENTIFIED WITH my_auth_plugin
  AS 'my_auth_string';

-- create proxied account and grant its privileges
CREATE USER 'employee'@'localhost'
  IDENTIFIED BY 'employee_password';
GRANT ALL
  ON employees.*
  TO 'employee'@'localhost';

-- grant PROXY privilege to proxy account for proxied account
GRANT PROXY
  ON 'employee'@'localhost'
  TO 'employee_ext'@'localhost';
```

When a client connects as employee_ext from the local host, MySQL uses the plugin named my_auth_plugin to perform authentication. Suppose that my_auth_plugin returns a user name of employee to the server, based on the content of 'my_auth_string' and perhaps by consulting some external authentication system. The name employee differs from employee_ext, so returning employee serves as a request to the server to treat the employee_ext external user, for purposes of privilege checking, as the employee local user.

In this case, employee_ext is the proxy user and employee is the proxied user.

The server verifies that proxy authentication for employee is possible for the employee_ext user by checking whether employee_ext (the proxy user) has the PROXY privilege for employee (the proxied user). If this privilege has not been granted, an error occurs. Otherwise, employee_ext assumes the privileges of employee. The server checks statements executed during the client session by employee_ext against the privileges granted to employee. In this case, employee_ext can access tables in the employees database.

When proxying occurs, the USER() and CURRENT_USER() functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------------+--------------------+
| USER()                 | CURRENT_USER()     |
|------------------------+--------------------+
| employee_ext@localhost | employee@localhost |
+------------------------+--------------------+
```
In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

### Granting and Revoking the PROXY Privilege

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

The statement creates a row in the `mysql.proxies_priv` grant table.

At connect time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. Examples:

- Grant `PROXY` to multiple accounts:
  ```
  GRANT PROXY ON 'a' TO 'b', 'c', 'd';
  ```

- Revoke `PROXY` from multiple accounts:
  ```
  REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';
  ```

- Grant `PROXY` to account and enable account to grant `PROXY` to proxied account:
  ```
  GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;
  ```

- Grant `PROXY` to anonymous account:
  ```
  GRANT PROXY ON 'a' TO '@';
  ```

The `PROXY` privilege can be granted in these cases:

- **By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.**

- **By `proxied_user` for itself:** The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial `root` account created during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for `''@''`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost'
  IDENTIFIED BY 'test';
GRANT PROXY
  ON ''@''
  TO 'admin'@'localhost'
  WITH GRANT OPTION;
```
Those statements create an admin user that can manage all GRANT PROXY mappings. For example, admin can do this:

```sql
GRANT PROXY ON sally TO joe;
```

### Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account ("@"), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). For example, suppose that there exists a plugin named ldap_auth that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```sql
-- create default proxy account
CREATE USER '0' IDENTIFIED WITH ldap_auth
  AS 'O=Oracle, OU=MySQL';

-- create proxied accounts
CREATE USER 'developer'@'localhost'
  IDENTIFIED BY 'developer_password';
CREATE USER 'manager'@'localhost'
  IDENTIFIED BY 'manager_password';

-- grant PROXY privilege to default proxy account for proxied accounts
GRANT PROXY
  ON 'manager'@'localhost'
  TO '0';
GRANT PROXY
  ON 'developer'@'localhost'
  TO '0';
```

Now assume that a client connects as follows:

```shell
shell> mysql --user=myuser --password ...
Enter password: myuser_password
```

The server will not find myuser defined as a MySQL user. But because there is a blank user account ("@") that matches the client user name and host name, the server authenticates the client against that account: The server invokes the ldap_auth authentication plugin and passes myuser and myuser_password to it as the user name and password.

If the ldap_auth plugin finds in the LDAP directory that myuser_password is not the correct password for myuser, authentication fails and the server rejects the connection.

If the password is correct and ldap_auth finds that myuser is a developer, it returns the user name developer to the MySQL server, rather than myuser. Returning a user name different from the client user name of myuser signals to the server that it should treat myuser as a proxy. The server verifies that "@" can authenticate as developer (because that account has the PROXY privilege to do so) and accepts the connection. The session proceeds with myuser having the privileges of developer, the proxied user. (These privileges should be set up by the DBA using GRANT statements, not shown.) The USER() and CURRENT_USER() functions return these values:

```sql
mysql> SELECT USER(), CURRENT_USER();
+------------------+---------------------+
| USER()           | CURRENT_USER()      |
+------------------+---------------------+
| myuser@localhost | developer@localhost |
```
Proxy Users

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of `manager`.

```
mysql> SELECT USER(), CURRENT_USER();
+-----------------+-------------------+
| USER()          | CURRENT_USER()    |
+-----------------+-------------------+
| myuser@localhost | manager@localhost |
+-----------------+-------------------+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the `developer` or `manager` account, which is why those proxied accounts should be assigned passwords.

Other ways to ensure that the proxied accounts cannot be used directly:

- Include the `ACCOUNT LOCK` option when you create the accounts. See Section 13.7.1.3, “CREATE USER Syntax”.
- Associate the accounts with the `mysql_no_login` authentication plugin. See Section 6.4.1.8, “No-Login Pluggable Authentication”.

Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user because they can prevent that user from working as intended.

In the preceding discussion, the default proxy user account has `'` in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and `%` in the host part, because `%` also matches any host, but has precedence over `'` by the rules that the server uses to sort account rows internally (see Section 6.2.6, “Access Control, Stage 1: Connection Verification”).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy account
CREATE USER ''@''
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
-- create anonymous account
CREATE USER ''@%''
  IDENTIFIED BY 'some_password';
```

The first account (`''@'''`) is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account (`''@%'''`) is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (`'''`), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of `%` ahead of `'`. For accounts that do not match any more-specific account, the server attempts to authenticate them against `'@%'''` (the anonymous user) rather than `'@'''` (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:
Proxy Users

- Remove the anonymous account so that it does not conflict with the default proxy user. This might be a good idea anyway if you want to associate every connection with a named user.

- Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only `localhost` proxy connections, use `'@localhost'`:

  ```sql
  CREATE USER ''@'localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
  ```

  In addition, modify any `GRANT PROXY` statements to name `'@localhost'` rather than `'@'` as the proxy user.

  Be aware that this strategy prevents anonymous-user connections from `localhost`.

- Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the `authentication_windows` plugin. See Section 6.4.1.6, “Windows Pluggable Authentication”

- Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

  Create the proxy users:

  ```sql
  -- create proxy user for local connections
  CREATE USER ''@'localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
  -- create proxy user for remote connections
  CREATE USER ''@'%'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
  ```

  Create the proxied users:

  ```sql
  -- create proxied user for local connections
  CREATE USER 'developer'@'localhost'
  IDENTIFIED BY 'some_password';
  -- create proxied user for remote connections
  CREATE USER 'developer'@'%'
  IDENTIFIED BY 'some_password';
  ```

  Grant the proxy privilege to each proxy user for the corresponding proxied user:

  ```sql
  GRANT PROXY
  ON 'developer'@'localhost'
  TO ''@'localhost';
  GRANT PROXY
  ON 'developer'@'%'
  TO ''@'%';
  ```

  Finally, grant appropriate privileges to the local and remote proxied users (not shown).

  Assume that the `some_plugin/'some_auth_string'` combination causes `some_plugin` to map the client user name to `developer`. Local connections match the `'@localhost'` proxy user, which maps to the `'developer'@'localhost'` proxied user. Remote connections match the `'@%'` proxy user, which maps to the `'developer'@'%'` proxied user.
Server Support for Proxy User Mapping

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`. If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request:

- By default, `check_proxy_users` is disabled, so the server performs no proxy user mapping even for authentication plugins that request server support for proxy users.
- If `check_proxy_users` is enabled, it may also be necessary to enable a plugin-specific system variable to take advantage of server proxy user mapping support:
  - For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
  - For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

Proxy user mapping performed by the server is subject to these restrictions:

- The server will not proxy to or from an anonymous user, even if the associated `PROXY` privilege is granted.
- When a single account has been granted proxy privileges for more than one proxied account, server proxy user mapping is nondeterministic. Therefore, granting to a single account proxy privileges for multiple proxied accounts is discouraged.

Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user`: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `''@''` proxy account, this variable is set as follows:

```sql
mysql> SELECT @@proxy_user;
+--------------+
| @@proxy_user |
+--------------+
| ''@''        |
```

- `external_user`: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

6.2.19 Account Locking

MySQL supports locking and unlocking user accounts using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` clauses for the `CREATE USER` and `ALTER USER` statements:

- When used with `CREATE USER`, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.
Setting Account Resource Limits

• When used with ALTER USER, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.

Account locking state is recorded in the account_locked column of the mysql.user system table. The output from SHOW CREATE USER indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the Locked_connects status variable that indicates the number of attempts to connect to a locked account, returns an ER_ACCOUNT_HAS_BEEN_LOCKED error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a DEFINER clause naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the account_locked column in the mysql.user system table. For upgrades from MySQL versions older than 5.7.6, perform the MySQL upgrade procedure to ensure that this column exists. See Section 2.11, “Upgrading MySQL”. For nonupgraded installations that have no account_locked column, the server treats all accounts as unlocked, and using the ACCOUNT LOCK or ACCOUNT UNLOCK clauses produces an error.

### 6.2.20 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global max_user_connections system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting max_user_connections does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

• The number of queries an account can issue per hour
• The number of updates an account can issue per hour
• The number of times an account can connect to the server per hour
• The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the mysql.user system table. That is, a connection is assessed against the User and Host values in the user table row that applies to the connection. For example, an account 'usera'@'%.example.com' corresponds to a row in the user table that has User and Host values of usera and '%.example.com', to permit usera to connect from any host in the example.com domain. In this case, the server applies resource limits in this row collectively to all connections by usera from any host in the example.com domain because all such connections use the same account.

Before MySQL 5.0, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the --old-style-user-limits option. In this case, if usera connects simultaneously from host1.example.com and host2.example.com, the server applies the account resource limits separately to each connection.
If usera connects again from host1.example.com, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account at account-creation time, use the `CREATE USER` statement. To modify the limits for an existing account, use `ALTER USER`. Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
    -> WITH MAX_QUERIES_PER_HOUR 20
    -> MAX_UPDATES_PER_HOUR 10
    -> MAX_CONNECTIONS_PER_HOUR 5
    -> MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use an `ALTER USER` statement. The following statement changes the query limit for francis to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour francis can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

user1 has a connection limit of 10 (the global `max_user_connections` value) because it has a `MAX_USER_CONNECTIONS` limit of zero. user2 and user3 have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See Section 6.2.3, "Grant Tables".)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the
Troubleshooting Problems Connecting to MySQL

account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

• To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).

• The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

6.2.21 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

• Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

  ```
  shell> mysql
  ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
  shell> mysql
  ERROR 2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (111)
  ```

• It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

  ```
  shell> netstat -ln | grep mysql
  ```

• Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
Troubleshooting Problems Connecting to MySQL

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the MySQL data directory, including the `mysql` system database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see Section 2.10, “Postinstallation Setup and Testing”.

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, initialize the data directory. After doing so and starting the server, you should be able to connect to the server.

- After a fresh installation, if you try to log on to the server as `root` without using a password, you might get the following error message.

  ```
  shell> mysql -u root
  ERROR 1045 (28000): Access denied for user 'root'@'localhost' (using password: NO)
  ```

  It means a root password has already been assigned during installation and it has to be supplied. See Section 2.10.4, “Securing the Initial MySQL Account” on the different ways the password could have been assigned and, in some cases, how to find it. If you need to reset the root password, see instructions in Section B.4.3.2, “How to Reset the Root Password”. After you have found or reset your password, log on again as `root` using the `--password` (or `-p`) option:

  ```
  shell> mysql -u root -p
  Enter password:
  ```

  However, the server is going to let you connect as `root` without using a password if you have initialized MySQL using `mysqld --initialize-insecure` (see Section 2.10.1, “Initializing the Data Directory” for details). That is a security risk, so you should set a password for the `root` account; see Section 2.10.4, “Securing the Initial MySQL Account” for instructions.

- If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 2.11, “Upgrading MySQL”.

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

  ```
  shell> mysql
  Client does not support authentication protocol requested by server; consider upgrading MySQL client
  ```

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!
You can suppress the use of option files by a client program by invoking it with the --no-defaults option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Section 4.2.2.2, “Using Option Files”. Environment variables are listed in Section 4.9, “MySQL Environment Variables”.

- If you get the following error, it means that you are using an incorrect root password:

```
shell> mysqladmin -u root -p xxxx
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the --no-defaults option as described in the previous item.

For information on changing passwords, see Section 6.2.14, “Assigning Account Passwords”.

If you have lost or forgotten the root password, see Section B.4.3.2, “How to Reset the Root Password”.

- localhost is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a --host=127.0.0.1 option to name the server host explicitly. This will make a TCP/IP connection to the local mysqld server. You can also use TCP/IP by specifying a --host option that uses the actual host name of the local host. In this case, the host name must be specified in a user table row on the server host, even though you are running the client program on the same host as the server.

- The Access denied error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the user table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains using password: NO, it means that you tried to log in without a password.

- If you get an Access denied error when trying to connect to the database with mysql -u user_name, you may have a problem with the user table. Check this by executing mysql -u root mysql and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the Host and User columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the user table with a Host value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.
Troubleshooting Problems Connecting to MySQL

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with '% ' as the Host column value in the user table. After trying to connect from the client machine, use a SELECT USER() query to see how you really did connect. Then change the '% ' in the user table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the glibc library than the one you are using. In this case, you should either upgrade your operating system or glibc, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

  ```shell
  mysqladmin -u root -pxxxxx -h some_hostname ver
  Access denied for user 'root'@'' (using password: YES)
  ```

  If you try to connect as root and get the following error, it means that you do not have a row in the user table with a User column value of 'root' and that mysqld cannot resolve the host name for your client:

  ```sql
  Access denied for user ''@'unknown'
  ```

  These errors indicate a DNS problem. To fix it, execute mysqladmin flush-hosts to reset the internal DNS host cache. See Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”.

  Some permanent solutions are:
  - Determine what is wrong with your DNS server and fix it.
  - Specify IP addresses rather than host names in the MySQL grant tables.
  - Put an entry for the client machine name in /etc/hosts on Unix or \windows\hosts on Windows.
  - Start mysqld with the --skip-name-resolve option.
  - Start mysqld with the --skip-host-cache option.
  - On Unix, if you are running the server and the client on the same machine, connect to localhost. For connections to localhost, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.
  - On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name . (period). Connections to . use a named pipe rather than TCP/IP.
  - If mysql -u root works but mysql -h your_hostname -u root results in Access denied (where your_hostname is the actual host name of the local host), you may not have the correct name for your host in the user table. A common problem here is that the Host value in the user table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host 'pluto' in the...
Troubleshooting Problems Connecting to MySQL

user table, but your DNS tells MySQL that your host name is 'pluto.example.com', the row does not work. Try adding a row to the user table that contains the IP address of your host as the Host column value. (Alternatively, you could add a row to the user table with a Host value that contains a wildcard (for example, 'pluto.%'). However, use of Host values ending with % is insecure and is not recommended!)

• If mysql -u user_name works but mysql -u user_name some_db does not, you have not granted access to the given user for the database named some_db.

• If mysql -u user_name works when executed on the server host, but mysql -h host_name -u user_name does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

• If you cannot figure out why you get Access denied, remove from the user table all rows that have Host values containing wildcards (rows that contain '%' or '_' characters). A very common error is to insert a new row with Host='%' and User='some_user', thinking that this enables you to specify localhost to connect from the same machine. The reason that this does not work is that the default privileges include a row with Host='localhost' and User=''. Because that row has a Host value 'localhost' that is more specific than '%', it is used in preference to the new row when connecting from localhost! The correct procedure is to insert a second row with Host='localhost' and User='some_user', or to delete the row with Host='localhost' and User=''. After deleting the row, remember to issue a FLUSH_PRIVILEGES statement to reload the grant tables. See also Section 6.2.6, “Access Control, Stage 1: Connection Verification”.

• If you are able to connect to the MySQL server, but get an Access denied message whenever you issue a SELECT ... INTO OUTFILE or LOAD DATA statement, your row in the user table does not have the FILE privilege enabled.

• If you change the grant tables directly (for example, by using INSERT, UPDATE, or DELETE statements) and your changes seem to be ignored, remember that you must execute a FLUSH_PRIVILEGES statement or a mysqladmin flush-privileges command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the root password with an UPDATE statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!

• If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 6.2.13, “When Privilege Changes Take Effect”.

• If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with mysql -u user_name db_name or mysql -u user_name -p password db_name. If you are able to connect using the mysql client, the problem lies with your program, not with the access privileges. (There is no space between -p and the password; you can also use the --password=password syntax to specify the password. If you use the -p or --password option with no password value, MySQL prompts you for the password.)

• For testing purposes, start the mysqld server with the --skip-grant-tables option. Then you can change the MySQL grant tables and use the SHOW GRANTS statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute mysqladmin flush-privileges to tell the mysqld server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

• If everything else fails, start the mysqld server with a debugging option (for example, --debug=d,general,query). This prints host and user information about attempted connections, as well as information about each command issued. See Section 29.5.4, “The DBUG Package”.  

1145
If you have any other problems with the MySQL grant tables and ask on the MySQL Community Slack, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.7, "How to Report Bugs or Problems". In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

### 6.2.22 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based on the client’s account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `''@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----------------+----------------+
| USER()          | CURRENT_USER() |
+-----------------+----------------+
| user1@localhost | @localhost     |
+-----------------+----------------+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'_` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:
Using Encrypted Connections

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```sql
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```sql
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+---------------------------------------+
| user1                                 |
+---------------------------------------+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+----------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+----------------------------------------+
| localhost                              |
+----------------------------------------+
```

6.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.
X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner’s public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

MySQL can be compiled for encrypted-connection support using OpenSSL or wolfSSL. For a comparison of the packages, see Section 6.3.3, “SSL Library-Dependent Capabilities” For information about the encryption protocols and ciphers each package supports, see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

By default, MySQL programs attempt to connect using encryption if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. For information about options that affect use of encrypted connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections” and Command Options for Encrypted Connections.

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the REQUIRE clause of the CREATE USER statement in Section 13.7.1.3, “CREATE USER Syntax”. See also the description of the require_secure_transport system variable at Section 5.1.8, “Server System Variables”.

Encrypted connections can be used between master and slave replication servers. See Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”.

For information about using encrypted connections from the MySQL C API, see Section 28.7.22, “C API Encrypted Connection Support”.

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see Section 6.3.6, “Connecting to MySQL Remotely from Windows with SSH”.

### 6.3.1 Configuring MySQL to Use Encrypted Connections

Several options are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- **Server-Side Startup Configuration for Encrypted Connections**
- **Server-Side Runtime Configuration for Encrypted Connections**
- **Client-Side Configuration for Encrypted Connections**
- **Configuring Encrypted Connections as Mandatory**

For a complete list of options related to establishment of encrypted connections, see Command Options for Encrypted Connections. Instructions for creating any required certificate and key files are available in Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.

Encrypted connections also can be used in these contexts:

- Between master and slave replication servers. See Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”.
- Among Group Replication servers. See Section 18.5.2, “Group Replication Secure Socket Layer (SSL) Support”.
• By client programs that are based on the MySQL C API. See Section 28.7.22, “C API Encrypted Connection Support”.

Server-Side Startup Configuration for Encrypted Connections

On the server side, the --ssl option specifies that the server permits but does not require encrypted connections. This option is enabled by default, so it need not be specified explicitly.

To require that clients connect using encrypted connections, enable the require_secure_transport system variable. See Configuring Encrypted Connections as Mandatory.

These options on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

• --ssl-ca: The path name of the Certificate Authority (CA) certificate file. (--ssl-capath is similar but specifies the path name of a directory of CA certificate files.)

• --ssl-cert: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.

• --ssl-key: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl-ca=ca.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

To specify in addition that clients are required to use encrypted connections, enable the require_secure_transport system variable:

```
[mysqld]
ssl-ca=ca.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
require_secure_transport=ON
```

Each certificate and key option names a file in PEM format. Should you need to create the required certificate and key files, see Section 6.3.2, “Creating SSL and RSA Certificates and Keys”. MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”. Alternatively, if you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its mysql-test/std_data directory.

The server performs certificate and key file autodiscovery. If --ssl is enabled (possibly along with --ssl-cipher) and other --ssl-xxx options are not given to configure encrypted connections explicitly, the server attempts to enable encrypted connection support automatically at startup:

• If the server discovers valid certificate and key files named ca.pem, server-cert.pem, and server-key.pem in the data directory, it enables support for encrypted connections by clients. (The files need not have been generated automatically; what matters is that they have those names and are valid.)

• If the server does not find valid certificate and key files in the data directory, it continues executing but without support for encrypted connections.
If the server automatically enables encrypted connection support, it writes a note to the error log. If the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server or manually using `mysql_ssl_rsa_setup`.)

MySQL also provides these options for server-side SSL control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)

The values of the `--ssl-xxx` options set the values of the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`, and so forth).

To explicitly specify which encryption protocols and ciphersuites the server permits for encrypted connections, use the `tls_version` and `tls_ciphersuites` system variables; see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”. For example, you can set `tls_version` to prevent clients from using less-secure protocols.

Server-Side Runtime Configuration for Encrypted Connections

Certain encryption-related system variables can be set at runtime: `require_secure_transport`, and (as of MySQL 8.0.16) `tls_version` and `tls_ciphersuites`. If changed with `SET GLOBAL`, the new values apply to connections established subsequent to the change, and apply only until server restart. If changed with `SET PERSIST`, the new values also apply to subsequent server restarts. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

In addition, as of MySQL 8.0.16, the SSL context the server uses for new connections is reconfigurable at runtime. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired.

The server creates the initial SSL context from the values that the context-related system variables have at startup. It also initializes a set of context-related status variables to indicate the values used in the context. The following table shows the system variables that define the SSL context and the corresponding status variables that indicate the currently active context values.

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>Status Variable Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl_ca</td>
<td>Current_tls_ca</td>
</tr>
<tr>
<td>ssl_capath</td>
<td>Current_tls_capath</td>
</tr>
<tr>
<td>ssl_cert</td>
<td>Current_tls_cert</td>
</tr>
<tr>
<td>ssl_cipher</td>
<td>Current_tls_cipher</td>
</tr>
<tr>
<td>ssl_crl</td>
<td>Current_tls_crl</td>
</tr>
<tr>
<td>ssl_crlpath</td>
<td>Current_tls_crlpath</td>
</tr>
<tr>
<td>ssl_key</td>
<td>Current_tls_key</td>
</tr>
<tr>
<td>tls_ciphersuites</td>
<td>Current_tls_ciphersuites</td>
</tr>
<tr>
<td>tls_version</td>
<td>Current_tls_version</td>
</tr>
</tbody>
</table>

To reconfigure the SSL context at runtime, use this procedure:

1. Set any SSL context-related system variables that should be changed to their new values.
2. Execute `ALTER INSTANCE RELOAD TLS`. This statement reconfigures the active SSL context from the current values of the SSL context-related system variables. It also sets the context-related status variables to reflect the new active context values. The statement requires the `CONNECTION_ADMIN` privilege.

3. New connections established after execution of `ALTER INSTANCE RELOAD TLS` use the new SSL context. Existing connections remain unaffected. If existing connections should be terminated, use the `KILL` statement.

The members of each pair of system and status variables may have different values temporarily due to the way the reconfiguration procedure works:

- Changes to the system variables prior to `ALTER INSTANCE RELOAD TLS` do not change the SSL context. At this point, those changes have no effect on new connections, and corresponding context-related system and status variables may have different values. This enables you to make any changes required to the system variables, then update the active SSL context atomically with `ALTER INSTANCE RELOAD TLS` after all system variable changes have been made.

- After `ALTER INSTANCE RELOAD TLS`, corresponding system and status variables have the same values. This remains true until the next change to the system variables.

In some cases, `ALTER INSTANCE RELOAD TLS` by itself may suffice to reconfigure the SSL context, without changing any system variables. Suppose that the certificate in the file named by `ssl_cert` has expired. It is sufficient to replace the existing file contents with a nonexpired certificate and execute `ALTER INSTANCE RELOAD TLS` to cause the new file contents to be read and used for new connections.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of a new SSL context. The previous context values continue to be used for new connections.

If the optional `NO ROLLBACK ON ERROR` clause is given and a new context cannot be created, rollback does not occur. Instead, a warning is generated and SSL is disabled for new connections.

The server-side `--ssl` option has an effect only at server startup on whether the server accepts SSL connections. It is ignored by, and has no effect on the operation of, `ALTER INSTANCE RELOAD TLS`. For example, you can use `--ssl=0` to start the server with SSL connections disabled, then reconfigure SSL and execute `ALTER INSTANCE RELOAD TLS` to enable SSL connections at runtime.

`ALTER INSTANCE RELOAD TLS` changes only the SSL context the server itself uses for new connections. It does not affect the SSL context used by other enabled server plugins or components such as X Plugin or Group Replication.

**Note**

Prior to MySQL 8.0.16, the SSL context-related system variables are not dynamic. They can be set at server startup, but cannot be changed thereafter. These system variables therefore determine the SSL context values the server uses for all new connections.

### Client-Side Configuration for Encrypted Connections

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the `--ssl-mode` option:

- In the absence of an `--ssl-mode` option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established. This is also the behavior with an explicit `--ssl-mode=PREFFERED` option.
Configuring MySQL to Use Encrypted Connections

- With `--ssl-mode=REQUIRED`, clients require an encrypted connection and fail if one cannot be established.
- With `--ssl-mode=DISABLED`, clients use an unencrypted connection.
- With `--ssl-mode=VERIFY_CA` or `--ssl-mode=VERIFY_IDENTITY`, clients require an encrypted connection, and also perform verification against the server CA certificate and (with `VERIFY_IDENTITY`) against the server host name in its certificate.

Attempts to establish an unencrypted connection fail if the `require_secure_transport` system variable is enabled on the server side to cause the server to require encrypted connections. See Configuring Encrypted Connections as Mandatory.

The following options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the options used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`), and specify `--ssl-mode=VERIFY_CA`.
- To enable host name identity verification as well, use `--ssl-mode=VERIFY_IDENTITY` rather than `--ssl-mode=VERIFY_CA`.

### Note

Host name identity verification with `VERIFY_IDENTITY` does not work with self-signed certificates that are created automatically by the server or manually using `mysql_ssl_rsa_setup` (see Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”). Such self-signed certificates do not contain the server name as the Common Name value.

Host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.

MySQL also provides these options for client-side SSL control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `--tls-version,--tls-ciphersuites`: The permitted encryption protocols and ciphersuites; see Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.
Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `CREATE USER` statement that included the `REQUIRE SSL` clause. Assuming that the server supports encrypted connections, a client can connect using encryption with no `--ssl-mode` option or with an explicit `--ssl-mode=PREFERRED` option:

```plaintext
mysql
```

Or:

```plaintext
mysql --ssl-mode=PREFERRED
```

For an account created with a `REQUIRE SSL` clause, the connection attempt fails if an encrypted connection cannot be established. For an account with no special encryption requirements, the attempt falls back to an unencrypted connection if an encrypted connection cannot be established. To prevent fallback and fail if an encrypted connection cannot be obtained, connect like this:

```plaintext
mysql --ssl-mode=REQUIRED
```

If the account has more stringent security requirements, other options must be specified to establish an encrypted connection:

- For accounts created with a `REQUIRE X509` clause, clients must specify at least `--ssl-cert` and `--ssl-key`. In addition, `--ssl-ca` (or `--ssl-capath`) is recommended so that the public certificate provided by the server can be verified. For example:

```plaintext
mysql --ssl-ca=ca.pem
     --ssl-cert=client-cert.pem
     --ssl-key=client-key.pem
```

- For accounts created with a `REQUIRE ISSUER` or `REQUIRE SUBJECT` clause, the encryption requirements are the same as for `REQUIRE X509`, but the certificate must match the issue or subject, respectively, specified in the account definition.

For additional information about the `REQUIRE` clause, see Section 13.7.1.3, “CREATE USER Syntax”.

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl-mode=DISABLED`:

```plaintext
mysql --ssl-mode=DISABLED
```

To determine whether the current connection with the server uses encryption, check the session value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```plaintext
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-------------------+---------------------------+
| Variable_name     | Value                     |
+-------------------+---------------------------+
| Ssl_cipher        | DHE-RSA-AES128-GCM-SHA256 |
+-------------------+---------------------------+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:
Configuring MySQL to Use Encrypted Connections

```
mysql> \s
...  
SSL: Not in use  
...
```

Or:

```
mysql> \s
...  
SSL: Cipher in use is DHE-RSA-AES128-GCM-SHA256  
...  
```

Configuring Encrypted Connections as Mandatory

For some MySQL deployments it may be not only desirable but mandatory to use encrypted connections (for example, to satisfy regulatory requirements). This section discusses configuration settings that enable you to do this. These levels of control are available:

- You can configure the server to require the clients connect using encrypted connections.
- You can invoke individual client programs to require an encrypted connection, even if the server permits but does not require encryption.
- You can configure individual MySQL accounts to be usable only over encrypted connections.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
require_secure_transport=ON
```

Alternatively, to set and persist the value at runtime, use this statement:

```
SET PERSIST require_secure_transport=ON;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. See Section 13.7.5.1, "SET Syntax for Variable Assignment".

With `require_secure_transport` enabled, client connections to the server are required to use some form of secure transport, and the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

To invoke a client program such that it requires an encrypted connection whether or not the server requires encryption, use an `--ssl-mode` option value of `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`. For example:

```
mysql --ssl-mode=REQUIRED
mysqldump --ssl-mode=VERIFY_CA
mysqladmin --ssl-mode=VERIFY_IDENTITY
```

To configure a MySQL account to be usable only over encrypted connections, include a `REQUIRE` clause in the `CREATE USER` statement that creates the account, specifying in that clause the encryption characteristics you require. For example, to require an encrypted connection and the use of a valid X.509 certificate, use `REQUIRE X509`:

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```
For additional information about the `REQUIRE` clause, see Section 13.7.1.3, “CREATE USER Syntax”.

To modify existing accounts that have no encryption requirements, use the `ALTER_USER` statement.

### 6.3.2 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the `openssl` command directly.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` or `caching_sha2_password` plugin. See Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

#### 6.3.2.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides these ways to create the SSL certificate and key files and RSA key-pair files required to support encrypted connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup, for MySQL distributions compiled using OpenSSL.
- Users can invoke the `mysql_ssl_rsa_setup` utility manually.
- For some distribution types, such as RPM packages, `mysql_ssl_rsa_setup` invocation occurs during data directory initialization. In this case, the MySQL distribution need not have been compiled using OpenSSL as long as the `openssl` command is available.

**Important**

Server autogeneration and `mysql_ssl_rsa_setup` help lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by these methods are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

- Automatic SSL and RSA File Generation
- Manual SSL and RSA File Generation Using `mysql_ssl_rsa_setup`
- SSL and RSA File Characteristics

#### Automatic SSL and RSA File Generation

For MySQL distributions compiled using OpenSSL, the MySQL server has the capability of automatically generating missing SSL and RSA files at startup. The `auto_generate_certs`, `sha256_password_auto_generate_rsa_keys`, and `caching_sha2_password_auto_generate_rsa_keys` system variables control automatic generation of these files. These variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files
enable encrypted client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

1. The server checks the data directory for SSL files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>Self-signed CA certificate</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
</tbody>
</table>

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>ca-key.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>Client certificate</td>
</tr>
<tr>
<td>client-key.pem</td>
<td>Client private key</td>
</tr>
</tbody>
</table>

3. If the server autogenerates SSL files, it uses the names of the ca.pem, server-cert.pem, and server-key.pem files to set the corresponding system variables (ssl_ca, ssl_cert, ssl_key).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The sha256_password_auto_generate_rsa_keys or caching_sha2_password_auto_generate_rsa_keys system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the sha256_password or caching_sha2_password plugin; see Section 6.4.1.2, “SHA-256 Pluggable Authentication”, and Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

1. The server checks the data directory for RSA files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>private_key.pem</td>
<td>Private member of private/public key pair</td>
</tr>
<tr>
<td>public_key.pem</td>
<td>Public member of private/public key pair</td>
</tr>
</tbody>
</table>

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.

3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (sha256_password_private_key_path and sha256_password_public_key_path; caching_sha2_password_private_key_path and caching_sha2_password_public_key_path).

Manual SSL and RSA File Generation Using mysql_ssl_rsa_setup

MySQL distributions include a mysql_ssl_rsa_setup utility that can be invoked manually to generate SSL and RSA files. This utility is included with all MySQL distributions (whether compiled using OpenSSL or wolfSSL), but it does require that the openssl command be available. For usage instructions, see Section 4.4.3, “mysql_ssl_rsa_setup — Create SSL/RSA Files”.

SSL and RSA File Characteristics

SSL and RSA files created automatically by the server or by invoking mysql_ssl_rsa_setup have these characteristics:

- SSL and RSA keys are have a size of 2048 bits.
- The SSL CA certificate is self signed.
Creating SSL and RSA Certificates and Keys

• The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.

• SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

  ca.pem: MySQL_Server_suffix_Auto_Generated_CA_Certificate
  server-cert.pem: MySQL_Server_suffix_Auto_Generated_Server_Certificate
  client-cert.pem: MySQL_Server_suffix_Auto_Generated_Client_Certificate

  The `suffix` value is based on the MySQL version number. For files generated by `mysql_ssl_rsa_setup`, the suffix can be specified explicitly using the `--suffix` option.

  For files generated by the server, if the resulting CN values exceed 64 characters, the `_suffix` portion of the name is omitted.

• SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.

• SSL files created by the server or by `mysql_ssl_rsa_setup` are valid for ten years from the time of generation.

• RSA files do not expire.

• SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).

• Files created automatically by the server are owned by the account that runs the server. Files created using `mysql_ssl_rsa_setup` are owned by the user who invoked that program. This can be changed on systems that support the `chown()` system call if the program is invoked by `root` and the `--uid` option is given to specify the user who should own the files.

• On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke `openssl` directly:

  openssl x509 -text -in ca.pem
  openssl x509 -text -in server-cert.pem
  openssl x509 -text -in client-cert.pem

It is also possible to check SSL certificate expiration information using this SQL statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----------------------+--------------------------+
| Variable_name         | Value                    |
|-----------------------+--------------------------+
| Ssl_server_not_after  | Apr 28 14:16:39 2027 GMT |
| Ssl_server_not_before | May  1 14:16:39 2017 GMT |
+-----------------------+--------------------------+
```

6.3.2.2 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.
Note
There are easier alternatives to generating the files required for SSL than the procedure described here: Let the server autogenerate them or use the \texttt{mysql_ssl_rsa_setup} program. See Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

Important
Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

- Example 1: Creating SSL Files from the Command Line on Unix
- Example 2: Creating SSL Files Using a Script on Unix
- Example 3: Creating SSL Files on Windows

**Example 1: Creating SSL Files from the Command Line on Unix**

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the \texttt{openssl} commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600
   -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600
   -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600
   -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600
   -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem

After generating the certificates, verify them:

openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
```
You should see a response like this:

```
server-cert.pem: OK
client-cert.pem: OK
```

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

Now you have a set of files that can be used as follows:

- **ca.pem**: Use this as the argument to `--ssl-ca` on the server and client sides. (The CA certificate, if used, must be the same on both sides.)

- **server-cert.pem, server-key.pem**: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the server side.

- **client-cert.pem, client-key.pem**: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the client side.

For additional usage instructions, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**Example 2: Creating SSL Files Using a Script on Unix**

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”:

```
DIR=`pwd`/openssl
PRIV=$DIR/private
mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)
touch $DIR/index.txt
echo "01" > $DIR/serial

# Generation of Certificate Authority (CA)
openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ................++++++
# .........++++++
# writing new private key to '/home/monty/openssl/private/cakey.pem'
# Enter PEM pass phrase: Enter PEM pass phrase:
# ----- You are about to be asked to enter information that will be incorporated into your certificate request.
```

[mysqld]
ssl-ca=$DIR/ca.pem
ssl-cert=$DIR/server-cert.pem
ssl-key=$DIR/server-key.pem
EOF

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

http://www.slproweb.com/products/Win32OpenSSL.html

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be C:\OpenSSL-Win32 or C:\OpenSSL-Win64, depending on which package you downloaded. The following instructions assume a default location of C:\OpenSSL-Win32. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '...critical component is missing: Microsoft Visual C++ 2008 Redistributables', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

- Visual C++ 2008 Redistributables (x64), available at:

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default C:\OpenSSL-Win32 as the install path, and also leave the default option 'Copy OpenSSL DLL files to the Windows system directory' selected.

When the installation has finished, add C:\OpenSSL-Win32\bin to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):
1. On the Windows desktop, right-click the My Computer icon, and select Properties.

2. Select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.

3. Under System Variables, select Path, then click the Edit button. The Edit System Variable dialogue should appear.

4. Add ';C:\OpenSSL-Win32\bin' to the end (notice the semicolon).

5. Press OK 3 times.

6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (Start>Run>cmd.exe) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.
C:\Windows\system32>cd \\
C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.
C:
```

7. After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

   • Change the following Unix commands:

     ```
     # Create clean environment
     rm -rf newcerts
     mkdir newcerts && cd newcerts
     ```

     On Windows, use these commands instead:

     ```
     # Create clean environment
     md c:\newcerts
     cd c:\newcerts
     ```

     • When a '\' character is shown at the end of a command line, this '\' character must be removed and the command lines entered all on a single line.

   After generating the certificate and key files, to use them for SSL connections, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

6.3.2.3 Creating RSA Keys Using openssl

This section describes how to use the openssl command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the sha256_password and caching_sha2_password plugins.

**Note**

There are easier alternatives to generating the files required for RSA than the procedure described here: Let the server autogenerate them or use the mysql_ssl_rsa_setup program. See Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

1163
To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so the files will be owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```
chmod 400 private_key.pem
chmod 444 public_key.pem
```

### 6.3.3 SSL Library-Dependent Capabilities

MySQL can be compiled using OpenSSL or wolfSSL, both of which enable encrypted connections based on the OpenSSL API:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use wolfSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using OpenSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or wolfSSL (see Section 6.3.4, “Building MySQL with Support for Encrypted Connections”).

OpenSSL and wolfSSL offer the same basic functionality, but MySQL distributions compiled using OpenSSL have additional features:

- OpenSSL supports a more flexible syntax for specifying ciphers for the `--ssl-cipher` option, and supports a wider range of encryption ciphers from which to choose. See Command Options for Encrypted Connections, and Section 6.3.5, “Encrypted Connection Protocols and Ciphers”.

- OpenSSL supports the `--ssl-capath`. MySQL distributions compiled using wolfSSL do not because wolfSSL does not look in any directory and do not follow a chained certificate tree. wolfSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this limitation, concatenate the individual certificate files comprising the certificate tree into a new file and specify that file as the value of the `--ssl-ca` option.

- OpenSSL supports the `--ssl-crl` and `--ssl-crlpath` options. Distributions compiled using wolfSSL do not because revocation lists do not work with wolfSSL. (wolfSSL accepts these options but silently ignores them.)

- OpenSSL 1.1.1 and higher supports the TLSv1.3 protocol.

- Accounts that authenticate using the `sha256_password` plugin can use RSA key files for secure password exchange over unencrypted connections. See Section 6.4.1.2, “SHA-256 Pluggable Authentication”. (Accounts that authenticate using the `caching_sha2_password` plugin can use RSA key pair-based password exchange regardless of whether MySQL was compiled using OpenSSL or wolfSSL. See Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.)

- The server can automatically generate missing SSL and RSA certificate and key files at startup. See Section 6.3.2.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

1164
• OpenSSL supports more encryption modes for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions. See Section 12.13, “Encryption and Compression Functions”

Certain OpenSSL-related system and status variables are present only if MySQL was compiled using OpenSSL:

• `auto_generate_certs`
• `caching_sha2_password_auto_generate_rsa_keys`
• `sha256_password_auto_generate_rsa_keys`
• `sha256_password_private_key_path`
• `sha256_password_public_key_path`
• `Rsa_public_key`

To determine whether a server was compiled using OpenSSL, test the existence of any of those variables. For example, this statement returns a row if OpenSSL was used and an empty result if wolfSSL was used:

```sql
SHOW STATUS LIKE 'Rsa_public_key';
```

### 6.3.4 Building MySQL with Support for Encrypted Connections

To use encrypted connections between the MySQL server and client programs, your system must support either OpenSSL or wolfSSL:

• MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use wolfSSL with MySQL Enterprise Edition.

• MySQL Community Edition binary distributions are compiled using OpenSSL.

• MySQL Community Edition source distributions can be compiled using either OpenSSL or wolfSSL.

If you compile MySQL from a source distribution, `CMake` configures the distribution to use OpenSSL by default.

To compile using OpenSSL, use this procedure:

1. Ensure that OpenSSL 1.0.1 or higher is installed on your system. If the installed OpenSSL version is lower than 1.0.1, `CMake` produces an error at MySQL configuration time. If it is necessary to obtain OpenSSL, visit [http://www.openssl.org](http://www.openssl.org).

2. The `WITH_SSL CMake` option determines which SSL library to use for compiling MySQL (see Section 2.9.4, “MySQL Source-Configuration Options”). The default is `~WITH_SSL=system`, which uses OpenSSL. To make this explicit, specify that option on the `CMake` command line. For example:

```sh
cmake . -DWITH_SSL=system
```

That command configures the distribution to use the installed OpenSSL library. Alternatively, to explicitly specify the path name to the OpenSSL installation, use the following syntax. This can be useful if you have multiple versions of OpenSSL installed, to prevent `CMake` from choosing the wrong one:

```sh
cmake . -DWITH_SSL=path_name
```
3. Compile and install the distribution.

To compile using wolfSSL, download the wolfSSL distribution and apply a small patch. For instructions, see the extra/README-wolfssl.txt file.

To check whether a mysqld server supports encrypted connections, examine the value of the have_ssl system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

If the value is YES, the server supports encrypted connections. If the value is DISABLED, the server is capable of supporting encrypted connections but was not started with the appropriate --ssl-xxx options to enable encrypted connections to be used; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

To determine whether a server was compiled using OpenSSL or wolfSSL, check the existence of any of the system or status variables that are present only for OpenSSL. See Section 6.3.3, “SSL Library-Dependent Capabilities”

6.3.5 Encrypted Connection Protocols and Ciphers

To determine which encryption protocol and cipher are in use for an encrypted connection, use the following statements to check the values of the Ssl_version and Ssl_cipher status variables:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_version';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Ssl_version   | TLSv1 |
+---------------+-------+
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+---------------------------+
| Variable_name | Value                     |
+---------------+---------------------------+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256 |
+---------------+---------------------------+
```

If the connection is not encrypted, both variables have an empty value.

MySQL supports encrypted connections using the TLSv1, TLSv1.1, TLSv1.2, and TLSv1.3 protocols.

Note

Support for the TLSv1.3 protocol is available as of MySQL 8.0.16, but requires compiling MySQL using OpenSSL 1.1.1 or higher. If the SSL library does not support TLSv1.3, neither does MySQL and the TLSv1.3-related parts of the following discussion do not apply.

Currently, Group Replication does not support TLSv1.3.

The value of the tls_version system variable determines which protocols a server permits for encrypted connections. The tls_version value applies to connections from clients and from slave servers using regular master/slave replication. The variable value is a list of one or more comma-separated protocol names from this list (not case-sensitive): TLSv1, TLSv1.1, TLSv1.2, and (if available) TLSV1.3. By default,
this variable lists all protocols supported by the SSL library used to compile MySQL. To determine the value of `tls_version` at runtime, use this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+---------------+-----------------------+
| Variable_name | Value                 |
+---------------+-----------------------+
| tls_version   | TLSv1,TLSv1.1,TLSv1.2 |
+---------------+-----------------------+
```

To change the value of `tls_version`, set it at server startup. For example, to permit connections that use the TLSv1.1 or TLSv1.2 protocol, but prohibit connections that use the less-secure TLSv1 protocol, use these lines in the server `my.cnf` file:

```
[mysqld]
tls_version=TLSv1.1,TLSv1.2
```

To be even more restrictive and permit only TLSv1.2 connections, set `tls_version` like this:

```
[mysqld]
tls_version=TLSv1.2
```

As of MySQL 8.0.16, `tls_version` can also be changed at runtime. See Server-Side Runtime Configuration for Encrypted Connections.

For client programs, the `--tls-version` option specifies which TLS protocols a client permits for connections to the server. The format of the option value is the same as for the `tls_version` system variable.

For regular replication, the `MASTER_TLS_VERSION` option for the `CHANGE MASTER TO` statement specifies which TLS protocols a slave server permits for connections to the master. The format of the option value is the same as for the `tls_version` system variable. See Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”.

The protocols that can be specified for `MASTER_TLS_VERSION` depend only on the SSL library. This option is independent of and not affected by the `tls_version` value configured on the slave server. For example, a server that acts as a replication slave can be configured with `tls_version` set to TLSv1.3 to permit only incoming connections that use TLSv1.3, but also configured with `MASTER_TLS_VERSION` set to TLSv1.2 to connect as a slave only to masters that permit TLSv1.2.

By default, MySQL attempts to use the highest TLS protocol version available, depending on the SSL library used to compile the server and client, which key size is used, and whether the server or client are restricted from using some protocols (for example, by means of `tls_version`/`--tls-version`):

- If TLSv1.3 is available, it is used if possible. If not, MySQL continues through the list of available protocols, using TLSv1.2 if possible, and so forth.
- TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, use `--ssl-cipher` to specify the cipher name explicitly:

```
AES128-SHA
AES128-SHA256
AES256-SHA
AES256-SHA256
CAMELLIA128-SHA
CAMELLIA256-SHA
DES-CBC3-SHA
```
Encrypted Connection Protocols and Ciphers

- For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client protocol capabilities have no protocol in common, the server terminates the connection request. Examples:

- if the server is configured with `tls_version=TLSv1.1,TLSv1.2`, connection attempts fail for clients invoked with `--tls-version=TLSv1`, and for older clients that do not support the `--tls-version` option and implicitly support only TLSv1.

- Similarly, connection attempts fail for replication slaves configured with `MASTER_TLS_VERSION = 'TLSv1'`, and for older slaves that do not support the `MASTER_TLS_VERSION` option and implicitly support only TLSv1.

OpenSSL 1.1.1 and higher supports the following ciphersuites, the first three of which are enabled by default:

```
TLS_AES_128_GCM_SHA256
TLS_AES_256_GCM_SHA384
TLS_CHACHA20_POLY1305_SHA256
TLS_AES_128_CCM_SHA256
TLS_AES_128_CCM_8_SHA256
```

To configure the permitted TLSv1.3 ciphersuites explicitly:

- On the server side, use the `tls_ciphersuites` system variable.
- On the client side, use the `--tls-ciphersuites` option.

In each case, the configuration value is a list of one or more colon-separated ciphersuite names.

MySQL permits specifying a list of protocols to support. This list is passed directly down to the underlying SSL library and is ultimately up to that library what protocols it actually enables from the supplied list. Please refer to the MySQL source code and the OpenSSL `SSL_CTX_new()` documentation for information about how the SSL library handles this.

To determine which ciphers a given server supports, use the following statement to check the value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites.

Order of ciphers passed by MySQL to the SSL library is significant. More secure ciphers are mentioned first in the list, and the first cipher supported by the provided certificate is selected.

MySQL passes this cipher list to the SSL library:

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES128-SHA256
ECDHE-RSA-AES128-SHA256
```

These cipher restrictions are in place:

- The following ciphers are permanently restricted:
6.3.6 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

2. Start your Windows SSH client. Set Host_Name = yourmysqlserver_URL_or_IP. Set userid=your_userid to log in to your server. This userid value might not be the same as the user name of your MySQL account.

3. Set up port forwarding. Either do a remote forward (Set local_port: 3306, remote_host: yourmysqlservername_or_ip, remote_port: 3306) or a local forward (Set port: 3306, host: localhost, remote port: 3306).

4. Save everything, otherwise you will have to redo it the next time.

5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in localhost for the MySQL host server, not yourmysqlservername.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

6.4 Security Components and Plugins

MySQL includes several components and plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see Section 6.2.17, “Pluggable Authentication”. For characteristics of specific authentication plugins, see Section 6.4.1, “Authentication Plugins”.

<table>
<thead>
<tr>
<th>Cipher</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHE-DSS-DES-CBC3-SHA</td>
<td>Cipher using DHE-DSS protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
<tr>
<td>DHE-RSA-DES-CBC3-SHA</td>
<td>Cipher using DHE-RSA protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
<tr>
<td>ECDH-RSA-DES-CBC3-SHA</td>
<td>Cipher using ECDH-RSA protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
<tr>
<td>ECDH-ECDSA-DES-CBC3-SHA</td>
<td>Cipher using ECDH-ECDSA protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
<tr>
<td>ECDHE-RSA-DES-CBC3-SHA</td>
<td>Cipher using ECDHE-RSA protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
<tr>
<td>ECDHE-ECDSA-DES-CBC3-SHA</td>
<td>Cipher using ECDHE-ECDSA protocol with DES-CBC3 encryption and SHA signature scheme.</td>
</tr>
</tbody>
</table>

If the server is started using a compatible certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for encrypted connections disabled.

The following categories of ciphers are permanently restricted:

- aNULL
- eNULL
- EXPORT
- LOW
- MD5
- DES
- RC2
- RC4
- PSK
- SSLv3
Authentication Plugins

- A password-validation component for implementing password strength policies and assessing the strength of potential passwords. See Section 6.4.3, “The Password Validation Component”.

- Keyring plugins that provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See Section 6.4.5, “MySQL Enterprise Audit”.

- A user-defined function enables applications to add their own message events to the audit log. See Section 6.4.6, “The Audit Message Component”.

- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. See Section 6.4.7, “MySQL Enterprise Firewall”.

- (MySQL Enterprise Edition only) MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. See Section 6.4.8, “MySQL Enterprise Data Masking and De-Identification”.

6.4.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see Section 6.2.17, “Pluggable Authentication”.

The default plugin is indicated by the value of the default_authentication_plugin system variable.

6.4.1.1 Native Pluggable Authentication

MySQL includes a mysql_native_password plugin that implements native authentication; that is, authentication based on the password hashing method in use from before the introduction of pluggable authentication.

The following table shows the plugin names on the server and client sides.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to native pluggable authentication:
• Installing Native Pluggable Authentication

• Using Native Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Installing Native Pluggable Authentication

The mysql_native_password plugin exists in server and client forms:

• The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.

• The client-side plugin is built into the libmysqlclient client library and is available to any program linked against libmysqlclient.

Using Native Pluggable Authentication

MySQL client programs use mysql_native_password by default. The --default-auth option can be used as a hint about which client-side plugin the program can expect to use:

shell> mysql --default-auth=mysql_native_password ...

6.4.1.2 SHA-256 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

• sha256_password: Implements basic SHA-256 authentication.

• caching_sha2_password: Implements SHA-256 authentication (like sha256_password), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the original noncaching SHA-2 authentication plugin. For information about the caching plugin, see Section 6.4.1.3, “Caching SHA-2 Pluggable Authentication”.

Important

In MySQL 8.0, caching_sha2_password is the default authentication plugin rather than mysql_native_password. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see caching_sha2_password as the Preferred Authentication Plugin.

Because caching_sha2_password is the default authentication plugin in MySQL 8.0 and provides a superset of the capabilities of the sha256_password authentication plugin, sha256_password is deprecated and will be removed in a future MySQL version. MySQL accounts that authenticate using sha256_password should be migrated to use caching_sha2_password instead.

Important

To connect to the server using an account that authenticates with the sha256_password plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the sha256_password plugin uses MySQL’s encryption capabilities. See Section 6.3, “Using Encrypted Connections”.
Note

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The following table shows the plugin names on the server and client sides.

**Table 6.13 Plugin and Library Names for SHA-256 Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- Installing SHA-256 Pluggable Authentication
- Using SHA-256 Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

**Installing SHA-256 Pluggable Authentication**

The `sha256_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

**Using SHA-256 Pluggable Authentication**

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```sql
CREATE USER 'sha256user'@'localhost' IDENTIFIED WITH sha256_password BY 'password';
```

The server assigns the `sha256_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `sha256_password` is the default authentication plugin. If `sha256_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `sha256_password`, put these lines in the server option file:

```
[mysqld]
```
That causes the `sha256_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `sha256_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:

```
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'password';
```

`sha256_password` supports connections over secure transport. `sha256_password` also supports encrypted password exchange using RSA over unencrypted connections if these conditions are satisfied:

- MySQL is compiled using OpenSSL. MySQL can be compiled using either OpenSSL or yaSSL (see Section 6.3.3, “SSL Library-Dependent Capabilities”), and `sha256_password` works with distributions compiled using either package, but RSA support requires OpenSSL.
- The MySQL server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `sha256_password_private_key_path` and `sha256_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
- The server uses the `sha256_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.
- The `Rsa_public_key` status variable displays the RSA public key value used by the `sha256_password` authentication plugin.
- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.
- For connections by accounts that authenticate with `sha256_password` and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:
  - For these command-line clients, use the `--server-public-key-path` option to specify the RSA public key file: `mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`, `mysqlshow`, `mysqlslap`, `mysqltest`, `mysql_upgrade`.
  - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file.
  - For replication slaves, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file. For Group Replication, the `group_replication_recovery_get_public_key` system variable serves the same purpose.
For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to encrypted connections that use TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.

- If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to unencrypted connections without TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

- If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL was compiled using OpenSSL. The implication for MySQL distributions compiled using wolfSSL is that, to use SHA-256 passwords, clients must use an encrypted connection to access the server. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**Note**

To use RSA password encryption with `sha256_password`, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server uses them automatically at startup.

   Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=myprivkey.pem
   sha256_password_public_key_path=mypubkey.pem
   ```

   If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
   sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
   ```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:

   ```
   mysql> SHOW STATUS LIKE '%Rsa_public_key'\G
   *************************** 1. row ***************************
   ```
If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the sha256_password plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by sha256user, the server determines that sha256_password is the appropriate authentication plugin and invokes it (because that was the plugin specified at CREATE USER time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the --server-public-key-path option:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the --server-public-key-path option should be the same as the key value in the server-side file named by the sha256_password_public_key_path system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the sha256_password plugin sends the public key to the client as if no --server-public-key-path option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a SHOW STATUS LIKE 'Rsa_public_key' statement and save the returned key value in a file.

### 6.4.1.3 Caching SHA-2 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- **sha256_password**: Implements basic SHA-256 authentication.
- **caching_sha2_password**: Implements SHA-256 authentication (like sha256_password), but uses caching on the server side for better performance and has additional features for wider applicability.
This section describes the caching SHA-2 authentication plugin. For information about the original basic (noncaching) plugin, see Section 6.4.1.2, “SHA-256 Pluggable Authentication”.

**Important**

In MySQL 8.0, `caching_sha2_password` is the default authentication plugin rather than `mysql_native_password`. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see `caching_sha2_password` as the Preferred Authentication Plugin.

**Important**

To connect to the server using an account that authenticates with the `caching_sha2_password` plugin, you must use either a secure connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `caching_sha2_password` plugin uses MySQL’s encryption capabilities. See Section 6.3, “Using Encrypted Connections”.

**Note**

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The `caching_sha2_password` plugin has these advantages, compared to `sha256_password`:

- On the server side, an in-memory cache enables faster reauthentication of users who have connected previously when they connect again.
- RSA-based password exchange is available regardless of the SSL library against which MySQL is linked.
- Support is provided for client connections that use the Unix socket-file and shared-memory protocols.

The following table shows the plugin names on the server and client sides.

**Table 6.14 Plugin and Library Names for SHA-2 Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>caching_sha2_password</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>caching_sha2_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to caching SHA-2 pluggable authentication:

- Installing SHA-2 Pluggable Authentication
- Using SHA-2 Pluggable Authentication
- Cache Operation for SHA-2 Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.
Installing SHA-2 Pluggable Authentication

The `caching_sha2_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

The server-side plugin uses the `sha2_cache_cleaner` audit plugin as a helper to perform password cache management. `sha2_cache_cleaner`, like `caching_sha2_password`, is built in and need not be installed.

Using SHA-2 Pluggable Authentication

To set up an account that uses the `caching_sha2_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha2user'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'password';
```

The server assigns the `caching_sha2_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `caching_sha2_password` is the default authentication plugin. If `caching_sha2_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

To start the server with the default authentication plugin set to `caching_sha2_password`, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=caching_sha2_password
```

That causes the `caching_sha2_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```
CREATE USER 'sha2user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default_authentication_plugin` to `caching_sha2_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the `mysql_native_password` plugin, use this statement:

```
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'password';
```

`caching_sha2_password` supports connections over secure transport. If you follow the RSA configuration procedure given later in this section, it also supports encrypted password exchange using RSA over unencrypted connections. RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
Authentication Plugins

- The server uses the `caching_sha2_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.

- The `Caching_sha2_password_rsa_public_key` status variable displays the RSA public key value used by the `caching_sha2_password` authentication plugin.

- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate with `caching_sha2_password` and RSA key pair-based password exchange, the server does not send the RSA public key to clients by default. Clients can use a client-side copy of the required public key, or request the public key from the server.

  Use of a trusted local copy of the public key enables the client to avoid a round trip in the client/server protocol, and is more secure than requesting the public key from the server. On the other hand, requesting the public key from the server is more convenient (it requires no management of a client-side file) and may be acceptable in secure network environments.

- For command-line clients, use the `--server-public-key-path` option to specify the RSA public key file. Use the `--get-server-public-key` option to request the public key from the server. The following programs support the two options: `mysql`, `mysqlsh`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`, `mysqlshow`, `mysqslap`, `mysqltest`, `mysql_upgrade`.

- For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file, or request the public key from the server by passing the `MYSQL_OPT_GET_SERVER_PUBLIC_KEY` option.

- For replication slaves, use the `CHANGE MASTER TO` statement with the `MASTER_PUBLIC_KEY_PATH` option to specify the RSA public key file, or the `GET_MASTER_PUBLIC_KEY` option to request the public key from the master. For Group Replication, the `group_replication_recovery_public_key_path` and `group_replication_recovery_get_public_key` system variables serve the same purpose.

  In all cases, if the option is given to specify a valid public key file, it takes precedence over the option to request the public key from the server.

For clients that use the `caching_sha2_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to encrypted TCP connections that use TLS, as well as Unix socket-file and shared-memory connections. The password is sent as cleartext but cannot be snooped because the connection is secure.

- If the connection is not secure, an RSA key pair is used. This applies to unencrypted TCP connections without TLS and named-pipe connections. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

To enable use of an RSA key pair for password exchange during the client connection process, use the following procedure:

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.2, “Creating SSL and RSA Certificates and Keys”.

1179
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
caching_sha2_password_private_key_path=myprivkey.pem
caching_sha2_password_public_key_path=mypubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variables, use full path names:

```
[mysqld]
caching_sha2_password_private_key_path=/usr/local/mysql/myprivkey.pem
caching_sha2_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Caching_sha2_password_rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'
*************************** 1. row ***************************
Variable_name: Caching_sha2_password_rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZy7cNBZMNpwX6MvE1PbJKQ7d299du/E71w6CVXw7VKrXpeHrVQUzGyUNkF45Nz/ckaaJaalG3OBCIDmVnyU54OT/11cs2xjyfAdMe8fCj64ZwTkY2qkt1IMjUAB5Od5kJg8aV7EMwhhIbHc3QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `caching_sha2_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha2user -p
Enter password: password
```

For this connection attempt by `sha2user`, the server determines that `caching_sha2_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. However, the server does not send the public key to the client, and the client provided no public key, so it cannot encrypt the password and the connection fails:

```
ERROR 2061 (HY000): Authentication plugin 'caching_sha2_password' reported error: Authentication requires secure connection.
```

To request the RSA public key from the server, specify the `--get-server-public-key` option:
shell> mysql --ssl-mode=DISABLED -u sha2user -p --get-server-public-key
Enter password: password

In this case, the server sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

Alternatively, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

shell> mysql --ssl-mode=DISABLED --server-public-key-path=filename
Enter password: password

In this case, the client uses the public key to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `caching_sha2_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'` statement and save the returned key value in a file.

**Cache Operation for SHA-2 Pluggable Authentication**

On the server side, the `caching_sha2_password` plugin uses an in-memory cache for faster authentication of clients who have connected previously. Entries consist of account-name/password-hash pairs. The cache works like this:

1. When a client connects, `caching_sha2_password` checks whether the client and password match some cache entry. If so, authentication succeeds.
2. If there is no matching cache entry, the plugin attempts to verify the client against the credentials in the `mysql.user` system table. If this succeeds, `caching_sha2_password` adds an entry for the client to the hash. Otherwise, authentication fails and the connection is rejected.

In this way, when a client first connects, authentication against the `mysql.user` system table occurs. When the client connects subsequently, faster authentication against the cache occurs.

Password cache operations other than adding entries are handled by the `sha2_cache_cleaner` audit plugin, which performs these actions on behalf of `caching_sha2_password`:

- It clears the cache entry for any account that is renamed or dropped, or any account for which the credentials or authentication plugin are changed.
- It empties the cache when the `FLUSH PRIVILEGES` statement is executed.
- It empties the cache at server shutdown. (This means the cache is not persistent across server restarts.)

Cache clearing operations affect the authentication requirements for subsequent client connections. For each user account, the first client connection for the user after any of the following operations must use a
secure connection (made using TCP using TLS credentials, a Unix socket file, or shared memory) or RSA key pair-based password exchange:

- After account creation.
- After a password change for the account.
- After `RENAME USER` for the account.
- After `FLUSH PRIVILEGES`.

`FLUSH PRIVILEGES` clears the entire cache and affects all accounts that use the `caching_sha2_password` plugin. The other operations clear specific cache entries and affect only accounts that are part of the operation.

Once the user authenticates successfully, the account is entered into the cache and subsequent connections do not require a secure connection or the RSA key pair, until another cache clearing event occurs that affects the account. (When the cache can be used, the server uses a challenge-response mechanism that does not use cleartext password transmission and does not require a secure connection.)

### 6.4.1.4 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_clear_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugin is built in)</td>
</tr>
</tbody>
</table>

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used, which enables the client to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, `mysql_clear_password` can be used on the client side in concert with any server-side plugin that needs a cleartext password. (Examples are the PAM and simple LDAP authentication plugins; see Section 6.4.1.5, “PAM Pluggable Authentication”, and Section 6.4.1.7, “LDAP Pluggable Authentication”.)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

**Note**

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects
To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqldump`, `mysqlshow`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

### 6.4.1.5 PAM Pluggable Authentication

**Note**

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- **External authentication**: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- **Proxy user support**: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named `joe` can connect and have the privileges of a MySQL user named `developer`.

PAM pluggable authentication has been tested on Linux and macOS.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing PAM Pluggable Authentication](https://www.mysql.com/products/).

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>authentication_pam</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_clear_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td><code>authentication_pam.so</code></td>
</tr>
</tbody>
</table>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including...
community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- How PAM Authentication of MySQL Users Works
- Installing PAM Pluggable Authentication
- Uninstalling PAM Pluggable Authentication
- Using PAM Pluggable Authentication
- Unix Password Authentication without Proxy Users
- LDAP Authentication without Proxy Users
- Unix Password Authentication with Proxy Users and Group Mapping
- PAM Authentication Access to Unix Password Store
- PAM Authentication Debugging

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For information about the `mysql_clear_password` plugin, see Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

How PAM Authentication of MySQL Users Works

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see Using PAM Pluggable Authentication.

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:

   - The client user name is the external user name.

   - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.

2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:

   - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.

   - Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is user_name' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service.

Examples:
Authentication Plugins

- For traditional Unix passwords, the service looks up passwords stored in the `/etc/shadow` file.
- For LDAP, the service looks up passwords stored in an LDAP directory.

If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.

5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:
   - For traditional Unix passwords, groups are Unix groups defined in the `/etc/group` file, possibly supplemented with additional PAM information in a file such as `/etc/security/group.conf`.
   - For LDAP, groups are LDAP groups defined in an LDAP directory.

If the proxy user (the external user) has the PROXY privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

**Installing PAM Pluggable Authentication**

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `authentication_pam`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to register the plugin at runtime, use this statement (adjust the `.so` suffix as necessary):

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
```
Authentication Plugins

<table>
<thead>
<tr>
<th>FROM INFORMATION_SCHEMA.PLUGINS</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHERE PLUGIN_NAME LIKE 'pam'</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see Using PAM Pluggable Authentication.

Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using `INSTALL PLUGIN`, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```sql
  UNINSTALL PLUGIN authentication_pam;
  ```

Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in Installing PAM Pluggable Authentication.

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_pam`. For example:

```sql
CREATE USER user
    IDENTIFIED WITH authentication_pam
    AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see How PAM Authentication of MySQL Users Works). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.

- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the `mysql-unix` PAM service name and should map operating system users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```sql
CREATE USER user
    IDENTIFIED WITH authentication_pam
    AS 'mysql-unix, root=developer, users=data_entry';
```
Authentication Plugins

Authentication string syntax for the PAM authentication plugin follows these rules:

• The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

```
pam_service_name[,pam_group_name=mysql_user_name]...
```

The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

• Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.

• Leading and trailing spaces not inside double quotation marks are ignored.

• Unquoted `pam_service_name, pam_group_name, and mysql_user_name` values can contain anything except equal sign, comma, or space.

• If a `pam_service_name, pam_group_name, or mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`\`). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

• If the authentication string contains no PAM group mapping list, the plugin returns the external name.

• If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

• No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `user_name@host_name` to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 32 characters (see Section 6.2.3, “Grant Tables”), which limits PAM nonproxy authentication to Unix accounts with names of at most 32 characters.

• Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The
discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible:

- You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.

- You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the mysql-unix PAM service for some users, and mysql-ldap for others.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The login name and password are antonio and antonio_password, respectively. Change these to correspond to the user you want to authenticate.

- The PAM configuration directory is /etc/pam.d.

- The PAM service name corresponds to the authentication method (mysql-unix or mysql-ldap in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must name the PAM service in the authentication string of the CREATE USER statement for any account that authenticates using that PAM service.

The PAM authentication plugin checks at initialization time whether the AUTHENTICATION_PAM_LOG environment value is set in the server’s startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related problems that occur when the plugin performs authentication. For more information, see PAM Authentication Debugging.

**Unix Password Authentication without Proxy Users**

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

**Note**

Traditional Unix passwords are checked using the /etc/shadow file. For information regarding possible problems related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name antonio and password antonio_password.

2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a mysql-unix PAM service file named /etc/pam.d/mysql-unix. The file contents are system dependent, so check existing login-related files in the /etc/pam.d directory to see what they look like. On Linux, the mysql-unix file might look like this:

```bash
#%PAM-1.0
auth include password-auth
account include password-auth
```
For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```plaintext
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-unix` PAM service:

```sql
CREATE USER 'antonio'@'localhost'
    IDENTIFIED WITH authentication_pam
    AS 'mysql-unix';
GRANT ALL PRIVILEGES
    ON mydb.*
    TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```bash
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query should return output as shown:

```plaintext
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+-------------------+--------------+
| USER()            | CURRENT_USER()    | @@proxy_user |
+-------------------+-------------------+--------------+
| antonio@localhost | antonio@localhost | NULL         |
+-------------------+-------------------+--------------+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.4, "Client-Side Cleartext Pluggable Authentication".
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".
Authentication Plugins

LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

Note

Another way to use LDAP for MySQL user authentication is to use the LDAP-specific authentication plugins. See Section 6.4.1.7, “LDAP Pluggable Authentication”.

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name antonio and password antonio_password.

2. Set up PAM to authenticate MySQL connections using LDAP by creating a mysql-ldap PAM service file named /etc/pam.d/mysql-ldap. The file contents are system dependent, so check existing login-related files in the /etc/pam.d directory to see what they look like. On Linux, the mysql-ldap file might look like this:

   ```
   #%PAM-1.0
   auth        required    pam_ldap.so
   account     required    pam_ldap.so
   ```

   If PAM object files have a suffix different from .so on your system, substitute the correct suffix.

   The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the mysql-ldap PAM service:

   ```
   CREATE USER 'antonio'@'localhost'
   IDENTIFIED WITH authentication_pam
   AS 'mysql-ldap';
   GRANT ALL PRIVILEGES
   ON mydb.*
   TO 'antonio'@'localhost';
   ```

   Here, the authentication string contains only the PAM service name, mysql-ldap, which authenticates using LDAP.

4. Connecting to the server is the same as described in Unix Password Authentication without Proxy Users.

Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they
connect through a default proxy user authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of LDAP Authentication without Proxy Users.

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible problems related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Verify that `antonio` is a member of the `root` or `users` PAM group.

3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
#%PAM-1.0
auth include password-auth
account include password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

4. Create a default proxy user (`''@''`) that maps external PAM users to the proxied accounts:

```
CREATE USER ''@'' IDENTIFIED WITH authentication_pam AS 'mysql-unix, root=developer, users=data_entry';
```

Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this problem, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

5. Create proxied accounts that have the required privileges for MySQL access:
CREATE USER 'developer'@'localhost'
    IDENTIFIED BY 'very secret password';
CREATE USER 'data_entry'@'localhost'
    IDENTIFIED BY 'very secret password';

GRANT ALL PRIVILEGES
    ON mydevdb.*
    TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
    ON mydb.*
    TO 'data_entry'@'localhost';

If you do not let anyone know the passwords for these accounts, clients cannot use them to connect
directly to the MySQL server. Instead, it is expected that users who authenticate using PAM will use the
developer or data_entry account by proxy based on their PAM group.

Other ways to ensure that the proxied accounts cannot be used directly:

- Include the ACCOUNT LOCK option when you create the accounts. See Section 13.7.1.3, “CREATE
    USER Syntax”.

- Associate the accounts with the mysql_no_login authentication plugin. See Section 6.4.1.8, “No-
    Login Pluggable Authentication”.

6. Grant the PROXY privilege to the proxy account for each proxied account:

---

GRANT PROXY
    ON 'developer'@'localhost'
    TO ''@'';
GRANT PROXY
    ON 'data_entry'@'localhost'
    TO ''@'';

7. Use the mysql command-line client to connect to the MySQL server as antonio.

---

shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password

The server authenticates the connection using the ''@'' proxy account. The resulting privileges for
antonio depend on which PAM groups antonio is a member of. If antonio is a member of the
root PAM group, the PAM plugin maps root to the developer MySQL user name and returns
that name to the server. The server verifies that ''@'' has the PROXY privilege for developer and
permits the connection. The following query should return output as shown:

---

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+---------------------+--------------+
| USER()            | CURRENT_USER()      | @@proxy_user |
+-------------------+---------------------+--------------+
| antonio@localhost | developer@localhost | ''@''        |
+-------------------+---------------------+--------------+

This demonstrates that the antonio operating system user is authenticated to have the privileges
granted to the developer MySQL user, and that proxying occurred through the default proxy account.

If antonio is not a member of the root PAM group but is a member of the users PAM group, a
similar process occurs, but the plugin maps user PAM group membership to the data_entry MySQL
user name and returns that name to the server:
This demonstrates that the **antoni**o operating system user is authenticated to have the privileges of the **data_entry** MySQL user, and that proxying occurred through the default proxy account.

**Note**

The client-side **mysql_clear_password** authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the **mysql_clear_password** plugin less likely, MySQL clients must explicitly enable it (for example, with the **--enable-cleartext-plugin** option). See Section 6.4.1.4, "Client-Side Cleartext Pluggable Authentication".

- To avoid password exposure with the **mysql_clear_password** plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

**PAM Authentication Access to Unix Password Store**

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing "password could not be checked" (due, for example, to inability to read `/etc/shadow`) from "password does not match." If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the **mysql** operating system account, put that account in the **shadow** group that has `/etc/shadow` access:

  1. Create a **shadow** group in `/etc/group`.
  2. Add the **mysql** operating system user to the **shadow** group in `/etc/group`.
  3. Assign `/etc/group` to the **shadow** group and enable the group read permission:

    ```
    chgrp shadow /etc/shadow
    chmod g+r /etc/shadow
    ```

  4. Restart the MySQL server.

- If you are using the **pam_unix** module and the **unix_chkpwd** utility, enable password store access as follows:

  ```
  chmod u-s /usr/sbin/unix_chkpwd
  ```
Authentication Plugins

```bash
setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
```

Adjust the path to `unix_chkpwd` as necessary for your platform.

### PAM Authentication Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a temporary basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```plaintext
#%PAM-1.0
auth        required    pam_permit.so
account     required    pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```sql
CREATE USER 'testuser'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

### 6.4.1.6 Windows Pluggable Authentication

**Note**

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the
Authentication Plugins

Windows OS. This identity includes the name of the client account. Windows pluggable authentication
uses the identity of the client to check whether it is a given account or a member of a group. By default,
negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

• External authentication: Windows authentication enables MySQL Server to accept connections from
users defined outside the MySQL grant tables who have logged in to Windows.

• Proxy user support: Windows authentication can return to MySQL a user name different from the
external user name passed by the client program. This means that the plugin can return the MySQL
user that defines the privileges the external Windows-authenticated user should have. For example, a
Windows user named joe can connect and have the privileges of a MySQL user named developer.

The following table shows the plugin and library file names. The file must be located in the directory named by the plugin_dir system variable.

Table 6.17 Plugin and Library Names for Windows Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>authentication_windows</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>authentication_windows_client</td>
</tr>
<tr>
<td>Library file</td>
<td>authentication_windows.dll</td>
</tr>
</tbody>
</table>

The library file includes only the server-side plugin. The client-side plugin is built into the
libmysqlclient client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not
included in MySQL community distributions. The client-side plugin is included in all distributions, including
community distributions. This permits clients from any distribution to connect to a server that has the
server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 8.0 (see

The following sections provide installation and usage information specific to Windows pluggable
authentication:

• Installing Windows Pluggable Authentication

• Uninstalling Windows Pluggable Authentication

• Using Windows Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable
Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

Installing Windows Pluggable Authentication

This section describes how to install the Windows authentication plugin. For general information about
installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the
directory named by the plugin_dir system variable). If necessary, configure the plugin directory location
by setting the value of plugin_dir at server startup.
To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to register the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
     FROM INFORMATION_SCHEMA.PLUGINS
     WHERE PLUGIN_NAME LIKE '%windows%';
```

| PLUGIN_NAME            | PLUGIN_STATUS |
|------------------------+---------------|
| authentication_windows | ACTIVE        |

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see Using Windows Pluggable Authentication.

### Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using `INSTALL PLUGIN`, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_windows;
```

In addition, remove any startup options that set Windows plugin-related system variables.

### Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in Installing Windows Pluggable Authentication. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and
**Tasha** should be permitted to connect to MySQL, as well as any users in the *Administrators* or *Power Users* group. To set this up, create a MySQL account named *sql_admin* that uses the Windows plugin for authentication:

```sql
CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is *authentication_windows*. The string following the *AS* keyword is the authentication string. It specifies that the Windows users named Rafal or Tasha are permitted to authenticate to the server as the MySQL user *sql_admin*, as are any Windows users in the *Administrators* or *Power Users* group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the *sql_admin* account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The *authentication_windows* plugin uses the Windows security API to check which Windows user is connecting. If that user is named Rafal or Tasha, or is a member of the *Administrators* or *Power Users* group, the server grants access and the client is authenticated as *sql_admin* and has whatever privileges are granted to the *sql_admin* account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

  ```
  win_user_or_group_name=mysql_user_name
  win_user_or_group_name
  ```

  For the latter syntax, with no *mysql_user_name* value given, the implicit value is the MySQL user created by the *CREATE USER* statement. Thus, these statements are equivalent:

```sql
CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal, Tasha, Administrators, "Power Users"';

CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
    "Power Users"=sql_admin';
```

- Each backslash (\) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted *win_user_or_group_name* and *mysql_user_name* values can contain anything except equal sign, comma, or space.
- If a *win_user_or_group_name* and or *mysql_user_name* value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the
name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.

- **win_user_or_group_name** values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
\domain\user
.\user
\domain\\group
.\\group
\BUILTIN\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding mysql_user_name to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting IDENTIFIED WITH authentication_windows AS 'SomeDomain\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see Section 6.2.18, “Proxy Users”). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The **local_user** and **MyDomain\domain_user** local and domain Windows users should map to the **local_wlad** MySQL account.
- Users in the **MyDomain\Developers** domain group should map to the **local_dev** MySQL account.
- Local machine administrators should map to the **local_admin** MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (**local_wlad, local_dev, local_admin**). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
AS 'local_user = local_wlad,
  MyDomain\domain_user = local_wlad,
  MyDomain\Developers = local_dev,
  BUILTIN\Administrators = local_admin';

Note
If your MySQL installation has anonymous users, they might conflict with the
default proxy user. For more information about this problem, and ways of
dealing with it, see Default Proxy User and Anonymous User Conflicts.

2. For proxying to work, the proxied accounts must exist, so create them:

CREATE USER local_wlad IDENTIFIED BY 'wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'dev_pass';
CREATE USER local_admin IDENTIFIED BY 'admin_pass';

If you do not let anyone know the passwords for these accounts, other users cannot use them to
connect directly to the MySQL server.

You should also issue GRANT statements (not shown) that grant each proxied account the privileges it
needs.

3. The proxy account must have the PROXY privilege for each proxied account:

GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;

Now the Windows users local_user and MyDomain\domain_user can connect to the MySQL server
as win_proxy and when authenticated have the privileges of the account given in the authentication
string—in this case, local_wlad. A user in the MyDomain\Developers group who connects as
win_proxy has the privileges of the local_dev account. A user in the BUILTIN\Administrators
group has the privileges of the local_admin account.

To configure authentication so that all Windows users who do not have their own MySQL account go
to through a proxy account, substitute the default proxy user ('@') for win_proxy in the preceding
instructions. For information about the default proxy user, see Section 6.2.18, “Proxy Users”.

To use the Windows authentication plugin with Connector.NET connection strings in Connector.NET 6.4.4
and higher, see Using the Windows Native Authentication Plugin.

Additional control over the Windows authentication plugin is provided by the
authentication_windows_use_principal_name and authentication_windows_log_level
system variables. See Section 5.1.8, “Server System Variables”.

6.4.1.7 LDAP Pluggable Authentication

Note
LDAP pluggable authentication is an extension included in MySQL Enterprise
Edition, a commercial product. To learn more about commercial products, see
https://www.mysql.com/products/.
MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. MySQL uses LDAP to fetch user, credential, and group information.

LDAP pluggable authentication provides these capabilities:

- External authentication: LDAP authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables in LDAP directories.

- Proxy user support: LDAP authentication can return to MySQL a user name different from the external user name passed by the client program, based on the LDAP groups the external user is a member of. This means that an LDAP plugin can return the MySQL user that defines the privileges the external LDAP-authenticated user should have. For example, an LDAP user named joe can connect and have the privileges of a MySQL user named developer, if the LDAP group for joe is developer.

- Security: Using TLS, connections to the LDAP server can be secure.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The files must be located in the directory named by the plugin_dir system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin names</td>
<td>authentication_ldap_sasl, authentication_ldap_simple</td>
</tr>
<tr>
<td>Client-side plugin names</td>
<td>authentication_ldap_sasl_client, mysql_clear_password</td>
</tr>
<tr>
<td>Library file names</td>
<td>authentication_ldap_sasl.so, authentication_ldap_sasl_client.so, authentication_ldap_simple.so</td>
</tr>
</tbody>
</table>

The library files include only the authentication_ldap_XXX authentication plugins. The client-side mysql_clear_password plugin is built into the libmysqlclient client library.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side authentication_ldap_simple plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side mysql_clear_password plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

- The server-side authentication_ldap_sasl plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side authentication_ldap_sasl_client plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

The following sections provide installation and usage information specific to LDAP pluggable authentication:

- Prerequisites for LDAP Pluggable Authentication
- How LDAP Authentication of MySQL Users Works
- Installing LDAP Pluggable Authentication
Authentication Plugins

• Uninstalling LDAP Pluggable Authentication

• Using LDAP Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For information about the `mysql_clear_password` plugin, see Section 6.4.1.4, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

Note

If your system supports PAM and permits LDAP as a PAM authentication method, another way to use LDAP for MySQL user authentication is to use the server-side `authentication_pam` plugin. See Section 6.4.1.5, “PAM Pluggable Authentication”.

Prerequisites for LDAP Pluggable Authentication

To use LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

• An LDAP server must be available for the LDAP authentication plugins to communicate with.

• LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

• An LDAP client library must be available on systems where the server-side `authentication_ldap_sasl` or `authentication_ldap_simple` plugin is used. Currently, supported libraries are the Windows native LDAP library, or the OpenLDAP library on non-Windows systems.

• To use SASL-based LDAP authentication:
  
  • The LDAP server must be configured to communicate with a SASL server.
  
  • A SASL client library must be is available on systems where the client-side `authentication_ldap_sasl_client` plugin is used. Currently, the only supported library is the Cyrus SASL library.

How LDAP Authentication of MySQL Users Works

This section provides a general overview of how MySQL and LDAP work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific LDAP authentication plugins, see Using LDAP Pluggable Authentication.

The client connects to the MySQL server, providing the MySQL client user name and the LDAP password:

• For simple LDAP authentication, the client-side and server-side plugins communicate the password as cleartext.

• For SASL-based LDAP authentication, the client-side and server-side plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

If the client user name and host name match no MySQL account, the connection is rejected.

If there is a matching MySQL account, authentication against LDAP occurs. The LDAP server looks for an entry matching the user and authenticates the entry against the LDAP password:
• If the MySQL account names an the LDAP user distinguished name (DN), LDAP authentication uses that value and the LDAP password provided by the client. (To associate an LDAP user DN with a MySQL account, include a `BY` clause that specifies an authentication string in the `CREATE USER` statement that creates the account.)

• If the MySQL account names no LDAP user DN, LDAP authentication uses the user name and LDAP password provided by the client. In this case, the authentication plugin first binds to the LDAP server using the root DN and password as credentials to find the user DN based on the client user name, then authenticates that user DN against the LDAP password. This bind using the root credentials fails if the root DN and password are set to incorrect values, or are empty (not set) and the LDAP server does not permit anonymous connections.

If the LDAP server finds no match or multiple matches, authentication fails and the client connection is rejected.

If the LDAP server finds a single match, LDAP authentication succeeds (assuming that the password is correct), the LDAP server returns the LDAP entry, and the authentication plugin determines the name of the authenticated user based on that entry:

• If the LDAP entry has a group attribute (by default, the `cn` attribute), the plugin returns its value as the authenticated user name.

• If the LDAP entry has no group attribute, the authentication plugin returns the client user name as the authenticated user name.

The MySQL server compares the client user name with the authenticated user name to determine whether proxying occurs for the client session:

• If the names are the same, no proxying occurs: The MySQL account matching the client user name is used for privilege checking.

• If the names differ, proxying occurs: MySQL looks for an account matching the authenticated user name. That account becomes the proxied user, which is used for privilege checking. The MySQL account that matched the client user name is treated as the external proxy user.

**Installing LDAP Pluggable Authentication**

This section describes how to install the LDAP authentication plugins. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library files must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base names are `authentication_ldap_sasl` and `authentication_ldap_simple`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use `--plugin-load-add` options to name the library files that contain them. With this plugin-loading method, the options must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure.

Each server-side LDAP plugin exposes a set of system variables that enable its operation to be configured. Setting most of these is optional, but you must set the variables that specify the LDAP server host (so the plugin knows where to connect) and base distinguished name for LDAP bind operations (to limit
the scope of searches and obtain faster searches). For details about all LDAP system variables, see Section 6.4.1.11, “Pluggable Authentication System Variables”.

To load the plugins and set the LDAP server host and base distinguished name for LDAP bind operations, put lines such as these in your `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
plugin-load-add=authentication_ldap_simple.so
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to register the plugins at runtime, use these statements (adjust the `.so` suffix as necessary):

```
INSTALL PLUGIN authentication_ldap_sasl
SONAME 'authentication_ldap_sasl.so';
INSTALL PLUGIN authentication_ldap_simple
SONAME 'authentication_ldap_simple.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup.

After installing the plugins at runtime, their system variables become available and you can add settings for them to your `my.cnf` file to configure the plugins for subsequent restarts. For example:

```
[mysqld]
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to set and persist the values at runtime, use these statements:

```
SET PERSIST authentication_ldap_sasl_server_host='127.0.0.1';
SET PERSIST authentication_ldap_sasl_bind_base_dn='dc=example,dc=com';
SET PERSIST authentication_ldap_simple_server_host='127.0.0.1';
SET PERSIST authentication_ldap_simple_bind_base_dn='dc=example,dc=com';
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. To change a value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'ldap%';
+-----------------+-----------------+
| PLUGIN_NAME     | PLUGIN_STATUS   |
+-----------------+-----------------+
```

1203
If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with an LDAP plugin, see Using LDAP Pluggable Authentication.

### Additional Notes for SELinux

On systems running EL6 or EL that have SELinux enabled, changes to the SELinux policy are required to enable the MySQL LDAP plugins to communicate with the LDAP service:

1. Create a file `mysqlldap.te` with these contents:
   ```
   module mysqlldap 1.0;
   require {
     type ldap_port_t;
     type mysqld_t;
     class tcp_socket name_connect;
   }
   #============= mysqld_t ==============
   allow mysqld_t ldap_port_t:tcp_socket name_connect;
   ```
2. Compile the security policy module into a binary representation:
   ```
   checkmodule -M -m mysqlldap.te -o mysqlldap.mod
   ```
3. Create an SELinux policy module package:
   ```
   semodule_package -m mysqlldap.mod -o mysqlldap.pp
   ```
4. Install the module package:
   ```
   semodule -i mysqlldap.pp
   ```
5. When the SELinux policy changes has been made, restart the MySQL server:
   ```
   service mysqld restart
   ```

### Uninstalling LDAP Pluggable Authentication

The method used to uninstall the LDAP authentication plugins depends on how you installed them:

- If you installed the plugins at server startup using `--plugin-load-add` options, restart the server without those options.

- If you installed the plugins at runtime using `INSTALL PLUGIN`, they remain installed across server restarts. To uninstall them, use `UNINSTALL PLUGIN`:
  ```
  UNINSTALL PLUGIN authentication_ldap_sasl;
  ```
UNINSTALL PLUGIN authentication_ldap_simple;

In addition, remove from your my.cnf file any startup options that set LDAP plugin-related system variables. If you used SET PERSIST to persist LDAP system variables, use RESET PERSIST to remove the settings.

Using LDAP Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using LDAP pluggable authentication. It is assumed that the server is running with the appropriate server-side plugins enabled, as described in Installing LDAP Pluggable Authentication, and that the appropriate client-side plugins are available on the client host.

This section does not describe LDAP configuration or administration. It is assumed that you are familiar with those topics.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side authentication_ldap_simple plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side mysql_clear_password plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

- The server-side authentication_ldap_sasl plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side authentication_ldap_sasl_client plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

Overall requirements for LDAP authentication of MySQL users:

- There must be an LDAP directory entry for each user to be authenticated.

- There must be a MySQL user account that specifies a server-side LDAP authentication plugin and optionally names the associated LDAP user distinguished name (DN). (To associate an LDAP user DN with a MySQL account, include a BY clause in the CREATE USER statement that creates the account.) If an account names no LDAP string, LDAP authentication uses the user name specified by the client to find the LDAP entry.

- Client programs connect using the connection method appropriate for the server-side authentication plugin the MySQL account uses. For LDAP authentication, connections require the MySQL user name and LDAP password. In addition, for accounts that use the server-side authentication_ldap_simple plugin, invoke client programs with the --enable-cleartext-plugin option to enable the client-side mysql_clear_password plugin.

The instructions here assume the following scenario:

- MySQL users betsy and boris authenticate to the LDAP entries for betsy_ldap and boris_ldap, respectively. (It is not necessary that the MySQL and LDAP user names differ. The use of different names in this discussion helps clarify whether an operation context is MySQL or LDAP.)

- LDAP entries use the uid attribute to specify user names. This may vary depending on LDAP server. Some LDAP servers use the cn attribute for user names rather than uid. To change the attribute, modify the authentication_ldap_simple_user_search_attr or authentication_ldap_sasl_user_search_attr system variable appropriately.
• These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
uid=boris_ldap,ou=People,dc=example,dc=com
```

• `CREATE USER` statements that create MySQL accounts name an LDAP user in the `BY` clause, to indicate which LDAP entry the MySQL account authenticates against.

The instructions for setting up an account that uses LDAP authentication depend on which server-side LDAP plugin is used.

• **Simple LDAP Authentication**

• **SASL-Based LDAP Authentication**

• **LDAP Authentication User DN Suffixes**

• **LDAP Authentication with Proxying**

• **LDAP Authentication Group Preference and Mapping Specification**

**Simple LDAP Authentication**

To configure a MySQL account for simple LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_simple` plugin, and optionally names the LDAP user distinguished name (DN):

```
CREATE USER user
    IDENTIFIED WITH authentication_ldap_simple
    [BY 'LDAP user DN'];
```

Suppose that a MySQL user `betsy` has this entry in the LDAP directory:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `betsy` looks like this:

```
CREATE USER 'betsy'@'localhost'
    IDENTIFIED WITH authentication_ldap_simple
    BY 'uid=betsy_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password, and by enabling the client-side `mysql_clear_password` plugin:

```
shell> mysql --user=betsy --password --enable-cleartext-plugin
Enter password: betsy_password (betsy_ldap LDAP password)
```

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to the LDAP server. A cleartext
password is necessary to use the server-side LDAP library without SASL, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.4, "Client-Side Cleartext Pluggable Authentication".

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

The authentication process occurs as follows:

1. The client-side plugin sends `betsy` and `betsy_password` as the client user name and LDAP password to the MySQL server.

2. The connection attempt matches the `betsy'@'localhost'` account. The server-side LDAP plugin finds that this account has an authentication string of `uid=betsy_ldap,ou=People,dc=example,dc=com` to name the LDAP user DN. The plugin sends this string and the LDAP password to the LDAP server.

3. The LDAP server finds the LDAP entry for `betsy_ldap` and the password matches, so LDAP authentication succeeds.

4. The LDAP entry has no group attribute, so the server-side plugin returns the client user name (`betsy`) as the authenticated user. This is the same user name supplied by the client, so no proxying occurs and the client session uses the `betsy'@'localhost'` account for privilege checking.

Had the matching LDAP entry contained a group attribute, that attribute value would have been the authenticated user name and, if the value differed from `betsy`, proxying would have occurred. For examples that use the group attribute, see LDAP Authentication with Proxying.

Had the `CREATE USER` statement contained no `BY` clause to specify the `betsy_ldap` LDAP distinguished name, authentication attempts would use the user name provided by the client (in this case, `betsy`). In the absence of an LDAP entry for `betsy`, authentication would fail.

**SASL-Based LDAP Authentication**

To configure a MySQL account for SASL LDAP authentication, the `CREATE USER` statement specifies the `authenticationldap_sasl` plugin, and optionally names the LDAP user distinguished name (DN):

```sql
CREATE USER user
  IDENTIFIED WITH authenticationldap_sasl
    [BY 'LDAP user DN'];
```

Suppose that a MySQL user `boris` has this entry in the LDAP directory:

```plaintext
uid=boris_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `boris` looks like this:

```sql
CREATE USER 'boris'@'localhost'
  IDENTIFIED WITH authenticationldap_sasl
```
The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password:

```shell
cat < mysql --user=boris --password
```

Enter password: `boris_password` (boris_ldap LDAP password)

For the server-side `authentication_ldap_sasl` plugin, clients use the client-side `authentication_ldap_sasl_client` plugin. If a client program does not find the client-side plugin, specify a `--plugin-dir` option that names the directory where the plugin library file is installed.

The authentication process for `boris` is similar to that previously described for `betsy` with simple LDAP authentication, except that the client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

### LDAP Authentication User DN Suffixes

LDAP authentication plugins permit the authentication string that provides user DN information to begin with a `+` prefix character:

- In the absence of a `+` character, the authentication string value is treated as is without modification.
- If the authentication string begins with `+`, the plugin constructs the full user DN value from the user name sent by the client, together with the DN specified in the authentication string (with the `+` removed). In the constructed DN, the client user name becomes the value of the attribute that specifies LDAP user names. This is `uid` by default; to change the attribute, modify the `authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr` system variable appropriately. The authentication string is stored as given in the `mysql.user` system table, with the full user DN constructed on the fly before authentication.

This account authentication string does not have `+` at the beginning, so it is taken as the full user DN:

```sql
CREATE USER 'baldwin'
    IDENTIFIED WITH authentication_ldap_simple
    BY 'uid=admin,ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`baldwin`). In this case, that name is not used because the authentication string has no prefix and thus fully specifies the user DN.

This account authentication string does have `+` at the beginning, so it is taken as just part of the user DN:

```sql
CREATE USER 'accounting'
    IDENTIFIED WITH authentication_ldap_simple
    BY '+ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`accounting`), which in this case is used as the `uid` attribute together with the authentication string to construct the user DN:

```
uid=accounting,ou=People,dc=example,dc=com
```

The accounts in the preceding examples have a nonempty user name, so the client always connects to the MySQL server using the same name as specified in the account definition. If an account has an empty
user name, such as the generic anonymous '@%' proxy account described in LDAP Authentication with Proxying, clients might connect to the MySQL server with varying user names. But the principle is the same: If the authentication string begins with +, the plugin uses the user name sent by the client together with the authentication string to construct the user DN.

**LDAP Authentication with Proxying**

LDAP authentication plugins support proxying, enabling a user to connect to the MySQL server as one user but assume the privileges of a different user. This section describes basic LDAP plugin proxy support. The LDAP plugins also support specification of group preference and proxy user mapping; see LDAP Authentication Group Preference and Mapping Specification.

The authentication scheme described here uses proxying based on mapping LDAP group attribute values to connecting MySQL users who authenticate using LDAP onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy user authenticated with LDAP, such that all the external logins are mapped to the MySQL accounts that hold the privileges. Any user who connects is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The instructions here assume the following scenario:

- LDAP entries use the `uid` and `cn` attributes to specify user name and group values, respectively. To use different user and group attribute names, set the appropriate system variables to configure the plugin:

  - For `authentication_ldap_simple`: Set `authentication_ldap_simple_user_search_attr` and `authentication_ldap_simple_group_search_attr`.
  - For `authentication_ldap_sasl`: Set `authentication_ldap_sasl_user_search_attr` and `authentication_ldap_sasl_group_search_attr`.

- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```plaintext
uid=basha,ou=People,dc=example,dc=com,cn=accounting
uid=basil,ou=People,dc=example,dc=com,cn=front_office
```

The group attribute values will become the authenticated user names, so they name the `accounting` and `front_office` proxied accounts.

- The examples assume use of SASL LDAP authentication. Make the appropriate adjustments for simple LDAP authentication.

Create the default proxy MySQL account:

```sql
CREATE USER '@%' IDENTIFIED WITH authentication_ldap_simple;
```

The proxy account definition has no `BY 'auth_string'` clause to name an LDAP user DN. Thus:

- When clients connect, the client user name is used as the LDAP user name to search for.

- The matching LDAP entry is expected to include a group attribute naming the proxied MySQL account that defines the privileges the client should have.
Authentication Plugins

Note
If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this problem, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

Create the proxied accounts and grant their privileges:

```
CREATE USER 'accounting'@'localhost' ACCOUNT LOCK;
CREATE USER 'front_office'@'localhost' ACCOUNT LOCK;

GRANT ALL PRIVILEGES
  ON accountingdb.*
  TO 'accounting'@'localhost';
GRANT ALL PRIVILEGES
  ON frontendb.*
  TO 'front_office'@'localhost';
```

Grant the `PROXY` privilege to the proxy account for each proxied account:

```
GRANT PROXY
  ON 'accounting'@'localhost'
  TO ''@'%';
GRANT PROXY
  ON 'front_office'@'localhost'
  TO ''@'%';
```

Use the `mysql` command-line client to connect to the MySQL server as `basha`.

```
shell> mysql --user=basha --password
Enter password: basha_password (basha LDAP password)
```

Authentication occurs as follows:

1. The server authenticates the connection using the `''@'%'` account, for client user `basha`.
2. The matching LDAP entry is:

   `uid=basha,ou=People,dc=example,dc=com,cn=accounting`

3. The matching LDAP entry has group attribute `cn=accounting`, so `accounting` becomes the authenticated user.
4. The authenticated user differs from the client user name `basha`, with the result that `basha` is treated as a proxy for `accounting`, and `basha` assumes the privileges of the `accounting` account. The following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----------------+----------------------+--------------+
| USER()          | CURRENT_USER()       | @@proxy_user |
|-----------------+----------------------+--------------+
| basha@localhost | accounting@localhost | ''@'%'       |
+-----------------+----------------------+--------------+
```

This demonstrates that `basha` uses the privileges granted to the `accounting` MySQL account, and that proxying occurred through the default proxy user account.

Now connect as `basil` instead:
The authentication process for `basil` is similar to that previously described for `basha`:

1. The server authenticates the connection using the `'@%'` account, for client user `basil`.
2. The matching LDAP entry is:
   
   ```
   uid=basil,ou=People,dc=example,dc=com,cn=front_office
   ```
3. The matching LDAP entry has group attribute `cn=front_office`, so `front_office` becomes the authenticated user.
4. The authenticated user differs from the client user name `basil`, with the result that `basil` is treated as a proxy for `front_office`, and `basil` assumes the privileges of the `front_office` account. The following query should return output as shown:
   
   ```
   mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
   +-----------------+------------------------+--------------+
   | USER()          | CURRENT_USER()         | @@proxy_user |
   +-----------------+------------------------+--------------+
   | basil@localhost | front_office@localhost | ''@'%'       |
   +-----------------+------------------------+--------------+
   ```

   This demonstrates that `basil` uses the privileges granted to the `front_office` MySQL account, and that proxying occurred through the default proxy user account.

**LDAP Authentication Group Preference and Mapping Specification**

As described in [LDAP Authentication with Proxying](#), basic LDAP authentication proxying works by the principle that the plugin uses the first group name returned by the LDAP server as the MySQL proxy user account name. This simple capability does not enable specifying any preference about which group name to use if the LDAP server returns multiple names, or any name other than the group name as the proxy user name.

As of MySQL 8.0.14, for MySQL accounts that use LDAP authentication, the authentication string can specify the following information to enable greater proxying flexibility:

- A list of groups in preference order, such that the plugin uses the first group name in the list that matches a group returned by the LDAP server.
- A mapping from group names to proxy user names, such that a group name when matched can provide a specified name to use as the proxy user. This provides an alternative to using the group name as the proxy user.

Consider the following MySQL proxy account definition:

```
CREATE USER ''@''
    IDENTIFIED WITH authentication_ldap_sasl
    BY '+ou=People,dc=example,dc=com#grp1=usera,grp2,grp3=userc';
```

The authentication string has a user DN suffix `ou=People,dc=example,dc=com` prefixed by the `+` character. Thus, as described in [LDAP Authentication User DN Suffixes](#), the full user DN is constructed from the user DN suffix as specified, plus the client user name as the `uid` attribute.
The remaining part of the authentication string begins with #, which signifies the beginning of group preference and mapping information. This part of the authentication string lists group names in the order grp1, grp2, grp3. The LDAP plugin compares that list with the set of group names returned by the LDAP server, looking in list order for a match against the returned names. The plugin uses the first match, or if there is no match, authentication fails.

Suppose that the LDAP server returns groups grp3, grp2, and grp7. The LDAP plugin uses grp2 because it is the first group in the authentication string that matches, even though it is not the first group returned by the LDAP server. If the LDAP server returns grp4, grp2, and grp1, the plugin uses grp1 even though grp2 also matches. grp1 has a precedence higher than grp2 because it is listed earlier in the authentication string.

Assuming that the plugin finds a group name match, it performs mapping from that group name to the MySQL proxy user name, if there is one. For the example proxy account, mapping occurs as follows:

- If the matching group name is grp1 or grp3, those are associated in the authentication string with user names usera and userc, respectively. The plugin uses the corresponding associated user name as the proxy user name.

- If the matching group name is grp2, there is no associated user name in the authentication string. The plugin uses grp2 as the proxy user name.

If the LDAP server returns a group in DN format, the LDAP plugin parses the group DN to extract the group name from it.

To specify LDAP group preference and mapping information, these principles apply:

- Begin the group preference and mapping part of the authentication string with a # prefix character.

- The group preference and mapping specification is a list of one or more items, separated by commas. Each item has the form group_name=user_name or group_name. Items should be listed in group name preference order. For a group name selected by the plugin as a match from set of group names returned by the LDAP server, the two syntaxes differ in effect as follows:

  - For an item specified as group_name=user_name (with a user name), the group name maps to the user name, which is used as the MySQL proxy user name.

  - For an item specified as group_name (with no user name), the group name is used as the MySQL proxy user name.

- To quote a group or user name that contains special characters such as space, surround it by double quote (") characters. For example, if an item has group and user names of my group name and my user name, it must be written in a group mapping using quotes:

"my group name"="my user name"

If an item has group and user names of my_group_name and my_user_name (which contain no special characters), it may but need not be written using quotes. Any of the following are valid:

my_group_name=my_user_name
my_group_name="my_user_name"
"my_group_name"=my_user_name
"my_group_name"="my_user_name"

- To escape a character, precede it by a backslash (\). This is useful particularly to include a literal double quote or backslash, which are otherwise not included literally.
• A user DN need not be present in the authentication string, but if present, it must precede the group preference and mapping part. A user DN can be given as a full user DN, or as a user DN suffix with a + prefix character.

6.4.1.8 No-Login Pluggable Authentication

The mysql_no_login server-side authentication plugin prevents all client connections to any account that uses it. Use cases for such a plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the plugin_dir system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_no_login</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None</td>
</tr>
<tr>
<td>Library file</td>
<td>mysql_no_login.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to no-login pluggable authentication:

• Installing No-Login Pluggable Authentication
• Uninstalling No-Login Pluggable Authentication
• Using No-Login Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”. For proxy user information, see Section 6.2.18, “Proxy Users”.

Installing No-Login Pluggable Authentication

This section describes how to install the no-login authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is mysql_no_login. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file (adjust the .so suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=mysql_no_login.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.
Alternatively, to register the plugin at runtime, use this statement (adjust the `.so` suffix as necessary):

```
INSTALL PLUGIN mysql_no_login SONAME 'mysql_no_login.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%login%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_no_login</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the no-login plugin, see Using No-Login Pluggable Authentication.

**Uninstalling No-Login Pluggable Authentication**

The method used to uninstall the no-login authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using `INSTALL PLUGIN`, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN mysql_no_login;
```

**Using No-Login Pluggable Authentication**

This section describes how to use the no-login authentication plugin to prevent connections from MySQL client programs to the server. It is assumed that the server is running with the server-side plugin enabled, as described in Installing No-Login Pluggable Authentication.

To refer to the no-login authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `mysql_no_login`.

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.

The following example provides a simple illustration of these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` system table:

```
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost'
```
IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.*
  TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user
  TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost'
   SQL SECURITY DEFINER
   VIEW nologindb.myview
   AS SELECT User, Host FROM mysql.user;

To provide protected access to the view to an ordinary user, do this:

GRANT SELECT ON nologindb.myview
  TO 'ordinaryuser'@'localhost';

Now the ordinary user can use the view to access the limited information it presents:

SELECT * FROM nologindb.myview;

Attempts by the user to access columns other than those exposed by the view result in an error, as do all attempts to select from the view by users not granted access to it.

Note

Because the nologin account cannot be used directly, the operations required to set up objects that it uses must be performed by root or similar account with the privileges required to create the objects and set DEFINER values.

An account that authenticates using mysql_no_login may be used as a proxied base user for proxy accounts:

-- create proxied account
CREATE USER 'proxy_base'@'localhost'
   IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ... 
  ON ... 
-- permit real_user to be a proxy account for proxied account
GRANT PROXY
  ON 'proxy_base'@'localhost'
  TO 'real_user'@'localhost';

This enables clients to access MySQL through the proxy account (real_user) but not to bypass the proxy mechanism by connecting directly as the proxied user (proxy_base).

6.4.1.9 Socket Peer-Credential Pluggable Authentication

The server-side auth_socket authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the SO_PEERCRED socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the SO_PEERCRED option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the plugin_dir system variable.
Table 6.20 Plugin and Library Names for Socket Peer-Credential Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>auth_socket</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_socket.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to socket pluggable authentication:

- Installing Socket Pluggable Authentication
- Uninstalling Socket Pluggable Authentication
- Using Socket Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=auth_socket.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to register the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%socket%';
```

```
+-------------+---------------+
| PLUGIN_NAME | PLUGIN_STATUS |
|-------------+---------------+
| auth_socket | ACTIVE        |
```
Authentication Plugins

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see Using Socket Pluggable Authentication.

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

• If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

• If you installed the plugin at runtime using `INSTALL PLUGIN`, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```
  UNINSTALL PLUGIN auth_socket;
  ```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server. If the names do not match, the plugin checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` system table row. If a match is found, the plugin permits the connection. The `authentication_string` value can be specified using an `IDENTIFIED ...AS` clause with `CREATE USER` or `ALTER USER`.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

  ```
  CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
  ```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stephanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

To permit both the `valerie` and `stephanie` operating system users to access MySQL through socket file connections that use the account, this can be done two ways:

• Name both users at account-creation time, one following `CREATE USER`, and the other in the `authentication_string`:

  ```
  CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
  ```

• If you have already used `CREATE USER` to create the account for a single user, use `ALTER USER` to add the second user:

  ```
  CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
  ALTER USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
  ```

To access the account, both `valerie` and `stephanie` specify `--user=valerie` at connect time.
6.4.1.10 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

Note

This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>test_plugin_server</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>auth_test_plugin</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_test_plugin.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to test pluggable authentication:

- Installing Test Pluggable Authentication
- Uninstalling Test Pluggable Authentication
- Using Test Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.17, “Pluggable Authentication”.

Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to register the plugin at runtime, use this statement (adjust the `.so` suffix as necessary):

```sql
LOAD PLUGIN auth_test_plugin.so;
```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%test_plugin%';
+--------------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>test_plugin_server</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+--------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see Using Test Pluggable Authentication.

### Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using INSTALL PLUGIN, it remains installed across server restarts. To uninstall it, use UNINSTALL PLUGIN:

```
UNINSTALL PLUGIN test_plugin_server;
```

### Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the IDENTIFIED WITH clause:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH test_plugin_server
BY 'testpassword';
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
shell> mysql --user=testuser --password
Enter password: testpassword
```

The plugin fetches the password as received from the client and compares it with the value stored in the authentication_string column of the account row in the mysql.user system table. If the two values match, the plugin returns the authentication_string value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the “user”):

```
[Note] Plugin test_plugin_server reported:
```

1219
6.4.1.11 Pluggable Authentication System Variables

These variables are unavailable unless the appropriate server-side plugin is installed:

- `authentication_ldap_sasl` for system variables with names of the form `authentication_ldap_sasl_xxx`
- `authentication_ldap_simple` for system variables with names of the form `authentication_ldap_simple_xxx`

Table 6.22 Authentication Plugin System Variable Summary

</tbody>
</table>
For SASL LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:
uid=user_name,ou=Admin,dc=example,dc=com

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_sasl_bind_root_dn`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--authentication-ldap-sasl-bind-root-dn=value</td>

<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_sasl_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_sasl` performs an initial LDAP binding using `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_sasl` performs a second bind using the user DN and client-supplied password.
- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_sasl` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

- `authentication_ldap_sasl_bind_root_pwd`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--authentication-ldap-sasl-bind-root-pwd=value</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>authentication_ldap_sasl_bind_root_pwd</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_sasl_bind_root_dn`. See the description of that variable.

- `authentication_ldap_sasl_ca_path`

For SASL LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

**Note**

In addition to setting the `authentication_ldap_sasl_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_sasl_tls` system variable.

- `authentication_ldap_sasl_group_search_attr`

For SASL LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_sasl_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.
This variable should be the empty string if you want no group or proxy authentication.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- **authentication_ldap_sasl_group_search_filter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>

</tbody>
</table>
| Default Value                    | `(|(&(objectClass=posixGroup)(memberUid=%s))

For SASL LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
(|(&(objectClass=posixGroup)(memberUid=\{UA\}))

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- **authentication_ldap_sasl_init_pool_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-sasl-init-pool-size=#</code></td>
</tr>
<tr>

<td><code>authentication_ldap_sasl_init_pool_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_sasl_init_pool_size` and `authentication_ldap_sasl_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_sasl_init_pool_size` connections, unless `authentication_ldap_sasl_max_pool_size=0` to disable pooling.

- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_sasl_max_pool_size`.

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_sasl_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_sasl_log_status`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-sasl-log-status=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_log_status</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the logging level. The following table shows the permitted level values and their meanings.

**Table 6.23 Log Levels for authentication_ldap_sasl_log_status**

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Types of Messages Logged</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No messages</td>
</tr>
<tr>
<td>2</td>
<td>Error messages</td>
</tr>
<tr>
<td>3</td>
<td>Error and warning messages</td>
</tr>
<tr>
<td>4</td>
<td>Error, warning, and information messages</td>
</tr>
<tr>
<td>5</td>
<td>All messages</td>
</tr>
</tbody>
</table>

On the client side, messages can be logged to the standard output by setting the `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable. The permitted and default values are the same as for `authentication_ldap_sasl_log_status`.

The `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable applies only to SASL LDAP authentication. It has no effect for simple LDAP authentication because the client plugin in that case is `mysql_clear_password`, which knows nothing about LDAP operations.

- `authentication_ldap_sasl_max_pool_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-sasl-max-pool-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_max_pool_size</code></td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with `authentication_ldap_sasl_init_pool_size`. See the description of that variable.

- `authentication_ldap_sasl_server_host`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-sasl-server-host=host_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_server_host</code></td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_sasl_auth_method_name=SCRAM-SHA-1`: The LDAP server host can be a host name or IP address.

- `authentication_ldap_sasl_server_port`

For SASL LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_sasl_tls`

For SASL LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. If you enable this variable, you may also wish to set the `authentication_ldap_sasl_ca_path` variable.
MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection. The `ldaps` method is deprecated and MySQL does not support it.

- `authentication_ldap_sasl_user_search_attr`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-sasl-user-search-attr=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_user_search_attr</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>uid</code></td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_sasl_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

- `authentication_ldap_simple_auth_method_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-auth-method-name=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_auth_method_name</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>SIMPLE</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method. These authentication method values are permitted:

- **SIMPLE**: This authentication method uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user distinguished name. See the description of `authentication_ldap_simple_bind_root_dn`.

- **AD-FOREST**: `authentication_ldap_simple` searches all the domains in the Active Directory forest, performing an LDAP bind to each Active Directory domain until the user is found in some domain.
Note
For simple LDAP authentication, it is recommended to also set TLS parameters to require that communication with the LDAP server take place over secure connections.

- `authentication_ldap_simple_bind_base_dn`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-bind-base-dn=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_bind_base_dn</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```plaintext
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```plaintext
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_simple_bind_root_dn`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-bind-root-dn=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_bind_root_dn</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
For simple LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_simple_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_simple` performs an initial LDAP binding using `authentication_ldap_simple_bind_root_dn` and `authentication_ldap_simple_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_simple` performs a second bind using the user DN and client-supplied password.

- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_simple` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

### authentication_ldap_simple_bind_root_pwd

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>

<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_simple_bind_root_dn`. See the description of that variable.

### authentication_ldap_simple_ca_path

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-ca-path=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_ca_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
For simple LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

**Note**

In addition to setting the `authentication_ldap_simple_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_simple_tls` system variable.

• `authentication_ldap_simple_group_search_attr`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-group-search-attr=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_group_search_attr</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>cn</code></td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_simple_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

• `authentication_ldap_simple_group_search_filter`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-group-search-filter=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_group_search_filter</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
For simple LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
(&(objectClass=posixGroup)(memberUid={UA}))
(&(objectClass=group)(member={UD}))
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- `authentication_ldap_simple_init_pool_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-init-pool-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_init_pool_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_simple_init_pool_size` and `authentication_ldap_simple_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_simple_init_pool_size` connections, unless `authentication_ldap_simple_max_pool_size=0` to disable pooling.

- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_simple_max_pool_size`. 
Authentication Plugins

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_simple_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_simple_max_pool_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with `authentication_ldap_simple_init_pool_size`. See the description of that variable.

- `authentication_ldap_simple_server_host`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-server-host=host_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_server_host</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_simple_auth_method_name=SIMPLE`: The LDAP server host can be a host name or IP address.

- For `authentication_ldap_simple_auth_method_name=AD-Forest`: The LDAP server host can be an Active Directory domain name. For example, for an LDAP server URL of `ldap://example.mem.local:389`, the server name can be `mem.local`.

An Active Directory forest setup can have multiple domains (LDAP server IPs), which can be discovered using DNS. On Unix and Unix-like systems, some additional setup may be required to configure your DNS server with SRV records that specify the LDAP servers for the Active Directory domain. Suppose that your configuration has these properties:

- The name server that provides information about Active Directory domains has IP address `10.172.166.100`.

- The LDAP servers have names `ldap1.mem.local` through `ldap3.mem.local` and IP addresses `10.172.166.101` through `10.172.166.103`.

You want the LDAP servers to be discoverable using SRV searches. For example, at the command line, a command like this should list the LDAP servers:
Perform the DNS configuration as follows:

1. Add a line to `/etc/resolv.conf` to specify the name server that provides information about Active Directory domains:

   ```
   nameserver 10.172.166.100
   ```

2. Configure the appropriate zone file for the name server with SRV records for the LDAP servers:

   ```
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap1.mem.local.
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap2.mem.local.
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap3.mem.local.
   ```

3. It may also be necessary to specify the IP address for the LDAP servers in `/etc/hosts` if the server host cannot be resolved. For example, add lines like this to the file:

   ```
   10.172.166.101 ldap1.mem.local
   10.172.166.102 ldap2.mem.local
   10.172.166.103 ldap3.mem.local
   ```

With the DNS configured as just described, the server-side LDAP plugin can discover the LDAP servers and will try to authenticate in all domains until authentication succeeds or there are no more servers.

Windows needs no such settings as just described. Given the LDAP server host in the `authentication_ldap_simple_server_host` value, the Windows LDAP library searches all domains and attempts to authenticate.

- **authentication_ldap_simple_server_port**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-server-port=port_num</code></td>
</tr>
<tr>

</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>389</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32376</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 8.0.14, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)
### The Connection-Control Plugins

 MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to clients after a certain number of consecutive failed connection attempts. This capability provides a deterrent that slows down brute force attacks that attempt to access MySQL user accounts. The plugin library contains two plugins:

- **CONNECTION_CONTROL** checks incoming connections and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

The **CONNECTION_CONTROL** plugin uses the audit plugin interface (see Section 29.2.4.8, “Writing Audit Plugins”). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and

<table>

</tbody>
</table>

For simple LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. If you enable this variable, you may also wish to set the `authentication_ldap_simple_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection. The `ldaps` method is deprecated and MySQL does not support it.

- **authentication_ldap_simple_user_search_attr**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--authentication-ldap-simple-user-search-attr=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_user_search_attr</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>uid</code></td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_simple_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

### 6.4.2 The Connection-Control Plugins

 MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to clients after a certain number of consecutive failed connection attempts. This capability provides a deterrent that slows down brute force attacks that attempt to access MySQL user accounts. The plugin library contains two plugins:

- **CONNECTION_CONTROL** checks incoming connections and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

The **CONNECTION_CONTROL** plugin uses the audit plugin interface (see Section 29.2.4.8, “Writing Audit Plugins”). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and
The Connection-Control Plugins

MySQL_AUDIT_CONNECTION_CHANGE_USER subevents to check whether the server should introduce a delay before responding to client connection attempts.

- CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS implements an INFORMATION_SCHEMA table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS table, see Section 25.41.1, “The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table”.

6.4.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, CONNECTION_CONTROL and CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is connection_control. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugins at server startup, use the --plugin-load-add option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file (adjust the .so suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to register the plugins at runtime, use these statements (adjust the .so suffix as necessary):

```
INSTALL PLUGIN CONNECTION_CONTROL SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS SONAME 'connection_control.so';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
         FROM INFORMATION_SCHEMA.PLUGINS
         WHERE PLUGIN_NAME LIKE 'connection%';
```

| PLUGIN_NAME                              | PLUGIN_STATUS |
|------------------------------------------+---------------|
| CONNECTION_CONTROL                       | ACTIVE        |
| CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS | ACTIVE        |

If a plugin fails to initialize, check the server error log for diagnostic messages.
If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-login-attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

**Note**

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin is of little use because without the `CONNECTION_CONTROL` plugin to provide the data that populates the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, retrievals from the table will always be empty.

- Connection Delay Configuration
- Connection Failure Assessment
- Connection Failure Monitoring

### Connection Delay Configuration

To enable you to configure its operation, the `CONNECTION_CONTROL` plugin exposes several system variables:

- `connection_control_failed_connections_threshold`: The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts.

- `connection_control_min_connection_delay`: The amount of delay to add for each consecutive connection failure above the threshold.

- `connection_control_max_connection_delay`: The maximum delay to add.

To entirely disable checking for failed connection attempts, set `connection_control_failed_connections_threshold` to zero. If `connection_control_failed_connections_threshold` is nonzero, the amount of delay is zero up through that many consecutive failed connection attempts. Thereafter, the amount of delay is the number of failed attempts above the threshold, multiplied by `connection_control_min_connection_delay` milliseconds. For example, with the default `connection_control_failed_connections_threshold` and `connection_control_min_connection_delay` values of 3 and 1000, respectively, there is no delay for the first three consecutive failed connection attempts by a client, a delay of 1000 milliseconds for the fourth failed attempt, 2000 milliseconds for the fifth failed attempt, and so on, up to the maximum delay permitted by `connection_control_max_connection_delay`.

You can set the `CONNECTION_CONTROL` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses,
and to increase the delay by 1500 milliseconds for each additional failure after that. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```ini
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=1500
```

To set and persist the variables at runtime, use these statements:

```sql
SET PERSIST connection_control_failed_connections_threshold = 4;
SET PERSIST connection_control_min_connection_delay = 1500;
```

`SET PERSIST` sets the value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. To change a value for the running MySQL instance without saving it for subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See Section 13.7.5.1, “SET Syntax for Variable Assignment”.

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables have fixed minimum and maximum values of 1000 and 2147483647, respectively. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

### Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

- If the client user proxies another user, the proxying user’s information is used. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see Section 6.2.18, “Proxy Users”).
• If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1@%.example.com`, `user1@%.com`, or `user1@%` entry instead, counting uses `user1@%.example.com`, `user1@%.com`, or `user1@%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

**Note**

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```sql
ERROR 1130 (HY000): Host 'host_name' is not allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `CONNECTION_CONTROL` does not see it, and does not count it.

### Connection Failure Monitoring

To monitor failed connections, use these information sources:

- The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

- The `INFORMATION_SCHEMA.CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per client user/host combination. This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets all accumulated failed-connection counters to zero, which has these visible effects:

- The `Connection_control_delay_generated` status variable is reset to zero.

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 6.4.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- Connection-Control System Variables
The Connection-Control Plugins

• Connection-Control Status Variables

Connection-Control System Variables

If the CONNECTION_CONTROL plugin is installed, it exposes these system variables:

• connection_control_failed_connections_threshold

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connection-control-failed-connections-threshold=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td>connection_control_failed_connections_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts:

• If the variable has a nonzero value \( N \), the server adds a delay beginning with consecutive failed attempt \( N+1 \). If a client has reached the point where connection responses are delayed, the delay also occurs for the next subsequent successful connection.

• Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how connection_control_failed_connections_threshold interacts with other connection-control system and status variables, see Section 6.4.2.1, "Connection-Control Plugin Installation".

• connection_control_max_connection_delay

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connection-control-max-connection-delay=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td>connection_control_max_connection_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2147483647</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>
The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

- **connection_control_min_connection_delay**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-control-min-connection-delay=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_min_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero. This is also the amount by which the server increases the delay for additional successive failures once it begins delaying.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

**Connection-Control Status Variables**

If the `CONNECTION_CONTROL` plugin is installed, it exposes this status variable:

- **Connection_control_delay_generated**

  The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

  This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA` `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see Section 25.41.1, “The `INFORMATION_SCHEMA` `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` Table”.

  Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

**6.4.3 The Password Validation Component**
The validate_password component serves to test passwords and improve security. This component exposes system variables that enable you to define password policy, and status variables for component monitoring.

**Note**

In MySQL 8.0.4, the validate_password plugin was reimplemented as the validate_password component. The following instructions describe how to use the component, not the plugin. For instructions on using the plugin, see The Password Validation Plugin in MySQL 5.7 Reference Manual.

The plugin form of validate_password is still available but is deprecated and will be removed in a future version of MySQL. MySQL installations that use the plugin should make the transition to using the component instead. See Section 6.4.3.3, “Transitioning to the Password Validation Component”.

The validate_password component implements these capabilities:

- In SQL statements that assign a password supplied as a cleartext value, the component checks the password against the current password policy and rejects the password if it is weak (the statement returns an ER_NOT_VALID_PASSWORD error). This applies to the ALTER USER, CREATE USER, GRANT, and SET PASSWORD statements.

- The VALIDATE_PASSWORD_STRENGTH() SQL function assesses the strength of potential passwords. The function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

For example, validate_password checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

```
mysql> ALTER USER USER() IDENTIFIED BY 'abc';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

Passwords specified as hashed values are not checked because the original password value is not available for checking:

```
mysql> ALTER USER 'jeffrey'@'localhost'
IDENTIFIED WITH mysql_native_password
AS '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

To configure password checking, modify the system variables having names of the form validate_password.xxx; these are the parameters that control password policy. See Section 6.4.3.2, “Password Validation Options and Variables”.

If validate_password is not installed, the validate_password.xxx system variables are not available, passwords in statements are not checked, and the VALIDATE_PASSWORD_STRENGTH() function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters.

Assuming that validate_password is installed, it implements three levels of password checking: LOW, MEDIUM, and STRONG. The default is MEDIUM; to change this, modify the value of validate_password.policy. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.
The Password Validation Component

- **LOW** policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password.length`.

- **MEDIUM** policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character. To change these values, modify `validate_password.number_count`, `validate_password.mixed_case_count`, and `validate_password.special_char_count`.

- **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password.dictionary_file`.

In addition, `validate_password` supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To provide control over this capability, `validate_password` exposes a `validate_password.check_user_name` system variable, which is enabled by default.

### 6.4.3.1 Password Validation Component Installation and Uninstallation

This section describes how to install and uninstall the `validate_password` password-validation component. For general information about installing and uninstalling components, see Section 5.5, “MySQL Server Components”.

**Note**

If you install MySQL 8.0 using the MySQL Yum repository, MySQL SLES Repository, or RPM packages provided by Oracle, the `validate_password` component is enabled by default after you start your MySQL Server for the first time.

Upgrades to MySQL 8.0 from 5.7 using Yum or RPM packages leave the `validate_password` plugin in place. To make the transition from the `validate_password` plugin to the `validate_password` component, see Section 6.4.3.3, “Transitioning to the Password Validation Component”.

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `validate_password` component, use this statement:

```
INSTALL COMPONENT 'file://component_validate_password';
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `validate_password` component, use this statement:

```
UNINSTALL COMPONENT 'file://component_validate_password';
```

`UNINSTALL COMPONENT` unloads the component, and deregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

### 6.4.3.2 Password Validation Options and Variables
This section describes the system and status variables that `validate_password` provides to enable its operation to be configured and monitored.

- **Password Validation Component System Variables**
- **Password Validation Component Status Variables**
- **Password Validation Plugin Options**
- **Password Validation Plugin System Variables**
- **Password Validation Plugin Status Variables**

**Password Validation Component System Variables**

If the `validate_password` component is enabled, it exposes several system variables that enable configuration of password checking:

```bash
mysql> SHOW VARIABLES LIKE 'validate_password.%';
+--------------------------------------+--------+
| Variable_name                        | Value  |
+--------------------------------------+--------+
| validate_password.check_user_name    | ON     |
| validate_password.dictionary_file    |        |
| validate_password.length             | 8      |
| validate_password.mixed_case_count   | 1      |
| validate_password.number_count       | 1      |
| validate_password.policy             | MEDIUM |
| validate_password.special_char_count | 1      |
+--------------------------------------+--------+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- **validate_password.check_user_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--validate-password.check-user-name [=OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password.check_user_name</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether `validate_password` compares passwords to the user name part of the effective user account for the current session and rejects them if they match. This variable is unavailable unless `validate_password` is installed.

By default, `validate_password.check_user_name` is enabled. This variable controls user name matching independent of the value of `validate_password.policy`.

When `validate_password.check_user_name` is enabled, it has these effects:
• Checking occurs in all contexts for which validate_password is invoked, which includes use of
  statements such as ALTER USER or SET PASSWORD to change the current user’s password, and
  invocation of functions such as VALIDATE_PASSWORD_STRENGTH().

• The user names used for comparison are taken from the values of the USER() and
  CURRENT_USER() functions for the current session. An implication is that a user who has
  sufficient privileges to set another user’s password can set the password to that user’s name, and
  cannot set that user’s password to the name of the user executing the statement. For example,
  ‘root’@‘localhost’ can set the password for ‘jeffrey’@‘localhost’ to ‘jeffrey’, but
  cannot set the password to ‘root’.

• Only the user name part of the USER() and CURRENT_USER() function values is used, not the host
  name part. If a user name is empty, no comparison occurs.

• If a password is the same as the user name or its reverse, a match occurs and the password is
  rejected.

• User-name matching is case sensitive. The password and user name values are compared as binary
  strings on a byte-by-byte basis.

• If a password matches the user name, VALIDATE_PASSWORD_STRENGTH() returns 0 regardless of
  how other validate_password system variables are set.

• validate_password.dictionary_file

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--validate-password.dictionary-file=file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password.dictionary_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the dictionary file that validate_password uses for checking passwords. This
variable is unavailable unless validate_password is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary
checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is
interpreted relative to the server data directory. File contents should be lowercase, one word per line.
Contents are treated as having a character set of utf8. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2
(STRONG); see the description of the validate_password.policy system variable. Assuming that is
true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file.
Any match causes the password to be rejected. Comparisons are not case sensitive.

For VALIDATE_PASSWORD_STRENGTH(), the password is checked against all policies,
including STRONG, so the strength assessment includes the dictionary check regardless of the
validate_password.policy value.
validate_password.dictionary_file can be set at runtime and assigning a value causes the named file to be read without a server restart.

- validate_password.length

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password.length=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password.length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of characters that validate_password requires passwords to have. This variable is unavailable unless validate_password is installed.

The validate_password.length minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

\[
\text{validate_password.number_count} + \text{validate_password.special_char_count} + (2 * \text{validate_password.mixed_case_count})
\]

If validate_password adjusts the value of validate_password.length due to the preceding constraint, it writes a message to the error log.

- validate_password.mixed_case_count

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password.mixed-case-count=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password.mixed_case_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of lowercase and uppercase characters that validate_password requires passwords to have if the password policy is MEDIUM or stronger. This variable is unavailable unless validate_password is installed.
For a given \texttt{validate\_password.mixed\_case\_count} value, the password must have that many lowercase characters, and that many uppercase characters.

- \texttt{validate\_password.number\_count}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--validate_password.number_count=#}</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{validate_password.number_count}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of numeric (digit) characters that \texttt{validate\_password} requires passwords to have if the password policy is \texttt{MEDIUM} or stronger. This variable is unavailable unless \texttt{validate\_password} is installed.

- \texttt{validate\_password.policy}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--validate_password.policy=value}</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{validate_password.policy}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The password policy enforced by \texttt{validate\_password}. This variable is unavailable unless \texttt{validate\_password} is installed.

\texttt{validate\_password.policy} affects how \texttt{validate\_password} uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by \texttt{validate\_password.check\_user\_name}.

The \texttt{validate\_password.policy} value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values \texttt{LOW}, \texttt{MEDIUM}, \texttt{STRONG}. The following table describes the tests performed for each policy. For the length test, the required length is the value of the
validate_password.length system variable. Similarly, the required values for the other tests are given by other validate_password.xxx variables.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Tests Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or LOW</td>
<td>Length</td>
</tr>
<tr>
<td>1 or MEDIUM</td>
<td>Length; numeric, lowercase/uppercase, and special characters</td>
</tr>
<tr>
<td>2 or STRONG</td>
<td>Length; numeric, lowercase/uppercase, and special characters; dictionary file</td>
</tr>
</tbody>
</table>

- **validate_password.special_char_count**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--validate-password.special-char-count=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password.special_char_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of nonalphanumeric characters that validate_password requires passwords to have if the password policy is MEDIUM or stronger. This variable is unavailable unless validate_password is installed.

**Password Validation Component Status Variables**

If the validate_password component is enabled, it exposes status variables that provide operational information:

```sql
mysql> SHOW STATUS LIKE 'validate_password.%';
+-----------------------------------------------+---------------------+
| Variable_name                                 | Value               |
+-----------------------------------------------+---------------------+
| validate_password.dictionary_file_last_parsed | 2018-01-15 08:33:49 |
| validate_password.dictionary_file_words_count | 1902                |
+-----------------------------------------------+---------------------+
```

The following list describes the meaning of each status variable.

- **validate_password.dictionary_file_last_parsed**

  When the dictionary file was last parsed. This variable is unavailable unless validate_password is installed.

- **validate_password.dictionary_file_words_count**

  The number of words read from the dictionary file. This variable is unavailable unless validate_password is installed.

**Password Validation Plugin Options**
To control activation of the validate_password plugin, use this option:

- `--validate-password[=value]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password[=value]</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the deprecated validate_password plugin at startup. The value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”. For example, `--validate-password=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the validate_password plugin has been previously registered with INSTALL PLUGIN or is loaded with `--plugin-load-add`. See Section 6.4.3.1, “Password Validation Component Installation and Uninstallation”.

## Password Validation Plugin System Variables

- `validate_password_check_user_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--validate-password-check-user-name=[OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_check_user_name</code></td>
</tr>
</tbody>
</table>
### The Password Validation Component

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.check_user_name` system variable of the `validate_password` component instead.

- `validate_password_dictionary_file`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-dictionary-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_dictionary_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file` system variable of the `validate_password` component instead.

- `validate_password_length`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-length=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.length` system variable of the `validate_password` component instead.

- `validate_password_mixed_case_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-mixed-case-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_mixed_case_count</code></td>
</tr>
</tbody>
</table>
The Password Validation Component

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.mixed_case_count` system variable of the `validate_password` component instead.

- `validate_password_number_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-number-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_number_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.number_count` system variable of the `validate_password` component instead.

- `validate_password_policy`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-policy=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>
The Password Validation Component

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.policy` system variable of the `validate_password` component instead.

- `validate_password_special_char_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-special-char-count=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_special_char_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This `validate_password` plugin system variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.special_char_count` system variable of the `validate_password` component instead.

Password Validation Plugin Status Variables

- `validate_password_dictionary_file_last_parsed`

This `validate_password` plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_last_parsed` status variable of the `validate_password` component instead.

- `validate_password_dictionary_file_words_count`

This `validate_password` plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_words_count` status variable of the `validate_password` component instead.

6.4.3.3 Transitioning to the Password Validation Component

- `validate_password_dictionary_file_last_parsed`

This plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_last_parsed` status variable of the `validate_password` component instead.

- `validate_password_dictionary_file_words_count`

This plugin status variable is deprecated and will be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_words_count` status variable of the `validate_password` component instead.
MySQL installations that currently use the `validate_password` plugin should make the transition to using the `validate_password` component instead. To do so, use the following procedure. The procedure installs the component before uninstalling the plugin, to avoid having a time window during which no password validation occurs. (The component and plugin can be installed simultaneously. In this case, the server attempts to use the component, falling back to the plugin if the component is unavailable.)

1. Install the `validate_password` component:
   ```sql
   INSTALL COMPONENT 'file://component_validate_password';
   ```

2. Test the `validate_password` component to ensure that it works as expected. If you need to set any `validate_password.xxx` system variables, you can do so at runtime using `SET GLOBAL`. (Any option file changes that must be made are performed in the next step.)

3. Adjust any references to the plugin system and status variables to refer to the corresponding component system and status variables. Suppose that you configure the plugin at startup using an option file like this:
   ```
   [mysqld]
   validate-password=FORCE_PLUS_PERMANENT
   validate_password_dictionary_file=/usr/share/dict/words
   validate_password_length=10
   validate_password_number_count=2
   ```
   To adjust the option file, omit the `--validate-password` option (it applies only to the plugin, not the component), and modify the system variable references:
   ```
   [mysqld]
   validate_password.dictionary_file=/usr/share/dict/words
   validate_password.length=10
   validate_password.number_count=2
   ```
   Similar adjustments are needed for applications that refer at runtime to `validate_password` plugin system and status variables.

4. Uninstall the `validate_password` plugin:
   ```sql
   UNINSTALL PLUGIN validate_password;
   ```
   If the `validate_password` plugin is loaded at server startup using a `--plugin-load` or `--plugin-load-add` option, omit that option from the server startup procedure. For example, if the option is listed in a server option file, remove it from the file.

5. Restart the server.

### 6.4.4 The MySQL Keyring

MySQL Server supports a keyring that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation is plugin-based:

- The `keyring_file` plugin stores keyring data in a file local to the server host. This plugin is available in all MySQL distributions, Community Edition and Enterprise Edition included. See Section 6.4.4.2, “Using the keyring_file File-Based Plugin”.

---

1254
• The `keyring_encrypted_file` plugin stores keyring data in an encrypted file local to the server host. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.3, “Using the `keyring_encrypted_file` Keyring Plugin”.

• `keyring_okv` is a KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.4, “Using the `keyring_okv` KMIP Plugin”.

• The `keyring_aws` plugin communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. This plugin is available in MySQL Enterprise Edition distributions. See Section 6.4.4.5, “Using the `keyring_aws` Amazon Web Services Keyring Plugin”.

• A MySQL server operational mode enables migration of keys between underlying keyring keystores. This enables DBAs to switch a MySQL installation from one keyring plugin to another. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”.

• An SQL interface for keyring key management is implemented as a set of user-defined functions (UDFs). See Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

• As of MySQL 8.0.16, the `keyring_keys` table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The `keyring_keys` table does not expose any sensitive keyring data such as key contents. See Section 26.12.17.2, “The `keyring_keys` table”.

**Warning**

The `keyring_file` and `keyring_encrypted_file` plugins for encryption key management are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

Uses for the keyring within MySQL include:

• The InnoDB storage engine uses the keyring to store its key for tablespace encryption. InnoDB can use any supported keyring plugin.

• MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. The audit log plugin can use any supported keyring plugin.

• When binary log encryption has been activated for a MySQL server (by setting `binlog_encryption=ON`), the binary log encryption keys used to encrypt the file passwords for the binary log files and relay log files are stored in the keyring. Any supported keyring plugin can be used to store binary log encryption keys. Binary log encryption keys are retained as long as there are files on the server that were encrypted using them. When the binary log master key is rotated manually, all binary log encryption keys that no longer apply to any retained binary log files or relay log files are cleared from the keyring. If a retained binary log file or relay log file cannot be initialized for re-encryption, the relevant binary log encryption keys are not deleted in case the files can be recovered in the future. For example, this might be the case if a file listed in a binary log index file is currently unreadable, or if a channel fails to initialize. For more information, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

For general keyring installation instructions, see Section 6.4.4.1, “Keyring Plugin Installation”. For information specific to a given keyring plugin, see the section describing that plugin.

For information about using the keyring UDFs, see Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
6.4.4.1 Keyring Plugin Installation

Keyring service consumers require a keyring plugin to be installed. MySQL provides these plugin choices:

- **keyring_file**: A plugin that stores keyring data in a file local to the server host. Available in all MySQL distributions.

- **keyring_encrypted_file**: A plugin that stores keyring data in an encrypted file local to the server host. Available in MySQL Enterprise Edition distributions.

- **keyring_okv**: A plugin that uses KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions.

- **keyring_aws**: A plugin that communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.

This section describes how to install the keyring plugin of your choosing. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

If you intend to use keyring user-defined functions (UDFs) in conjunction with the keyring plugin, install the UDFs following keyring installation using the instructions in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

Installation for each keyring plugin is similar. The following instructions use keyring_file. Users of a different keyring plugin can substitute its name for keyring_file.

The keyring_file plugin library file base name is keyring_file. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

![Note]

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is unsupported and results may not be as anticipated.

The keyring plugin must be loaded early during the server startup sequence so that server components can access it as necessary during their own initialization. For example, the InnoDB storage engine uses the keyring for tablespace encryption, so the keyring plugin must be loaded and available prior to InnoDB initialization.

To load the plugin, use the **--early-plugin-load** option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is .so, use these lines in the server my.cnf file (adjust the .so suffix for your platform as necessary):

```
[mysqld]
early-plugin-load=keyring_file.so
```

Before starting the server, check the notes for your chosen keyring plugin to see whether it permits or requires additional configuration.
The MySQL Keyring

- For `keyring_file`: Section 6.4.4.2, “Using the keyring_file File-Based Plugin”.
- For `keyring_okv`: Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”.
- For `keyring_aws`: Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”

After performing any plugin-specific configuration, verify plugin installation. With the MySQL server running, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'keyring%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyring_file</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

If no keyring plugin is available when a server component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if InnoDB finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, InnoDB can access only unencrypted tablespaces. To ensure that InnoDB can access encrypted tablespaces as well, use `--early-plugin-load` to load the keyring plugin.

Plugins can be loaded by other methods, such as the `--plugin-load` or `--plugin-load-add` option or the `INSTALL PLUGIN` statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain server components, such as InnoDB:

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after InnoDB initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an InnoDB table, any plugins named in it can be loaded during startup only after InnoDB initialization.

### 6.4.4.2 Using the keyring_file File-Based Plugin

The `keyring_file` plugin is a keyring plugin that stores keyring data in a file local to the server host.

**Warning**

The `keyring_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_file` plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_file` found here.

To be usable during the server startup process, `keyring_file` must be loaded using the `--early-plugin-load` option. The `keyring_file_data` system variable optionally configures the location of the file used by the `keyring_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file location for your platform as necessary):
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

For additional information about `keyring_file_data`, see Section 6.4.4.11, "Keyring System Variables".

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_file` plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 29.3.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

The key types permitted by `keyring_file` are described in Section 6.4.4.7, “Supported Keyring Key Types”.

### 6.4.4.3 Using the keyring_encrypted_file Keyring Plugin

**Note**

The `keyring_encrypted_file` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The `keyring_encrypted_file` plugin is a keyring plugin that stores keyring data in an encrypted file local to the server host. This plugin is available as of MySQL 5.7.21.

**Warning**

The `keyring_encrypted_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_encrypted_file` plugin, use the general keyring installation instructions found in Section 6.4.4.1, "Keyring Plugin Installation", together with the configuration information specific to `keyring_encrypted_file` found here.

To be usable during the server startup process, `keyring_encrypted_file` must be loaded using the `--early-plugin-load` option. To specify the password for encrypting the keyring data file, set the `keyring_encrypted_file_password` system variable. (The password is mandatory; if not specified at server startup, `keyring_encrypted_file` initialization fails.) The `keyring_encrypted_file_data`
The MySQL Keyring

system variable optionally configures the location of the file used by the `keyring_encrypted_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file location for your platform as necessary and substitute your chosen password):

```
[mysqld]
early-plugin-load=keyring_encrypted_file.so
keyring_encrypted_file_data=/usr/local/mysql/mysql-keyring/keyring-encrypted
keyring_encrypted_file_password=password
```

Because the `my.cnf` file stores a password when written as shown, it should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

For additional information about the system variables used to configure the `keyring_encrypted_file` plugin, see Section 6.4.4.11, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_encrypted_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum. In addition, `keyring_encrypted_file` encrypts file contents using AES before writing the file, and decrypts file contents after reading the file.

The `keyring_encrypted_file` plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 29.3.2, “The Keyring Service”.

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

The key types permitted by `keyring_encrypted_file` are described in Section 6.4.4.7, “Supported Keyring Key Types”.

### 6.4.4.4 Using the keyring_okv KMIP Plugin

#### Note

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys between a key management server and its clients. The `keyring_okv` keyring plugin uses the KMIP 1.1 protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively by the back end, not by `keyring_okv`. The plugin works with these KMIP-compatible products:

- Oracle Key Vault
The keyring_okv plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- **SQL interface**: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- **C interface**: In C-language code, call the keyring service functions described in Section 29.3.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

The key types permitted by keyring_okv are described in Section 6.4.4.7, “Supported Keyring Key Types”.

To install the keyring_okv plugin, use the general keyring installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to keyring_okv found here.

- **General keyring_okv Configuration**
- **Configuring keyring_okv for Oracle Key Vault**
- **Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance**
- **Password-Protecting the keyring_okv Key File**

### General keyring_okv Configuration

Regardless of which KMIP back end the keyring_okv plugin uses for keyring storage, the keyring_okv_conf_dir system variable configures the location of the directory used by keyring_okv for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, keyring_okv writes a message to the error log during server startup that it cannot communicate:

```
[Warning] Plugin keyring_okv reported: 'For keyring_okv to be initialized, please point the keyring_okv_conf_dir variable to a directory containing Oracle Key Vault configuration file and ssl materials'
```

The keyring_okv_conf_dir variable must name a directory that contains the following items:

- **okvclient.ora**: A file that contains details of the KMIP back end with which keyring_okv will communicate.

- **ssl**: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: `CA.pem`, `cert.pem`, and `key.pem`. If the key file is password-protected, the ssl directory can contain a single-line text file named `password.txt` containing the password needed to decrypt the key file.

Both the okvclient.ora file and ssl directory with the certificate and key files are required for keyring_okv to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with keyring_okv, as described elsewhere.

The configuration directory used by keyring_okv as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example,
on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

To be usable during the server startup process, `keyring_okv` must be loaded using the `--early-plugin-load` option. Also, set the `keyring_okv_conf_dir` system variable to tell `keyring_okv` where to find its configuration directory. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and directory location for your platform as necessary):

```
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```

For additional information about `keyring_okv_conf_dir`, see Section 6.4.4.11, “Keyring System Variables”.

### Configuring keyring_okv for Oracle Key Vault

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- Oracle Key Vault site
- Oracle Key Vault documentation

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.
2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the Oracle Key Vault site and consult the Oracle Key Vault Administrator’s Guide.

1. Create the configuration directory that will contain the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see General `keyring_okv` Configuration).
2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
5. Log out from the Oracle Key Vault server.

6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.

7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

   ```bash
   java -jar okvclient.jar -d dir_name [-v]
   ```

   The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

   When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password will be required when the endpoint connects to Oracle Key Vault.)

8. The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

   ```bash
   install_dir/conf/okvclient.ora
   ```

   The file contents include lines that look something like this:

   ```bash
   SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num
   ```

   The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails:

   - For the `SERVER` variable, a setting in the `okvclient.ora` file is mandatory.
   - For the `STANDBY_SERVER` variable, a setting in the `okvclient.ora` file is optional.

9. Go to the Oracle Key Vault installer directory and test the setup by running this command:

   ```bash
   okvutil/bin/okvutil list
   ```

   The output should look something like this:

   ```bash
   Unique ID                               Type            Identifier
   255AB8DE-C97F-482C-E053-0100007F28B9 Symmetric Key -
   264BF6E0-A20E-7C42-E053-0100007FB29C Symmetric Key -
   ```

   For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

   ```bash
   no objects found
   ```

10. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

    ```bash
    jar xf okvclient.jar ssl
    ```

11. Copy the Oracle Key Vault support files (the `okvclient.ora` file and the `ssl` directory) into the configuration directory.
12. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okv Key File.

After completing the preceding procedure, restart the MySQL server. It loads the keyring_okv plugin and keyring_okv uses the files in its configuration directory to communicate with Oracle Key Vault.

**Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance**

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). The keyring_okv keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure keyring_okv and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the KeySecure User Guide.

1. Create the configuration directory that will contain the KeySecure support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see General keyring_okv Configuration).

2. In the configuration directory, create a subdirectory named `ssl` to use for storing the required SSL certificate and key files.

3. In the configuration directory, create a file named `okvclient.ora`. It should have following format:

   ```
   SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num
   
   For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, the `okvclient.ora` file looks like this:
   
   ```
   ```
   SERVER=198.51.100.20:9002
   STANDBY_SERVER=198.51.100.20:9002
   ```

4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.

5. Navigate to Security >> Local CAs and create a local certificate authority (CA).

6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.

7. Download the CA and save it in the `ssl` directory as a file named `CA.pem`.

8. Navigate to Security >> Certificate Requests and create a certificate. Then you will be able to download a compressed `tar` file containing certificate PEM files.

9. Extract the PEM files from in the downloaded file. For example, if the file name is `csr_w_pk_pkcs8.gz`, decompress and unpack it using this command:

   ```
   tar zxfv csr_w_pk_pkcs8.gz
   ```

   Two files result from the extraction operation: `certificate_request.pem` and `private_key_pkcs8.pem`.

10. Use this `openssl` command to decrypt the private key and create a file named `key.pem`:

    ```
    openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
    ```
11. Copy the `key.pem` file into the `ssl` directory.

12. Copy the certificate request in `certificate_request.pem` into the clipboard.

13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the `CA.pem` file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.

14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named `cert.pem` in the `ssl` directory.

15. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the `keyring_okv` Key File.

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with KeySecure.

### Password-Protecting the `keyring_okv` Key File

You can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To so do, change location to the `ssl` directory and perform these steps:

1. Encrypt the `key.pem` key file. For example, use a command like this, and enter the encryption password at the prompts:

   ```shell
   openssl rsa -des3 -in key.pem -out key.pem.new
   Enter PEM pass phrase: 
   Verifying - Enter PEM pass phrase: 
   ```

2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.

3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

   ```shell
   openssl rsa -in key.pem.new -passin file:password.txt
   ```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.

5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

### 6.4.4.5 Using the `keyring_aws` Amazon Web Services Keyring Plugin

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The `keyring_aws` plugin is a keyring plugin that communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

`keyring_aws` is available on these platforms:

- Debian 8
The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- AWS site
- KMS documentation

The following sections provide configuration and usage information for the keyring_aws keyring plugin:

- keyring_aws Configuration
- keyring_aws Operation
- keyring_aws Credential Changes

**keyring_aws Configuration**

To install the keyring_aws plugin, use the general installation instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the plugin-specific configuration information found here.

The plugin library file contains the keyring_aws plugin and two user-defined functions (UDFs), keyring_aws_rotate_cmk() and keyring_aws_rotate_keys().

To configure keyring_aws, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.
2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.
3. Use the AWS KMS account to create a customer master key (CMK) ID. At MySQL startup, set the keyring_aws_cmk_id system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using SET GLOBAL.)
4. If necessary, create the directory in which the configuration file will be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use /usr/local/mysql/mysql-keyring/keyring_aws_conf as the file name, the following commands (executed as root) create its parent directory and set the directory mode and ownership:

```
shell> cd /usr/local/mysql
shell> mkdir mysql-keyring
shell> chmod 750 mysql-keyring
shell> chown mysql mysql-keyring
shell> chgrp mysql mysql-keyring
```

At MySQL startup, set the keyring_aws_conf_file system variable to /usr/local/mysql/mysql-keyring/keyring_aws_conf to indicate the configuration file location to the server.
The MySQL Keyring

5. Prepare the `keyring_aws` configuration file, which should contain two lines:

   • Line 1: The secret access key ID
   • Line 2: The secret access key

   For example, if the key ID is `wwwwwwwwwwwwwEXAMPLE` and the key is `xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY`, the configuration file looks like this:

   ```
   wwwwwwwwwwwwwEXAMPLE
   xxxxxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY
   ```

   To be usable during the server startup process, `keyring_aws` must be loaded using the `--early-plugin-load` option. The `keyring_aws_cmk_id` system variable is mandatory and configures the customer master key (CMK) ID obtained from the AWS KMS server. The `keyring_aws_conf_file` and `keyring_aws_data_file` system variables optionally configure the locations of the files used by the `keyring_aws` plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file locations for your platform as necessary):

   ```
   [mysqld]
   early-plugin-load=keyring_aws.so
   keyring_aws_cmk_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
   keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
   keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
   ```

   For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, `keyring_aws` attempts to create it (as well as its parent directory, if necessary).

   For additional information about the system variables used to configure the `keyring_aws` plugin, see Section 6.4.4.11, “Keyring System Variables”.

   Start the MySQL server and install the UDFs associated with the `keyring_aws` plugin. This is a one-time operation, performed by executing the following statements (adjust the `.so` suffix for your platform as necessary):

   ```
   CREATE FUNCTION keyring_aws_rotate_cmk RETURNS INTEGER SONAME 'keyring_aws.so';
   CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER SONAME 'keyring_aws.so';
   ```

   **keyring_aws Operation**

   At plugin startup, the `keyring_aws` plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.

   During operation, `keyring_aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring_aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

   To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.
The MySQL Keyring

The **keyring_aws** plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- **C interface**: In C-language code, call the keyring service functions described in Section 29.3.2, "The Keyring Service".

- **SQL interface**: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, "General-Purpose Keyring Key-Management Functions".

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the **keyring_aws_rotate_cmk()** and **keyring_aws_rotate_keys()** UDFs "extend" the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling the UDFs. There are no corresponding C-language key service functions.

The key types permitted by **keyring_aws** are described in Section 6.4.4.7, "Supported Keyring Key Types".

**keyring_aws Credential Changes**

Assuming that the **keyring_aws** plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.

2. Store the new credentials in the configuration file (the file named by the **keyring_aws_conf_file** system variable). The file format is as described previously.

3. Reinitialize the **keyring_aws** plugin so that it rereads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- Restart the server. This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.

- Reinitialize the plugin without restarting the server by executing the following statements (adjust the **.so** suffix for your platform as necessary):

```sql
UNINSTALL PLUGIN keyring_aws;
INSTALL PLUGIN keyring_aws SONAME 'keyring_aws.so';
```

**Note**

In addition to loading a plugin at runtime, **INSTALL PLUGIN** has the side effect of registering the plugin it in the **mysql.plugin** system table. Because of this, if you decide to stop using **keyring_aws**, it is not sufficient to remove the **--early-plugin-load** option from the set of options used to start the server. That stops the plugin from loading early, but the server still attempts to load it when it gets to the point in the startup sequence where it loads the plugins registered in **mysql.plugin**.
Consequently, if you execute the UNINSTALL PLUGIN plus INSTALL PLUGIN sequence just described to change the AWS KMS credentials, then to stop using keyring_aws, it is necessary to execute UNINSTALL PLUGIN again to unregister the plugin in addition to removing the --early-plugin-load option.

6.4.4.6 Migrating Keys Between Keyring Keystores

The MySQL server supports an operational mode that enables migration of keys between underlying keyring keystores. This enables DBAs to switch a MySQL installation from one keyring plugin to another. A migration server (that is, a server started in key migration mode) does not accept client connections. Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

It is possible to perform offline or online key migration:

• If you are sure that no running server on the local host is using the source or destination keystore, an offline migration is possible. In this case, the migration server can modify the keystores without possibility of a running server modifying keystore content during the migration.

• If a running server on the local host is using the source or destination keystore, an online migration must be performed. In this case, the migration server connects to the running server and instructs it to pause keyring operations while key migration is in progress.

The result of a key migration operation is that the destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore. The source keystore is the same before and after the migration because keys are copied, not moved. If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.

The user who invokes the server in key-migration mode must not be the root operating system user, and must have permission to read and write the keyring files.

To perform a key migration operation, determine which key migration options are needed. Migration options indicate which keyring plugins are involved, and whether to perform an offline or online migration:

• To indicate the source and destination keyring plugins, specify these options:

  • --keyring-migration-source: The source keyring plugin that manages the keys to be migrated.
  • --keyring-migration-destination: The destination keyring plugin to which the migrated keys are to be copied.

These options tell the server to run in key migration mode. Both options are mandatory for all key migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

• For an offline migration, no additional key migration options are needed.

  Warning
  Do not perform offline migration involving a keystore that is in use by a running server.

• For an online migration, some running server currently is using the source or destination keystore. Specify the key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.
Use of any of the following options signifies an online migration:

- **--keyring-migration-host**: The host where the running server is located. This is always the local host.

- **--keyring-migration-user, --keyring-migration-password**: The user name and password for the account to use to connect to the running server.

- **--keyring-migration-port**: For TCP/IP connections, the port number to connect to on the running server.

- **--keyring-migration-socket**: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For additional details about the key migration options, see Section 6.4.4.10, “Keyring Command Options”.

Start the migration server with the key migration options determined as just described, possibly with other options. Keep the following considerations in mind:

- Other server options might be required, such as other configuration parameters for the two keyring plugins. For example, if `keyring_file` is one of the plugins, you must set the `keyring_file_data` system variable if the keyring data file location is not the default location. Other non-keyring options may be required as well. One way to specify these options is by using `--defaults-file` to name an option file that contains the required options.

- If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server will be owned by `isabel`. Subsequent startup will fail when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this problem, start the migration server as the `root` operating system user and provide a `--user=user_name` option, where `user_name` is the system account normally used to run MySQL.

- The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.

Example command line for offline key migration:

```bash
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_file.so
--keyring-migration-destination=keyring_encrypted_file.so
--keyring_encrypted_file_password=password
```

Example command line for online key migration:

```bash
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_file.so
--keyring-migration-destination=keyring_encrypted_file.so
--keyring_encrypted_file_password=password
--keyring-migration-host=localhost
--keyring-migration-user=root
--keyring-migration-password=root_password
```

The key migration server performs the migration operation as follows:
1. (Online migration only) Connect to the running server using the connection options. The account used to connect must have the privileges required to modify the global `keyring_operations` system variable (`ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or `SUPER`).

2. (Online migration only) Disable `keyring_operations` on the running server. (The running server must support `keyring_operations`.)

3. Load the source and destination keyring plugins.

4. Copy keys from the source keyring to the destination keyring.

5. Unload the keyring plugins.

6. (Online migration only) Enable `keyring_operations` on the running server.

7. (Online migration only) Disconnect from the running server.

8. Exit.

If an error occurs during key migration, any keys that were copied to the destination plugin are removed, leaving the destination keystore unchanged.

**Important**

For an online migration operation, the migration server takes care of enabling and disabling `keyring_operations` on the running server. However, if the migration server exits abnormally (for example, if someone forcibly terminates it), it is possible that `keyring_operations` will not have been re-enabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore, it need not be restarted after the migration.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keyring plugin and restarted.
- If the running server was using the destination keystore and will continue to use it, it should be restarted after the migration to load all keys migrated into the destination keystore.

**Note**

MySQL server key migration mode supports pausing a single running server. To perform a key migration if multiple key servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set `keyring_operations=OFF`.
2. Use the migration server to perform an offline key migration.
3. Connect to each running server manually and set `keyring_operations=ON`.

All running servers must support the `keyring_operations=ON` system variable.

### 6.4.4.7 Supported Keyring Key Types

MySQL Keyring supports generating keys of different types (encryption algorithms) and lengths. The available key types depend on which keyring plugin is installed. A given plugin may also impose constraints on key lengths per key type.
Table 6.25, “Keyring Plugin Key Types” summarizes the permitted key types per keyring plugin. Lengths are in bytes. For a key generated using one of the keyring user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”, the length can be no more than 2,048 bytes, due to limitations of the UDF interface.

6.4.4.8 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval.

MySQL Server also includes an SQL interface for keyring key management, implemented as a set of general-purpose user-defined functions (UDFs) that access the functions provided by the internal keyring service. The keyring UDFs are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to UDF invocation. For these UDFs to be used, a keyring plugin such as `keyring_file` or `keyring_okv` must be enabled.

The UDFs described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have UDFs of its own that are intended for use only with that plugin; see Section 6.4.4.9, “Plugin-Specific Keyring Key-Management Functions”.

The following sections provide installation instructions for the keyring UDFs and demonstrate how to use them. For information about the keyring service functions invoked by the UDFs, see Section 29.3.2, “The Keyring Service”. For general keyring information, see Section 6.4.4, “The MySQL Keyring”.

Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring user-defined functions (UDFs), which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and UDFs, see Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

The keyring UDFs enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the UDFs will not work correctly without it. Attempts to use the UDFs without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
The plugin library file base name is **keyring_udf**. The file name suffix differs per platform (for example, **.so** for Unix and Unix-like systems, **.dll** for Windows).

To install the **keyring_udf** plugin and the UDFs, use the **INSTALL PLUGIN** and **CREATE FUNCTION** statements (adjust the **.so** suffix for your platform as necessary):

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER
  SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER
  SONAME 'keyring_udf.so';
```

If the plugin and UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the **UNINSTALL PLUGIN** and **DROP FUNCTION** statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

### Using General-Purpose Keyring Functions

Before using the keyring user-defined functions (UDFs), install them according to the instructions provided in [Installing or Uninstalling General-Purpose Keyring Functions](#).

The keyring UDFs are subject to these constraints:

- To use any keyring UDF, the **keyring_udf** plugin must be enabled. Otherwise, an error occurs:

  ```
  ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
  This function requires keyring_udf plugin which is not installed.
  Please install
  ```

  To install the **keyring_udf** plugin, see [Installing or Uninstalling General-Purpose Keyring Functions](#).

- The keyring UDFs invoke keyring service functions (see Section 29.3.2, "The Keyring Service"). The service functions in turn use whatever keyring plugin is installed (for example, **keyring_file** or **keyring_okv**). Therefore, to use any keyring UDF, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

  ```
  ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
  ```

  To install a keyring plugin, see Section 6.4.4.1, “Keyring Plugin Installation”. 

• To use any keyring UDF, a user must possess the global `EXECUTE` privilege. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

• A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring UDFs for manipulation of instance-wide keys, such as those created by InnoDB to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

• Keyring UDFs support the key types and lengths supported by the underlying keyring plugin, with the additional constraint that keys cannot be longer than 2,048 bytes (16,384 bits), due to limitations of the UDF interface. See Section 6.4.4.7, “Supported Keyring Key Types”.

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-------------------------------------------+
| keyring_key_generate('MyKey', 'DSA', 256) |
| +-------------------------------------------+
| 1 |
+-------------------------------------------+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified combination of key type and key length; see Section 6.4.4.7, “Supported Keyring Key Types”.

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
mysql> SELECT @x;
+------+
| @x   |
+------+
| NULL |
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
mysql> SELECT @x;
+------+
| @x   |
+------+
```

The MySQL Keyring

1273
This technique also applies to other keyring UDFs that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent UDF calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```
mysql> SELECT keyring_key_type_fetch('MyKey');
+---------------------------------+
| keyring_key_type_fetch('MyKey') |
| DSA                             |
+---------------------------------+

mysql> SELECT keyring_key_length_fetch('MyKey');
+-----------------------------------+
| keyring_key_length_fetch('MyKey') |
| 256                              |
+-----------------------------------+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+----------------------------------------------+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
| 1                                             |
+----------------------------------------------+

mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+--------------------------------------+
| HEX(keyring_key_fetch('MyShortKey')) |
| 1DB3B0FC3328A24C                     |
+--------------------------------------+
```

Keyring UDFs treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

```
mysql> SELECT keyring_key_remove('MyKey');
+-----------------------------+
| keyring_key_remove('MyKey') |
| 1                           |
+-----------------------------+
```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```
mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+------------------------------------------------------+
| keyring_key_store('AES_key', 'AES', 'Secret string') |
+------------------------------------------------------+
```
As indicated previously, a user must have the global `EXECUTE` privilege to call keyring UDFs, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each UDF call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.

2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.

3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account (`'root'@'localhost'` in this example), create the administrative schema and the stored function to access the key:

```
mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost' FUNCTION key_schema.get_shared_key() 
RETURNS BLOB READS SQL DATA 
RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
```

From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost' IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
```
The MySQL Keyring

for routine 'key_schema.get_shared_key'

From the administrative account, grant EXECUTE to key_user for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
    TO 'key_user'@'localhost';
```

From the key_user account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
+----------------------------------+
| HEX(key_schema.get_shared_key()) |
+----------------------------------+
| 9BAFB9E75CEEB013                 |
+----------------------------------+
```

General-Purpose Keyring Function Reference

For each general-purpose keyring user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see Using General-Purpose Keyring Functions.

- **keyring_key_fetch(key_id)**
  
  Given a key ID, deobfuscates and returns the key value.

  Arguments:

  - **key_id**: A string that specifies the key ID.

  Return value:

  Returns the key value as a string for success, **NULL** if the key does not exist, or **NULL** and an error for failure.

  **Note**

  Keyring values retrieved using **keyring_key_fetch()** are limited to 2,048 bytes, due to limitations of the UDF interface. A keyring value longer than that length can be stored using a keyring service function (see Section 29.3.2, ”The Keyring Service”), but if retrieved using **keyring_key_fetch()**, is truncated to 2,048 bytes.

  Example:

  ```
  mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
  +--------------------------------------------+
  | keyring_key_generate('RSA_key', 'RSA', 16) |
  +--------------------------------------------+
  |                                          1 |
  +--------------------------------------------+
  mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
  +-----------------------------------+
  | HEX(keyring_key_fetch('RSA_key')) |
  +-----------------------------------+
  | 91C2253B696064D3556984B6630F891A     |
  +-----------------------------------+
  mysql> SELECT keyring_key_type_fetch('RSA_key');
  +-----------------------------------+
  ```
The example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- **keyring_key_generate(key_id, key_type, key_length)**

  Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin, with the additional constraint that keys cannot be longer than 2,048 bytes (16,384 bits), due to limitations of the UDF interface. For the permitted types per plugin, see Section 29.3.2, "The Keyring Service".

  **Arguments:**
  - `key_id`: A string that specifies the key ID.
  - `key_type`: A string that specifies the key type.
  - `key_length`: An integer that specifies the key length in bytes. The maximum length is 2,048.

  **Return value:**
  Returns 1 for success, or `NULL` and an error for failure.

  **Example:**

  ```sql
  SELECT keyring_key_generate('RSA_key', 'RSA', 384);
  ```

- **keyring_key_length_fetch(key_id)**

  Given a key ID, returns the key length.

  **Arguments:**
  - `key_id`: A string that specifies the key ID.

  **Return value:**
  Returns the key length in bytes as an integer for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

  **Example:**

  ```sql
  SELECT keyring_key_length_fetch('RSA_key');
  ```

- **keyring_key_remove(key_id)**

  Removes a specified key from the keyring.
The MySQL Keyring

Removes the key with a given ID from the keyring.

Arguments:

• **key_id**: A string that specifies the key ID.

Return value:

Returns 1 for success, or **NULL** for failure.

Example:

```sql
mysql> SELECT keyring_key_remove('AES_key');
+-------------------------------+
| keyring_key_remove('AES_key') |
|                              1 |
+-------------------------------+
```

**keyring_key_store(key_id, key_type, key)**

Obfuscates and stores a key in the keyring.

Arguments:

• **key_id**: A string that specifies the key ID.

• **key_type**: A string that specifies the key type.

• **key**: A string that specifies the key value.

Return value:

Returns 1 for success, or **NULL** and an error for failure.

Example:

```sql
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----------------------------------------------------+
| keyring_key_store('new key', 'DSA', 'My key value') |
|                                                   1 |
+-----------------------------------------------------+
```

**keyring_key_type_fetch(key_id)**

Given a key ID, returns the key type.

Arguments:

• **key_id**: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, **NULL** if the key does not exist, or **NULL** and an error for failure.

Example:
See the description of `keyring_key_fetch()`.

### 6.4.4.9 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring UDFs, see Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

- **keyring_aws_rotate_cmk()**

  This UDF is associated with the `keyring_aws` plugin. Its use requires the **SUPER** privilege.

  `keyring_aws_rotate_cmk()` rotates the customer master key (CMK). Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.

  Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

  Arguments:

  None.

  Return value:

  Returns 1 for success, or **NULL** and an error for failure.

- **keyring_aws_rotate_keys()**

  This UDF is associated with the `keyring_aws` plugin. Its use requires the **SUPER** privilege.

  `keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

  `keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

  - After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` UDF
  - After changing the `keyring_aws_cmk_id` system variable to a different key value

  Arguments:

  None.

  Return value:

  Returns 1 for success, or **NULL** and an error for failure.

### 6.4.4.10 Keyring Command Options

MySQL supports the following keyring-related command-line options:

- **--keyring-migration-destination=plugin**
The destination keyring plugin for key migration. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”. The format and interpretation of the option value is the same as described for the `--keyring-migration-source` option.

Note

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

* `--keyring-migration-host=host_name`

The host location of the running server that is currently using one of the key migration keystores. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”. Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as `localhost`, `127.0.0.1`, `::1`, or the local host IP address or host name.

* `--keyring-migration-password[=password]`

The password for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”. If you omit the `password` value following the option name on the command line, the server prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

* `--keyring-migration-port=port_num`
### Property Value

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
</tbody>
</table>

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”.

- `--keyring-migration-socket=path`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--keyring-migration-socket={file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”.

- `--keyring-migration-source=plugin`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-migration-source=plugin_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The source keyring plugin for key migration. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”.

The option value is similar to that for `--plugin-load`, except that only one plugin library can be specified. The value is given as `name=plugin_library` or `plugin_library`. The `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If the plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Note

---

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- `--keyring-migration-user=user_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-migration-user=user_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
6.4.11 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see Section 6.4.4.1, “Keyring Plugin Installation”).

- **keyring_aws_cmk_id**
  
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-aws-cmk-id=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_aws_cmk_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The customer master key (CMK) ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed, but if it is installed, a value for this variable is mandatory.

- **keyring_aws_conf_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-aws-conf-file=file_name</code></td>
</tr>
<tr>

<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>platform specific</code></td>
</tr>
</tbody>
</table>

The location of the configuration file for the `keyring_aws` keyring plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described in Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”.

The default file name is `keyring_aws_conf`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.
The location of the storage file for the `keyring_aws` keyring plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, if the value assigned to `keyring_aws_data_file` specifies a file that does not exist, the `keyring_aws` plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, `keyring_aws` reads any encrypted keys contained in the file into its in-memory cache. `keyring_aws` does not cache unencrypted keys in memory.

The default file name is `keyring_aws_data`, located in the default keyring file directory. The location of this default directory is the same as for the `keyring_file_data` system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

</tr>
</thead>
<tbody>
<tr>
<td>sa-east-1</td>
<td></td>
</tr>
<tr>
<td>us-east-1</td>
<td></td>
</tr>
<tr>
<td>us-west-1</td>
<td></td>
</tr>
<tr>
<td>us-west-2</td>
<td></td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_encrypted_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring_encrypted`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th><code>INSTALL_LAYOUT</code> Value</th>
<th>Default <code>keyring_encrypted_file_data</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring_encrypted</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring_encrypted</code> under the <code>CMAKE_INSTALL_PREFIX</code> value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_encrypted_file_data` specifies a file that does not exist, the `keyring_encrypted_file` plugin attempts to create it (as well as its parent directory, if necessary).
If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the /usr/local/mysql/mysql-keyring directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_encrypted_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_encrypted_file_data` results in an error, the variable value remains unchanged.

### Important

Once the `keyring_encrypted_file` plugin has created its data file and started to use it, it is important not to remove the file. Loss of the file will cause data encrypted using its keys to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_encrypted_file_data` to match.)

- `keyring_encrypted_file_password`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-encrypted-file-password=password</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_encrypted_file_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The password used by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed. The password is mandatory for plugin operation; if not specified at server startup, `keyring_encrypted_file` initialization fails.

If this variable is specified in an option file, the file should have a restrictive mode and be accessible only to the account used to run the MySQL server.

### Important

Once the `keyring_encrypted_file_password` value has been set, changing it does not rotate the keyring password and could make the server inaccessible. If an incorrect password is provided, the `keyring_encrypted_file` plugin cannot load keys from the encrypted keyring file.

The password value cannot be displayed at runtime with `SHOW VARIABLES` or the Performance Schema `global_variables` table because the display value is obfuscated.
keyring_file_data

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-file-data=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_file_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the `keyring_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default keyring_file_data Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring</code> under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_file_data` specifies a file that does not exist, the `keyring_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
chgrp mysql mysql-keyring
```

If the `keyring_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_file_data` results in an error, the variable value remains unchanged.
Important

Once the `keyring_file` plugin has created its data file and started to use it, it is important not to remove the file. For example, InnoDB uses the file to store the master key used to decrypt the data in tables that use InnoDB tablespace encryption; see Section 15.6.3.9, “InnoDB Data-at-Rest Encryption”. Loss of the file will cause data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_file_data` to match.) It is recommended that you create a separate backup of the keyring data file immediately after you create the first encrypted table and before and after master key rotation.

- `keyring_okv_conf_dir`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--keyring-okv-conf-dir=dir_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_okv_conf_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>empty string</code></td>
</tr>
</tbody>
</table>

The path name of the directory that stores configuration information used by the `keyring_okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring_okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring_okv_conf_dir` value is empty. For the `keyring_okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see Section 6.4.4.4, “Using the `keyring_okv` KMIP Plugin”.

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```bash
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to `keyring_okv_conf_dir` specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, `keyring_okv` writes an error message to the error log. If an attempted runtime assignment to `keyring_okv_conf_dir` results in an error, the variable value and keyring operation remain unchanged.
MySQL Enterprise Audit

</tr>
</tbody>
</table>

Whether keyring operations are enabled. This variable is used during key migration operations. See Section 6.4.4.6, “Migrating Keys Between Keyring Keystores”. The privileges required to modify this variable are ENCRYPTION_KEY_ADMIN in addition to either SYSTEM_VARIABLES_ADMIN or SUPER.

### 6.4.5 MySQL Enterprise Audit

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy-to-use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the audit plugin (see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see Section 6.4.5.4, “Audit Log File Formats”.

For more information about controlling how logging occurs, including audit log file naming and format selection, see Section 6.4.5.5, “Audit Log Logging Configuration”. To perform filtering of audited events, see Section 6.4.5.6, “Audit Log Filtering”. For descriptions of the parameters used to configure the audit log plugin, see Audit Log Options and Variables.

If the audit log plugin is enabled, the Performance Schema (see Chapter 26, MySQL Performance Schema) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
```
WHERE NAME LIKE '/*/alog/*';

6.4.5.1 Audit Log Components

MySQL Enterprise Audit is based on the audit log plugin and related components:

- A server-side plugin named `audit_log` examines auditable events and determines whether to write them to the audit log.

- User-defined functions enable manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.

- Tables in the `mysql` system database provide persistent storage of filter and user account data.

- System variables enable audit log configuration and status variables provide runtime operational information.

- An `AUDIT_ADMIN` privilege enable users to administer the audit log.

6.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related components described in Section 6.4.5.1, “Audit Log Components”. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

Important

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

Note

If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `audit_log_filter_win_install.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.

- `audit_log_filter_linux_install.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

Run the script as follows. The example here uses the Linux installation script. Make the appropriate substitution for your system.

```
shell> mysql -u root -p < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```
Note

Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL 8.0, perform the MySQL upgrade procedure, making sure to use the option that forces an update (see Section 2.11, “Upgrading MySQL”). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

As of MySQL 8.0.12, for new MySQL installations, the `USER` and `HOST` columns in the `audit_log_user` table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the `User` and `Host` columns in the `mysql.user` system table. For upgrades to an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```sql
ALTER TABLE mysql.audit_log_user
  DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
  MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
  ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);
```

Note

To use MySQL Enterprise Audit in the context of master/slave replication, Group Replication, or InnoDB cluster, you must prepare the slave or secondary nodes prior to running the installation script on the master or primary node. This is necessary because the `INSTALL PLUGIN` statement in the script is not replicated.

1. On each slave or secondary node, extract the `INSTALL PLUGIN` statement from the installation script and execute it manually.
2. On the master or primary node, run the installation script as described previously.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'audit%';
+--------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit_log</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+--------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:
If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a
value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize
successfully.

Important

By default, rule-based audit log filtering logs no auditable events for any users.
This differs from legacy audit log behavior, which logs all auditable events for all
users (see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”). Should you wish to
produce log-everything behavior with rule-based filtering, create a simple filter to
enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no
explicitly assigned filter (which initially is true for all accounts).

Once installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it,
execute the following statements:

```
DROP TABLE IF EXISTS mysql.audit_log_user;
DROP TABLE IF EXISTS mysql.audit_log_filter;
UNINSTALL PLUGIN audit_log;
DROP FUNCTION audit_log_filter_set_filter;
DROP FUNCTION audit_log_filter_remove_filter;
DROP FUNCTION audit_log_filter_set_user;
DROP FUNCTION audit_log_filter_remove_user;
DROP FUNCTION audit_log_filter_flush;
DROP FUNCTION audit_log_encryption_password_get;
DROP FUNCTION audit_log_encryption_password_set;
DROP FUNCTION audit_log_read;
DROP FUNCTION audit_log_read_bookmark;
```

6.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain
sensitive information, such as the text of SQL statements. For security reasons, audit log files should be
written to a directory accessible only to the MySQL server and to users with a legitimate reason to view
the log. The default file name is `audit.log` in the data directory. This can be changed by setting the
`audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See Audit Log File Encryption.

6.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable
event occurs. Typically the first audit record written after plugin startup contains the server description
and startup options. Elements following that one represent events such as client connect and disconnect
events, executed SQL statements, and so forth. Only top-level statements are logged, not statements
within stored programs such as triggers or stored procedures. Contents of files referenced by statements
such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format`
system variable at server startup. These formats are available:
• New-style XML format (audit_log_format=NEW): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 8.0 uses new-style XML format by default.

• Old-style XML format (audit_log_format=OLD): The original audit log format used by default in older MySQL series.

• JSON format (audit_log_format=JSON)

By default, audit log file contents are written in new-style XML format, without compression or encryption.

Note
For information about issues to consider when changing the log format, see Audit Log File Format.

The following sections describe the available audit logging formats:

• New-Style XML Audit Log File Format
• Old-Style XML Audit Log File Format
• JSON Audit Log File Format

New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (audit_log_format=NEW), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
      --socket=/usr/local/mysql/mysql.sock
      --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
  </AUDIT_RECORD>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>2_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Connect</NAME>
    <CONNECTION_ID>5</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root</USER>
    <OS_LOGIN/>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>connect</COMMAND_CLASS>
    <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
    <PRIV_USER>root</PRIV_USER>
    <PROXY_USER/>
    <DB>test</DB>
  </AUDIT_RECORD>
  ...
</AUDIT>
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
MySQL Enterprise Audit

- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

  | #x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF] |

  The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  Example:

  `<NAME>Query</NAME>`

  Some common `<NAME>` values:

  - Audit: When auditing starts, which may be server startup time
  - Connect: When a client connects, also known as logging in
  - Query: An SQL statement (executed directly)
  - Prepare: Preparation of an SQL statement; usually followed by Execute
  - Execute: Execution of an SQL statement; usually follows Prepare
  - Shutdown: Server shutdown
  - Quit: When a client disconnects
  - NoAudit: Auditing has been turned off

  The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, Time.

  With the exception of Audit and NoAudit, these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, Create DB and Change user correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

- `<RECORD_ID>`

  A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format SEQ_TIMESTAMP. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in YYYY-MM-DDThh:mm:ss format indicating the date and time when the audit log plugin opened the file.

  Example:

  `<RECORD_ID>12_2017-10-16T14:06:33</RECORD_ID>`
• <TIMESTAMP>

A string representing a UTC value in YYYY-MM-DDTh:mm:ss UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a <TIMESTAMP> value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2017-10-16T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in <AUDIT_RECORD> elements. Many of them occur only with specific <NAME> element values.

• <COMMAND_CLASS>

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values correspond to the statement/sql/xxx command counters. For example, xxx is drop_table and select for DROP TABLE and SELECT statements, respectively. The following statement displays the possible names:

```sql
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

• <CONNECTION_ID>

An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

• <CONNECTION_TYPE>

The security state of the connection to the server. Permitted values are TCP/IP (TCP/IP connection established without encryption), SSL/TLS (TCP/IP connection established with encryption), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), and Shared Memory (Windows shared memory connection).

Example:

```
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

• <DB>

A string representing the default database name.
Example:

```
<DB>test</DB>
```

- **<HOST>**
  
  A string representing the client host name.

  Example:

  ```
  <HOST>localhost</HOST>
  ```

- **<IP>**
  
  A string representing the client IP address.

  Example:

  ```
  <IP>127.0.0.1</IP>
  ```

- **<MYSQL_VERSION>**
  
  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

  Example:

  ```
  <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
  ```

- **<OS_LOGIN>**
  
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.18, “Proxy Users”).

  Example:

  ```
  <OS_LOGIN>jeffrey</OS_LOGIN>
  ```

- **<OS_VERSION>**
  
  A string representing the operating system on which the server was built or is running.

  Example:

  ```
  <OS_VERSION>x86_64-Linux</OS_VERSION>
  ```

- **<PRIV_USER>**
  
  A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

  Example:
**MySQL Enterprise Audit**

- **<PRIV_USER>jeffrey</PRIV_USER>**
- **<PROXY_USER>**
  A string representing the proxy user (see Section 6.2.18, “Proxy Users”). The value is empty if user proxying is not in effect.
  
  Example:
  
  `<PROXY_USER>developer</PROXY_USER>`

- **<SERVER_ID>**
  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.
  
  Example:
  
  `<SERVER_ID>1</SERVER_ID>`

- **<SQLTEXT>**
  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.
  
  Example:
  
  `<SQLTEXT>DELETE FROM t1</SQLTEXT>`

- **<STARTUP_OPTIONS>**
  A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.
  
  Example:
  
  `<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld --port=3306 --log_output=FILE</STARTUP_OPTIONS>`

- **<STATUS>**
  An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.
  
  The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Section B.3.1, “Server Error Message Reference”.
  
  Warnings are not logged.
  
  Example:
<STATUS>1051</STATUS>

- <STATUS_CODE>

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The <STATUS_CODE> value differs from the <STATUS> value: <STATUS_CODE> is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. <STATUS> is the value of the mysql_errno() C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

<STATUS_CODE>0</STATUS_CODE>

- <USER>

A string representing the user name sent by the client. This may differ from the <PRIV_USER> value.

Example:

<User>root[root]@localhost[127.0.0.1]</User>

- <VERSION>

An unsigned integer representing the version of the audit log file format.

Example:

<VERSION>1</VERSION>

Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (audit_log_format=OLD), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:00 UTC"
    RECORD_ID="1_2017-10-16T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.7.21-log"/>
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="2_2017-10-16T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is <AUDIT>. The root element contains <AUDIT_RECORD> elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening <AUDIT> root element tag. When the plugin closes a log file, it writes the closing </AUDIT> root element tag. The closing tag is not present while the file is open.

Attributes of <AUDIT_RECORD> elements have these characteristics:

- Some attributes appear in every <AUDIT_RECORD> element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an <AUDIT_RECORD> element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The <, >, "", and & characters are encoded as &lt;, &gt;, &quot;, and &amp;, respectively. NUL bytes (U+00) are encoded as the ? character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:
The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  **Example:** NAME="Query"

  Some common NAME values:

  - `Audit`    When auditing starts, which may be server startup time
  - `Connect`  When a client connects, also known as logging in
  - `Query`    An SQL statement (executed directly)
  - `Prepare`  Preparation of an SQL statement; usually followed by Execute
  - `Execute`  Execution of an SQL statement; usually follows Prepare
  - `Shutdown` Server shutdown
  - `Quit`     When a client disconnects
  - `NoAudit`  Auditing has been turned off

  The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`.

  With the exception of "Audit" and "NoAudit", these values correspond to the COM_xxx command values listed in the `my_command.h` header file. For example, "Create DB" and "Change user" correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

- **RECORD_ID**

  A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

  **Example:** RECORD_ID="12_2017-10-16T14:25:00"

- **TIMESTAMP**

  A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a TIMESTAMP value occurring after the statement finishes, not when it was received.

  **Example:** TIMESTAMP="2017-10-16T14:25:32 UTC"

The following attributes are optional in `<AUDIT_RECORD>` elements. Many of them occur only for elements with specific values of the NAME attribute.

- **COMMAND_CLASS**

  A string that indicates the type of action performed.
Example: `COMMAND_CLASS="drop_table"`

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- **CONNECTION_ID**

  An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

  Example: `CONNECTION_ID="127"`

- **CONNECTION_TYPE**

  The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

  Example: `CONNECTION_TYPE="SSL/TLS"`

- **DB**

  A string representing the default database name.

  Example: `DB="test"`

- **HOST**

  A string representing the client host name.

  Example: `HOST="localhost"`

- **IP**

  A string representing the client IP address.

  Example: `IP="127.0.0.1"`

- **MYSQL_VERSION**

  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

  Example: `MYSQL_VERSION="5.7.21-log"`

- **OS_LOGIN**

  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.18, “Proxy Users”).
Example: `OS_LOGIN="jeffrey"`

- **OS_VERSION**
  
  A string representing the operating system on which the server was built or is running.

  Example: `OS_VERSION="x86_64-Linux"`

- **PRIV_USER**
  
  A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.

  Example: `PRIV_USER="jeffrey"`

- **PROXY_USER**
  
  A string representing the proxy user (see Section 6.2.18, “Proxy Users”). The value is empty if user proxying is not in effect.

  Example: `PROXY_USER="developer"`

- **SERVER_ID**
  
  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

  Example: `SERVER_ID="1"`

- **SQLTEXT**
  
  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

  Example: `SQLTEXT="DELETE FROM t1"`

- **STARTUP_OPTIONS**
  
  A string representing the options that were given on the command line or in option files when the MySQL server was started.

  Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- **STATUS**
  
  An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `STATUS_CODE` for information about how it differs from `STATUS`.

  The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Section B.3.1, “Server Error Message Reference”.

  Warnings are not logged.

  Example: `STATUS="1051"`
• **STATUS_CODE**

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The **STATUS_CODE** value differs from the **STATUS** value: **STATUS_CODE** is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. **STATUS** is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: **STATUS_CODE**="0"

• **USER**

A string representing the user name sent by the client. This may differ from the **PRIV_USER** value.

• **VERSION**

An unsigned integer representing the version of the audit log file format.

Example: **VERSION**="1"

**JSON Audit Log File Format**

For JSON-format audit logging (**audit_log_format=JSON**), the log file contents form a JSON array with each array element representing an audited event as a JSON hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```json
[
  {
    "timestamp": "2018-01-15 13:50:01",
    "id": 0,
    "class": "audit",
    "event": "startup",
    ...
  },
  {
    "timestamp": "2018-01-15 15:02:32",
    "id": 0,
    "class": "connection",
    "event": "connect",
    ...
  },
  ...
  {
    "timestamp": "2018-01-15 17:37:26",
    "id": 0,
    "class": "table_access",
    "event": "insert",
    ...
  }
]
```

The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening `[` array marker. When the plugin closes a log file, it writes the closing `]` array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

• Some items appear in every audit record. Others are optional and may appear depending on the audit record type.
• Order of items within an audit record is not guaranteed.

• Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.

• The " and \ characters are encoded as "]" and \", respectively.

The following examples show the JSON object formats for different event types (as indicated by the class and event items), reformatted slightly for readability:

Auditing startup event:

```json
{ "timestamp": "2018-01-15 14:21:56",
 "id": 0,
 "class": "audit",
 "event": "startup",
 "connection_id": 0,
 "startup_data": { "server_id": 1,
   "os_version": "i686-Linux",
   "mysql_version": "5.7.21-log",
   "args": ["/usr/local/mysql/bin/mysqld",
     "--loose-audit-log-format=JSON",
     "--log-error=log.err",
     "--pid-file=mysqld.pid",
     "--port=3306" ] } }
```

When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), connection_id is set to 0, and account and login are not present.

Auditing shutdown event:

```json
{ "timestamp": "2018-01-15 14:28:20",
 "id": 3,
 "class": "audit",
 "event": "shutdown",
 "connection_id": 0,
 "shutdown_data": { "server_id": 1 } }
```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), connection_id is set to 0, and account and login are not present.

Connect or change-user event:

```json
{ "timestamp": "2018-01-15 14:23:18",
 "id": 1,
 "class": "connection",
 "event": "connect",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": ":1", "proxy": "" },
 "connection_data": { "connection_type": "ssl",
   "status": 0,
   "db": "test" } }
```

Disconnect event:

```json
{ "timestamp": "2018-01-15 14:24:45",
 "id": 3,
 "class": "connection",
 "event": "disconnect",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
```

1304
MySQL Enterprise Audit

Query event:

```json
{ "timestamp": "2018-01-15 14:23:35",
 "id": 2,
 "class": "general",
 "event": "status",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
 "general_data": { "command": "Query",
 "sql_command": "show_variables",
 "query": "SHOW VARIABLES",
 "status": 0 } }
```

Table access event (read, delete, insert, update):

```json
{ "timestamp": "2018-01-15 14:23:41",
 "id": 0,
 "class": "table_access",
 "event": "insert",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "127.0.0.1", "proxy": "" },
 "table_access_data": { "db": "test",
 "table": "t1",
 "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
 "sql_command": "insert" }
```

The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a JSON hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- **account**

  The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the `CURRENT_USER()` function within the section: **user, host**.

  Example:

  ```json
  "account": { "user": "root", "host": "localhost" }
  ```

- **class**

  A string representing the event class. The class defines the type of event, when taken together with the event item that specifies the event subclass.

  Example:

  ```json
  "class": "connection"
  ```

The following table shows the permitted combinations of **class** and **event** values.

<table>
<thead>
<tr>
<th>Class Value</th>
<th>Permitted Event Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit</td>
<td>startup, shutdown</td>
</tr>
<tr>
<td>Class Value</td>
<td>Permitted Event Values</td>
</tr>
<tr>
<td>----------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>connection</td>
<td>connect, change_user, disconnect</td>
</tr>
<tr>
<td>general</td>
<td>status</td>
</tr>
<tr>
<td>table_access_data</td>
<td>read, delete, insert, update</td>
</tr>
</tbody>
</table>

- **connection_data**

  Information about a client connection. The value is a hash containing these items: connection_type, status, db. This item occurs only for audit records with a class value of connection.

  Example:

  ```json
  "connection_data": {
    "connection_type": "ssl",
    "status": 0,
    "db": "test"  
  }
  ```

- **connection_id**

  An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

  Example:

  ```json
  "connection_id": 5
  ```

- **event**

  A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the class item that specifies the event class. For more information, see the class item description.

  Example:

  ```json
  "event": "connect"
  ```

- **general_data**

  Information about an executed statement or command. The value is a hash containing these items: command, sql_command, query, status. This item occurs only for audit records with a class value of general.

  Example:

  ```json
  "general_data": {
    "command": "Query",
    "sql_command": "show_variables",
    "query": "SHOW VARIABLES",
    "status": 0  
  }
  ```

- **id**

  An unsigned integer representing an event ID.

  Example:
For audit records that have the same timestamp value, their id values distinguish them and form a sequence. Within the audit log, timestamp/id pairs are unique. These pairs are bookmarks that identify event locations within the log.

• **login**

Information indicating how a client connected to the server. The value is a hash containing these items: user, os, ip, proxy.

Example:

```
"login": { "user": "root", "os": ", "ip": ":1", "proxy": "" }
```

• **shutdown_data**

Information pertaining to audit log plugin termination. The value is a hash containing these items: server_id. This item occurs only for audit records with class and event values of audit and shutdown, respectively.

Example:

```
"shutdown_data": { "server_id": 1 } }
```

• **startup_data**

Information pertaining to audit log plugin initialization. The value is a hash containing these items: server_id, os_version, mysql_version, args. This item occurs only for audit records with class and event values of audit and startup, respectively.

Example:

```
"startup_data": { "server_id": 1,
 "os_version": "i686-Linux",
 "mysql_version": "5.7.21-log",
 "args": ["/usr/local/mysql/bin/mysqld",
 "--loose-audit-log-format=JSON",
 "--log-error=log.err",
 "--pid-file=mysqld.pid",
 "--port=3306" ] }
```

• **table_access_data**

Information about an access to a table. The value is a hash containing these items: db, table, query, sql_command. This item occurs only for audit records with a class value of table_access.

Example:

```
"table_access_data": { "db": "test",
 "table": "t1",
 "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
 "sql_command": "insert" }
```

• **timestamp**
A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

Example:

```
"timestamp": "2018-01-15 13:50:01"
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

These items appear within hash values associated with top-level items of JSON-format audit records:

- **args**
  
  An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

  Example:

  ```
  "args": ["/usr/local/mysql/bin/mysqld",
           "--loose-audit-log-format=JSON",
           "--log-error=log.err",
           "--pid-file=mysqld.pid",
           "--port=3306"
          ]
  ```

- **command**
  
  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  Example:

  ```
  "command": "Query"
  ```

- **connection_type**
  
  The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

  Example:

  ```
  "connection_type": "tcp/tcp"
  ```

- **db**
  
  A string representing a database name. For `connection_data`, it is the default database. For `table_access_data`, it is the table database.

  Example:
MySQL Enterprise Audit

*db*: "test"

- **host**

  A string representing the client host name.

  Example:

  "host": "localhost"

- **ip**

  A string representing the client IP address.

  Example:

  "ip": "::1"

- **mysql_version**

  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

  Example:

  "mysql_version": "5.7.21-log"

- **os**

  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See Section 6.2.18, “Proxy Users”.

  Example:

  "os": "jeffrey"

- **os_version**

  A string representing the operating system on which the server was built or is running.

  Example:

  "os_version": "i686-Linux"

- **proxy**

  A string representing the proxy user (see Section 6.2.18, “Proxy Users”). The value is empty if user proxying is not in effect.

  Example:

  "proxy": "developer"
MySQL Enterprise Audit

- **query**

  A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

  Example:

  
  ```json
  "query": "DELETE FROM t1"
  ```

- **server_id**

  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

  Example:

  ```json
  "server_id": 1
  ```

- **sql_command**

  A string that indicates the SQL statement type.

  Example:

  ```json
  "sql_command": "insert"
  ```

  The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

  ```sql
  SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
  FROM performance_schema.events_statements_summary_global_by_event_name
  WHERE EVENT_NAME LIKE 'statement/sql/%'
  ORDER BY name;
  ```

- **status**

  An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

  The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Section B.3.1, “Server Error Message Reference”.

  Warnings are not logged.

  Example:

  ```json
  "status": 1051
  ```

- **table**

  A string representing a table name.
Example:

```
"table": "t1"
```

- **user**

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

- Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.

- Within `login` items, `user` is a string representing the user name sent by the client.

Example:

```
"user": "root"
```

### 6.4.5.5 Audit Log Logging Configuration

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, and whether to enable log file compression and encryption.

- **Audit Log File Name**
  - **Audit Log File Format**
  - **Audit Log File Compression**
  - **Audit Log File Encryption**
  - **Audit Log File Manual Uncompression and Decryption**
  - **Audit Log File Space Management and Name Rotation**
  - **Audit Logging Write Strategy**
  - **Audit Log File Reading**

For additional information about the user-defined functions and system variables that affect audit logging, see [Audit Log Functions](#), and [Audit Log Options and Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See Section 6.4.5.6, “Audit Log Filtering”.

**Audit Log File Name**

To configure the audit log file name, set the `audit_log_file` system variable at server startup. By default, the name is `audit.log` in the server data directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

The plugin interprets the `audit_log_file` value as composed of a base name and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:
• If compression is enabled, the plugin adds a suffix of \texttt{.gz}.

• If encryption is enabled, the plugin adds a suffix of \texttt{.enc}.

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured \texttt{audit\_log\_file} value is \texttt{audit.log}, the effective file name is one of the values shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Effective File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td>\texttt{audit.log}</td>
</tr>
<tr>
<td>Compression</td>
<td>\texttt{audit.log.gz}</td>
</tr>
<tr>
<td>Encryption</td>
<td>\texttt{audit.log.enc}</td>
</tr>
<tr>
<td>Compression, encryption</td>
<td>\texttt{audit.log.gz.enc}</td>
</tr>
</tbody>
</table>

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

• During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.

• During termination, the plugin renames the audit log file.

• File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic log file rotation; see \texttt{Automatic Audit Log File Rotation}.

Audit Log File Format

To configure the audit log file format, set the \texttt{audit\_log\_format} system variable at server startup. By default, the format is \texttt{NEW} (new-style XML format). For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

If you change \texttt{audit\_log\_format}, it is recommended that you also change \texttt{audit\_log\_file}. Otherwise, there will be two sets of log files with the same base name but different formats.

Audit Log File Compression

Audit log file compression can be enabled for any logging format.

To configure audit log file compression, set the \texttt{audit\_log\_compression} system variable at server startup. Permitted values are \texttt{NONE} (no compression; the default) and \texttt{GZIP} (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See \texttt{Audit Log File Manual Uncompression and Decryption}.

Audit Log File Encryption

Audit log file encryption can be enabled for any logging format. Encryption is based on a user-defined password (with the exception of the initial password that the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

To configure audit log file encryption, set the \texttt{audit\_log\_encryption} system variable at server startup. Permitted values are \texttt{NONE} (no encryption; the default) and \texttt{AES} (AES-256-CBC cipher encryption).
To set or get an encryption password, use these user-defined functions (UDFs):

- To set the current encryption password, invoke `audit_log_encryption_password_set()`. This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic log file rotation; see Automatic Audit Log File Rotation.

  Previously written audit log files are not re-encrypted with the new password. Keep a record of the previous password should you need to decrypt those files manually.

- To get the current encryption password, invoke `audit_log_encryption_password_get()`, which retrieves the password from the keyring.

For additional information about audit log encryption functions, see Audit Log Functions.

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Audit Log File Manual Uncompression and Decryption.

### Audit Log File Manual Uncompression and Decryption

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that `audit_log_file` is set to `audit.log`. In that case, an archived audit log file has one of the names shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Archived File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.timestamp.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.timestamp.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>
<td><code>audit.timestamp.log.enc</code></td>
</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.timestamp.log.gz.enc</code></td>
</tr>
</tbody>
</table>

To uncompress a compressed log file manually, use `gunzip`, `gzip -d`, or equivalent command. For example:

```
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the `openssl` command. For example:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
  -in audit.timestamp.log.enc
  -out audit.timestamp.log
```

If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.enc` suffixes added, corresponding to the order in which those
operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
        -in audit.timestamp.log.gz.enc
        -out audit.timestamp.log.gz
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

### Audit Log File Space Management and Name Rotation

The audit log file has the potential to grow very large and consume a lot of disk space. To enable management of the space used by its log files, the audit log plugin provides for log file rotation, either manually or automatically. Rotation capabilities use the `audit_log_flush` and `audit_log_rotate_on_size` system variables:

- By default, `audit_log_rotate_on_size=0` and no log rotation occurs unless performed manually. In this case, use `audit_log_flush` to close and reopen the current log file after manually renaming it.

- If `audit_log_rotate_on_size` is greater than 0, automatic rotation occurs when a write to the current log file causes its size to exceed this value. The audit log plugin closes the file, renames it, and opens a new log file. With automatic rotation enabled, `audit_log_flush` has no effect.

- Automatic rotation also occurs under several other conditions, described later.

#### Note

Renamed log files are not removed automatically. For example, with size-based log file rotation, renamed log files do not rotate off the end of the name sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary.

The following discussion describes log file rotation methods in greater detail.

- Manual Audit Log File Rotation
- Automatic Audit Log File Rotation

### Manual Audit Log File Rotation

If `audit_log_rotate_on_size=0` (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

   ```
   mv audit.log.2 audit.log.3
   mv audit.log.1 audit.log.2
   mv audit.log audit.log.1
   ```

   This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:
SET GLOBAL audit_log_flush = ON;

`audit_log_flush` is special in that its value remains OFF so that you need not disable it explicitly before enabling it again to perform another flush.

**Note**

For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin no longer can determine that they are part of the log file sequence (see Audit Log File Reading). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

### Automatic Audit Log File Rotation

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the file, renames it, and opens a new log file.

Automatic rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see Audit Log File Name).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password.

The plugin renames the original file by inserting a timestamp just after its base name. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20180115T140633.log`. The timestamp is a UTC value in `YYYYMMDDTHHmmss` format. The timestamp indicates rotation time for XML logging, and the timestamp of the last event written to the file for JSON logging.

### Audit Logging Write Strategy

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.
With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

**Audit Log File Reading**

The audit log plugin enables bookmarking and reading of JSON-format audit log files. (These capabilities do not apply to files written in other log formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the audit log file (determined from the `audit_log_file` value) as the location to search for readable audit log files. To do this, it uses the value of `audit_log_file` to determine the file base name and suffix values, then looks for files with names that match the following pattern, where (...) indicates optional file name parts:

```
basename[.timestamp].suffix[.gz][.enc]
```

The plugin opens each matching file, checks that it really contains JSON audit records, and sorts them using the timestamps from the first record of each file to construct a list of log files that are subject to use with the log-reading functions.

The plugin cannot include in the sequence files that were renamed manually and do not match the preceding pattern, or that were encrypted with a password no longer available in the keyring.

To read events from the audit log, use these user-defined functions (UDFs):

- **audit_log_read_bookmark()** returns a JSON string representing a bookmark for the most recently written audit log event. This bookmark is suitable for passing to `audit_log_read()` to indicate to that function where to begin reading. Example bookmark:
  ```json
  { "timestamp": "2018-01-15 21:03:44", "id": 0 }
  ```

- **audit_log_read()** reads events from the audit log and returns a JSON string containing an array of audit events. Example `audit_log_read()` invocation using the current bookmark:
  ```sql
  mysql> SELECT audit_log_read(audit_log_read_bookmark());
  +-----------------------------------------------------------------------+
  | audit_log_read(audit_log_read_bookmark())                             |
  +-----------------------------------------------------------------------+
  | [ { "timestamp": "2018-01-15 22:41:24", "id": 0, "class": "connection", ... } |
  +-----------------------------------------------------------------------+
  ```

Each event in the `audit_log_read()` return value is a JSON hash, except that the last array element may be a JSON `null` value to indicate no following events are available to read. For example:

```json
[
  { "timestamp": "2018-01-15 22:08:08", "id": 10, "class": "general", "event": "status", ... },
  { "timestamp": "2018-01-15 22:08:08", "id": 11,
```
Use `audit_log_read()` like this:

- For the first call to `audit_log_read()` within a session, pass a bookmark indicating where to begin reading.

- If the final value of the returned array is not a **JSON null** value, there are more events following those just read and `audit_log_read()` can be called without or with a bookmark argument. Without an argument, reading continues with the next unread event. With a bookmark argument, reading continues from the bookmark.

- If the final value of the returned array is a **JSON null** value, there are no more events left to be read and the next call to `audit_log_read()` must include a bookmark argument.

A bookmark is a **JSON** hash that indicates where and how much to read. The following items are significant in the bookmark value (other items are ignored):

- **timestamp, id**: The location within the audit log of the first event to read. Both items must be present to completely specify a position.

- **max_array_length**: The maximum number of events to read from the log. If omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

The result returned from either log-reading function is a binary string. To use the string with functions that require a nonbinary string (such as the functions that manipulate **JSON** values), convert it to **utf8mb4**.

Suppose that a bookmark has this value:

```sql
mysql> SELECT @mark := audit_log_read_bookmark() AS mark;
+-------------------------------------------------+
| mark                                            |
+-------------------------------------------------+
| { "timestamp": "2018-01-15 16:10:28", "id": 2 } |
+-------------------------------------------------+
```

Calling `audit_log_read()` with that bookmark can return multiple events. To set a limit on the number of events read by `audit_log_read()`, convert the bookmark to **utf8mb4**, then add to it a `max_array_length` item with a value of 1. For example, using the preceding bookmark, convert and modify it as follows:
The modified bookmark, when passed to `audit_log_read()`, produces a result of a single audit record.

To set a limit on the number of bytes that `audit_log_read()` reads, set the `audit_log_read_buffer_size` system variable. As of MySQL 8.0.12, this variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`. Prior to MySQL 8.0.12, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

Each call to `audit_log_read()` returns as many available items as fit within the buffer size, skipping items that do not fit within the buffer size. Given this behavior, consider these factors when assessing the proper buffer size for an application:

- There is a tradeoff between number of calls to `audit_log_read()` and items returned per call. With a smaller buffer size, calls return fewer items, so more calls are needed. With a larger buffer size, calls return more items, so fewer calls are needed.

- With a smaller buffer size, such as the default size of 32KB, there is a greater chance that items will exceed the buffer size and `audit_log_read()` will skip them. Skipped items generate warnings.

For additional information about audit log-reading functions, see Audit Log Functions.

### 6.4.5.6 Audit Log Filtering

This section describes how audit log filtering works if the audit log plugin and the accompanying audit tables and UDFs are installed. If the plugin is installed but not the accompanying audit tables and UDFs, the plugin operates in legacy filtering mode, described in Section 6.4.5.7, “Legacy Mode Audit Log Filtering”. Legacy mode is filtering behavior as it was prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

The audit log plugin has the capability of controlling logging of audited events by filtering them:

- Audited events can be filtered using these characteristics:
  - User account
  - Audit event class
  - Audit event subclass
  - Value of event fields such as those that indicate operation status or SQL statement executed
  - Audit filtering is rule based:
    - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
- Filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.

- Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.

- It is possible to define a default filter to use with any user account that has no explicitly assigned filter.

- Audit filters can be defined, displayed, and modified using an SQL interface based on user-defined functions (UDFs).

- Audit filter definitions are stored in the tables in the `mysql` system database.

- Within a given session, the value of the read-only `audit_log_filter_id` system variable indicates whether a filter has been assigned to the session.

**Note**

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```sql
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

The following list briefly summarizes the UDFs that implement the SQL interface for audit filtering control:

- `audit_log_filter_set_filter()`: Define a filter
- `audit_log_filter_remove_filter()`: Remove a filter
- `audit_log_filter_set_user()`: Start filtering a user account
- `audit_log_filter_remove_user()`: Stop filtering a user account
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see Using Audit Log Filtering Functions, and Audit Log Functions.

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the `audit_log` plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the `audit_log` plugin and its accompanying UDFs and tables, see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

- To use any filtering function, a user must possess the `SUPER` privilege or an error occurs. To grant the `SUPER` privilege to a user account, use this statement:

  ```sql
  GRANT SUPER ON *.* TO user;
  ```

  Alternatively, should you prefer to avoid granting the `SUPER` privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring UDFs in Using General-Purpose Keyring Functions; it can be adapted for use with filtering UDFs.
• The audit_log plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering, which has not been installed yet. Audit Log plugin will run in the legacy mode, which will be disabled in the next release.'
```

In legacy mode, filtering can be done based only on event account or status. For details, see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”.

### Using Audit Log Filtering Functions

Before using the audit log user-defined functions (UDFs), install them according to the instructions provided in Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”. The `SUPER` privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.6, “The JSON Data Type”. This section shows some simple filter definitions. For more information about filter definitions, see Writing Audit Log Filter Definitions.

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, the audit log uses that filter.
- Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (`%`), the audit log uses the default filter.
- Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see Section 28.7.7.3, “mysql_change_user()”), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that instead you want the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
```
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');  
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');  

Now full logging is enabled for user1@localhost and user2@localhost. Connections from other accounts continue to be filtered using the default account filter.  

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:  

- To unassign the filter from the user account:  

  SELECT audit_log_filter_remove_user('user1@localhost');  

  Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.  

- To assign a different filter to the user account:  

  SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');  
  SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');  

  Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from user1@localhost.  

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.  

To remove a filter, do this:  

SELECT audit_log_filter_remove_filter('log_nothing');  

Removing a filter also unassigns it from any users to whom it has been assigned, including any current sessions for those users.  

The filtering UDFs just described affect audit filtering immediately and update the audit log tables in the mysql system database that store filters and user accounts (see Audit Log Tables). It is also possible to modify the audit log tables directly using statements such as INSERT, UPDATE, and DELETE, but such changes do not affect filtering immediately. To flush your changes and make them operational, call audit_log_filter_flush():  

SELECT audit_log_filter_flush();  

Warning  

audit_log_filter_flush() should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the audit_log plugin with UNINSTALL PLUGIN plus INSTALL PLUGIN.  

audit_log_filter_flush() affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.  

To determine whether a filter has been assigned to the current session, check the session value of the read-only audit_log_filter_id system variable. If the value is 0, no filter is assigned. A nonzero value indicates the internally maintained ID of the assigned filter:
Writing Audit Log Filter Definitions

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.6, “The JSON Data Type”.

Filter definitions have this form, where actions indicates how filtering takes place:

```json
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

- Logging All Events
- Logging Specific Event Classes
- Logging Specific Event Subclasses
- Inclusive and Exclusive Logging
- Testing Event Field Values
- Blocking Execution of Specific Events
- Logical Operators
- Referencing Predefined Variables
- Referencing Predefined Functions
- Replacing a User Filter

Logging All Events

To explicitly enable or disable logging of all events, use a log element in the filter:

```json
{   "filter": {   "log": true  }
}
```

The log value can be either true or false.

The preceding filter enables logging of all events. It is equivalent to:

```json
{   "filter": {}  }
```

Logging behavior depends on the log value and whether class or event items are specified:

- With log specified, its given value is used.
- Without log specified, logging is true if no class or event item is specified, and false otherwise (in which case, class or event can include their own log item).
Logging Specific Event Classes

To log events of a specific class, use a `class` element in the filter, with its `name` field denoting the name of the class to log:

```json
{
    "filter": {
        "class": { "name": "connection" }
    }
}
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```json
{
    "filter": {
        "log": false,
        "class": { "log": true, "name": "connection" }
    }
}
```

To enable logging of multiple classes, define the `class` value as a JSON array element that names the classes:

```json
{
    "filter": {
        "class": [
            { "name": "connection" },
            { "name": "general" },
            { "name": "table_access" }
        ]
    }
}
```

Note

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```json
{
    "filter": {
        "class": {
            "name": [ "connection", "general", "table_access" ]
        }
    }
}
```

Logging Specific Event Subclasses

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```json
{
    "filter": {
        "event": [ "statement_select", "statementUpdate" ]
    }
}
```
The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```
"event": [
  { "name": "read", "log": false },
  { "name": "insert", "log": true },
  { "name": "delete", "log": true },
  { "name": "update", "log": true }
]
```

The `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see Blocking Execution of Specific Events.

Table 6.27, “Event Class and Subclass Combinations” describes the permitted subclass values for each event class.

### Table 6.27 Event Class and Subclass Combinations

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Event Subclass</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

**Inclusive and Exclusive Logging**

A filter can be defined in inclusive or exclusive mode:

- **Inclusive mode** logs only explicitly specified items.
- **Exclusive mode** logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```json
{
    "filter": {
        "log": false,
        "class": [
            {
                "name": "connection",
                "event": [
                    { "name": "connect", "log": true },
                    { "name": "disconnect", "log": true }
                ]
            },
            { "name": "general", "log": true }
        ]
    }
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```json
{
    "filter": {
        "log": true,
        "class":
            { "name": "general", "log": false }
    }
}
```
This filter logs `change_user` events in the `connection` class, `message` events, and `table_access` events:

```json
{
  "filter": {
    "log": true,
    "class": {
      "name": "connection",
      "event": {
        "name": "connect", "log": false,
        "name": "disconnect", "log": false
      }
    },
    "name": "general", "log": false
  }
}
```

**Testing Event Field Values**

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "field": { "name": "general_command.str", "value": "Query" }
        }
      }
    }
  }
}
```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

A connection event indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. Table 6.29, “Connection Event Fields” indicates the permitted fields for connection events.

**Table 6.29 Connection Event Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Connection ID</td>
</tr>
<tr>
<td>user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>priv_user.str</td>
<td>string</td>
<td>Authenticated user name (account user name)</td>
</tr>
</tbody>
</table>
### Table 6.30 General Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_error_code</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>general_thread_id</td>
<td>unsigned integer</td>
<td>Connection/thread ID</td>
</tr>
<tr>
<td>general_user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>general_user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>general_command.str</td>
<td>string</td>
<td>Command name</td>
</tr>
<tr>
<td>general_command.length</td>
<td>unsigned integer</td>
<td>Command name length</td>
</tr>
<tr>
<td>general_query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>general_query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

A general event indicates the status code of an operation and its details. Table 6.30, "General Event Fields" indicates the permitted fields for general events.
A general event with the `general_command.str` field set to `Query` or `Execute` contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. These values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```sql
mysql> SELECT NAME FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
+---------------------------------------+
| NAME                                  |
+---------------------------------------+
| statement/sql/alter_db                |
| statement/sql/alter_db_upgrade        |
| statement/sql/alter_event             |
| statement/sql/alter_function          |
| statement/sql/alter_instance          |
| statement/sql/alter_procedure         |
| statement/sql/alter_server            |
| ...                                   |
```

A table-access event provides information about specific table accesses. Table 6.31, “Table-Access Event Fields” indicates the permitted fields for table-access events.

### Table 6.31 Table-Access Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Event connection ID</td>
</tr>
<tr>
<td>sql_command_id</td>
<td>integer</td>
<td>SQL command ID</td>
</tr>
<tr>
<td>query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>table_database.str</td>
<td>string</td>
<td>Database name associated with event</td>
</tr>
<tr>
<td>table_database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>table_name.str</td>
<td>string</td>
<td>Table name associated with event</td>
</tr>
<tr>
<td>table_name.length</td>
<td>unsigned integer</td>
<td>Table name length</td>
</tr>
</tbody>
</table>

The following list shows which statements produce which table-access events:

- `read` event:
• SELECT
• INSERT ... SELECT (for tables referenced in SELECT clause)
• REPLACE ... SELECT (for tables referenced in SELECT clause)
• UPDATE ... WHERE (for tables referenced in WHERE clause)
• HANDLER ... READ

• delete event:
  • DELETE
  • TRUNCATE TABLE

• insert event:
  • INSERT
  • INSERT ... SELECT (for table referenced in INSERT clause)
  • REPLACE
  • REPLACE ... SELECT (for table referenced in REPLACE clause)
  • LOAD DATA
  • LOAD XML

• update event:
  • UPDATE
  • UPDATE ... WHERE (for tables referenced in UPDATE clause)

Blocking Execution of Specific Events

Event items can include an abort item that indicates whether to prevent qualifying events from executing. For example, abort enables rules to be written that block execution of specific SQL statements.

The abort item must appear within an event item. For example:

```
"event": {
  "name": qualifying event subclass names
  "abort": condition
}
```

For event subclasses selected by the name item, the abort action is true or false, depending on condition evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The condition specification can be as simple as true or false, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks INSERT, UPDATE, and DELETE statements:
This more complex filter blocks the same statements, but only for a specific table (finances.bank_account):

Statements matched and blocked by the filter return an error to the client:

ERROR 1045 (28000): Statement was aborted by an audit log filter

Not all events can be blocked (see Table 6.28, “Log and Abort Characteristics Per Event Class and Subclass Combination”). For an event that cannot, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the abort item appears elsewhere than in an event item, an error occurs.

Logical Operators

Logical operators (and, or, not) can be used in log items. This permits construction of more advanced filtering configurations:
Referencing Predefined Variables

To refer to a predefined variable in a log condition, use a variable item, which tests equality against a given value:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "variable": {
            "name": "audit_log_connection_policy_value", "value": "::none"
          }
        }
      }
    }
  }
}
```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the `audit_log_connection_policy_value` predefined variable, you can modify filter operation by changing the value of the `audit_log_connection_policy` system variable.

The `audit_log_xxx_policy` system variables are used for the legacy mode audit log (see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”). With rule-based audit log filtering, those variables remain visible (for example, using `SHOW VARIABLES`), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for variable items:

- `audit_log_connection_policy_value`

This variable corresponds to the value of the `audit_log_connection_policy` system variable. The value is an unsigned integer. Table 6.32, “`audit_log_connection_policy_value` Values” shows the permitted values and the corresponding `audit_log_connection_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding <code>audit_log_connection_policy</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
</tbody>
</table>
### MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_connection_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_policy_value**

  This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. Table 6.33, "audit_log_policy_value Values" shows the permitted values and the corresponding `audit_log_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::logins&quot;</td>
<td>LOGINS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
<tr>
<td>3 or &quot;::queries&quot;</td>
<td>QUERIES</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_statement_policy_value**

  This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. Table 6.34, "audit_log_statement_policy_value Values" shows the permitted values and the corresponding `audit_log_statement_policy` values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

**Referencing Predefined Functions**

To refer to a predefined function in a log condition, use a `function` item, which takes `name` and `args` values to specify the function name and its arguments, respectively:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "function": {
```
The function as specified in the `name` item should be the function name only, without parentheses or the argument list. Arguments in the `args` item, if there is one, must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for `function` items:

- **audit_log_exclude_accounts_is_null()**
  
  Checks whether the `audit_log_exclude_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

  Arguments:
  
  None.

- **audit_log_include_accounts_is_null()**
  
  Checks whether the `audit_log_include_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

  Arguments:
  
  None.

- **debug_sleep(millisec)**
  
  Sleeps for the given number of milliseconds. This function is used during performance measurement. `debug_sleep()` is available for debug builds only.

  Arguments:
  
  - `millisec`: An unsigned integer that specifies the number of milliseconds to sleep.

- **find_in_exclude_list(account)**
  
  Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).

  Arguments:
  
  - `account`: A string that specifies the user account name.

- **find_in_include_list(account)**
Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).

Arguments:

- **account**: A string that specifies the user account name.
- **string_find(text, substr)**

Checks whether the `substr` value is contained in the `text` value. This search is case-sensitive.

Arguments:

- **text**: The text string to search.
- **substr**: The substring to search for in `text`.

**Replacing a User Filter**

In some cases, the filter definition can be changed dynamically. To do this, define a `filter` configuration within an existing `filter`. For example:

```json
{
    "filter": {
        "id": "main",
        "class": {
            "name": "table_access",
            "event": ["update", "delete"],
            "log": false,
            "filter": {
                "class": {
                    "name": "general",
                    "event": { "name": "status", "filter": { "ref": "main" } }
                },
                "activate": {
                    "or": [
                        { "field": { "name": "table_name.str", "value": "temp_1" } },
                        { "field": { "name": "table_name.str", "value": "temp_2" } }
                    ]
                }
            }
        }
    }
}
```

A new filter is activated when the `activate` element within a subfilter evaluates to `true`. Using `activate` in a top-level `filter` is not permitted.

A new filter can be replaced with the original one by using a `ref` item inside the subfilter to refer to the original filter `id`.

The filter shown operates like this:

- The `main` filter waits for `table_access` events, either `update` or `delete`.
- If the `update` or `delete` `table_access` event occurs on the `temp_1` or `temp_2` table, the filter is replaced with the internal one (without an `id`, since there is no need to refer to it explicitly).
• If the end of the command is signalled (general / status event), an entry is written to the audit log file and the filter is replaced with the main filter.

The filter is useful to log statements that update or delete anything from the temp_1 or temp_2 tables, such as this one:

```sql
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```

The statement generates multiple table_access events, but the audit log file will contain only general / status entries.

**Note**

Any id values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the audit_log_filter_id system variable.

### 6.4.5.7 Legacy Mode Audit Log Filtering

**Note**

This section describes legacy audit log filtering, which applies if the audit_log plugin is installed but not the accompanying audit tables and UDFs needed for rule-based filtering.

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

- **Event Filtering by Account**
- **Event Filtering by Status**

#### Event Filtering by Account

To filter audited events based on the originating account, set one of these system variables at server startup or runtime:

- **audit_log_include_accounts**: The accounts to include in audit logging. If this variable is set, only these accounts are audited.

- **audit_log_exclude_accounts**: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be NULL or a string containing one or more comma-separated account names, each in user_name@host_name format. By default, both variables are NULL, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to audit_log_include_accounts or audit_log_exclude_accounts affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the user1 and user2 local host account accounts, set the audit_log_include_accounts system variable like this:

```sql
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```
Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-NULL at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to NULL.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is NULL. In this case, you must first clear `audit_log_include_accounts` by setting it to NULL.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;
-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;
-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays NULL as an empty string. To avoid this, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+----------------------------+-------+
| Variable_name              | Value |
+----------------------------+-------+
| audit_log_include_accounts |       |
+----------------------------+-------+
mysql> SELECT @@audit_log_include_accounts;
+------------------------------+
| @@audit_log_include_accounts |
| NULL                         |
+------------------------------+
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local root account and are equivalent, even though the quoting styles differ:

```
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log.include_accounts = '''root''@''localhost''';
SET GLOBAL audit_log.include_accounts = '\root\@\localhost\';
SET GLOBAL audit_log.include_accounts = 'root'@'localhost';
```

The last statement will not work if the ANSI_QUOTES SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

**Event Filtering by Status**

To filter audited events based on status, set the following system variables at server startup or runtime. These variables apply only for legacy audit log filtering. For JSON audit log filtering, different status variables apply; see Audit Log Options and Variables.

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events
Each variable takes a value of **ALL** (log all associated events; this is the default), **ERRORS** (log only failed events), or **NONE** (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```
SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup. At runtime, it is a read-only variable. It takes a value of **ALL** (log all events; this is the default), **LOGINS** (log connection events), **QUERIES** (log statement events), or **NONE** (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of **ALL**, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to **ALL**.
- If you set `audit_log_policy` to a non-**ALL** value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of **ALL**, the server writes a message to the error log to indicate that their values are being overridden.

<table>
<thead>
<tr>
<th>Startup audit_log_policy Value</th>
<th>Resulting audit_log_connection_policy Value</th>
<th>Resulting audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGINS</td>
<td>ALL</td>
<td>NONE</td>
</tr>
<tr>
<td>QUERIES</td>
<td>NONE</td>
<td>ALL</td>
</tr>
<tr>
<td>NONE</td>
<td>NONE</td>
<td>NONE</td>
</tr>
</tbody>
</table>

### 6.4.5.8 Audit Log Reference

The following discussion serves as a reference to MySQL Enterprise Audit components:

- **Audit Log Tables**
- **Audit Log Functions**
- **Audit Log Option and Variable Reference**
- **Audit Log Options and Variables**
- **Audit Log Status Variables**

To install the audit log tables and functions, use the instructions provided in Section 6.4.5.2, "Installing or Uninstalling MySQL Enterprise Audit". Unless those components are installed, the `audit_log` plugin operates in legacy mode. See Section 6.4.5.7, "Legacy Mode Audit Log Filtering".

**Audit Log Tables**

MySQL Enterprise Audit uses tables in the `mysql` system database for persistent storage of filter and user account data. The tables can be accessed only by users with privileges for that database. The tables use the InnoDB storage engine.

If these tables are missing, the `audit_log` plugin operates in legacy mode. See Section 6.4.5.7, "Legacy Mode Audit Log Filtering".
The `audit_log_filter` table stores filter definitions. The table has these columns:

- **NAME**
  The filter name.

- **FILTER**
  The filter definition associated with the filter name. Definitions are stored as JSON values.

The `audit_log_user` table stores user account information. The table has these columns:

- **USER**
  The user name part of an account. For an account `user1@localhost`, the USER part is `user1`.

- **HOST**
  The host name part of an account. For an account `user1@localhost`, the HOST part is `localhost`.

- **FILTERNAME**
  The name of the filter assigned to the account. The filter name associates the account with a filter defined in the `audit_log_filter` table.

### Audit Log Functions

This section describes, for each audit log user-defined function (UDF), its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see Section 6.4.5.6, “Audit Log Filtering”.

Each audit log UDF returns a string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

These audit log UDFs are available:

- **audit_log_encryption_password_get()**

  Retrieves the current audit log encryption password as a binary string. The password is fetched from the MySQL keyring, which must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

  For additional information about audit log encryption, see Audit Log File Encryption.

  **Arguments:**
  None.

  **Return value:**
  The password string for success (up to 766 bytes), or **NULL** and an error for failure.

  **Example:**

  ```sql
  mysql> SELECT audit_log_encryption_password_get();
  +-------------------------------------+
  | audit_log_encryption_password_get() |
  +-------------------------------------+
  ```
• **audit_log_encryption_password_set (password)**

Sets the audit log encryption password to the argument, stores the password in the MySQL keyring. If encryption is enabled, the function performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. The keyring must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

For additional information about audit log encryption, see Audit Log File Encryption.

Arguments:

**password**: The password string. The maximum permitted length is 766 bytes.

Return value:

1 for success, 0 for failure.

Example:

```
mysql> SELECT audit_log_encryption_password_set(password);
+---------------------------------------------+
| audit_log_encryption_password_set(password) |
| 1                                           |
+---------------------------------------------+
```

• **audit_log_filter_flush()**

Calling any of the other filtering UDFs affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, the changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`.

**Warning**

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the audit_log plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to `audit_log_filter_flush()`.

Arguments:

None.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.
Example:

```
mysql> SELECT audit_log_filter_flush();
+--------------------------+
| audit_log_filter_flush() |
| OK                       |
+--------------------------+
```

• **audit_log_filter_remove_filter** (*filter_name*)

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Arguments:

• **filter_name**: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR**: **message** indicates failure.

Example:

```
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+---------------------------------------------------+
| audit_log_filter_remove_filter('SomeFilter')      |
| OK                                               |
+---------------------------------------------------+
```

• **audit_log_filter_remove_user** (*user_name*)

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected. New connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is %, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Arguments:

• **user_name**: The user account name as a string in `user_name@host_name` format, or % to represent the default account.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR**: **message** indicates failure.

Example:
1341

MySQL Enterprise Audit

```
mysql> SELECT audit_log_filter_remove_user('user1@localhost');
+---------------------------------------------------------------------+
| audit_log_filter_remove_user('user1@localhost')                     |
+---------------------------------------------------------------------+
| OK                                                                   |
+---------------------------------------------------------------------+
```

- **audit_log_filter_set_filter(filter_name, definition)**

  Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

  Arguments:

  - **filter_name**: A string that specifies the filter name.
  - **definition**: A JSON value that specifies the filter definition.

  Return value:

  A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

  Example:

  ```
  mysql> SET @f = '{ "filter": { "log": false } }';
  mysql> SELECT audit_log_filter_set_filter('SomeFilter', @f);
  +---------------------------------------------------------------------+
  | audit_log_filter_set_filter('SomeFilter', @f)                       |
  +---------------------------------------------------------------------+
  | OK                                                                   |
  +---------------------------------------------------------------------+
  ```

- **audit_log_filter_set_user(user_name, filter_name)**

  Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

  As a special case, the name `%` represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.

  Arguments:

  - **user_name**: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.
  - **filter_name**: A string that specifies the filter name.

  Return value:

  A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

  Example:

  ```
  mysql> SET @f = '{ "filter": { "log": false } }';
  mysql> SELECT audit_log_filter_set_user('SomeFilter', @f);
  +---------------------------------------------------------------------+
  | audit_log_filter_set_user('SomeFilter', @f)                          |
  +---------------------------------------------------------------------+
  | OK                                                                   |
  +---------------------------------------------------------------------+
  ```
MySQL Enterprise Audit

mysql> SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+------------------------------------------------------------+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+------------------------------------------------------------+
| OK
|
+------------------------------------------------------------+

• audit_log_read([arg])
Reads events from the audit log and returns a binary JSON string containing an array of audit events. If
the audit log format is not JSON, an error occurs.
Each event in the return value is a JSON hash, except that the last array element may be a JSON null
value to indicate no following events are available to read.
For the first call to audit_log_read() within a session, pass a bookmark indicating where to begin
reading. If the final value of the returned array is not a JSON null value, there are more events following
those just read and audit_log_read() can be called without or with a bookmark argument. Without
an argument, reading continues with the next unread event. With a bookmark argument, reading
continues from the bookmark.
If the final value of the returned array is a JSON null value, there are no more events left to be read and
the next call to audit_log_read() must include a bookmark argument.
To obtain a bookmark for the most recently written event, call audit_log_read_bookmark().
For additional information about audit log-reading functions, see Audit Log File Reading.
Arguments:
arg: An optional bookmark, represented as a string containing a JSON hash that indicates where and
how much to read. The following items are significant in the arg value (other items are ignored):
• timestamp, id: The location within the audit log of the first event to read. Both items must be present
to completely specify a position.
• max_array_length: The maximum number of events to read from the log. If omitted, the default is
to read to the end of the log or until the read buffer is full, whichever comes first.
Return value:
A binary JSON string containing an array of audit events for success, or NULL and an error for failure.
Example:
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())
|
+-----------------------------------------------------------------------+
| [ {"timestamp":"2018-01-15 22:41:24","id":0,"class":"connection", ... |
+-----------------------------------------------------------------------+

• audit_log_read_bookmark()
Returns a binary JSON string representing a bookmark for the most recently written audit log event. If the
audit log format is not JSON, an error occurs.
1342


The bookmark is a JSON hash with `timestamp` and `id` items indicating the event position within the audit log. It is suitable for passing to `audit_log_read()` to indicate to that function where to begin reading.

For additional information about audit log-reading functions, see Audit Log File Reading.

Arguments:

None.

Return value:

A binary JSON string containing a bookmark for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
+-------------------------------------------------+
| { "timestamp": "2018-01-15 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

### Audit Log Options and Variables

This section describes the command options and system variables that configure operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the `audit_log` plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To configure activation of the audit log plugin, use this option:

- `--audit-log[=value]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log[=value]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 6.4.5.2, "Installing or Uninstalling MySQL Enterprise Audit".

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, "Installing and Uninstalling Plugins". For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----------------------------+--------------+
| Variable_name               | Value        |
+-----------------------------+--------------+
| audit_log_buffer_size       | 1048576      |
| audit_log_connection_policy | ALL          |
| audit_log_current_session   | OFF          |
| audit_log_exclude_accounts  |              |
| audit_log_file              | audit.log    |
| audit_log_filter_id         | 0            |
+-----------------------------+--------------+
```
You can set any of these variables at server startup, and some of them at runtime. Those that are available only for legacy mode audit log filtering are so noted.

- **audit_log_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-buffer-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- **audit_log_compression**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-compression=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_compression</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE, GZIP</td>
</tr>
</tbody>
</table>
The type of compression for the audit log file. Permitted values are NONE (no compression; the default) and GZIP (GNU Zip compression). For more information, see Audit Log File Compression.

- **audit_log_connection_policy**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-connection-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_connection_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ALL</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ALL</code>, <code>ERRORS</code>, <code>NONE</code></td>
</tr>
</tbody>
</table>

**Note**

This variable applies only to legacy mode audit log filtering (see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”).

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ALL</code></td>
<td>Log all connection events</td>
</tr>
<tr>
<td><code>ERRORS</code></td>
<td>Log only failed connection events</td>
</tr>
<tr>
<td><code>NONE</code></td>
<td>Do not log connection events</td>
</tr>
</tbody>
</table>

**Note**

At server startup, any explicit value given for `audit_log_connection_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.5.5, “Audit Log Logging Configuration”.

- **audit_log_current_session**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_current_session</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the `audit_log_include_accounts` and `audit_log_exclude_accounts` system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- `audit_log_encryption`

  The type of encryption for the audit log file. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption). For more information, see Audit Log File Encryption.

- `audit_log_exclude_accounts`

  This variable applies only to legacy mode audit log filtering (see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”).
The accounts for which events should not be logged. The value should be NULL or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5.6, "Audit Log Filtering".

Modifications to audit_log_exclude_accounts affect only connections created subsequent to the modification, not existing connections.

- **audit_log_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--audit-log-file=file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>audit.log</td>
</tr>
</tbody>
</table>

The base name and suffix of the file to which the audit log plugin writes events. The default value is audit.log, regardless of logging format. To have the name suffix correspond to the format, set the name explicitly, choosing a different suffix (for example, audit.xml for XML format, audit.json for JSON format).

If the value of audit_log_file is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

For details about how the audit log plugin interprets the audit_log_file value and the rules for file renaming that occurs at plugin initialization and termination, see Audit Log File Name.

The audit log plugin uses the directory containing the audit log file (determined from the audit_log_file value) as the location to search for readable audit log files. From these log files and the current file, the plugin constructs a list of the ones that are subject to use with the audit log bookmarking and reading functions. See Audit Log File Reading.

- **audit_log_filter_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_filter_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- **audit_log_flush**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_flush</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0. For more information, see Section 6.4.5.5, “Audit Log Logging Configuration”.

- **audit_log_format**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-format=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_format</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NEW</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OLD, NEW, JSON</td>
</tr>
</tbody>
</table>

The audit log file format. Permitted values are `OLD` (old-style XML), `NEW` (new-style XML; the default), and `JSON`. For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

**Note**

For information about issues to consider when changing the log format, see Audit Log File Format.

- **audit_log_include_accounts**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-include-accounts=value</code></td>
</tr>
</tbody>
</table>
### audit_log_include_accounts

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>audit_log_include_accounts</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

**Note**

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.7, “Legacy Mode Audit Log Filtering”](#)).

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 6.4.5.6, “Audit Log Filtering”](#).

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_policy`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--audit-log-policy=value</code></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>audit_log_policy</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>ALL</code></td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td><code>ALL</code></td>
</tr>
<tr>
<td></td>
<td><code>LOGINS</code></td>
</tr>
<tr>
<td></td>
<td><code>QUERIES</code></td>
</tr>
<tr>
<td></td>
<td><code>NONE</code></td>
</tr>
</tbody>
</table>

**Note**

This variable applies only to legacy mode audit log filtering (see [Section 6.4.5.7, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all events</td>
</tr>
<tr>
<td>LOGINS</td>
<td>Log only login events</td>
</tr>
<tr>
<td>QUERIES</td>
<td>Log only query events</td>
</tr>
<tr>
<td>NONE</td>
<td>Log nothing (disable the audit stream)</td>
</tr>
</tbody>
</table>

The buffer size for reading from the audit log file, in bytes. The `audit_log_read()` function reads no more than this many bytes. Log file reading is supported only for JSON log format. For more information, see [Audit Log File Reading](#). As of MySQL 8.0.12, this variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`. Prior to MySQL 8.0.12, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

**audit_log_rotate_on_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-rotate-on-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
</tbody>
</table>

The `audit_log_rotate_on_size` property controls the size at which the audit log file is rotated. The `audit_log_rotate()` function rotates the file when it reaches this size.
### `audit_log_rotate_on_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_rotate_on_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If the `audit_log_rotate_on_size` value is 0, the audit log plugin does not perform automatic log file rotation. Instead, use `audit_log_flush` to close and reopen the log on demand. In this case, manually rename the file externally to the server before flushing it.

If the `audit_log_rotate_on_size` value is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the current log file, renames it, and opens a new log file.

For more information about audit log file rotation, see [Audit Log File Space Management and Name Rotation](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs, except manually.)

- `audit_log_statement_policy`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-statement-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_statement_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL, ERRORS, NONE</td>
</tr>
</tbody>
</table>

**Note**

This variable applies only to legacy mode audit log filtering (see Section 6.4.5.7, “Legacy Mode Audit Log Filtering”).

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.
### Value Description

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all statement events</td>
</tr>
<tr>
<td>ERRORS</td>
<td>Log only failed statement events</td>
</tr>
<tr>
<td>NONE</td>
<td>Do not log statement events</td>
</tr>
</tbody>
</table>

**Note**

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.5.5, “Audit Log Logging Configuration”.

- **audit_log_strategy**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-strategy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_strategy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ASYNCHRONOUS</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ASYNCHRONOUS, PERFORMANCE, SEMISYNCHRONOUS, SYNCHRONOUS</td>
</tr>
</tbody>
</table>

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

### Audit Log Status Variables

If the audit log plugin is enabled, it exposes several status variables that provide operational information. These variables are available for legacy mode audit filtering and JSON mode audit filtering.

- **Audit_log_current_size**

  The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.
MySQL Enterprise Audit

- **Audit_log_event_max_drop_size**
  The size of the largest dropped event in performance logging mode. For a description of logging modes, see Section 6.4.5.5, “Audit Log Logging Configuration”.

- **Audit_log_events**
  The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see Section 6.4.5.5, “Audit Log Logging Configuration”).

- **Audit_log_events_filtered**
  The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see Section 6.4.5.5, “Audit Log Logging Configuration”).

- **Audit_log_events_lost**
  The number of events lost in performance logging mode because an event was larger than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see Section 6.4.5.5, “Audit Log Logging Configuration”.

- **Audit_log_events_written**
  The number of events written to the audit log.

- **Audit_log_total_size**
  The total size of events written to all audit log files. Unlike `Audit_log_current_size`, the value of `Audit_log_total_size` increases even when the log is rotated.

- **Audit_log_write_waits**
  The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see Section 6.4.5.5, “Audit Log Logging Configuration”.

### 6.4.5.9 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.

- Contents of files referenced by statements such as `LOAD DATA` are not logged.

**NDB Cluster.** It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.

- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.

- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.
6.4.6 The Audit Message Component

As of MySQL 8.0.14, the `audit_api_message_emit` component enables applications to add their own message events to the audit log, using the `audit_api_message_emit_udf()` user-defined function.

The `audit_api_message_emit` component cooperates with all plugins of audit type. For concreteness, examples use the `audit_log` plugin described in Section 6.4.5, “MySQL Enterprise Audit”.

- Installing or Uninstalling the Audit Message Component
- Audit Message Function

Installing or Uninstalling the Audit Message Component

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `audit_api_message_emit` component, use this statement:

```
INSTALL COMPONENT "file://component_audit_api_message_emit";
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `audit_api_message_emit` component, use this statement:

```
UNINSTALL COMPONENT "file://component_audit_api_message_emit";
```

`UNINSTALL COMPONENT` unloads the component, and deregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

Installing or uninstalling the `audit_api_message_emit` component installs or uninstalls the `audit_api_message_emit_udf()` function that the component implements. It is not necessary to use `CREATE FUNCTION` or `DROP FUNCTION` to do so.

Audit Message Function

This section describes the `audit_api_message_emit_udf()` user-defined function (UDF) implemented by the `audit_api_message_emit` component.

Before using the audit message function, install the audit message component according to the instructions provided at Installing or Uninstalling the Audit Message Component.

```
audit_api_message_emit_udf(component, producer, message[, key, value] ...)
```

Adds a message event to the audit log. Message events include component, producer, and message strings of the caller's choosing, and optionally a set of key-value pairs.

An event posted by this UDF is sent to all enabled plugins of audit type, each of which handles the event according to its own rules. If no plugin of audit type is enabled, posting the event has no effect.

Arguments:

- `component`: A string that specifies a component name.
- `producer`: A string that specifies a producer name.
The Audit Message Component

- **message**: A string that specifies the event message.
- **key, value**: Events may include 0 or more key-value pairs that specify an arbitrary application-provided data map. Each key argument is a string that specifies a name for its immediately following value argument. Each value argument specifies a value for its immediately following key argument. Each value can be a string or numeric value, or NULL.

Return value:

The string **OK** to indicate success. An error occurs if the function fails.

Example:

```sql
mysql> SELECT audit_api_message_emit_udf('component_text',
                               'producer_text',
                               'message_text',
                               'key1', 'value1',
                               'key2', 123,
                               'key3', NULL) AS 'Message';
+---------+
| Message |
+---------+
| OK      |
+---------+
```

Additional information:

Each audit plugin that receives an event posted by `audit_api_message_emit_udf()` logs the event in plugin-specific format. For example, the `audit_log` plugin (see Section 6.4.5, "MySQL Enterprise Audit") logs message values as follows, depending on the log format configured by the `audit_log_format` system variable:

- **JSON format** (`audit_log_format=JSON`):

  ```json
  {
  ...
  "class": "message",
  "event": "user",
  ...
  "message_data": {
  "component": "component_text",
  "producer": "producer_text",
  "message": "message_text",
  "map": {
  "key1": "value1",
  "key2": 123,
  "key3": null
  }
  }
  }
  ```

- **New-style XML format** (`audit_log_format=NEW`):

  ```xml
  <AUDIT_RECORD>
  ...<NAME>Message</NAME>
  ...
  <COMMAND_CLASS>user</COMMAND_CLASS>
  <COMPONENT>component_text</COMPONENT>
  ```
Old-style XML format (audit_log_format=OLD):

```xml
<AUDIT_RECORD
  ...,
  NAME="Message",
  ...
  COMMAND_CLASS="user",
  COMPONENT="component_text",
  PRODUCER="producer_text",
  MESSAGE="message_text"/>
```

**Note**

Message events logged in old-style XML format do not include the key-value map due to representational constraints imposed by this format.

Messages posted by `audit_api_message_emit_udf()` have an event class of `MYSQL_AUDIT_MESSAGE_CLASS` and a subclass of `MYSQL_AUDIT_MESSAGE_USER`. (Internally generated audit messages have the same class and a subclass of `MYSQL_AUDIT_MESSAGE_INTERNAL`; this subclass currently is unused.) To refer to such events in `audit_log` filtering rules, use a `class` element with a `name` value of `message`. For example:

```json
{
  "filter": {
    "class": {
      "name": "message"
    }
  }
}
```

Should it be necessary to distinguish user-generated and internally generated message events, test the `subclass` value against `user` or `internal`.

Filtering based on the contents of the key-value map is not supported.

For information about writing filtering rules, see Section 6.4.5.6, “Audit Log Filtering”.

### 6.4.7 MySQL Enterprise Firewall
MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.

Figure 6.1 MySQL Enterprise Firewall Operation

The following sections describe the components of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its components.

6.4.7.1 MySQL Enterprise Firewall Components

MySQL Enterprise Firewall is based on a plugin library that implements these components:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on its in-memory cache, renders a decision whether to execute or reject each statement.

- Server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement `INFORMATION_SCHEMA` tables that provide views into the firewall data cache.
• System tables named `firewall_users` and `firewall_whitelist` in the `mysql` database provide persistent storage of firewall data.

• Stored procedures named `sp_set_firewall_mode()` and `sp_reload_firewall_rules()` perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables.

• A set of user-defined functions provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.

• System variables enable firewall configuration and status variables provide runtime operational information.

• `FIREWALL_ADMIN` and `FIREWALL_USER` privileges enable users to administer firewall rules for any user, and their own firewall rules, respectively.

### 6.4.7.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the components described in Section 6.4.7.1, “MySQL Enterprise Firewall Components”. Installation can be performed using a graphical interface or manually:

• On Windows, MySQL Installer includes an option to enable MySQL Enterprise Firewall for you.

• MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.

• Manual MySQL Enterprise Firewall installation involves running a script located in the `share` directory of your MySQL installation.

**Important**

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

**Note**

If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

**Note**

MySQL Enterprise Firewall does not work together with the query cache. If the query cache is enabled, disable it before installing the firewall (see Query Cache Configuration).

For usage instructions, see Section 6.4.7.3, “Using MySQL Enterprise Firewall”. For reference information, see Section 6.4.7.4, “MySQL Enterprise Firewall Reference”.

• Installing MySQL Enterprise Firewall

• Uninstalling MySQL Enterprise Firewall

#### Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.
On Windows, you can use MySQL Installer to install MySQL Enterprise Firewall, as shown in Figure 6.2, “MySQL Enterprise Firewall Installation on Windows”. Check the **Enable Enterprise Firewall** checkbox. *(Open Firewall port for network access has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)*

**Figure 6.2 MySQL Enterprise Firewall Installation on Windows**

To install MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface.

To install MySQL Enterprise Firewall manually, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- **win_install_firewall.sql**: Choose this script for Windows systems that use `.dll` as the file name suffix.
- **linux_install_firewall.sql**: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

The installation script creates stored procedures in the default database, so choose a database to use. Then run the script as follows, naming the chosen database on the command line. The example here uses the `mysql` database and the Linux installation script. Make the appropriate substitutions for your system.
shell> mysql -u root -p mysql < linux_install_firewall.sql
Enter password: (enter root password here)

Note

To use MySQL Enterprise Firewall in the context of master/slave replication, Group Replication, or InnoDB cluster, you must prepare the slave or secondary nodes prior to running the installation script on the master or primary node. This is necessary because the INSTALL PLUGIN statements in the script are not replicated.

1. On each slave or secondary node, extract the INSTALL PLUGIN statements from the installation script and execute them manually.
2. On the master or primary node, run the installation script as described previously.

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';

+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| mysql_firewall_mode | ON    |
+---------------------+-------+

If the plugin fails to initialize, check the server error log for diagnostic messages.

Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface.

To uninstall MySQL Enterprise Firewall manually, execute the following statements. It is assumed that the stored procedures were created in the mysql database. Adjust the DROP PROCEDURE statements appropriately if the procedures were created in a different database.

DROP TABLE mysql.firewall_whitelist;
DROP TABLE mysql.firewall_users;
UNINSTALL PLUGIN mysql_firewall;
UNINSTALL PLUGIN mysql_firewall_whitelist;
UNINSTALL PLUGIN mysql_firewall_users;
DROP FUNCTION set_firewall_mode;
DROP FUNCTION normalize_statement;
DROP FUNCTION read_firewall_whitelist;
DROP FUNCTION read_firewall_users;
DROP FUNCTION mysql_firewall_flush_status;
DROP PROCEDURE mysql.sp_set_firewall_mode;
DROP PROCEDURE mysql.sp_reload_firewall_rules;

6.4.7.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”. Also, MySQL Enterprise Firewall does not work together with the query cache; disable the query cache if it is enabled (see Query Cache Configuration).
This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See MySQL Enterprise Firewall Interface.

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

It is also possible to disable or enable the firewall at runtime:

```
mysql> SET GLOBAL mysql_firewall_mode = OFF;
mysql> SET GLOBAL mysql_firewall_mode = ON;
```

In addition to the global on/off firewall mode, each account registered with the firewall has its own operational mode. For an account in recording mode, the firewall learns an application’s “fingerprint,” that is, the acceptable statement patterns that, taken together, form a whitelist. After training, switch the firewall to protecting mode to harden MySQL against access by statements that deviate from the fingerprint. For additional training, switch the firewall back to recording mode as necessary to update the whitelist with new statement patterns. An intrusion-detection mode is available that writes suspicious statements to the error log but does not deny access.

The firewall maintains whitelist rules on a per-account basis, enabling implementation of protection strategies such as these:

- For an application that has unique protection requirements, configure it to use an account that is not used for any other purpose.
- For applications that are related and share protection requirements, configure them as a group to use the same account.

Firewall operation is based on conversion of SQL statements to normalized digest form. Firewall digests are like the statement digests used by the Performance Schema (see Section 26.10, “Performance Schema Statement Digests and Sampling”). However, unlike the Performance Schema, the relevant digest-related system variable is `max_digest_length`.

For a connection from a registered account, the firewall converts each incoming statement to normalized form and processes it according to the account mode:

- In recording mode, the firewall adds the normalized statement to the account whitelist rules.
- In protecting mode, the firewall compares the normalized statement to the account whitelist rules. If there is a match, the statement passes and the server continues to process it. Otherwise, the server rejects the statement and returns an error to the client. The firewall also writes the rejected statement to the error log if the `mysql_firewall_trace` system variable is enabled.
- In detecting mode, the firewall matches statements as in protecting mode, but writes nonmatching statements to the error log without denying access.

Accounts that have a mode of `OFF` or are not registered with the firewall are ignored by it.

To protect an account using MySQL Enterprise Firewall, follow these steps:

1. Register the account and put it in recording mode.
2. Connect to the MySQL server using the registered account and execute statements to be learned. This establishes the account’s whitelist of accepted statements.

3. Switch the registered account to protecting mode.

The following example shows how to register an account with the firewall, use the firewall to learn acceptable statements for that account, and protect the account against execution of unacceptable statements. The example account, 'fwuser'@'localhost', is for use by an application that accesses tables in the sakila database. (This database is available at https://dev.mysql.com/doc/index-other.html.)

Note
The user and host parts of the account name are quoted separately for statements such as CREATE USER and GRANT, whereas to specify an account for use with a firewall component, name it as a single quoted string 'fwuser@localhost'.

The convention for naming accounts as a single quoted string for firewall components means that you cannot use accounts that have embedded @ characters in the user name.

Perform the steps in the following procedure using an administrative MySQL account, except those designated for execution by the account registered with the firewall. The default database should be sakila for statements executed using the registered account.

1. If necessary, create the account to be protected (choose an appropriate password) and grant it privileges for the sakila database:

```sql
mysql> CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'fWp@3sw0rd';
mysql> GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
```

2. Use the sp_set_firewall_mode() stored procedure to register the account with the firewall and place it in recording mode (if the procedure is located in a database other than mysql, adjust the statement accordingly):

```sql
mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
```

During the course of its execution, the stored procedure invokes firewall user-defined functions, which may produce output of their own.

3. Using the registered account, connect to the server, then execute some statements that are legitimate for it:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1;
mysql> UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
mysql> SELECT get_customer_balance(1, NOW());
```

The firewall converts the statements to digest form and records them in the account whitelist.

Note
Until the account executes statements in recording mode, its whitelist is empty, which is equivalent to “deny all.” If switched to protecting mode, the account will be effectively prohibited from executing statements.

4. At this point, the user and whitelist information is cached and can be seen in the firewall INFORMATION_SCHEMA tables:
MySQL Enterprise Firewall

mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
    WHERE USERHOST = 'fwuser@localhost';
+-----------+
<table>
<thead>
<tr>
<th>MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECORDING</td>
</tr>
</tbody>
</table>
+------------+
mysql>

mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
    WHERE USERHOST = 'fwuser@localhost';
+----------------------------------------------------------------------------+
| RULE                                                                       |
+----------------------------------------------------------------------------+
| SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?  |
| SELECT `get_customer_balance` ( ? , NOW ( ) )                              |
| UPDATE `rental` SET `return_date` = NOW ( ) WHERE `rental_id` = ?          |
| SELECT @@`version_comment` LIMIT ?                                         |
+----------------------------------------------------------------------------+

**Note**

The `@@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server as the registered user.

It is important to train the firewall under conditions matching application use. For example, a given MySQL connector might send statements to the server at the beginning of a connection to determine server characteristics and capabilities. If an application normally is used through that connector, train the firewall that way, too. That enables those initial statements to become part of the whitelist for the account associated with the application.

5. Use the stored procedure to switch the registered user to protecting mode:

   mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');

**Important**

Switching the account out of RECORDING mode synchronizes its firewall cache data to the underlying `mysql` system database tables for persistent storage. If you do not switch the mode for a user who is being recorded, the cached whitelist data is not written to the system tables and will be lost when the server is restarted.

6. Using the registered account, execute some acceptable and unacceptable statements. The firewall matches each one against the account whitelist and accepts or rejects it.

   This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

   mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+------------+-----------+
<table>
<thead>
<tr>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANN</td>
<td>EVANS</td>
</tr>
</tbody>
</table>
+------------+-----------+

These statements do not match anything in the whitelist and each results in an error:
The firewall also writes the rejected statements to the error log if the `mysql_firewall_trace` system variable is enabled. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
  'ACCESS DENIED for fwuser@localhost. Reason: No match in whitelist.
  Statement: TRUNCATE TABLE `mysql`.`slow_log` '
```

You can use these log messages in your efforts to identify the source of attacks.

7. You can log nonmatching statements as suspicious without denying access. To do this, put the account in intrusion-detecting mode:

```
mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

8. Using the registered account, connect to the server, then execute a statement that does not match the whitelist:

```
mysql> SHOW TABLES LIKE 'customer%';
```

```
+------------------------------+
| Tables_in_sakila (customer%) |
| customer                     |
| customer_list                |
+------------------------------+
```

In detecting mode, the firewall permits the nonmatching statement to execute but writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
  'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in whitelist.
  Statement: SHOW TABLES LIKE ? '
```

```
Note

Detection mode writes messages as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that the `log_error_verbosity` system variable is set to a value of 3.
```

9. To assess firewall activity, examine its status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
```

```
+----------------------------+-------+
| Variable_name              | Value |
+----------------------------+-------+
| Firewall_access_denied     | 3     |
| Firewall_access_granted    | 4     |
| Firewall_access_suspicious | 1     |
| Firewall_cached_entries    | 4     |
```
The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three time you used it to connect as the registered user, plus the `SHOW TABLES` statement that was not blocked in `DETECTING` mode.

Should additional training for an account be necessary, switch it to recording mode again, then back to protecting mode after executing statements to be added to the whitelist.

### 6.4.7.4 MySQL Enterprise Firewall Reference

The following discussion serves as a reference to MySQL Enterprise Firewall components:

- **MySQL Enterprise Firewall Tables**
- **MySQL Enterprise Firewall Procedures and Functions**
- **MySQL Enterprise Firewall System Variables**
- **MySQL Enterprise Firewall Status Variables**

#### MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains account and whitelist information. It uses `INFORMATION_SCHEMA` tables to provide views into cached data, and tables in the `mysql` system database to store this data in persistent form. When enabled, the firewall bases its operational decisions on the cached data.

The `INFORMATION_SCHEMA` tables are accessible by anyone. The `mysql` tables can be accessed only by users with privileges for that database.

The `INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS` and `mysql.firewall_users` tables list registered firewall accounts and their operational modes. The tables have these columns:

- **USERHOST**
  
  An account registered with the firewall. Each account has the format `user_name@host_name` and represents actual user and host names as authenticated by the server. Patterns and netmasks should not be used when registering users.

- **MODE**

  The current firewall operational mode for the account. The permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see the description of `sp_set_firewall_mode()` in MySQL Enterprise Firewall Procedures and Functions.

The `INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST` and `mysql.firewall_whitelist` tables list registered firewall accounts and their whitelists. The tables have these columns:

- **USERHOST**

  An account registered with the firewall. The format is the same as for the user account tables.

- **RULE**

  A normalized statement indicating an acceptable statement pattern for the account. An account whitelist is the union of its rules.
MySQL Enterprise Firewall Procedures and Functions

MySQL Enterprise Firewall has stored procedures that perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables. It also has a set of user-defined functions (UDFs) that provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.

Under normal operation, the stored procedures implement the user interface. The UDFs are invoked by the stored procedures, not directly by users.

To invoke a stored procedure when the default database is not the database that contains the procedure, qualify the procedure name with the database name. For example:

```
CALL mysql.sp_set_firewall_mode(user, mode);
```

The following list describes each firewall stored procedure and UDF:

- **sp_reload_firewall_rules(user)**
  This stored procedure uses firewall UDFs to reset a registered account and reload the in-memory rules for it from the rules stored in the `mysql.firewall_whitelist` table. This procedure provides control over firewall operation for individual accounts.

  The `user` argument names the affected account, as a string in `user_name@host_name` format.

  Example:

  ```
  CALL mysql.sp_reload_firewall_rules('fwuser@localhost');
  ```

  **Warning**

  This procedure sets the account mode to **RESET**, which clears the account whitelist and sets its mode to **OFF**. If the account mode was not **OFF** prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the account was in **PROTECTING** mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to **PROTECTING** again explicitly.

- **sp_set_firewall_mode(user, mode)**
  This stored procedure registers a MySQL account with the firewall and establishes its operational mode. The procedure also invokes firewall UDFs as necessary to transfer firewall data between the cache and the underlying system tables. This procedure may be called even if the `mysql_firewall_mode` system variable is **OFF**, although setting the mode for an account has no operational effect while the firewall is disabled.

  The `user` argument names the affected account, as a string in `user_name@host_name` format.

  The `mode` is the operational mode for the user, as a string. These mode values are permitted:
  - **OFF**: Disable the firewall for the account.
MySQL Enterprise Firewall

- **DETECTING**: Intrusion-detection mode: Write suspicious (nonmatching) statements to the error log but do not deny access.
- **PROTECTING**: Protect the account by matching incoming statements against the account whitelist.
- **RECORDING**: Training mode: Record acceptable statements for the account. Incoming statements that do not immediately fail with a syntax error are recorded to become part of the account whitelist rules.
- **RESET**: Clear the account whitelist and set the account mode to **OFF**.

Switching the mode for an account to any mode but **RECORDING** synchronizes the firewall cache data to the underlying **mysql** system database tables for persistent storage. Switching the mode from **OFF** to **RECORDING** reloads the whitelist from the **mysql.firewall_whitelist** table into the cache.

If an account has an empty whitelist, setting its mode to **PROTECTING** produces an error message that is returned in a result set, but not an SQL error:

```sql
mysql> CALL mysql.sp_set_firewall_mode('a@b','PROTECTING');
+----------------------------------------------------------------------+
| set_firewall_mode(arg_userhost, arg_mode)                            |
| ERROR: PROTECTING mode requested for a@b but the whitelist is empty. |
+----------------------------------------------------------------------+
1 row in set (0.02 sec)
```

- **mysql_firewall_flush_status()**
  This UDF resets several firewall status variables to 0:

    ```sql
    Firewall_access_denied
    Firewall_access_granted
    Firewall_access_suspicious
    ```

  Example:

  ```sql
  SELECT mysql_firewall_flush_status();
  ```

- **normalize_statement**
  This UDF normalizes an SQL statement into the digest form used for whitelist rules.

  Example:

  ```sql
  SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
  ```

- **read_firewall_users**
  This aggregate UDF updates the firewall user cache through a `SELECT` statement on the **mysql.firewall_users** table.

  Example:

  ```sql
  SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
  FROM mysql.firewall_users;
  ```
MySQL Enterprise Firewall

- **read_firewall_whitelist**(user, rule)

  This aggregate UDF updates the recorded statement cache through a SELECT statement on the `mysql.firewall_whitelist` table.

  Example:

  ```
  SELECT read_firewall_whitelist('fwuser@localhost', 'RECORDING')
  FROM mysql.firewall_whitelist;
  ```

- **set_firewall_mode**(user, mode)

  This UDF manages the user cache and establishes the user operational mode.

  Example:

  ```
  SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
  ```

### MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”).

- **mysql_firewall_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--mysql-firewall-mode=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysql_firewall_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

  Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- **mysql_firewall_trace**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--mysql-firewall-trace=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysql_firewall_trace</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Whether the MySQL Enterprise Firewall trace is enabled or disabled (the default). When `mysql_firewall_trace` is enabled, for PROTECTING mode, the firewall writes rejected statements to the error log.

**MySQL Enterprise Firewall Status Variables**

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see Section 6.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` UDF (see MySQL Enterprise Firewall Procedures and Functions).

- **Firewall_access_denied**
  
  The number of statements rejected by MySQL Enterprise Firewall.

- **Firewall_access_granted**
  
  The number of statements accepted by MySQL Enterprise Firewall.

- **Firewall_access_suspicious**
  
  The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in DETECTING mode.

- **Firewall_cached_entries**
  
  The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

### 6.4.8 MySQL Enterprise Data Masking and De-Identification

**Note**

MySQL Enterprise Data Masking and De-Identification is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

As of MySQL 8.0.13, MySQL Enterprise Edition provides data masking and de-identification capabilities:

- Transformation of existing data to mask it and remove identifying characteristics, such as changing all digits of a credit card number but the last four to 'X' characters.

- Generation of random data, such as email addresses and payment card numbers.

The way that applications use these capabilities depends on the purpose for which the data will be used and who will access it:

- Applications that use sensitive data may protect it by performing data masking and permitting use of partially masked data for client identification. Example: A call center may ask for clients to provide their last four Social Security number digits.

- Applications that require properly formatted data, but not necessarily the original data, can synthesize sample data. Example: An application developer who is testing data validators but has no access to original data may synthesize random data with the same format.

**Example 1:**
Medical research facilities can hold patient data that comprises a mix of personal and medical data. This may include genetic sequences (long strings), test results stored in JSON format, and other data types. Although the data may be used mostly by automated analysis software, access to genome data or test results of particular patients is still possible. In such cases, data masking should be used to render this information not personally identifiable.

Example 2:

A credit card processor company provides a set of services using sensitive data, such as:

- Processing a large number of financial transactions per second.
- Storing a large amount of transaction-related data.
- Protecting transaction-related data with strict requirements for personal data.
- Handling client complaints about transactions using reversible or partially masked data.

A typical transaction may include many types of sensitive information, including:

- Credit card number.
- Transaction type and amount.
- Merchant type.
- Transaction cryptogram (to confirm transaction legitimacy).
- Geolocation of GPS-equipped terminal (for fraud detection).

Those types of information may then be joined within a bank or other card-issuing financial institution with client personal data, such as:

- Full client name (either person or company).
- Address.
- Date of birth.
- Social Security number.
- Email address.
- Phone number.

Various employee roles within both the card processing company and the financial institution require access to that data. Some of these roles may require access only to masked data. Other roles may require access to the original data on a case-to-case basis, which is recorded in audit logs.

Masking and de-identification are core to regulatory compliance, so MySQL Enterprise Data Masking and De-Identification can help application developers satisfy privacy requirements:

- PCI – DSS: Payment Card Data.
- HIPAA: Privacy of Health Data, Health Information Technology for Economic and Clinical Health Act (HITECH Act).
- Data Protection Act (UK): Protection of Personal Data.
The following sections describe the components of MySQL Enterprise Data Masking and De-Identification, discuss how to install and use it, and provide reference information for its components.

6.4.8.1 MySQL Enterprise Data Masking and De-Identification Components

MySQL Enterprise Data Masking and De-Identification is based on a plugin library that implements these components:

- A server-side plugin named `data_masking`.
- A set of user-defined functions (UDFs) provides an SQL-level API for performing masking and de-identification operations. Some of these functions require the `SUPER` privilege.

6.4.8.2 Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification

This section describes how to install or uninstall MySQL Enterprise Data Masking and De-Identification, which is implemented as a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see Section 5.6.1, “Installing and Uninstalling Plugins”, and Section 5.7.1, “Installing and Uninstalling User-Defined Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `data_masking`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the MySQL Enterprise Data Masking and De-Identification plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements (adjust the `.so` suffix for your platform as necessary):

```sql
INSTALL PLUGIN data_masking SONAME 'data_masking.so';
CREATE FUNCTION gen_blacklist RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_drop RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_load RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_range RETURNS INTEGER
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_email RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_ssn RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_us_phone RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_inner RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_outer RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan_relaxed RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_ssn RETURNS STRING
  SONAME 'data_masking.so';
```
If the plugin and UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN data_masking;
DROP FUNCTION gen_blacklist;
DROP FUNCTION gen_dictionary;
DROP FUNCTION gen_dictionary_drop;
DROP FUNCTION gen_dictionary_load;
DROP FUNCTION gen_range;
DROP FUNCTION gen_rnd_email;
DROP FUNCTION gen_rnd_pan;
DROP FUNCTION gen_rnd_ssn;
DROP FUNCTION gen_rnd_us_phone;
DROP FUNCTION mask_inner;
DROP FUNCTION mask_outer;
DROP FUNCTION mask_pan;
DROP FUNCTION mask_pan_relaxed;
DROP FUNCTION mask_ssn;
```

### 6.4.8.3 Using MySQL Enterprise Data Masking and De-Identification

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at Section 6.4.8.2, “Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification”.

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see Section 6.4.8.4, “MySQL Enterprise Data Masking and De-Identification User-Defined Function Reference”. This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:

- Masking Data to Remove Identifying Characteristics
- Generating Random Data with Specific Characteristics
- Generating Random Data Using Dictionaries
- Using Masked Data for Customer Identification
- Creating Views that Display Masked Data

#### Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

**General-Purpose Masking Functions**

```
mask_inner() and mask_outer() are general-purpose functions that mask parts of arbitrary strings based on position within the string:
```

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```sql
mysql> SELECT mask_inner('This is a string', 5, 1);
+--------------------------------------+
| This is a string                     |
+--------------------------------------+
```

```sql
mysql> SELECT mask_outer('This is a string', 5, 1);
+--------------------------------------+
| This is a string                     |
+--------------------------------------+
```
MySQL Enterprise Data Masking and De-Identification

<table>
<thead>
<tr>
<th>mask_inner('This is a string', 5, 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>This XXXXXXXXg</td>
</tr>
</tbody>
</table>
mysql> SELECT mask_inner('This is a string', 1, 5);
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_inner('This is a string', 1, 5)</td>
</tr>
<tr>
<td>TXXXXXXXXXtring</td>
</tr>
</tbody>
</table>

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

mysql> SELECT mask_outer('This is a string', 5, 1);
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_outer('This is a string', 5, 1)</td>
</tr>
<tr>
<td>XXXXXis a strinX</td>
</tr>
</tbody>
</table>
mysql> SELECT mask_outer('This is a string', 1, 5);
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_outer('This is a string', 1, 5)</td>
</tr>
<tr>
<td>Xhis is a sXXXXX</td>
</tr>
</tbody>
</table>

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

mysql> SELECT mask_inner('This is a string', 5, 1, '*');
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_inner('This is a string', 5, 1, '*')</td>
</tr>
<tr>
<td>This **********g</td>
</tr>
</tbody>
</table>
mysql> SELECT mask_outer('This is a string', 5, 1, '#');
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_outer('This is a string', 5, 1, '#')</td>
</tr>
<tr>
<td>#####is a strin#</td>
</tr>
</tbody>
</table>

**Special-Purpose Masking Functions**

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

**Note**

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see Generating Random Data with Specific Characteristics.

**Payment card Primary Account Number masking.** Masking functions provide strict and relaxed masking of Primary Account Numbers.

- `mask_pan()` masks all but the last four digits of the number:

mysql> SELECT mask_pan(gen_rnd_pan());
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mask_pan(gen_rnd_pan())</td>
</tr>
</tbody>
</table>
MySQL Enterprise Data Masking and De-Identification

- `mask_pan_relaxed()` is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

  ```
  mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
  +---------------------------------+
  | mask_pan_relaxed(gen_rnd_pan()) |
  +---------------------------------+
  | 770630XXXXXX0807                |
  +---------------------------------+
  ```

U.S. Social Security number masking. `mask_ssn()` masks all but the last four digits of the number:

  ```
  mysql> SELECT mask_ssn(gen_rnd_ssn());
  +-------------------------+
  | mask_ssn(gen_rnd_ssn()) |
  +-------------------------+
  | XXX-XX-1723             |
  +-------------------------+
  ```

Generating Random Data with Specific Characteristics

Several functions generate random values. These values can be used for testing, simulation, and so forth.

`gen_range()` returns a random integer selected from a given range:

  ```
  mysql> SELECT gen_range(1, 10);
  +------------------+
  | gen_range(1, 10) |
  +------------------+
  | 6                |
  +------------------+
  ```

`gen_rnd_email()` returns a random email address in the `example.com` domain:

  ```
  mysql> SELECT gen_rnd_email();
  +---------------------------+
  | gen_rnd_email()           |
  +---------------------------+
  | ayxnq.xmkpvy@example.com  |
  +---------------------------+
  ```

`gen_rnd_pan()` returns a random payment card Primary Account Number:

  ```
  mysql> SELECT gen_rnd_pan();
  (The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)
  ```

`gen_rnd_ssn()` returns a random U.S. Social Security number with the first and second parts each chosen from a range not used for legitimate numbers:

  ```
  mysql> SELECT gen_rnd_ssn();
  +---------------+
  | gen_rnd_ssn() |
  +---------------+
  ```
MySQL Enterprise Data Masking and De-Identification

---

**MySQL Enterprise Data Masking and De-Identification**

---

### Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values. To use a dictionary, it must first be loaded from a file and given a name. Each loaded dictionary becomes part of the dictionary registry. Items then can be selected from registered dictionaries and used as random values or as replacements for other values.

A valid dictionary file has these characteristics:

- The file contents are plain text, one term per line.
- Empty lines are ignored.
- The file must contain at least one term.

Suppose that a file named `de_cities.txt` contains these city names in Germany:

```
Berlin
Munich
Bremen
```

Also suppose that a file named `us_cities.txt` contains these city names in the United States:

```
Chicago
Houston
Phoenix
El Paso
Detroit
```

Assume that the `secure_file_priv` system variable is set to `/usr/local/mysql/mysql-files`. In that case, copy the dictionary files to that directory so that the MySQL server can access them. Then use `gen_dictionary_load()` to load the dictionaries into the dictionary registry and assign them names:

```sql
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities');
+--------------------------------------------------------------------------------+
<p>| gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities') |</p>
<table>
<thead>
<tr>
<th>Dictionary load success</th>
</tr>
</thead>
</table>
```

```sql
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities');
+--------------------------------------------------------------------------------+
<p>| gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities') |</p>
<table>
<thead>
<tr>
<th>Dictionary load success</th>
</tr>
</thead>
</table>
```

To select a random term from a dictionary, use `gen_dictionary()`:

```sql
mysql> SELECT gen_dictionary();
+---------------------+
| gen_dictionary()     |  
| 1-555-747-5627      |  
+---------------------+
```

---

### gen_rnd_us_phone()

`gen_rnd_us_phone()` returns a random U.S. phone number in the 555 area code not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_us_phone();
+--------------------+
| gen_rnd_us_phone()  |
+--------------------+
| 1-555-747-5627      |
+--------------------+
```
To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```sql
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+---------------------------------------------------------------+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
| Detroit                                                       |
+---------------------------------------------------------------+
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+---------------------------------------------------------------+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
| Bremen                                                        |
+---------------------------------------------------------------+
```

The `gen_blacklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a U.S. city for a German city, or vice versa, use `gen_blacklist()` like this:

```sql
mysql> SELECT gen_blacklist('Munich', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_blacklist('Munich', 'DE_Cities', 'US_Cities') |
| Houston                                           |
+---------------------------------------------------+
mysql> SELECT gen_blacklist('El Paso', 'US_Cities', 'DE_Cities');
+----------------------------------------------------+
| gen_blacklist('El Paso', 'US_Cities', 'DE_Cities') |
| Bremen                                             |
+----------------------------------------------------+
```

If the term to replace is not in the first dictionary, `gen_blacklist()` returns it unchanged:

```sql
mysql> SELECT gen_blacklist('Moscow', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_blacklist('Moscow', 'DE_Cities', 'US_Cities') |
| Moscow                                            |
+---------------------------------------------------+
```

Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.
Suppose that a `customer` table containing customer records has these columns:

- **id**: Customer ID number.
- **first_name**: Customer first name.
- **last_name**: Customer last name.
- **ssn**: Customer Social Security number.

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```sql
mysql> SELECT id, ssn
        
mysql> FROM customer
        
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
```

```plaintext
+-----+-------------+
<table>
<thead>
<tr>
<th>id</th>
<th>ssn</th>
</tr>
</thead>
<tbody>
<tr>
<td>786</td>
<td>906-39-0007</td>
</tr>
</tbody>
</table>
+-----+-------------+
```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```sql
mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary))
        
mysql> FROM customer
        
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
```

```plaintext
+-----+-------------------------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>mask_ssn(CONVERT(ssn USING binary))</th>
</tr>
</thead>
<tbody>
<tr>
<td>786</td>
<td>XXX-XX-0007</td>
</tr>
</tbody>
</table>
+-----+-------------------------------------+
```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11, and because UDFs treat string arguments as binary strings, with one byte per character. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it appears to be longer than 11 bytes when passed to a UDF, and an error occurs. Converting the value to a binary string ensures that the UDF sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

### Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```sql
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name, mask_ssn(CONVERT(ssn USING binary)) AS ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```sql
mysql> SELECT id, ssn
```

```plaintext
+-----+-------------+
<table>
<thead>
<tr>
<th>id</th>
<th>ssn</th>
</tr>
</thead>
<tbody>
<tr>
<td>786</td>
<td>906-39-0007</td>
</tr>
</tbody>
</table>
+-----+-------------+
```
6.4.8.4 MySQL Enterprise Data Masking and De-Identification User-Defined Function Reference

The MySQL Enterprise Data Masking and De-Identification plugin library includes several user-defined functions (UDFs), which may be grouped into these categories:

- Data Masking Functions
- Random Data Generation Functions
- Random Data Dictionary-Based Functions

These UDFs treat string arguments as binary strings, which means they are implicitly case sensitive. In addition, string UDF return values are binary strings. If a string return value should be in a different character set, convert it. The following example shows how to convert the result of `gen_rnd_email()` to the `utf8mb4` character set:

```
SET @email = CONVERT(gen_rnd_email() USING utf8mb4);
```

It may also be necessary to convert string arguments, as illustrated in Using Masked Data for Customer Identification.

Data Masking Functions

Each function in this section performs a masking operation on its string argument and returns the masked result.

- `mask_inner(str, margin1, margin2 [, mask_char])`

  Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

Arguments:

- `str`: The string to mask.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
- `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Because UDF string arguments are treated as binary strings, the masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or `NULL` if either margin is negative.
If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

Example:

```sql
mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef', 0, 5);
+----------------------------+---------------------------+
| mask_inner('abcdef', 1, 2) | mask_inner('abcdef', 0, 5) |
| aXXXef                    | Xbcdef                    |
+----------------------------+---------------------------+
mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef', 0, 5, '#');
+---------------------------------+--------------------------------+
| mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef', 0, 5, '#') |
| a***ef                          | #bcdef                         |
+---------------------------------+--------------------------------+
```

- `mask_outer(str, margin1, margin2 [, mask_char])`

  Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

  Arguments:
  - `str`: The string to mask.
  - `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
  - `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.
  - `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

  Because UDF string arguments are treated as binary strings, the masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

  Return value:
  - The masked string, or `NULL` if either margin is negative.

  If the sum of the margin values is larger than the argument length, the entire argument is masked.

Example:

```sql
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef', 0, 5);
+----------------------------+---------------------------+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef', 0, 5) |
| XbcdXX                    | aXXXXX                    |
+----------------------------+---------------------------+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef', 0, 5, '#');
+---------------------------------+--------------------------------+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef', 0, 5, '#') |
| *bcd**                          | a#####                         |
+---------------------------------+--------------------------------+
```
• \texttt{mask\_pan(str)}

Masks a payment card Primary Account Number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

• \texttt{str}: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```sql
mysql> SELECT mask\_pan(gen\_rnd\_pan());
+-------------------------+
| mask\_pan(gen\_rnd\_pan()) |
| Xxxxxxxxxx9102           |
+-------------------------+

mysql> SELECT mask\_pan(gen\_rnd\_pan(19));
+---------------------------------+
| mask\_pan(gen\_rnd\_pan(19))    |
| 551279XXXXXXXX3108             |
+---------------------------------+

mysql> SELECT mask\_pan('a*Z');
+-----------------+
| mask\_pan('a*Z')|
| a*Z             |
+-----------------+
```

• \texttt{mask\_pan\_relaxed(str)}

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer.

Arguments:

• \texttt{str}: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```sql
mysql> SELECT mask\_pan\_relaxed(gen\_rnd\_pan());
+---------------------------------+
| mask\_pan\_relaxed(gen\_rnd\_pan())    |
| 551279XXXXXXXX3108                 |
+---------------------------------+

mysql> SELECT mask\_pan\_relaxed(gen\_rnd\_pan(19));
```
MySQL Enterprise Data Masking and De-Identification

```
| mask_pan_relaxed(gen_rnd_pan(19)) |
| 462634XXXXXXXXX6739 |
mysql> SELECT mask_pan_relaxed('a*Z');
+-------------------------+-------------------------+
| mask_pan_relaxed('a*Z') | a*Z                     |
+-------------------------+-------------------------+
```

• `mask_ssn(str)`

Masks a U.S. Social Security number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

• `str`: The string to mask. The string must be 11 characters long, but is not otherwise checked.

Return value:

The masked Social Security number as a string, or `NULL` if the argument is not the correct length.

Example:

```
mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('abcdefghijk');
+-------------------------+-------------------------+
| mask_ssn('909-63-6922') | mask_ssn('abcdefghijk') |
| XXX-XX-6922             | XXX-XX-hijk             |
+-------------------------+-------------------------+
mysql> SELECT mask_ssn('909');
+-----------------+
| mask_ssn('909') |
| NULL            |
+-----------------+
```

Random Data Generation Functions

The functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a U.S. phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

• `gen_range(lower, upper)`

Generates a random number chosen from a specified range.

Arguments:

• `lower`: An integer that specifies the lower boundary of the range.

• `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

Return value:
A random integer in the range from lower to upper, inclusive, or NULL if the upper argument is less than lower.

Example:

```sql
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+---------------------+------------------------+
<table>
<thead>
<tr>
<th>gen_range(100, 200)</th>
<th>gen_range(-1000, -800)</th>
</tr>
</thead>
<tbody>
<tr>
<td>177</td>
<td>-917</td>
</tr>
</tbody>
</table>
+---------------------+------------------------+
mysql> SELECT gen_range(1, 0);
+------------------+
| gen_range(1, 0)  |
+------------------+
|            NULL  |
+------------------+
```

- **gen_rnd_email()**

Generates a random email address in the example.com domain.

Arguments:

None.

Return value:

A random email address as a string.

Example:

```sql
mysql> SELECT gen_rnd_email();
+---------------------------+
| gen_rnd_email()           |
| ijocv.mwvhuhf@example.com |
+---------------------------+
```

- **gen_rnd_pan([size])**

Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

**Warning**

Values returned from gen_rnd_pan() should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a gen_rnd_pan() result, consider masking it with mask_pan() or mask_pan_relaxed().

Arguments:

- **size**: (Optional) An integer that specifies the size of the result. The default is 16 if size is not given. If given, size must be an integer in the range from 12 to 19.

Return value:
A random payment number as a string, or **NULL** if a `size` argument outside the permitted range is given.

Example:

```sql
mysql> SELECT mask_pan(gen_rnd_pan());
+-------------------------+
| mask_pan(gen_rnd_pan()) |
| XXXXXXXXXXXXXXX5805     |
+-------------------------+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+---------------------------+
| mask_pan(gen_rnd_pan(19)) |
| XXXXXXXXXXXXXXX5067       |
+---------------------------+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+---------------------------------+
| mask_pan_relaxed(gen_rnd_pan()) |
| 398403XXXXXX9547               |
+---------------------------------+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----------------------------------+
| mask_pan_relaxed(gen_rnd_pan(19)) |
| 578416XXXXXXXXX6509               |
+-----------------------------------+
mysql> SELECT gen_rnd_pan(11), gen_rnd_pan(20);
+-----------------+-----------------+
| gen_rnd_pan(11) | gen_rnd_pan(20) |
| NULL            | NULL            |
+-----------------+-----------------+
```

- **`gen_rnd_ssn()`**

  Generates a random U.S. Social Security number in `AAA-BB-CCCC` format. The `AAA` part is greater than 900 and the `BB` part is less than 70, which are characteristics not used for legitimate Social Security numbers.

  **Arguments:**

  None.

  **Return value:**

  A random Social Security number as a string.

  **Example:**

  ```sql
  mysql> SELECT gen_rnd_ssn();
  +---------------+
  | gen_rnd_ssn() |
  | 951-26-0058   |
  +---------------+
  ```

- **`gen_rnd_us_phone()`**
Generates a random U.S. phone number in 1-555-AAA-BBBB format. The 555 area code is not used for legitimate phone numbers.

Arguments:
None.

Return value:
A random U.S. phone number as a string.

Example:
```sql
mysql> SELECT gen_rnd_us_phone();
+--------------------+
<table>
<thead>
<tr>
<th>gen_rnd_us_phone()</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-555-682-5423</td>
</tr>
</tbody>
</table>
+--------------------+
```

Random Data Dictionary-Based Functions

The functions in this section manipulate dictionaries of terms and perform generation and masking operations based on them. Some of these functions require the SUPER privilege.

When a dictionary is loaded, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions. Dictionaries are loaded from plain text files containing one term per line. Empty lines are ignored. To be valid, a dictionary file must contain at least one nonempty line.

• `gen_blacklist(str, dictionary_name, replacement_dictionary_name)`

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution.

Arguments:
• `str`: A string that indicates the term to replace.
• `dictionary_name`: A string that names the dictionary containing the term to replace.
• `replacement_dictionary_name`: A string that names the dictionary from which to choose the replacement term.

Return value:
A string randomly chosen from `replacement_dictionary_name` as a replacement for `str`, or `str` if it does not appear in `dictionary_name`, or `NULL` if either dictionary name is not in the dictionary registry.

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:
```sql
mysql> SELECT gen_blacklist('Berlin', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_blacklist('Berlin', 'DE_Cities', 'US_Cities') |
+---------------------------------------------------+
- **gen_dictionary(dictionary_name)**

  Returns a random term from a dictionary.

  **Arguments:**

  - **dictionary_name**: A string that names the dictionary from which to choose the term.

  **Return value:**

  A random term from the dictionary as a string, or **NULL** if the dictionary name is not in the dictionary registry.

  **Example:**

  ```
  mysql> SELECT gen_dictionary('mydict');
  +--------------------------+
  | gen_dictionary('mydict') |
  +--------------------------+
  | My term                  |
  +--------------------------+
  mysql> SELECT gen_dictionary('no-such-dict');
  +--------------------------------+
  | gen_dictionary('no-such-dict') |
  +--------------------------------+
  | NULL                           |
  +--------------------------------+
  ```

- **gen_dictionary_drop(dictionary_name)**

  Removes a dictionary from the dictionary registry.

  This function requires the **SUPER** privilege.

  **Arguments:**

  - **dictionary_name**: A string that names the dictionary to remove from the dictionary registry.

  **Return value:**

  A string that indicates whether the drop operation succeeded. **Dictionary removed** indicates success. **Dictionary removal error** indicates failure.

  **Example:**

  ```
  mysql> SELECT gen_dictionary_drop('mydict');
  +-------------------------------+
  | gen_dictionary_drop('mydict') |
  +-------------------------------+
  | Dictionary removed            |
  +-------------------------------+
  mysql> SELECT gen_dictionary_drop('no-such-dict');
  +-------------------------------------+
  | gen_dictionary_drop('no-such-dict') |
  +-------------------------------------+
  | Dictionary removal error            |
  +-------------------------------------+
  ```
• `gen_dictionary_load(dictionary_path, dictionary_name)`

Loads a file into the dictionary registry and assigns the dictionary a name to be used with other functions that require a dictionary name argument.

This function requires the `SUPER` privilege.

**Important**

Dictionaries are not persistent. Any dictionary used by applications must be loaded for each server startup.

Once loaded into the registry, a dictionary is used as is, even if the underlying dictionary file changes. To reload a dictionary, first drop it with `gen_dictionary_drop()`, then load it again with `gen_dictionary_load()`.

Arguments:

• `dictionary_path`: A string that specifies the path name of the dictionary file.

• `dictionary_name`: A string that provides a name for the dictionary.

Return value:

A string that indicates whether the load operation succeeded. `Dictionary load success` indicates success. `Dictionary load error` indicates failure. Dictionary load failure can occur for several reasons, including:

• A dictionary with the given name is already loaded.

• The dictionary file is not found.

• The dictionary file contains no terms.

• The `secure_file_priv` system variable is set and the dictionary file is not located in the directory named by the variable.

Example:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict');
+---------------------------------------------------------------------+
| gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict') |
| Dictionary load success                                             |
+---------------------------------------------------------------------+

mysql> SELECT gen_dictionary_load('/dev/null','null');
+-----------------------------------------+
| gen_dictionary_load('/dev/null','null') |
| Dictionary load error                   |
+-----------------------------------------+
```

6.5 FIPS Support

MySQL supports FIPS mode, if compiled using OpenSSL, and an OpenSSL library and FIPS Object Module are available at runtime.
FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (master/slave and Group Replication) and X Plugin, which run within the server. FIPS mode also applies to attempts by clients to connect to the server.

The following sections describe FIPS mode and how to take advantage of it within MySQL:

• FIPS Overview
• System Requirements for FIPS Mode in MySQL
• Configuring FIPS Mode in MySQL

FIPS Overview

Federal Information Processing Standards 140-2 (FIPS 140-2) describes a security standard that can be required by Federal (US Government) agencies for cryptographic modules used to protect sensitive or valuable information. To be considered acceptable for such Federal use, a cryptographic module must be certified for FIPS 140-2. If a system intended to protect sensitive data lacks the proper FIPS 140-2 certificate, Federal agencies cannot purchase it.

Products such as OpenSSL can be used in FIPS mode, although the OpenSSL library itself is not validated for FIPS. Instead, the OpenSSL library is used with the OpenSSL FIPS Object Module to enable OpenSSL-based applications to operate in FIPS mode.

For general information about FIPS and its implementation in OpenSSL, these references may be helpful:

• National Institute of Standards and Technology FIPS PUB 140-2
• OpenSSL FIPS 140-2 Security Policy
• User Guide for the OpenSSL FIPS Object Module v2.0

Important

FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. For OpenSSL, the exact FIPS behavior depends on the OpenSSL version. For details, refer to the OpenSSL FIPS User Guide.

System Requirements for FIPS Mode in MySQL

For MySQL to support FIPS mode, these system requirements must be satisfied:

• At build time, MySQL must be compiled using OpenSSL. FIPS mode cannot be used in MySQL if compilation uses a different SSL library.

• At runtime, the OpenSSL library and OpenSSL FIPS Object Module must be available as shared (dynamically linked) objects. It is possible to build statically linked OpenSSL objects, but MySQL will not use them.

FIPS mode has been tested for MySQL on EL7, but may work on other systems.

If your platform or operating system provides the OpenSSL FIPS Object Module, you can use it. Otherwise, you can build the OpenSSL library and FIPS Object Module from source. Use the instructions in the OpenSSL FIPS User Guide (see FIPS Overview).

Configuring FIPS Mode in MySQL

MySQL enables control of FIPS mode on the server side and the client side:
Configuring FIPS Mode in MySQL

- The `ssl_fips_mode` system variable controls whether the server operates in FIPS mode.
- The `--ssl-fips-mode` client option controls whether a given MySQL client operates in FIPS mode.

The `ssl_fips_mode` system variable and `--ssl-fips-mode` client option permit these values:

- **OFF**: Disable FIPS mode.
- **ON**: Enable FIPS mode.
- **STRICT**: Enable “strict” FIPS mode.

On the server side, numeric `ssl_fips_mode` values of 0, 1, and 2 are equivalent to **OFF, ON**, and **STRICT**, respectively.

---

**Important**

In general, **STRICT** imposes more restrictions than **ON**, but MySQL itself has no FIPS-specific code other than to specify to OpenSSL the FIPS mode value. The exact behavior of FIPS mode for **ON** or **STRICT** depends on the OpenSSL version. For details, refer to the OpenSSL FIPS User Guide (see FIPS Overview).

---

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` and `--ssl-fips-mode` is **OFF**. An error occurs for attempts to set the FIPS mode to a different value.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (master/slave and Group Replication) and X Plugin, which run within the server.

FIPS mode also applies to attempts by clients to connect to the server. When enabled, on either the client or server side, it restricts which of the supported encryption ciphers can be chosen. However, enabling FIPS mode does not require that an encrypted connection must be used, or that user credentials must be encrypted. For example, if FIPS mode is enabled, stronger cryptographic algorithms are required. In particular, MD5 is restricted, so trying to establish an encrypted connection using an encryption cipher such as **RC4-MD5** does not work. But there is nothing about FIPS mode that prevents establishing an unencrypted connection. (To do that, you can use the **REQUIRE** clause for **CREATE_USER** or **ALTER_USER** for specific user accounts, or set the **require_secure_transport** system variable to affect all accounts.)
Chapter 7 Backup and Recovery

Table of Contents

7.1 Backup and Recovery Types ................................................................. 1392
7.2 Database Backup Methods ................................................................. 1395
7.3 Example Backup and Recovery Strategy ............................................. 1397
   7.3.1 Establishing a Backup Policy ...................................................... 1398
   7.3.2 Using Backups for Recovery ....................................................... 1400
   7.3.3 Backup Strategy Summary ......................................................... 1400
7.4 Using mysqldump for Backups ......................................................... 1401
   7.4.1 Dumping Data in SQL Format with mysqldump ......................... 1401
   7.4.2 Reloading SQL-Format Backups ................................................. 1402
   7.4.3 Dumping Data in Delimited-Text Format with mysqldump .......... 1403
   7.4.4 Reloading Delimited-Text Format Backups ............................... 1404
   7.4.5 mysqldump Tips ....................................................................... 1405
7.5 Point-in-Time (Incremental) Recovery Using the Binary Log .................. 1407
   7.5.1 Point-in-Time Recovery Using Event Times ............................... 1409
   7.5.2 Point-in-Time Recovery Using Event Positions ......................... 1409
7.6 MyISAM Table Maintenance and Crash Recovery ............................... 1410
   7.6.1 Using myisamchk for Crash Recovery ....................................... 1411
   7.6.2 How to Check MyISAM Tables for Errors .................................. 1411
   7.6.3 How to Repair MyISAM Tables .................................................. 1412
   7.6.4 MyISAM Table Optimization ...................................................... 1414
   7.6.5 Setting Up a MyISAM Table Maintenance Schedule ................... 1415

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

• Types of backups: Logical versus physical, full versus incremental, and so forth.

• Methods for creating backups.

• Recovery methods, including point-in-time recovery.

• Backup scheduling, compression, and encryption.

• Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

• Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.
• A forum dedicated to backup issues is available at https://forums.mysql.com/list.php?28.

• Details for mysqldump can be found in Chapter 4, MySQL Programs.

• The syntax of the SQL statements described here is given in Chapter 13, SQL Statement Syntax.

• For additional information about InnoDB backup procedures, see Section 15.17.1, “InnoDB Backup”.

• Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See Chapter 17, Replication.

• MySQL InnoDB cluster is a collection of products that work together to provide a high availability solution. A group of MySQL servers can be configured to create a cluster using MySQL Shell. The cluster of servers has a single master, called the primary, which acts as the read-write master. Multiple secondary servers are replicas of the master. A minimum of three servers are required to create a high availability cluster. A client application is connected to the primary via MySQL Router. If the primary fails, a secondary is automatically promoted to the role of primary, and MySQL Router routes requests to the new primary.

• NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See Chapter 22, MySQL NDB Cluster 8.0, which provides information about MySQL NDB Cluster 8.0.

### 7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

#### Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure (CREATE DATABASE, CREATE TABLE statements) and content (INSERT statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

• The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.

• Physical backup methods are faster than logical because they involve only file copying without conversion.

• Output is more compact than for logical backup.

• Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.

• Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For
example, **InnoDB** tables can each be in a separate file, or share file storage with other **InnoDB** tables; each **MyISAM** table corresponds uniquely to a set of files.

- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from **MEMORY** tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from **MEMORY** tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.
- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for **InnoDB** or any other tables, or file system-level commands (such as `cp`, `scp`, `tar`, `rsync`) for **MyISAM** tables.
- For restore:
  - MySQL Enterprise Backup restores **InnoDB** and other tables that it backed up.
  - `ndb_restore` restores NDB tables.
  - Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even **MEMORY**.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA` statement or the `mysqlimport` client.

### Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also
be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

• The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.

• Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

• Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replication slave server that can be taken offline without harming availability.

• The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

• \texttt{mysqldump} can connect to local or remote servers. For SQL output (\texttt{CREATE} and \texttt{INSERT} statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the \texttt{--tab} option), data files are created on the server host.

• \texttt{SELECT ... INTO OUTFILE} can be initiated from a local or remote client host, but the output file is created on the server host.

• Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section.
Incremental backups are made possible by enabling the server’s binary log, which the server uses to record data changes.

**Full Versus Point-in-Time (Incremental) Recovery**

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server’s state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

**Table Maintenance**

Data integrity can be compromised if tables become corrupt. For InnoDB tables, this is not a typical issue. For programs to check MyISAM tables and repair them if problems are found, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

**Backup Scheduling, Compression, and Encryption**

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress InnoDB backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

**7.2 Database Backup Methods**

This section summarizes some general methods for making backups.

**Making a Hot Backup with MySQL Enterprise Backup**

Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product to do physical backups of entire instances or selected databases, tables, or both. This product includes features for incremental and compressed backups. Backing up the physical database files makes restore much faster than logical techniques such as the mysqldump command. InnoDB tables are copied using a hot backup mechanism. (Ideally, the InnoDB tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a warm backup mechanism. For an overview of the MySQL Enterprise Backup product, see Section 30.2, “MySQL Enterprise Backup Overview”.

**Making Backups with mysqldump**

The mysqldump program can make backups. It can back up all kinds of tables. (See Section 7.4, “Using mysqldump for Backups”.)

For InnoDB tables, it is possible to perform an online backup that takes no locks on tables using the --single-transaction option to mysqldump. See Section 7.3.1, “Establishing a Backup Policy”.

**Making Backups by Copying Table Files**

MyISAM tables can be backed up by copying table files (*.MYD, *.MYI files, and associated *.sdi files). To get a consistent backup, stop the server or lock and flush the relevant tables:
Making Delimited-Text File Backups

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”, and Section 13.7.7.3, “FLUSH Syntax”.

You can also create a binary backup simply by copying the table files, as long as the server isn’t updating anything. (But note that table file copying methods do not work if your database contains InnoDB tables. Also, even if the server is not actively updating data, InnoDB may still have modified data cached in memory and not flushed to disk.)

For an example of this backup method, refer to the export and import example in Section 13.2.5, “IMPORT TABLE Syntax”.

Making Delimited-Text File Backups

To create a text file containing a table’s data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See Section 13.2.10, “SELECT Syntax”. This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See Section 7.4.3, “Dumping Data in Delimited-Text Format with mysqldump”.

To reload a delimited-text data file, use `LOAD DATA` or `mysqlimport`.

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` option to enable binary logging; see Section 5.4.4, “The Binary Log”. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”. The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS` or `mysqldump --flush-logs`. See Section 4.5.4, “mysqldump — A Database Backup Program”.

Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Section 17.3.1, “Using Replication for Backups”.

If you are backing up a slave replication server, you should back up its master info and relay log info repositories (see Section 17.2.4, “Replication Relay and Status Logs”) when you back up the slave’s databases, regardless of the backup method you choose. This information is always needed to resume replication after you restore the slave’s data. If your slave is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The
slate needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

**Recovering Corrupt Tables**

If you have to restore MyISAM tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

**Making Backups Using a File System Snapshot**

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

**7.3 Example Backup and Recovery Strategy**

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the InnoDB storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL’s disk data is available after a restart. The InnoDB data files might not contain consistent data due to the crash, but InnoDB reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. InnoDB automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
```
Establishing a Backup Policy

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is not available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, MySQL Enterprise Backup can perform a physical backup of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up InnoDB data files; mysqldump provides online logical backup. This discussion uses mysqldump.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```shell
mysqldump --all-databases --master-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting .sql file produced by mysqldump contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using FLUSH TABLES WITH READ LOCK). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so --single-transaction uses a consistent read and guarantees that data seen by mysqldump does not change. (Changes made by other clients to InnoDB tables are not seen by the mysqldump process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the mysql database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an
Establishing a Backup Policy

initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

<table>
<thead>
<tr>
<th>Mode</th>
<th>User</th>
<th>Group</th>
<th>Size</th>
<th>Date</th>
<th>Log File</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 4 Nov 10 23:59 gbichot2-bin.000002</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 79 Nov 11 11:06 gbichot2-bin.000003</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 508 Nov 11 11:08 gbichot2-bin.000004</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 998412 Nov 14 10:08 gbichot2-bin.000006</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>rw-rw-</td>
<td>guilhem guilhem 361 Nov 14 10:07 gbichot2-bin.index</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).
The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

**Note**
Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

### 7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

### 7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, InnoDB itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
• Make periodic full backups, using the `mysqldump` command shown earlier in Section 7.3.1, "Establishing a Backup Policy", that makes an online, nonblocking backup.

• Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

### 7.4 Using mysqldump for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

• As a backup to enable data recovery in case of data loss.

• As a source of data for setting up replication slaves.

• As a source of data for experimentation:
  • To make a copy of a database that you can use without changing the original data.
  • To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

• Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.

• With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 7.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see Section 7.4.2, "Reloading SQL-Format Backups".

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```bash
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```bash
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```bash
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.
Reloading SQL-Format Backups

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

By default, if GTIDs are in use on the server where you create the dump file (`gtid_mode=ON`), `mysqldump` includes a `SET @@GLOBAL.gtid_purged` statement in the output to add the GTIDs from the `gtid_executed` set on the source server to the `gtid_purged` set on the target server. If you are dumping only specific databases or tables, it is important to note that the value that is included by `mysqldump` includes the GTIDs of all transactions in the `gtid_executed` set on the source server, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. If you only replay one partial dump file on the target server, the extra GTIDs do not cause any problems with the future operation of that server. However, if you replay a second dump file on the target server that contains the same GTIDs (for example, another partial dump from the same source server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. To avoid this issue, either set the `mysqldump` option `--set-gtid-purged` to `OFF` or `COMMENTED` to output the second dump file without an active `SET @@GLOBAL.gtid_purged` statement, or remove the statement manually before replaying the dump file.

7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:
7.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use mysqldump to create delimited-text dump files. For information about reloading such dump files, see Section 7.4.4, “Reloading Delimited-Text Format Backups”.

If you invoke mysqldump with the --tab=dir_name option, it uses dir_name as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named t1, the files are named t1.sql and t1.txt. The .sql file contains a CREATE TABLE statement for the table. The .txt file contains the table data, one line per table row.

The following command dumps the contents of the db1 database to files in the /tmp database:

```
shell> mysqldump --tab=/tmp db1
```

The .txt files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses SELECT ... INTO OUTFILE to write the files, so you must have the FILE privilege to perform this operation, and an error occurs if a given .txt file already exists.

The server sends the CREATE definitions for dumped tables to mysqldump, which writes them to .sql files. These files therefore are owned by the user who executes mysqldump.

It is best that --tab be used only for dumping a local server. If you use it with a remote server, the --tab directory must exist on both the local and remote hosts, and the .txt files will be written by the server in the remote directory (on the server host), whereas the .sql files will be written by mysqldump in the local directory (on the client host).
For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=STR`
  The string for separating column values (default: tab).
- `--fields-enclosed-by=CHAR`
  The character within which to enclose column values (default: no character).
- `--fields-optionally-enclosed-by=CHAR`
  The character within which to enclose non-numeric column values (default: no character).
- `--fields-escaped-by=CHAR`
  The character for escaping special characters (default: no escaping).
- `--lines-terminated-by=STR`
  The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='''
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,' --fields-enclosed-by=''' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

### 7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:
An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA` statement from within the `mysql` client:

```mysql
USE db1;
LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA` to ensure proper interpretation of the data file contents:

```shell
mysqlimport --fields-terminated-by=,
--fields-enclosed-by='"'
--lines-terminated-by=0x0d0a
db1 t1.txt
```

Or:

```mysql
USE db1;
LOAD DATA INFILE 't1.txt' INTO TABLE t1
FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
LINES TERMINATED BY '\\r\n';
```

### 7.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

#### 7.4.5.1 Making a Copy of a Database

```shell
mysqldump db1 > dump.sql
mysqladmin create db2
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

#### 7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```shell
mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```shell
mysql < dump.sql
```
Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```shell
shell> mysqldump db1 > dump.sql
```

On Server 2:

```shell
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

### 7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

### 7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```shell
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```shell
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

### 7.4.5.5 Using mysqldump to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the
production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

### 7.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in Section 7.2, “Database Backup Methods”.) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

**Note**

Many of the examples here use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains \0 (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see Section 5.4.4, “The Binary Log”).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. Section 5.4.4, “The Binary Log”.

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```
To determine the name of the current binary log file, issue the following statement:

```sql
mysql> SHOW MASTER STATUS;
```

The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```bash
shell> mysqlbinlog binlog_files | mysql -u root -p
```

If binary log files have been encrypted, which can be done from MySQL 8.0.14 onwards, `mysqlbinlog` cannot read them directly as in the above example, but can read them from the server using the `--read-from-remote-server (-R)` option. For example:

```bash
shell> mysqlbinlog --read-from-remote-server --host=host_name --port=3306 --user=root --password --ssl-mode=required binlog_files | mysql -u root -p
```

Here, the option `--ssl-mode=required` has been used to ensure that the data from the binary log files is protected in transit, because it is sent to `mysqlbinlog` in an unencrypted format.

Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```bash
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```bash
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```bash
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be unsafe:

```bash
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a single connection to execute the contents of all binary logs that you want to process. Here is one way to do so:
Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

When writing to a dump file while reading back from a binary log containing GTIDs (see Section 17.1.3, "Replication with Global Transaction Identifiers"), use the --skip-gtids option with `mysqlbinlog`, like this:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

### 7.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the --start-datetime and --stop-datetime options for `mysqlbinlog`, in DATETIME format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the --stop-datetime option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

### 7.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the --start-position and --stop-position options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around...
the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \   --stop-datetime="2005-04-20 10:05:00" \   /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \   | mysql -u root -p
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \   | mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

## 7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see Section 4.6.4, "myisamchk — MyISAM Table-Maintenance Utility". Other table-repair information can be found at Section 2.11.13, “Rebuilding or Repairing Tables or Indexes”.

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see Section 4.6.4.5, “Obtaining Table Information with myisamchk”.

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup before doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.4.1, “myisamchk General Options”.

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.
For additional information about these statements, see Section 13.7.3, “Table Maintenance Statements”.

These statements can be used directly or by means of the mysqlcheck client program. One advantage of these statements over myisamchk is that the server does all the work. With myisamchk, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between myisamchk and the server.

### 7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 16.2.4, “MyISAM Table Problems”.

If you run mysqld with external locking disabled (which is the default), you cannot reliably use myisamchk to check a table when mysqld is using the same table. If you can be certain that no one will access the tables through mysqld while you run myisamchk, you only have to execute mysqladmin flush-tables before you start checking the tables. If you cannot guarantee this, you must stop mysqld while you check the tables. If you run myisamchk to check tables that mysqld is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use myisamchk to check tables at any time. In this case, if the server tries to update a table that myisamchk is using, the server will wait for myisamchk to finish before it continues.

If you use myisamchk to repair or optimize tables, you must always ensure that the mysqld server is not using the table (this also applies if external locking is disabled). If you do not stop mysqld, you should at least do a mysqladmin flush-tables before you run myisamchk. Your tables may become corrupted if the server and myisamchk access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table tbl_name in a database corresponds to the three files in the database directory shown in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.MYD</td>
<td>Data file</td>
</tr>
<tr>
<td>tbl_name.MYI</td>
<td>Index file</td>
</tr>
</tbody>
</table>

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

myisamchk works by creating a copy of the .MYD data file row by row. It ends the repair stage by removing the old .MYD file and renaming the new file to the original file name. If you use --quick, myisamchk does not create a temporary .MYD file, but instead assumes that the .MYD file is correct and generates only a new index file without touching the .MYD file. This is safe, because myisamchk automatically detects whether the .MYD file is corrupt and aborts the repair if it is. You can also specify the --quick option twice to myisamchk. In this case, myisamchk does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the .MYD file. Normally the use of two --quick options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running myisamchk.

### 7.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:
• **myisamchk tbl_name**

This finds 99.99% of all errors. What it cannot find is corruption that involves only the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

• **myisamchk -m tbl_name**

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

• **myisamchk -e tbl_name**

This does a complete and thorough check of all data (`-e` means "extended check"). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

• **myisamchk -e -i tbl_name**

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

### 7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See Section 13.7.3.2, “CHECK TABLE Syntax”, and Section 13.7.3.5, “REPAIR TABLE Syntax”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

• Can't find file `tbl_name.MYI` (Errcode: `nnn`)
• Unexpected end of file
• Record file is crashed
• Got error `nnn` from table handler

To get more information about the error, run `perror nnn`, where `nnn` is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
```
How to Repair MyISAM Tables

MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to three stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 7.6.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”. `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See Section 4.6.4.6, “myisamchk Memory Usage”.

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

**Stage 1: Checking your tables**

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as out of memory errors), or if `myisamchk` crashes, go to Stage 3.

**Stage 2: Easy safe repair**

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as out of memory errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.

2. Use the table description file to create new (empty) data and index files:

   ```
   shell> mysql db_name
   mysql> SET autocommit=1;
   mysql> TRUNCATE TABLE tbl_name;
   mysql> quit
   ```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See Section 13.7.3.5, “REPAIR TABLE Syntax”.

7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```shell
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.7.3.4, “OPTIMIZE TABLE Syntax”.

1414
myisamchk has a number of other options that you can use to improve the performance of a table:

- **--analyze** or **-a**: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.

- **--sort-index** or **-S**: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.

- **--sort-records=index_num** or **--R index_num**: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based SELECT and ORDER BY operations that use this index.

For a full description of all available options, see Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”.

### 7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the CHECK TABLE and REPAIR TABLE statements. See Section 13.7.3, “Table Maintenance Statements”.

Another way to check tables is to use myisamchk. For maintenance purposes, you can use myisamchk **-s**. The **-s** option (short for **--silent**) causes myisamchk to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the **--myisam-recover-options** option. See Section 5.1.7, “Server Command Options”.

You should also check your tables regularly during normal system operation. For example, you can run a cron job to check important tables once a week, using a line like this in a crontab file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute myisamchk **-s** each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with VARCHAR, BLOB, or TEXT columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using OPTIMIZE TABLE on the tables in question. Alternatively, if you can stop the mysqld server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M */*.MYI
```

### 8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.
which you must minimize and make as efficient as possible. As you work on database performance, you
start by learning the high-level rules and guidelines for the software side, and measuring performance
using wall-clock time. As you become an expert, you learn more about what happens internally, and start
measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware
configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop
their own storage engines and hardware appliances to expand the MySQL ecosystem.

- Optimizing at the Database Level
- Optimizing at the Hardware Level
- Balancing Portability and Performance

**Optimizing at the Database Level**

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does
each table have the appropriate columns for the type of work? For example, applications that perform
frequent updates often have many tables with few columns, while applications that analyze large
amounts of data often have few tables with many columns.

- Are the right indexes in place to make queries efficient?

- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and
features of each storage engine you use? In particular, the choice of a transactional storage engine
such as InnoDB or a nontransactional one such as MyISAM can be very important for performance and
scalability.

  **Note**

  InnoDB is the default storage engine for new tables. In practice, the advanced
  InnoDB performance features mean that InnoDB tables often outperform the
  simpler MyISAM tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used
  for the table. In particular, compressed tables use less disk space and so require less disk I/O to read
  and write the data. Compression is available for all kinds of workloads with InnoDB tables, and for read-
  only MyISAM tables.

- Does the application use an appropriate locking strategy? For example, by allowing shared access
  when possible so that database operations can run concurrently, and requesting exclusive access when
  appropriate so that critical operations get top priority. Again, the choice of storage engine is significant.
The InnoDB storage engine handles most locking issues without involvement from you, allowing for
better concurrency in the database and reducing the amount of experimentation and tuning for your
code.

- Are all memory areas used for caching sized correctly? That is, large enough to hold frequently
  accessed data, but not so large that they overload physical memory and cause paging. The main
  memory areas to configure are the InnoDB buffer pool and the MyISAM key cache.

**Optimizing at the Hardware Level**

Any database application eventually hits hardware limits as the database becomes more and more busy.
A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these
bottlenecks, or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.

- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.

- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/*! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see Section 9.6, “Comment Syntax”.

8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

8.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

NDB Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see Conditions for NDB pushdown joins.

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.
Indexes are especially important for queries that reference different tables, using features such as joins and foreign keys. You can use the EXPLAIN statement to determine which indexes are used for a SELECT. See Section 8.3.1, “How MySQL Uses Indexes” and Section 8.8.1, “Optimizing Queries with EXPLAIN”.

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.

- Minimize the number of full table scans in your queries, particularly for big tables.

- Keep table statistics up to date by using the ANALYZE TABLE statement periodically, so the optimizer has the information needed to construct an efficient execution plan.

- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both InnoDB and MyISAM have sets of guidelines for enabling and sustaining high performance in queries. For details, see Section 8.5.6, “Optimizing InnoDB Queries” and Section 8.6.1, “Optimizing MyISAM Queries”.

- You can optimize single-query transactions for InnoDB tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.

- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the EXPLAIN plan and adjusting your indexes, WHERE clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the EXPLAIN plan might be your first step for every query.)

- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the InnoDB buffer pool, MyISAM key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.

- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.

- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

8.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing WHERE clauses. The examples use SELECT statements, but the same optimizations apply for WHERE clauses in DELETE and UPDATE statements.

Note
Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and
leaves the query in a more understandable and maintainable form. Some of the optimizations performed by
MySQL follow:

- **Removal of unnecessary parentheses:**

  
  \[
  \text{((a AND b) AND c OR (((a AND b) AND (c AND d))))} \\
  \rightarrow (a AND b AND c) OR (a AND b AND c AND d)
  \]

- **Constant folding:**

  \[
  (a<b AND b=c) AND a=5 \\
  \rightarrow b>5 AND b=c AND a=5
  \]

- **Constant condition removal:**

  \[
  (b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6) \\
  \rightarrow b=5 OR b=6
  \]

In MySQL 8.0.14 and later, this takes place during preparation rather than during the optimization
phase, which helps in simplification of joins. See Section 8.2.1.8, “Outer Join Optimization”, for further
information and examples.

- **Constant expressions used by indexes are evaluated only once.**

- **Beginning with MySQL 8.0.16,** comparisons of columns of numeric types with constant values are
  checked and folded or removed for invalid or out-of-range values:

  ```
  # CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
  SELECT * FROM t WHERE c < 256;
  SELECT * FROM t WHERE 1;
  ```

  See Section 8.2.1.13, “Constant-Folding Optimization”, for more information.

- **COUNT(*) on a single table without a WHERE is retrieved directly from the table information for MyISAM
  and MEMORY tables. This is also done for any NOT NULL expression when used with only one table.**

- **Early detection of invalid constant expressions.** MySQL quickly detects that some SELECT statements
  are impossible and returns no rows.

- **HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT(), MIN(),
  and so on).**

- For each table in a join, a simpler WHERE is constructed to get a fast WHERE evaluation for the table and
  also to skip rows as soon as possible.

- **All constant tables are read first before any other tables in the query.** A constant table is any of the
  following:

  - An empty table or a table with one row.

  - A table that is used with a WHERE clause on a PRIMARY KEY or a UNIQUE index, where all index parts
    are compared to constant expressions and are defined as NOT NULL.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
```
SELECT * FROM t1,t2
    WHERE t1.primary_key=1 AND t2.primary_key=t1.id;

• The best join combination for joining the tables is found by trying all possibilities. If all columns in ORDER BY and GROUP BY clauses come from the same table, that table is preferred first when joining.

• If there is an ORDER BY clause and a different GROUP BY clause, or if the ORDER BY or GROUP BY contains columns from tables other than the first table in the join queue, a temporary table is created.

• If you use the SQL_SMALL_RESULT modifier, MySQL uses an in-memory temporary table.

• Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.

• In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.

• Before each row is output, those that do not match the HAVING clause are skipped.

Some examples of queries that are very fast:

SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
    WHERE key_part1=constant;

SELECT ... FROM tbl_name
    ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
    ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
    WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

SELECT ... FROM tbl_name
    ORDER BY key_part1,key_part2,...;

SELECT ... FROM tbl_name
    ORDER BY key_part1 DESC, key_part2 DESC, ...;

### 8.2.1.2 Range Optimization

The range access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections describe conditions under which the optimizer uses range access.
Optimizing SELECT Statements

- Range Access Method for Single-Part Indexes
- Range Access Method for Multiple-Part Indexes
- Equality Range Optimization of Many-Valued Comparisons
- Skip Scan Range Access Method
- Range Optimization of Row Constructor Expressions
- Limiting Memory Use for Range Optimization

Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the WHERE clause, denoted as range conditions rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both BTREE and HASH indexes, comparison of a key part with a constant value is a range condition when using the =, <=>, IN(), IS NULL, or IS NOT NULL operators.

- Additionally, for BTREE indexes, comparison of a key part with a constant value is a range condition when using the >, <, >=, <=, BETWEEN, !+, or <> operators, or LIKE comparisons if the argument to LIKE is a constant string that does not start with a wildcard character.

- For all index types, multiple range conditions combined with OR or AND form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string

- A column of a const or system table from the same join

- The result of an uncorrelated subquery

- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the WHERE clause:

```sql
SELECT * FROM t1
WHERE key_col > 1
AND key_col < 10;

SELECT * FROM t1
WHERE key_col = 1
OR key_col IN (15,18,20);

SELECT * FROM t1
WHERE key_col LIKE 'ab%' 
OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the WHERE clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where key1 is an indexed column and nonkey is not indexed:
SELECT * FROM t1 WHERE
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z');

The extraction process for key key1 is as follows:

1. Start with original WHERE clause:

(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')

2. Remove nonkey = 4 and key1 LIKE '%b' because they cannot be used for a range scan. The correct way to remove them is to replace them with TRUE, so that we do not miss any matching rows when doing the range scan. Replacing them with TRUE yields:

(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')

3. Collapse conditions that are always true or false:

- (key1 LIKE 'abcde%' OR TRUE) is always true
- (key1 < 'uux' AND key1 > 'z') is always false

Replacing these conditions with constants yields:

(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)

Removing unnecessary TRUE and FALSE constants yields:

(key1 < 'abc') OR (key1 < 'bar')

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

(key1 < 'bar')

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the WHERE clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full WHERE clause.

The range condition extraction algorithm can handle nested AND/OR constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in WHERE clause.

MySQL does not support merging multiple ranges for the range access method for spatial indexes. To work around this limitation, you can use a UNION with identical SELECT statements, except that you put each spatial predicate in a different SELECT.

Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.
For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<table>
<thead>
<tr>
<th>key_part1</th>
<th>key_part2</th>
<th>key_part3</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>NULL</td>
<td>1</td>
<td>'xyz'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'foo'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>'abc'</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>'aaa'</td>
</tr>
</tbody>
</table>

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For **HASH** indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1, const2, ...` are constants, `cmp` is one of the `=, <=>, or IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part **HASH** index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Range Access Method for Single-Part Indexes](#).

- For a **BTREE** index, an interval might be usable for conditions combined with **AND**, where each condition compares a key part with a constant value using `=, <=>, IS NULL, >, <, >=, =, !>, BETWEEN, or LIKE 'pattern'` (where 'pattern' does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=, <=>`, or **IS NULL**. If the operator is `>`, `<`, `>=`, `=`, `!>, BETWEEN`, or LIKE, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:
Optimizing SELECT Statements

('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value ('foo', 11, 0), which does not satisfy the original condition.

• If conditions that cover sets of rows contained within intervals are combined with OR, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with AND, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)

The intervals are:

(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The key_len column in the EXPLAIN output indicates the maximum length of the key prefix used.

In some cases, key_len may indicate that a key part was used, but that might be not what you would expect. Suppose that key_part1 and key_part2 can be NULL. Then the key_len column displays two key part lengths for the following condition:

key_part1 >= 1 AND key_part2 < 2

But, in fact, the condition is converted to this:

key_part1 >= 1 AND key_part2 IS NOT NULL

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see Range Access Method for Single-Part Indexes. Analogous steps are performed for range conditions on multiple-part indexes.

Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where col_name is an indexed column:

col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN

Each expression is true if col_name is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

• If there is a unique index on col_name, the row estimate for each range is 1 because at most one row can have the given value.

• Otherwise, any index on col_name is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.
With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression `col_name IN (10, 20, 30)` has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The `eq_range_index_dive_limit` system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to \( N \) equality ranges, set `eq_range_index_dive_limit` to \( N + 1 \). To disable use of statistics and always use index dives regardless of \( N \), set `eq_range_index_dive_limit` to 0.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

Prior to MySQL 8.0, there is no way of skipping the use of index dives to estimate index usefulness, except by using the `eq_range_index_dive_limit` system variable. In MySQL 8.0, index dive skipping is possible for queries that satisfy all these conditions:

- The query is for a single table, not a join on multiple tables.
- A single-index `FORCE INDEX` index hint is present. The idea is that if index use is forced, there is nothing to be gained from the additional overhead of performing dives into the index.
- The index is nonunique and not a `FULLTEXT` index.
- No subquery is present.
- No `DISTINCT`, `GROUP BY`, or `ORDER BY` clause is present.

For `EXPLAIN FOR CONNECTION`, the output changes as follows if index dives are skipped:

- For traditional output, the `rows` and `filtered` values are `NULL`.
- For JSON output, `rows_examined_per_scan` and `rows_produced_per_join` do not appear, `skip_index_dive_due_to_force` is `true`, and cost calculations are not accurate.

Without `FOR CONNECTION`, `EXPLAIN` output does not change when index dives are skipped.

After execution of a query for which index dives are skipped, the corresponding row in the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table contains an `index_dives_for_range_access` value of `skipped_due_to_force_index`.

### Skip Scan Range Access Method

Consider the following scenario:

```sql
CREATE TABLE t1 (f1 INT NOT NULL, f2 INT NOT NULL, PRIMARY KEY(f1, f2));
INSERT INTO t1 VALUES
  (1,1), (1,2), (1,3), (1,4), (1,5),
  (2,1), (2,2), (2,3), (2,4), (2,5);
INSERT INTO t1 SELECT f1, f2 + 5 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 10 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 20 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 40 FROM t1;
ANALYZE TABLE t1;
```
EXPLAIN SELECT f1, f2 FROM t1 WHERE f2 > 40;

To execute this query, MySQL can choose an index scan to fetch all rows (the index includes all columns to be selected), then apply the f2 > 40 condition from the WHERE clause to produce the final result set.

A range scan is more efficient than a full index scan, but cannot be used in this case because there is no condition on f1, the first index column. However, as of MySQL 8.0.13, the optimizer can perform multiple range scans, one for each value of f1, using a method called Skip Scan that is similar to Loose Index Scan (see Section 8.2.1.16, “GROUP BY Optimization”):

1. Skip between distinct values of the first index part, f1 (the index prefix).
2. Perform a subrange scan on each distinct prefix value for the f2 > 40 condition on the remaining index part.

For the data set shown earlier, the algorithm operates like this:

1. Get the first distinct value of the first key part (f1 = 1).
2. Construct the range based on the first and second key parts (f1 = 1 AND f2 > 40).
3. Perform a range scan.
4. Get the next distinct value of the first key part (f1 = 2).
5. Construct the range based on the first and second key parts (f1 = 2 AND f2 > 40).
6. Perform a range scan.

Using this strategy decreases the number of accessed rows because MySQL skips the rows that do not qualify for each constructed range. This Skip Scan access method is applicable under the following conditions:

- Table T has at least one compound index with key parts of the form ([A_1, ..., A_k,] B_1, ..., B_m, C [, D_1, ..., D_n]). Key parts A and D may be empty, but B and C must be nonempty.
- The query references only one table.
- The query does not use GROUP BY or DISTINCT.
- The query references only columns in the index.
- The predicates on A_1, ..., A_k must be equality predicates and they must be constants. This includes the IN() operator.
- The query must be a conjunctive query; that is, an AND of OR conditions: (cond1(key_part1) OR cond2(key_part1)) AND (cond1(key_part2) OR ...) AND ...
- There must be a range condition on C.
- Conditions on D columns are permitted. Conditions on D must be in conjunction with the range condition on C.

Use of Skip Scan is indicated in EXPLAIN output as follows:

- Using index for skip scan in the Extra column indicates that the loose index Skip Scan access method is used.
- If the index can be used for Skip Scan, the index should be visible in the possible_keys column.
Optimizing SELECT Statements

Use of Skip Scan is indicated in optimizer trace output by a "skip scan" element of this form:

```
"skip_scan_range": {
  "type": "skip_scan",
  "index": index_used_for_skip_scan,
  "key_parts_used_for_access": [key_parts_used_for_access],
  "range": [range]
}
```

You may also see a "best_skip_scan_summary" element. If Skip Scan is chosen as the best range access variant, a "chosen_range_access_summary" is written. If Skip Scan is chosen as the overall best access method, a "best_access_path" element is present.

Use of Skip Scan is subject to the value of the skip_scan flag of the optimizer_switch system variable. See Section 8.9.2, “Switchable Optimizations”. By default, this flag is on. To disable it, set skip_scan to off.

In addition to using the optimizer_switch system variable to control optimizer use of Skip Scan session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

Range Optimization of Row Constructor Expressions

The optimizer is able to apply the range scan access method to queries of this form:

```
SELECT ... FROM t1 WHERE ( col_1, col_2 ) IN (( 'a', 'b' ), ( 'c', 'd' ));
```

Previously, for range scans to be used, it was necessary to write the query as:

```
SELECT ... FROM t1 WHERE ( col_1 = 'a' AND col_2 = 'b' )
OR ( col_1 = 'c' AND col_2 = 'd' );
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only IN() predicates are used, not NOT IN().
- On the left side of the IN() predicate, the row constructor contains only column references.
- On the right side of the IN() predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.
- On the right side of the IN() predicate, there is more than one row constructor.

For more information about the optimizer and row constructors, see Section 8.2.1.21, “Row Constructor Expression Optimization”

Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the range_optimizer_max_mem_size system variable:

- A value of 0 means “no limit.”
- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this
happens, the following warning occurs (where \( N \) is the current `range_optimizer_max_mem_size` value):

```
Warning 3170 Memory capacity of \( N \) bytes for
'range_optimizer_max_mem_size' exceeded. Range
optimization was not done for this query.
```

- For **UPDATE** and **DELETE** statements, if the optimizer falls back to a full table scan and the `sql_safe_updates` system variable is enabled, an error occurs rather than a warning because, in effect, no key is used to determine which rows to modify. For more information, see Using Safe-Updates Mode (--safe-updates).

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with `OR` uses approximately 230 bytes:

  ```
  SELECT COUNT(*) FROM t
  WHERE a=1 OR a=2 OR a=3 OR .. . a=\( N \);
  ```

- Similarly for a query such as the following, each predicate combined with `AND` uses approximately 125 bytes:

  ```
  SELECT COUNT(*) FROM t
  WHERE a=1 AND b=1 AND c=1 .. . \( N \);
  ```

- For a query with `IN()` predicates:

  ```
  SELECT COUNT(*) FROM t
  WHERE a IN (1,2, ..., \( M \)) AND b IN (1,2, ..., \( N \));
  ```

  Each literal value in an `IN()` list counts as a predicate combined with `OR`. If there are two `IN()` lists, the number of predicates combined with `OR` is the product of the number of literal values in each list. Thus, the number of predicates combined with `OR` in the preceding case is \( M \times N \).

### 8.2.1.3 Index Merge Optimization

The **Index Merge** access method retrieves rows with multiple `range` scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;
SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;
SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
    AND t2.key1 = t1.some_col;
```
### SELECT * FROM t1, t2
WHERE t1.key1 = 1
AND (t2.key1 = t1.some_col OR t2.key2 = t1.some_col2);

#### Note

The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

  \[(x \text{ AND } y) \text{ OR } z \Rightarrow (x \text{ OR } z) \text{ AND } (y \text{ OR } z)\]

  \[(x \text{ OR } y) \text{ AND } z \Rightarrow (x \text{ AND } z) \text{ OR } (y \text{ AND } z)\]

- Index Merge is not applicable to full-text indexes.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the `Extra` field of `EXPLAIN` output:

- Using `intersect(...)`
- Using `union(...)`
- Using `sort_union(...)`

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

- **Index Merge Intersection Access Algorithm**
- **Index Merge Union Access Algorithm**
- **Index Merge Sort-Union Access Algorithm**
- **Influencing Index Merge Optimization**

#### Index Merge Intersection Access Algorithm

This access algorithm is applicable when a `WHERE` clause is converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- An \( N \)-part expression of this form, where the index has exactly \( N \) parts (that is, all index parts are covered):

  \[\text{key_part1} = \text{const1 AND key_part2} = \text{const2 ... AND key_partN} = \text{constN}\]

- Any range condition over the primary key of an InnoDB table.

Examples:
Optimizing SELECT Statements

```
SELECT * FROM innodb_table
  WHERE primary_key < 10 AND key_col1 = 20;
SELECT * FROM tbl_name
  WHERE key1_part1 = 1 AND key1_part2 = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (EXPLAIN output contains Using index in Extra field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an InnoDB table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

**Index Merge Union Access Algorithm**

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table's WHERE clause is converted to several range conditions on different keys combined with OR, and each condition is one of the following:

- An \(N\)-part expression of this form, where the index has exactly \(N\) parts (that is, all index parts are covered):

  \[
  key_part1 = \text{const}1 \quad \text{AND} \quad key_part2 = \text{const}2 \quad \ldots \quad \text{AND} \quad key_partN = \text{const}N
  \]

- Any range condition over a primary key of an InnoDB table.

- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1
  WHERE key1 = 1 OR key2 = 2 OR key3 = 3;
SELECT * FROM innodb_table
  WHERE (key1 = 1 AND key2 = 2)
    OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;
```

**Index Merge Sort-Union Access Algorithm**

This access algorithm is applicable when the WHERE clause is converted to several range conditions combined by OR, but the Index Merge union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name
  WHERE key_col1 < 10 OR key_col2 < 20;
SELECT * FROM tbl_name
  WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;
```
Optimizing SELECT Statements

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

**Influencing Index Merge Optimization**

Use of Index Merge is subject to the value of the `index_merge`, `index_merge_intersection`, `index_merge_union`, and `index_merge_sort_union` flags of the `optimizer_switch` system variable. See Section 8.9.2, “Switchable Optimizations”. By default, all those flags are on. To enable only certain algorithms, set `index_merge` to off, and enable only such of the others as should be permitted.

In addition to using the `optimizer_switch` system variable to control optimizer use of the Index Merge algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

**8.2.1.4 Engine Condition Pushdown Optimization**

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the NDB storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster’s data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

```sql
CREATE TABLE t1 (
    a INT,
    b INT,
    KEY(a)
) ENGINE=NDB;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```sql
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of `EXPLAIN`:

```sql
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using where with pushed condition
```

However, condition pushdown cannot be used with either of these two queries:

```sql
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```
Optimizing SELECT Statements

Condition pushdown is not applicable to the first query because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.)

Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column `b` is indirect. (However, condition pushdown could be applied if you were to reduce `b + 1 = 10` to `b = 9` in the `WHERE` clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2
```

```
+----+-------------+----------+-------+----------------+---------+------------+-------+----------------+
| id | select_type | type     | possible_keys | key    | key_len | ref | rows | Extra               |
+----+-------------+----------+-------+----------------+---------+------------+-------+----------------+
| 1  | SIMPLE      | range    | a     | a              | 5       | NULL      | 2     | Using where with pushed condition |
+----+-------------+----------+-------+----------------+---------+------------+-------+----------------+
```

Other supported comparisons for condition pushdown include the following:

- `column [NOT] LIKE pattern`

  `pattern` must be a string literal containing the pattern to be matched; for syntax, see Section 12.5.1, “String Comparison Functions and Operators”.

- `column IS [NOT] NULL`

- `column IN (value_list)`

  Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

  `constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable. For example, in a `my.cnf` file, use these lines:

```
[mysqld]
optimizer_switch=engine_condition_pushdown=off
```

At runtime, disable condition pushdown like this:

```
SET optimizer_switch='engine_condition_pushdown=off';
```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the `NDB` storage engine.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
• Columns used in comparisons cannot be of any of the BLOB or TEXT types.

• A string value to be compared with a column must use the same collation as the column.

• Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended EXPLAIN output to determine which conditions are actually pushed down. See Section 8.8.3, “Extended EXPLAIN Output Format”.

Previously, condition pushdown was limited to terms referring to column values from the same table to which the condition was being pushed. Beginning with NDB 8.0.16, column values from tables earlier in the query plan can also be referred to from pushed conditions. This reduces the number of rows which must be handled by the SQL node during join processing. Filtering can be also performed in parallel in the LDM threads, rather than in a single mysqld process. This has the potential to improve performance of queries by a significant margin.

Join algorithms cannot be combined with referring columns from previous tables in the following two situations:

1. When any of the referred previous tables are in a join buffer. In this case, each row retrieved from the scan-filtered table is matched against every row in the buffer. This means that there is no single specific row from which column values can be fetched from when generating the scan filter.

2. When the column originates from a child operation in a pushed join. This is because rows referenced from ancestor operations in the join have not yet been retrieved when the scan filter is generated.

### 8.2.1.5 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the WHERE condition for the rows. With ICP enabled, and if parts of the WHERE condition can be evaluated by using only columns from the index, the MySQL server pushes this part of the WHERE condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Applicability of the Index Condition Pushdown optimization is subject to these conditions:

• ICP is used for the range, ref, eq_ref, and ref_or_null access methods when there is a need to access full table rows.

• ICP can be used for InnoDB and MyISAM tables, including partitioned InnoDB and MyISAM tables.

• For InnoDB tables, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-row reads and thereby reduce I/O operations. For InnoDB clustered indexes, the complete record is already read into the InnoDB buffer. Using ICP in this case does not reduce I/O.

• ICP is not supported with secondary indexes created on virtual generated columns. InnoDB supports secondary indexes on virtual generated columns.

• Conditions that refer to subqueries cannot be pushed down.

• Conditions that refer to stored functions cannot be pushed down. Storage engines cannot invoke stored functions.

• Triggered conditions cannot be pushed down. (For information about triggered conditions, see Section 8.2.2.3, “Optimizing Subqueries with the EXISTS Strategy”.)
To understand how this optimization works, first consider how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.

2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

Using Index Condition Pushdown, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).

2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.

3. If the condition is satisfied, use the index tuple to locate and read the full table row.

4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

`EXPLAIN` output shows `Using index condition` in the `Extra` column when Index Condition Pushdown is used. It does not show `Using index` because that does not apply when full table rows must be read.

Suppose that a table contains information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```sql
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL checks the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to index tuples that match the `zipcode` condition but not the `lastname` condition.

Index Condition Pushdown is enabled by default. It can be controlled with the `optimizer_switch` system variable by setting the `index_condition_pushdown` flag:

```sql
SET optimizer_switch = 'index_condition_pushdown=off';
SET optimizer_switch = 'index_condition_pushdown=on';
```

See Section 8.9.2, "Switchable Optimizations".

### 8.2.1.6 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- Nested-Loop Join Algorithm
- Block Nested-Loop Join Algorithm
Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables $t_1$, $t_2$, and $t_3$ is to be executed using the following join types:

<table>
<thead>
<tr>
<th>Table</th>
<th>Join Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t_1$</td>
<td>range</td>
</tr>
<tr>
<td>$t_2$</td>
<td>ref</td>
</tr>
<tr>
<td>$t_3$</td>
<td>ALL</td>
</tr>
</tbody>
</table>

If a simple NLJ algorithm is used, the join is processed like this:

```sql
for each row in t1 matching range {
    for each row in t2 matching reference key {
        for each row in t3 {
            if row satisfies join conditions, send to client
        }
    }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces by an order of magnitude the number of times the inner table must be read.

MySQL join buffering has these characteristics:

- Join buffering can be used when the join is of type **ALL** or **index** (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or **range**. Use of buffering is also applicable to outer joins, as described in Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.
- A join buffer is never allocated for the first nonconstant table, even if it would be of type **ALL** or **index**.
- Only columns of interest to a join are stored in its join buffer, not whole rows.
- The `join_buffer_size` system variable determines the size of each join buffer used to process a query.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is allocated prior to executing the join and freed after the query is done.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```sql
for each row in t1 matching range {
    for each row in t2 matching reference key {
        for each row in t3 {
            if row satisfies join conditions, send to client
        }
    }
}
```
store used columns from t1, t2 in join buffer
if buffer is full {
    for each row in t3 {
        for each t1, t2 combination in join buffer {
            if row satisfies join conditions, send to client
        }
    }
    empty join buffer
}
}
if buffer is not empty {
    for each row in t3 {
        for each t1, t2 combination in join buffer {
            if row satisfies join conditions, send to client
        }
    }
}

If \( S \) is the size of each stored \( t1, t2 \) combination in the join buffer and \( C \) is the number of combinations in the buffer, the number of times table \( t3 \) is scanned is:

\[
\frac{(S \times C)}{\text{join_buffer_size}} + 1
\]

The number of \( t3 \) scans decreases as the value of \( \text{join_buffer_size} \) increases, up to the point when \( \text{join_buffer_size} \) is large enough to hold all previous row combinations. At that point, no speed is gained by making it larger.

### 8.2.1.7 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in Section 13.2.10.2, “JOIN Syntax”.

The syntax of \( \text{table_factor} \) is extended in comparison with the SQL Standard. The latter accepts only \( \text{table_reference} \), not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of \( \text{table_reference} \) items as equivalent to an inner join. For example:

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```sql
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, \( \text{CROSS JOIN} \) is syntactically equivalent to \( \text{INNER JOIN} \); they can replace each other. In standard SQL, they are not equivalent. \( \text{INNER JOIN} \) is used with an \( \text{ON} \) clause; \( \text{CROSS JOIN} \) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```sql
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
    ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:
Yet, the two expressions are not equivalent. To see this, suppose that the tables \( t_1, t_2, \) and \( t_3 \) have the following state:

- Table \( t_1 \) contains rows (1), (2)
- Table \( t_2 \) contains row (1,101)
- Table \( t_3 \) contains row (101)

In this case, the first expression returns a result set including the rows \( (1,1,101,101) \), \( (2,NULL,NULL,NULL) \), whereas the second expression returns the rows \( (1,1,101,101) \), \( (2,NULL,NULL,101) \):

```
mysql> SELECT * 
    > FROM t1 
    > LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL) 
    > ON t1.a=t2.a;
```

```
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+------+------+------+------+
```

```
mysql> SELECT * 
    > FROM (t1 LEFT JOIN t2 ON t1.a=t2.a) 
    > LEFT JOIN t3 
    > ON t2.b=t3.b OR t2.b IS NULL;
```

```
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>101</td>
</tr>
</tbody>
</table>
+------+------+------+------+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT * 
    > FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

```
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>101</td>
</tr>
</tbody>
</table>
+------+------+------+------+
```

```
mysql> SELECT * 
```

```
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+------+------+------+------+
```
Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

\[(t1, t2) \text{ LEFT JOIN } t3 \text{ ON } P(t2.b, t3.b)\]

Is equivalent to this expression for any tables \(t1, t2, t3\) and any condition \(P\) over attributes \(t2.b\) and \(t3.b\):

\[t1, t2 \text{ LEFT JOIN } t3 \text{ ON } P(t2.b, t3.b)\]

Whenever the order of execution of join operations in a join expression (\(\text{joined_table}\)) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
  WHERE t1.a > 1
```

```
SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
  WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
```

\(t2, t3\)

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in \((t2, t3)\) of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because LEFT JOIN and ON play the role of the left and right delimiters for the expression \((t2, t3)\).

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.
Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see Section 8.2.1.6, “Nested-Loop Join Algorithms”). Suppose that a join query over 3 tables $T_1, T_2, T_3$ has this form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
    INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3)
```

Here, $P_1(T_1,T_2)$ and $P_2(T_3,T_3)$ are some join conditions (on expressions), whereas $P(T_1,T_2,T_3)$ is a condition over columns of tables $T_1, T_2, T_3$.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row $t_1$ in $T_1$ {
    FOR each row $t_2$ in $T_2$ such that $P_1(t_1,t_2)$ {
        FOR each row $t_3$ in $T_3$ such that $P_2(t_2,t_3)$ {
            IF $P(t_1,t_2,t_3)$ {
                $t:=t_1||t_2||t_3$; OUTPUT $t$;
            }
        }
    }
}
```

The notation $t_1||t_2||t_3$ indicates a row constructed by concatenating the columns of rows $t_1$, $t_2$, and $t_3$. In some of the following examples, NULL where a table name appears means a row in which NULL is used for each column of that table. For example, $t_1||t_2||$ NULL indicates a row constructed by concatenating the columns of rows $t_1$ and $t_2$, and NULL for each column of $t_3$. Such a row is said to be NULL-complemented.

Now consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN 
    (T2 LEFT JOIN T3 ON P2(T2,T3))
    ON P1(T1,T2)
WHERE P(T1,T2,T3)
```

For this query, modify the nested-loop pattern to obtain:

```
FOR each row $t_1$ in $T_1$ {
    BOOL $f_1:=FALSE$;
    FOR each row $t_2$ in $T_2$ such that $P_1(t_1,t_2)$ {
        BOOL $f_2:=FALSE$;
        FOR each row $t_3$ in $T_3$ such that $P_2(t_2,t_3)$ {
            IF $P(t_1,t_2,t_3)$ {
                $t:=t_1||t_2||t_3$; OUTPUT $t$;
            }
            $f_2=TRUE$;
            $f_1=TRUE$;
        }
        IF (!$f_2$) {
            IF $P(t_1,t_2,NULL)$ {
                $t:=t_1||t_2||$ NULL; OUTPUT $t$;
            }
            $f_1=TRUE$;
        }
    }
    IF (!$f_1$) {
        IF $P(t_1,NULL,NULL)$ {
            $t:=t_1||$ NULL $||$ NULL$; OUTPUT $t$;
        }
    }
}
```
In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by NULL values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

\[(T2 \text{ LEFT JOIN } T3 \text{ ON } P2(T2,T3))\]

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```sql
FOR each row t3 in T3 {
    FOR each row t2 in T2 such that P2(t2,t3) {
        FOR each row t1 in T1 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}
```

For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, \(T1\) must be processed in the outer loop because it is used in an outer join. \(T2\) and \(T3\) are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, \(T2\) and \(T3\) can be processed in either order.

```sql
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)
```

One nesting evaluates \(T2\), then \(T3\):

```sql
FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) {
        FOR each row t3 in T3 such that P2(t1,t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}
```

The other nesting evaluates \(T3\), then \(T2\):
FOR each row \( t_1 \) in \( T_1 \) {
    BOOL \( f_1 := \text{FALSE} \); 
    FOR each row \( t_3 \) in \( T_3 \) such that \( P_2(t_1,t_3) \) {
        FOR each row \( t_2 \) in \( T_2 \) such that \( P_1(t_1,t_2) \) {
            IF \( P(t_1,t_2,t_3) \) {
                \( t := t_1 || t_2 || t_3; \) OUTPUT \( t \);
            }
            \( f_1 := \text{TRUE} \);
        }
    }
    IF (!\( f_1 \)) {
        IF \( P(t_1,\text{NULL},\text{NULL}) \) {
            \( t := t_1 || \text{NULL} || \text{NULL}; \) OUTPUT \( t \);
        }
    }
}

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our \( \text{WHERE} \) condition \( P(T_1,T_2,T_3) \) can be represented by a conjunctive formula:

\[
P(T_1,T_2,T_2) = C_1(T_1) \land C_2(T_2) \land C_3(T_3).
\]

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

FOR each row \( t_1 \) in \( T_1 \) such that \( C_1(t_1) \) {
    FOR each row \( t_2 \) in \( T_2 \) such that \( P_1(t_1,t_2) \land C_2(t_2) \) {
        FOR each row \( t_3 \) in \( T_3 \) such that \( P_2(t_2,t_3) \land C_3(t_3) \) {
            IF \( P(t_1,t_2,t_3) \) {
                \( t := t_1 || t_2 || t_3; \) OUTPUT \( t \);
            }
        }
    }
}

You see that each of the conjuncts \( C_1(T_1), C_2(T_2), C_3(T_3) \) are pushed out of the most inner loop to the most outer loop where it can be evaluated. If \( C_1(T_1) \) is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table \( T_1 \) passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the \( \text{WHERE} \) condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

\[
P(T_1,T_2,T_3) = C_1(T_1) \land C(T_2) \land C_3(T_3)
\]

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

FOR each row \( t_1 \) in \( T_1 \) such that \( C_1(t_1) \) {
    BOOL \( f_1 := \text{FALSE} \); 
    FOR each row \( t_2 \) in \( T_2 \) such that \( P_1(t_1,t_2) \land (f_1?C_2(t_2):\text{TRUE}) \) {
        BOOL \( f_2 := \text{FALSE} \); 
        \( \ldots \)
In general, pushed-down predicates can be extracted from join conditions such as $P_1(T_1,T_2)$ and $P(T_2,T_3)$. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the NULL-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the WHERE condition.

### 8.2.1.8 Outer Join Optimization

Outer joins include LEFT JOIN and RIGHT JOIN.

MySQL implements an A LEFT JOIN B join_specification as follows:

- Table $B$ is set to depend on table $A$ and all tables on which $A$ depends.
- Table $A$ is set to depend on all tables (except $B$) that are used in the LEFT JOIN condition.
- The LEFT JOIN condition is used to decide how to retrieve rows from table $B$. (In other words, any condition in the WHERE clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.
- All standard WHERE optimizations are performed.
- If there is a row in $A$ that matches the WHERE clause, but there is no row in $B$ that matches the ON condition, an extra $B$ row is generated with all columns set to NULL.
- If you use LEFT JOIN to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the WHERE part, where col_name is a column that is declared as NOT NULL, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the LEFT JOIN condition.

The RIGHT JOIN implementation is analogous to that of LEFT JOIN with the table roles reversed. Right joins are converted to equivalent left joins, as described in Section 8.2.1.9, “Outer Join Simplification”.

For a LEFT JOIN, if the WHERE condition is always false for the generated NULL row, the LEFT JOIN is changed to an inner join. For example, the WHERE clause would be false in the following query if $t2.column1$ were NULL:
### Optimizing SELECT Statements

**SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;**

Therefore, it is safe to convert the query to an inner join:

**SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;**

In MySQL 8.0.14 and later, trivial **WHERE** conditions arising from constant literal expressions are removed during preparation, rather than at a later stage in optimization, by which time joins have already been simplified. Earlier removal of trivial conditions allows the optimizer to convert outer joins to inner joins; this can result in improved plans for queries with outer joins containing trivial conditions in the **WHERE** clause, such as this one:

**SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2 OR 0 = 1**

The optimizer now sees during preparation that 0 = 1 is always false, making **OR 0 = 1** redundant, and removes it, leaving this:

**SELECT * FROM t1 LEFT JOIN t2 ON condition_1 where condition_2**

Now the optimizer can rewrite the query as an inner join, like this:

**SELECT * FROM t1 JOIN t2 WHERE condition_1 AND condition_2**

Now the optimizer can use table **t2** before table **t1** if doing so would result in a better query plan. To provide a hint about the table join order, use optimizer hints; see Section 8.9.3, “Optimizer Hints”. Alternatively, use **STRAIGHT_JOIN**; see Section 13.2.10, “SELECT Syntax”. However, **STRAIGHT_JOIN** may prevent indexes from being used because it disables semi-join transformations; see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations”.

### 8.2.1.9 Outer Join Simplification

Table expressions in the **FROM** clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```sql
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```

Becomes this equivalent left join:

```sql
(T2, ...) LEFT JOIN (T1, ...) ON P(T1, ..., T2, ...)
```

All inner join expressions of the form **T1 INNER JOIN T2 ON P(T1,T2)** are replaced by the list **T1, T2, P(T1,T2)** being joined as a conjunct to the **WHERE** condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where **R(T2)** greatly narrows the number of matching rows from table **T2**:

**SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)**
If the query is executed as written, the optimizer has no choice but to access the less-restricted table T1 before the more-restricted table T2, which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the WHERE condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an outer join operation if it evaluates to FALSE or UNKNOWN for any NULL-complemented row generated for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected because they cannot be true for any NULL-complemented row (with T2 columns set to NULL):

```
T2.B IS NOT NULL
T2.B > 3
T2.C <= T1.C
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected because they might be true for a NULL-complemented row:

```
T2.B IS NULL
T1.B < 3 OR T2.B IS NOT NULL
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form A IS NOT NULL, where A is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to UNKNOWN when one of its arguments is NULL
- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the WHERE condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

If the WHERE condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```
For the original query, the optimizer evaluates only plans compatible with the single table-access order \(T_1,T_2,T_3\). For the rewritten query, it additionally considers the access order \(T_3,T_1,T_2\).

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Is first converted to the query:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
   INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Which is equivalent to the query:

```sql
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
   WHERE T3.C > 0 AND T3.B=T2.B
```

The remaining outer join operation can also be replaced by an inner join because the condition \(T_3.B=T_2.B\) is null-rejected. This results in a query with no outer joins at all:

```sql
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
   WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```sql
SELECT * FROM T1 LEFT JOIN
         (T2 LEFT JOIN T3 ON T3.B=T2.B)
   ON T2.A=T1.A
WHERE T3.C > 0
```

Is converted to:

```sql
SELECT * FROM T1 LEFT JOIN
         (T2 INNER JOIN T3 ON T3.B=T2.B)
   ON T2.A=T1.A
WHERE T3.C > 0
```

That can be rewritten only to the form still containing the embedding outer join operation:

```sql
SELECT * FROM T1 LEFT JOIN
   (T2,T3)
WHERE T3.C > 0
```

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the WHERE condition. In this query, the WHERE condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join \(T_2.A=T_1.A \text{ AND } T_3.C=T_1.C\) is null-rejected:

```sql
SELECT * FROM T1 LEFT JOIN
   (T2 LEFT JOIN T3 ON T3.B=T2.B)
```
Consequently, the query can be converted to:

```
WHERE T3.D > 0 OR T1.D > 0

WHERE T3.D > 0 OR T1.D > 0
```

### 8.2.1.10 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.

- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on virtual generated columns. **InnoDB** supports secondary indexes on virtual generated columns.

The following scenarios illustrate when MRR optimization can be advantageous:

**Scenario A:** MRR can be used for **InnoDB** and **MyISAM** tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.

2. The tuples in the buffer are sorted by their data row ID.

3. Data rows are accessed according to the sorted index tuple sequence.

**Scenario B:** MRR can be used for **NDB** tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.

2. The ranges are sent to the execution nodes that access data rows.

3. The accessed rows are packed into packages and sent back to the central node.

4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the Extra column in EXPLAIN output shows Using MRR.

InnoDB and MyISAM do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a covering index); MRR provides no benefit.

Two optimizer_switch system variable flags provide an interface to the use of MRR optimization. The mrr flag controls whether MRR is enabled. If mrr is enabled (on), the mrr_cost_based flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR (on) or uses MRR whenever possible (off). By default, mrr is on and mrr_cost_based is on. See Section 8.9.2, “Switchable Optimizations”.

For MRR, a storage engine uses the value of the read_rnd_buffer_size system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to read_rnd_buffer_size bytes and determines the number of ranges to process in a single pass.

8.2.1.11 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semi-join operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semi-join operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semi-join strategies, see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations”

- Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms
- Block Nested-Loop Algorithm for Outer Joins and Semi-Joins
- Batched Key Access Joins
- Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semi-joins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is NULL, and the minimum number of bytes is allocated for any value of the VARCHAR type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer B1 is employed to join tables t1 and t2 and the result of this operation is joined with table t3 using join buffer B2:

- A regular join buffer contains columns from each join operand. If B2 is a regular join buffer, each row r put into B2 is composed of the columns of a row ri from B1 and the interesting columns of a matching row r2 from table t3.

- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If B2 is an incremental join buffer, it contains the interesting columns of the row r2 together with a link to the row ri from B1.
Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer \( B_1 \) used to join tables \( t_1 \) and \( t_2 \) must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row \( r \) whose columns are stored in the previous join buffers insofar as all these rows match row \( r \).

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `block_nested_loop` and `batched_key_access` flags of the `optimizer_switch` system variable control how the optimizer uses the Block Nested-Loop and Batched Key Access join algorithms. By default, `block_nested_loop` is on and `batched_key_access` is off. See Section 8.9.2, “Switchable Optimizations”. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

For information about semi-join strategies, see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations”

**Block Nested-Loop Algorithm for Outer Joins and Semi-Joins**

The original implementation of the MySQL BNL algorithm is extended to support outer join and semi-join operations.

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by NULL complements (NULL values for each column in the second operand) and sent for further extensions by the remaining join operations.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls how the optimizer uses the Block Nested-Loop algorithm. By default, `block_nested_loop` is on. See Section 8.9.2, “Switchable Optimizations”. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer (Block Nested Loop)` and the `type` value is `ALL`, `index`, or `range`.

For information about semi-join strategies, see Section 8.2.2.1, “Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations”

**Batched Key Access Joins**

MySQL implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the
BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see Section 8.2.1.10, “Multi-Range Read Optimization”). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as InnoDB and MyISAM. For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.

- The second scenario is used for remote storage engines such as NDB. A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In `EXPLAIN` output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer (Batched Key Access)` and the `type` value is `ref` or `eq_ref`.

**Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms**

In addition to using the `optimizer_switch` system variable to control optimizer use of the BNL and BKA algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, “Optimizer Hints”.

1452
To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

### 8.2.1.12 Condition Filtering

In join processing, prefix rows are those rows passed from one table in a join to the next. In general, the optimizer attempts to put tables with low prefix counts early in the join order to keep the number of row combinations from increasing rapidly. To the extent that the optimizer can use information about conditions on rows selected from one table and passed to the next, the more accurately it can compute row estimates and choose the best execution plan.

Without condition filtering, the prefix row count for a table is based on the estimated number of rows selected by the `WHERE` clause according to whichever access method the optimizer chooses. Condition filtering enables the optimizer to use other relevant conditions in the `WHERE` clause not taken into account by the access method, and thus improve its prefix row count estimates. For example, even though there might be an index-based access method that can be used to select rows from the current table in a join, there might also be additional conditions for the table in the `WHERE` clause that can filter (further restrict) the estimate for qualifying rows passed to the next table.

A condition contributes to the filtering estimate only if:

- It refers to the current table.
- It depends on a constant value or values from earlier tables in the join sequence.
- It was not already taken into account by the access method.

In `EXPLAIN` output, the `rows` column indicates the row estimate for the chosen access method, and the `filtered` column reflects the effect of condition filtering. `filtered` values are expressed as percentages. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering.

The prefix row count (the number of rows estimated to be passed from the current table in a join to the next) is the product of the `rows` and `filtered` values. That is, the prefix row count is the estimated row count, reduced by the estimated filtering effect. For example, if `rows` is 1000 and `filtered` is 20%, condition filtering reduces the estimated row count of 1000 to a prefix row count of $1000 \times 20\% = 1000 \times 0.2 = 200$.

Consider the following query:

```sql
SELECT * 
FROM employee JOIN department ON employee.dept_no = department.dept_no
WHERE employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01';
```

Suppose that the data set has these characteristics:

- The `employee` table has 1024 rows.
- The `department` table has 12 rows.
- Both tables have an index on `dept_no`.
- The `employee` table has an index on `first_name`.
- 8 rows satisfy this condition on `employee.first_name`.
employee.first_name = 'John'

150 rows satisfy this condition on employee.hire_date:

employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'

1 row satisfies both conditions:

employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'

Without condition filtering, EXPLAIN produces output like this:

<table>
<thead>
<tr>
<th>id</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>employee</td>
<td>ref</td>
<td>name,h_date,dept</td>
<td>name</td>
<td>const</td>
<td>8</td>
<td>100.00</td>
</tr>
<tr>
<td>1</td>
<td>department</td>
<td>eq_ref</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>dept_no</td>
<td>1</td>
<td>100.00</td>
</tr>
</tbody>
</table>

For employee, the access method on the name index picks up the 8 rows that match a name of 'John'. No filtering is done (filtered is 100%), so all rows are prefix rows for the next table: The prefix row count is rows × filtered = 8 × 100% = 8.

With condition filtering, the optimizer additionally takes into account conditions from the WHERE clause not taken into account by the access method. In this case, the optimizer uses heuristics to estimate a filtering effect of 16.31% for the BETWEEN condition on employee.hire_date. As a result, EXPLAIN produces output like this:

<table>
<thead>
<tr>
<th>id</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>employee</td>
<td>ref</td>
<td>name,h_date,dept</td>
<td>name</td>
<td>const</td>
<td>8</td>
<td>16.31</td>
</tr>
<tr>
<td>1</td>
<td>department</td>
<td>eq_ref</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>dept_no</td>
<td>1</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Now the prefix row count is rows × filtered = 8 × 16.31% = 1.3, which more closely reflects actual data set.

Normally, the optimizer does not calculate the condition filtering effect (prefix row count reduction) for the last joined table because there is no next table to pass rows to. An exception occurs for EXPLAIN: To provide more information, the filtering effect is calculated for all joined tables, including the last one.

To control whether the optimizer considers additional filtering conditions, use the condition_fanout_filter flag of the optimizer_switch system variable (see Section 8.9.2, “Switchable Optimizations”). This flag is enabled by default but can be disabled to suppress condition filtering (for example, if a particular query is found to yield better performance without it).

If the optimizer overestimates the effect of condition filtering, performance may be worse than if condition filtering is not used. In such cases, these techniques may help:

1. If a column is not indexed, index it so that the optimizer has some information about the distribution of column values and can improve its row estimates.
2. Similarly, if no column histogram information is available, generate a histogram (see Section 8.9.6, “Optimizer Statistics”).
• Change the join order. Ways to accomplish this include join-order optimizer hints (see Section 8.9.3, "Optimizer Hints"), STRAIGHT_JOIN immediately following the SELECT, and the STRAIGHT_JOIN join operator.

• Disable condition filtering for the session:

```
SET optimizer_switch = 'condition_fanout_filter=off';
```

Or, for a given query, using an optimizer hint:

```
SELECT /*+ SET_VAR(optimizer_switch = 'condition_fanout_filter=off') */ ...
```

### 8.2.1.13 Constant-Folding Optimization

Comparisons between constants and column values in which the constant value is out of range or of the wrong type with respect to the column type are now handled once during query optimization rather row-by-row than during execution. The comparisons that can be treated in this manner are >, >=, <, <=, ! =, =, and <= > .

Consider the table created by the following statement:

```
CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
```

The WHERE condition in the query SELECT * FROM t WHERE c < 256 contains the integral constant 256 which is out of range for a TINYINT UNSIGNED column. Previously, this was handled by treating both operands as the larger type, but now, since any allowed value for c is less than the constant, the WHERE expression can instead be folded as WHERE 1, so that the query is rewritten as SELECT * FROM t WHERE 1.

This makes it possible for the optimizer to remove the WHERE expression altogether. If the column c were nullable (that is, defined only as TINYINT UNSIGNED) the query would be rewritten like this:

```
SELECT * FROM t WHERE ti IS NOT NULL
```

Folding is performed for constants compared to supported MySQL column types as follows:

- **Integer column type.** Integer types are compared with constants of the following types as described here:
  - **Integer value.** If the constant is out of range for the column type, the comparison is folded to 1 or IS NOT NULL, as already shown.

  If the constant is a range boundary, the comparison is folded to =. For example (using the same table as already defined):

  ```
  mysql> EXPLAIN SELECT * FROM t WHERE c >= 255;
  *************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: t
  partitions: NULL
  type: ALL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  ```
Optimizing SELECT Statements

• **Floating- or fixed-point value.** If the constant is one of the decimal types (such as DECIMAL, REAL, DOUBLE, or FLOAT) and has a nonzero decimal portion, it cannot be equal; fold accordingly. For other comparisons, round up or down to an integer value according to the sign, then perform a range check and handle as already described for integer-integer comparisons.

  A REAL value that is too small to be represented as DECIMAL is rounded to .01 or -.01 depending on the sign, then handled as a DECIMAL.

• **String types.** Try to interpret the string value as an integer type, then handle the comparison as between integer values. If this fails, attempt to handle the value as a REAL.

• **DECIMAL or REAL column.** Decimal types are compared with constants of the following types as described here:

  • **Integer value.** Perform a range check against the column value's integer part. If no folding results, convert the constant to DECIMAL with the same number of decimal places as the column value, then check it as a DECIMAL (see next).

  • **DECIMAL or REAL value.** Check for overflow (that is, whether the constant has more digits in its integer part than allowed for the column's decimal type). If so, fold.

    If the constant has more significant fractional digits than column's type, truncate the constant. If the comparison operator is = or <>, fold. If the operator is >= or <=, adjust the operator due to truncation. For example, if column's type is DECIMAL(3,1), SELECT * FROM t WHERE f >= 10.13 becomes SELECT * FROM t WHERE f > 10.1.

    If the constant has fewer decimal digits than the column's type, convert it to a constant with same number of digits. For underflow of a REAL value (that is, too few fractional digits to represent it), convert the constant to decimal 0.

  • **String value.** If the value can be interpreted as an integer type, handle it as such. Otherwise, try to handle it as REAL.

• **FLOAT or DOUBLE column.** FLOAT \((m, n)\) or DOUBLE \((m, n)\) values compared with constants are handled as follows:

  If the value overflows the range of the column, fold.

  If the value has more than \(n\) decimals, truncate, compensating during folding. For \(=\) and \(<>\) comparisons, fold to TRUE, FALSE, or IS [NOT] NULL as described previously; for other operators, adjust the operator.

  If the value has more than \(m\) integer digits, fold.

**Limitations.** This optimization cannot be used in the following cases:

1. With comparisons using BETWEEN or IN.
2. With BIT columns or columns using date or time types.

3. During the preparation phase for a prepared statement, although it can be applied during the optimization phase when the prepared statement is actually executed. This due to the fact that, during statement preparation, the value of the constant is not yet known.

### 8.2.1.14 IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```sql
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name
  WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```sql
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
    OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```sql
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL)
    OR (t1.b=t2.b AND t2.b IS NULL);
```

### 8.2.1.15 ORDER BY Optimization
This section describes when MySQL can use an index to satisfy an ORDER BY clause, the filesort operation used when an index cannot be used, and execution plan information available from the optimizer about ORDER BY.

An ORDER BY with and without LIMIT may return rows in different orders, as discussed in Section 8.2.1.18, "LIMIT Query Optimization".

- Use of Indexes to Satisfy ORDER BY
- Use of filesort to Satisfy ORDER BY
- Influencing ORDER BY Optimization
- ORDER BY Execution Plan Information Available

Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an ORDER BY clause and avoid the extra sorting involved in performing a filesort operation.

The index may also be used even if the ORDER BY does not match the index exactly, as long as all unused portions of the index and all extra ORDER BY columns are constants in the WHERE clause. If the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on \( (key_{part1}, key_{part2}) \), the following queries may use the index to resolve the ORDER BY part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on \( (key_{part1}, key_{part2}) \) enables the optimizer to avoid sorting:

```sql
SELECT * FROM t1
ORDER BY key_{part1}, key_{part2};
```

However, the query uses SELECT *, which may select more columns than `key_{part1}` and `key_{part2}`. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer probably will not use the index. If SELECT * selects only the index columns, the index will be used and sorting avoided.

If t1 is an InnoDB table, the table primary key is implicitly part of the index, and the index can be used to resolve the ORDER BY for this query:

```sql
SELECT pk, key_{part1}, key_{part2} FROM t1
ORDER BY key_{part1}, key_{part2};
```

- In this query, `key_{part1}` is constant, so all rows accessed through the index are in `key_{part2}` order, and an index on \( (key_{part1}, key_{part2}) \) avoids sorting if the WHERE clause is selective enough to make an index range scan cheaper than a table scan:

```sql
SELECT * FROM t1
WHERE key_{part1} = constant
ORDER BY key_{part2};
```

- In the next two queries, whether the index is used is similar to the same queries without DESC shown previously:
Optimizing SELECT Statements

SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2 DESC;

• Two columns in an ORDER BY can sort in the same direction (both ASC, or both DESC) or in opposite directions (one ASC, one DESC). A condition for index use is that the index must have the same homogeneity, but need not have the same actual direction.

If a query mixes ASC and DESC, the optimizer can use an index on the columns if the index also uses corresponding mixed ascending and descending columns:

SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 ASC;

The optimizer can use an index on (key_part1, key_part2) if key_part1 is descending and key_part2 is ascending. It can also use an index on those columns (with a backward scan) if key_part1 is ascending and key_part2 is descending. See Section 8.3.13, “Descending Indexes”

• In the next two queries, key_part1 is compared to a constant. The index will be used if the WHERE clause is selective enough to make an index range scan cheaper than a table scan:

SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;

SELECT * FROM t1
WHERE key_part1 < constant
ORDER BY key_part1 DESC;

• In the next query, the ORDER BY does not name key_part1, but all rows selected have a constant key_part1 value, so the index can still be used:

SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;

In some cases, MySQL cannot use indexes to resolve the ORDER BY, although it may still use indexes to find the rows that match the WHERE clause. Examples:

• The query uses ORDER BY on different indexes:

SELECT * FROM t1 ORDER BY key1, key2;

• The query uses ORDER BY on nonconsecutive parts of an index:

SELECT * FROM t1 WHERE key2=constant ORDER BY key1_part1, key1_part3;

• The index used to fetch the rows differs from the one used in the ORDER BY:

SELECT * FROM t1 WHERE key2=constant ORDER BY key1;

• The query uses ORDER BY with an expression that includes terms other than the index column name:
Optimizing SELECT Statements

- The query joins many tables, and the columns in the ORDER BY are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the EXPLAIN output that does not have a const join type.)

- The query has different ORDER BY and GROUP BY expressions.

- There is an index on only a prefix of a column named in the ORDER BY clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a CHAR(20) column are indexed, the index cannot distinguish values past the 10th byte and a filesort is needed.

- The index does not store rows in order. For example, this is true for a HASH index in a MEMORY table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column t1.a is indexed. In this statement, the name of the column in the select list is a. It refers to t1.a, as does the reference to a in the ORDER BY, so the index on t1.a can be used:

```sql
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also a, but it is the alias name. It refers to ABS(a), as does the reference to a in the ORDER BY, so the index on t1.a cannot be used:

```sql
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the ORDER BY refers to a name that is not the name of a column in the select list. But there is a column in t1 named a, so the ORDER BY refers to t1.a and the index on t1.a can be used. (The resulting sort order may be completely different from the order for ABS(a), of course.)

```sql
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

Previously (MySQL 5.7 and lower), GROUP BY sorted implicitly under certain conditions. In MySQL 8.0, that no longer occurs, so specifying ORDER BY NULL at the end to suppress implicit sorting (as was done previously) is no longer necessary. However, query results may differ from previous MySQL versions. To produce a given sort order, provide an ORDER BY clause.

**Use of filesort to Satisfy ORDER BY**

If an index cannot be used to satisfy an ORDER BY clause, MySQL performs a filesort operation that reads table rows and sorts them. A filesort constitutes an extra sorting phase in query execution.

To obtain memory for filesort operations, as of MySQL 8.0.12, the optimizer allocates memory buffers incrementally as needed, up to the size indicated by the sort_buffer_size system variable, rather than allocating a fixed amount of sort_buffer_size bytes up front, as was done prior to MySQL 8.0.12. This enables users to set sort_buffer_size to larger values to speed up larger sorts, without concern for excessive memory use for small sorts. (This benefit may not occur for multiple concurrent sorts on Windows, which has a weak multithreaded malloc.)

A filesort operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory filesort operations. For example, the optimizer can use filesort to efficiently handle in memory, without temporary files, the ORDER BY operation for queries (and subqueries) of the following form:
SELECT ... FROM `single_table` ... ORDER BY `non_index_column` [DESC] LIMIT \([M, N]\);

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

SELECT `col1`, ... FROM `t1` ... ORDER BY `name` LIMIT 10;
SELECT `col1`, ... FROM `t1` ... ORDER BY RAND() LIMIT 15;

Influencing ORDER BY Optimization

For slow ORDER BY queries for which filesort is not used, try lowering the `max_length_for_sort_data` system variable to a value that is appropriate to trigger a filesort. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

To increase ORDER BY speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the `sort_buffer_size` variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes).

  Take into account that the size of column values stored in the sort buffer is affected by the `max_sort_length` system variable value. For example, if tuples store values of long string columns and you increase the value of `max_sort_length`, the size of sort buffer tuples increases as well and may require you to increase `sort_buffer_size`.

  To monitor the number of merge passes (to merge temporary files), check the `Sort_merge_passes` status variable.

- Increase the `read_rnd_buffer_size` variable value so that more rows are read at a time.

- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different physical disks, not different partitions on the same disk.

ORDER BY Execution Plan Information Available

With `EXPLAIN` (see Section 8.8.1, “Optimizing Queries with EXPLAIN”), you can check whether MySQL can use indexes to resolve an ORDER BY clause:

- If the Extra column of `EXPLAIN` output does not contain Using filesort, the index is used and a filesort is not performed.

- If the Extra column of `EXPLAIN` output contains Using filesort, the index is not used and a filesort is performed.

In addition, if a filesort is performed, optimizer trace output includes a filesort_summary block. For example:

```json
"sort_for_sort_data": {
  "rows": 100,
  "examined_rows": 100,
  "number_of_tmp_files": 0,
  "peak_memory_used": 25192
}
```
**Optimizing SELECT Statements**

```json
{  "sort_mode": "<sort_key, packed_additional_fields>"
}
```

`peak_memory_used` indicates the maximum memory used at any one time during the sort. This is a value up to but not necessarily as large as the value of the `sort_buffer_size` system variable. Prior to MySQL 8.0.12, the output shows `sort_buffer_size` instead, indicating the value of `sort_buffer_size`. (Prior to MySQL 8.0.12, the optimizer always allocates `sort_buffer_size` bytes for the sort buffer. As of 8.0.12, the optimizer allocates sort-buffer memory incrementally, beginning with a small amount and adding more as necessary, up to `sort_buffer_size` bytes.)

The `sort_mode` value provides information about the contents of tuples in the sort buffer:

- `<sort_key, rowid>`: This indicates that sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.

- `<sort_key, additional_fields>`: This indicates that sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.

- `<sort_key, packed_additional_fields>`: Like the previous variant, but the additional columns are packed tightly together instead of using a fixed-length encoding.

`EXPLAIN` does not distinguish whether the optimizer does or does not perform a `filesort` in memory. Use of an in-memory `filesort` can be seen in optimizer trace output. Look for `filesort_priority_queue_optimization`. For information about the optimizer trace, see *MySQL Internals: Tracing the Optimizer*.

### 8.2.1.16 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a `BTREE` index, but not for a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

- **Loose Index Scan**
- **Tight Index Scan**

Loose Index Scan can also be used in the absence of `GROUP BY` under some conditions. See *Skip Scan Range Access Method*.

**Loose Index Scan**

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having
to consider all keys in the index that satisfy all \texttt{WHERE} conditions. This access method considers only a fraction of the keys in an index, so it is called a \textit{Loose Index Scan}. When there is no \texttt{WHERE} clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the \texttt{WHERE} clause contains range predicates (see the discussion of the \texttt{range} join type in Section 8.8.1, “Optimizing Queries with EXPLAIN”), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.

- The \texttt{GROUP BY} names only columns that form a leftmost prefix of the index and no other columns. (If, instead of \texttt{GROUP BY}, the query has a \texttt{DISTINCT} clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table \texttt{t1} has an index on \texttt{(c1,c2,c3)}, Loose Index Scan is applicable if the query has \texttt{GROUP BY c1, c2}. It is not applicable if the query has \texttt{GROUP BY c2, c3} (the columns are not a leftmost prefix) or \texttt{GROUP BY c1, c2, c4} (\texttt{c4} is not in the index).

- The only aggregate functions used in the select list (if any) are \texttt{MIN()} and \texttt{MAX()}, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the \texttt{GROUP BY}.

- Any other parts of the index than those from the \texttt{GROUP BY} referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of \texttt{MIN()} or \texttt{MAX()} functions.

- For columns in the index, full column values must be indexed, not just a prefix. For example, with \texttt{c1 VARCHAR(20), INDEX (c1(10))}, the index uses only a prefix of \texttt{c1} values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the \texttt{EXPLAIN} output shows \texttt{Using index for group-by} in the \texttt{Extra} column.

Assume that there is an index \texttt{idx(c1,c2,c3)} on table \texttt{t1(c1,c2,c3,c4)}. The Loose Index Scan access method can be used for the following queries:

```sql
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < \texttt{const} GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > \texttt{const} GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < \texttt{const} GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = \texttt{const} GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than \texttt{MIN()} or \texttt{MAX()}:

```sql
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the \texttt{GROUP BY} clause do not form a leftmost prefix of the index:

```sql
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the \texttt{GROUP BY} part, and for which there is no equality with a constant:

```sql
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```
Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.
- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```sql
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

**Tight Index Scan**

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a **Tight Index Scan**. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:
  ```sql
  SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
  ```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:
  ```sql
  SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
  ```

**8.2.1.17 DISTINCT Optimization**
**DISTINCT** combined with **ORDER BY** needs a temporary table in many cases.

Because **DISTINCT** may use **GROUP BY**, learn how MySQL works with columns in **ORDER BY** or **HAVING** clauses that are not part of the selected columns. See Section 12.20.3, “MySQL Handling of GROUP BY”.

In most cases, a **DISTINCT** clause can be considered as a special case of **GROUP BY**. For example, the following two queries are equivalent:

```sql
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to **GROUP BY** queries can be also applied to queries with a **DISTINCT** clause. Thus, for more details on the optimization possibilities for **DISTINCT** queries, see Section 8.2.1.16, “GROUP BY Optimization”.

When combining **LIMIT row_count** with **DISTINCT**, MySQL stops as soon as it finds **row_count** unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with **EXPLAIN**), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```sql
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

### 8.2.1.18 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a **LIMIT** clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a **LIMIT row_count** clause and no **HAVING** clause:

- If you select only a few rows with **LIMIT**, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.

- If you combine **LIMIT row_count** with **ORDER BY**, MySQL stops sorting as soon as it has found the first **row_count** rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the **LIMIT** clause are selected, and most or all of them are sorted, before the first **row_count** are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an **ORDER BY** query with and without **LIMIT** may return rows in different order, as described later in this section.

- If you combine **LIMIT row_count** with **DISTINCT**, MySQL stops as soon as it finds **row_count** unique rows.

- In some cases, a **GROUP BY** can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, **LIMIT row_count** does not calculate any unnecessary **GROUP BY** values.

- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using **SQL_CALC_FOUND_ROWS**. In that case, the number of rows can be retrieved with **SELECT FOUND_ROWS()**. See Section 12.15, “Information Functions”.

---

1465
- **LIMIT 0** quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL API that makes result set metadata available. With the `mysql` client program, you can use the `-column-type-info` option to display result column types.

- If the server uses temporary tables to resolve a query, it uses the `LIMIT row_count` clause to calculate how much space is required.

- If an index is not used for ORDER BY but a LIMIT clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory using an in-memory `filesort` operation.

If multiple rows have identical values in the ORDER BY columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is LIMIT, so an ORDER BY query with and without LIMIT may return rows in different orders. Consider this query, which is sorted by the category column but nondeterministic with respect to the id and rating columns:

```sql
mysql> SELECT * FROM ratings ORDER BY category;
+----+----------+--------+
| id | category | rating |
+----+----------+--------+
|  1 |        1 |    4.5 |
|  5 |        1 |    3.2 |
|  3 |        2 |    3.7 |
|  4 |        2 |    3.5 |
|  6 |        2 |    3.5 |
|  2 |        3 |    5.0 |
|  7 |        3 |    2.7 |
+----+----------+--------+
```

Including LIMIT may affect order of rows within each category value. For example, this is a valid query result:

```sql
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
+----+----------+--------+
| id | category | rating |
+----+----------+--------+
|  1 |        1 |    4.5 |
|  5 |        1 |    3.2 |
|  4 |        2 |    3.5 |
|  3 |        2 |    3.7 |
|  6 |        2 |    3.5 |
+----+----------+--------+
```

In each case, the rows are sorted by the ORDER BY column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without LIMIT, include additional columns in the ORDER BY clause to make the order deterministic. For example, if id values are unique, you can make rows for a given category value appear in id order by sorting like this:

```sql
mysql> SELECT * FROM ratings ORDER BY category, id;
+----+----------+--------+
| id | category | rating |
+----+----------+--------+
|  1 |        1 |    4.5 |
|  5 |        1 |    3.2 |
+----+----------+--------+
```
8.2.1.19 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: `RAND()`, `UUID()`.

If a function is tagged nondeterministic, a reference to it in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses `RAND()` but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because `POW()` with constant arguments is a constant value and is used for index lookup.

- The second query contains an expression that uses the nondeterministic function `RAND()`, which is not constant in the query but in fact has a new value for every row of table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The effects of nondeterminism are not limited to `SELECT` statements. This `UPDATE` statement uses a nondeterministic function to select rows to be modified:
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the \texttt{id} column values and the values in the \texttt{RAND()} sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- \texttt{InnoDB} might escalate to a range-key lock rather than taking a single row lock for one matching row.
- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the \texttt{RAND()} function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

  ```sql
  SET @keyval = FLOOR(1 + RAND() * 49);
  UPDATE t SET col_a = some_expr WHERE id = @keyval;
  ```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the \texttt{WHERE} clause:

  ```sql
  UPDATE /*+ NO_MERGE(dt) */ t, (SELECT FLOOR(1 + RAND() * 49) AS r) AS dt
  SET col_a = some_expr WHERE id = dt.r;
  ```

As mentioned previously, a nondeterministic expression in the \texttt{WHERE} clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the \texttt{WHERE} clause if other expressions are deterministic. For example:

```sql
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use \texttt{partial_key} to reduce the set of rows selected, \texttt{RAND()} is executed fewer times, which diminishes the effect of nondeterminism on optimization.

### 8.2.1.20 Window Function Optimization

Window functions affect the strategies the optimizer considers:

- Derived table merging for a subquery is disabled if the subquery has window functions. The subquery is always materialized.
- Semi-joins are not applicable to window function optimization because semi-joins apply to subqueries in \texttt{WHERE} and \texttt{JOIN ... ON}, which cannot contain window functions.
- The optimizer processes multiple windows that have the same ordering requirements in sequence, so sorting can be skipped for windows following the first one.
- The optimizer makes no attempt to merge windows that could be evaluated in a single step (for example, when multiple \texttt{OVER} clauses contain identical window definitions). The workaround is to define the window in a \texttt{WINDOW} clause and refer to the window name in the \texttt{OVER} clauses.
An aggregate function not used as a window function is aggregated in the outermost possible query. For example, in this query, MySQL sees that \( \text{COUNT}(t1.b) \) is something that cannot exist in the outer query because of its placement in the `WHERE` clause:

```
SELECT * FROM t1 WHERE t1.a = (SELECT COUNT(t1.b) FROM t2);
```

Consequently, MySQL aggregates inside the subquery, treating \( t1.b \) as a constant and returning the count of rows of \( t2 \).

Replacing `WHERE` with `HAVING` results in an error:

```
mysql> SELECT * FROM t1 HAVING t1.a = (SELECT COUNT(t1.b) FROM t2);
ERROR 1140 (42000): In aggregated query without `GROUP BY`, expression #1 of SELECT list contains nonaggregated column 'test.t1.a'; this is incompatible with sql_mode=only_full_group_by
```

The error occurs because \( \text{COUNT}(t1.b) \) can exist in the `HAVING`, and so makes the outer query aggregated.

Window functions (including aggregate functions used as window functions) do not have the preceding complexity. They always aggregate in the subquery where they are written, never in the outer query.

Window function evaluation may be affected by the value of the `windowing_use_high_precision` system variable, which determines whether to compute window operations without loss of precision. By default, `windowing_use_high_precision` is enabled.

For some moving frame aggregates, the inverse aggregate function can be applied to remove values from the aggregate. This can improve performance but possibly with a loss of precision. For example, adding a very small floating-point value to a very large value causes the very small value to be "hidden" by the large value. When inverting the large value later, the effect of the small value is lost.

Loss of precision due to inverse aggregation is a factor only for operations on floating-point (approximate-value) data types. For other types, inverse aggregation is safe; this includes `DECIMAL`, which permits a fractional part but is an exact-value type.

For faster execution, MySQL always uses inverse aggregation when it is safe:

- For floating-point values, inverse aggregation is not always safe and might result in loss of precision. The default is to avoid inverse aggregation, which is slower but preserves precision. If it is permissible to sacrifice safety for speed, `windowing_use_high_precision` can be disabled to permit inverse aggregation.

- For nonfloating-point data types, inverse aggregation is always safe and is used regardless of the `windowing_use_high_precision` value.

- `windowing_use_high_precision` has no effect on `MIN()` and `MAX()`, which do not use inverse aggregation in any case.

For evaluation of the variance functions `STDDEV_POP()`, `STDDEV_SAMP()`, `VAR_POP()`, `VAR_SAMP()`, and their synonyms, evaluation can occur in optimized mode or default mode. Optimized mode may produce slightly different results in the last significant digits. If such differences are permissible, `windowing_use_high_precision` can be disabled to permit optimized mode.

For `EXPLAIN`, windowing execution plan information is too extensive to display in traditional output format. To see windowing information, use `EXPLAIN FORMAT=JSON` and look for the `windowing` element.

**8.2.1.21 Row Constructor Expression Optimization**
Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on \((c1, c2, c3)\):

```
CREATE TABLE t1 (
    c1 INT, c2 INT, c3 INT, c4 CHAR(100),
    PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only \(c1\) (\(key_len=4\), the size of \(c1\)):

```
mysql> EXPLAIN SELECT * FROM t1 WHERE c1=1 AND (c2,c3) > (1,1)
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
    table: t1
partitions: NULL
      type: ref
possible_keys: PRIMARY
      key: PRIMARY
     key_len: 4
    ref: const
    rows: 3
  filtered: 100.00
Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

\[(c2,c3) > (1,1)\]
\[c2 > 1 OR ((c2 = 1) AND (c3 > 1))\]

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (\(key_len=12\)):

```
mysql> EXPLAIN SELECT * FROM t1
    WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
    table: t1
partitions: NULL
      type: range
possible_keys: PRIMARY
      key: PRIMARY
     key_len: 12
    ref: NULL
    rows: 3
  filtered: 100.00
Extra: Using where
Thus, for better results, avoid mixing row constructors with AND/OR expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to IN() expressions that have row constructor arguments. See Range Optimization of Row Constructor Expressions.

8.2.1.22 Avoiding Full Table Scans

The output from EXPLAIN shows ALL in the type column when MySQL uses a full table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the ON or WHERE clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 8.2.1.1, "WHERE Clause Optimization".
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use ANALYZE TABLE tbl_name to update the key distributions for the scanned table. See Section 13.7.3.1, “ANALYZE TABLE Syntax”.
- Use FORCE INDEX for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See Section 8.9.4, “Index Hints”.
- Start mysql with the --max-seeks-for-key=1000 option or use SET max_seeks_for_key=1000 to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.8, “Server System Variables”.

8.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

The MySQL query optimizer has different strategies available to evaluate subqueries:

- For IN (or =ANY) subqueries, the optimizer has these choices:
  - Semi-join
  - Materialization
  - EXISTS strategy
- For NOT IN (or <>ALL) subqueries, the optimizer has these choices:
  - Materialization
• **EXISTS** strategy

For derived tables, the optimizer has these choices (which also apply to view references and common table expressions):

• Merge the derived table into the outer query block

• Materialize the derived table to an internal temporary table

The following discussion provides more information about the preceding optimization strategies.

---

**Note**

A limitation on `UPDATE` and `DELETE` statements that use a subquery to modify a single table is that the optimizer does not use semi-join or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table `UPDATE` and `DELETE` statements that use a join rather than a subquery.

### 8.2.2.1 Optimizing IN and EXISTS Subquery predicates with Semi-Join Transformations

A semi-join is a preparation-time transformation that enables multiple execution strategies such as table pullout, duplicate weedout, first match, loose scan, and materialization. The optimizer uses semi-join strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named `class` and `roster` that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```sql
SELECT class.class_num, class.class_name
FROM class INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that `class_num` is a primary key in the `class` table, duplicate suppression is possible by using `SELECT DISTINCT`, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```sql
SELECT class_num, class_name
FROM class
WHERE class_num IN (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the `IN` clause requires the subquery to return only one instance of each class number from the `roster` table. In this case, the query can use a semi-join; that is, an operation that returns only one instance of each row in `class` that is matched by rows in `roster`.

In MySQL 8.0.16 and later, this strategy can also be employed with `EXISTS` subqueries by transforming an `EXISTS` subquery that appears at the top level of a `WHERE` or `ON` clause of an `IN` or `EXISTS` predicate that refers to a subquery:

```sql
WHERE ... EXISTS (SELECT ... FROM ...)
```
-> WHERE ... 1 IN (SELECT 1 FROM ...)

After this, the subquery operation can be handled as a semi-join.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables, derived tables, view references, or common table expressions.

In MySQL, a subquery must satisfy these criteria to be handled as a semi-join:

- It must be an IN (or =ANY) subquery that appears at the top level of the WHERE or ON clause, possibly as a term in an AND expression. For example:

```
SELECT ...
FROM ot1, ...
WHERE (oe1, ...) IN (SELECT ie1, ... FROM it1, ... WHERE ...);
```

Here, `ot_i` and `it_i` represent tables in the outer and inner parts of the query, and `oe_i` and `ie_i` represent expressions that refer to columns in the outer and inner tables.

- It must be a single SELECT without UNION constructs.
- It must not contain a GROUP BY or HAVING clause.
- It must not be implicitly grouped (it must contain no aggregate functions).
- It must not have ORDER BY with LIMIT.
- The statement must not use the STRAIGHT_JOIN join type in the outer query.
- The STRAIGHT_JOIN modifier must not be present.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.

The subquery may be correlated or uncorrelated. In MySQL 8.0.16 and later, decorrelation looks at equality predicates in the WHERE clause of a subquery used as the argument to EXISTS, and makes it possible to optimize it as if it was used within IN (SELECT b FROM ...). The term trivially correlated means that the predicate is an equality predicate, that it is the sole predicate in the WHERE clause (or is combined with AND), and that one operand is from a table referenced in the subquery and the other operand is from the outer query block.

DISTINCT is permitted, as is LIMIT unless ORDER BY is also used.

If a subquery meets the preceding criteria, MySQL converts it to a semi-join and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- Duplicate Weedout: Run the semi-join as if it was a join and remove duplicate records using a temporary table.
- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This “shortcuts” scanning and eliminates production of unnecessary rows.
- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery’s value group.
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

- Materialize the subquery into an indexed temporary table that is used to perform a join, where the index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned. For more information about materialization, see Section 8.2.2.2, “Optimizing Subqueries with Materialization”.

Each of these strategies can be enabled or disabled using the following `optimizer_switch` system variable flags:

- The `semijoin` flag controls whether semi-joins are used.
- If `semijoin` is enabled, the `firstmatch`, `loosescan`, `duplicateweedout`, and `materialization` flags enable finer control over the permitted semi-join strategies.
- If the `duplicateweedout` semi-join strategy is disabled, it is not used unless all other applicable strategies are also disabled.
- If `duplicateweedout` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

These flags are enabled by default. See Section 8.9.2, “Switchable Optimizations”.

The optimizer minimizes differences in handling of views and derived tables. This affects queries that use the `STRAIGHT_JOIN` modifier and a view with an `IN` subquery that can be converted to a semi-join. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```sql
CREATE VIEW v AS
SELECT *
FROM t1
WHERE a IN (SELECT b
            FROM t2);

SELECT STRAIGHT_JOIN *
FROM t3 JOIN v ON t3.x = v.a;
```

The optimizer first looks at the view and converts the `IN` subquery to a semi-join, then checks whether it is possible to merge the view into the outer query. Because the `STRAIGHT_JOIN` modifier in the outer query prevents semi-join, the optimizer refuses the merge, causing derived table evaluation using a materialized table.

`EXPLAIN` output indicates the use of semi-join strategies as follows:

- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` shows the rewritten query, which displays the semi-join structure. (See Section 8.8.3, “Extended EXPLAIN Output Format”.) From this you can get an idea about which tables were pulled out of the semi-join. If a subquery was converted to a semi-join, you will see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.

- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` have their `rowid` in the temporary table.

- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.

- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.
Temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

### 8.2.2.2 Optimizing Subqueries with Materialization

The optimizer uses materialization to enable more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The optimizer may index the table with a hash index to make lookups fast and inexpensive. The index contains unique values to eliminate duplicates and make the table smaller.

Subquery materialization uses an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See Section 8.4.4, "Internal Temporary Table Use in MySQL".

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following `IN` subquery is noncorrelated (`where_condition` involves only columns from `t2` and not `t1`):

```sql
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an `EXISTS` correlated subquery:

```sql
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the `optimizer_switch` system variable `materialization` flag must be enabled. (See Section 8.9.2, "Switchable Optimizations"). With the `materialization` flag enabled, materialization applies to subquery predicates that appear anywhere (in the select list, `WHERE`, `GROUP BY`, `HAVING`, or `ORDER BY`), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression `oe_i` or inner expression `ie_i` is nullable. `N` is 1 or larger.

  ```sql
  (oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, i_2, ..., ie_N ...)
  ```

- The predicate has this form, when there is a single outer expression `oe` and inner expression `ie`. The expressions can be nullable.

  ```sql
  oe [NOT] IN (SELECT ie ...) 
  ```

- The predicate is `IN` or `NOT IN` and a result of `UNKNOWN` (`NULL`) has the same meaning as a result of `FALSE`.

The following examples illustrate how the requirement for equivalence of `UNKNOWN` and `FALSE` predicate evaluation affects whether subquery materialization can be used. Assume that `where_condition` involves columns only from `t2` and not `t1` so that the subquery is noncorrelated.

This query is subject to materialization:

```sql
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);

Here, it does not matter whether the IN predicate returns UNKNOWN or FALSE. Either way, the row from t1 is not included in the query result.

An example where subquery materialization is not used is the following query, where t2.b is a nullable column:

SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
WHERE where_condition);

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal, but cannot if one expression is integer and the other is decimal.
- The inner expression cannot be a BLOB.

Use of EXPLAIN with a query provides some indication of whether the optimizer uses subquery materialization:

- Compared to query execution that does not use materialization, select_type may change from DEPENDENT SUBQUERY to SUBQUERY. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once.
- For extended EXPLAIN output, the text displayed by a following SHOW WARNINGS includes materialize and materialized-subquery.

### 8.2.2.3 Optimizing Subqueries with the EXISTS Strategy

Certain optimizations are applicable to comparisons that use the IN (or =ANY) operator to test subquery results. This section discusses these optimizations, particularly with regard to the challenges that NULL values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression outer_expr, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression inner_expr is equal to outer_expr. This is done by pushing down an appropriate equality into the subquery's WHERE clause to make it more restrictive. The converted comparison looks like this:

EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.

More generally, a comparison of N values to a subquery that returns N-value rows is subject to the same conversion. If oe_i and ie_i represent corresponding outer and inner expression values, this subquery comparison:
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

\[
(oe_1, \ldots, oe_N) \text{ IN} \\
(SELECT ie_1, \ldots, ie_N \text{ FROM } \ldots \text{ WHERE subquery\_where})
\]

Becomes:

\[
\text{EXISTS} \ (\text{SELECT} \ 1 \ \text{FROM} \ \ldots \ \text{WHERE} \ \text{subquery\_where} \ \\
\quad \text{AND} \ oe_1 = ie_1 \\
\quad \text{AND} \ \ldots \\
\quad \text{AND} \ oe_N = ie_N)
\]

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The conversion just described has its limitations. It is valid only if we ignore possible NULL values. That is, the "pushdown" strategy works as long as both of these conditions are true:

- \textit{outer\_expr} and \textit{inner\_expr} cannot be NULL.
- You need not distinguish NULL from FALSE subquery results. If the subquery is a part of an OR or AND expression in the WHERE clause, MySQL assumes that you do not care. Another instance where the optimizer notices that NULL and FALSE subquery results need not be distinguished is this construct:

\[
\ldots \ \text{WHERE} \ \text{outer\_expr} \ \text{IN} \ (\text{subquery})
\]

In this case, the WHERE clause rejects the row whether IN (subquery) returns NULL or FALSE.

When either or both of those conditions do not hold, optimization is more complex.

Suppose that \textit{outer\_expr} is known to be a non-NULL value but the subquery does not produce a row such that \textit{outer\_expr} = \textit{inner\_expr}. Then \textit{outer\_expr} IN (SELECT ...) evaluates as follows:

- NULL, if the SELECT produces any row where inner\_expr is NULL
- FALSE, if the SELECT produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with outer\_expr = inner\_expr is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where inner\_expr is NULL. Roughly speaking, the subquery can be converted to something like this:

\[
\text{EXISTS} \ (\text{SELECT} \ 1 \ \text{FROM} \ \ldots \ \text{WHERE} \ \text{subquery\_where} \ \\
\quad \text{AND} \ (outer\_expr = inner\_expr \ \text{OR} \ inner\_expr \ \text{IS NULL}))
\]

The need to evaluate the extra IS NULL condition is why MySQL has the ref\_or\_null access method:

mysql> \texttt{EXPLAIN SELECT outer\_expr IN (SELECT t2.maybe\_null\_key} \\
\texttt{FROM t2, t3 WHERE ...)}

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>t1</td>
<td>PRIMARY</td>
</tr>
<tr>
<td>2</td>
<td>DEPENDENT SUBQUERY</td>
<td>t2</td>
<td>ref_or_null</td>
</tr>
</tbody>
</table>
The unique_subquery and index_subquery subquery-specific access methods also have “or NULL” variants.

The additional OR ... IS NULL condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when outer_expr can be NULL. According to the SQL interpretation of NULL as “unknown value,” NULL IN (SELECT inner_expr ...) should evaluate to:

- **NULL**, if the SELECT produces any rows
- **FALSE**, if the SELECT produces no rows

For proper evaluation, it is necessary to be able to check whether the SELECT has produced any rows at all, so outer_expr = inner_expr cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of outer_expr.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that outer_expr might be NULL:

- **If** outer_expr **is** NULL, to evaluate the following expression, it is necessary to execute the SELECT to determine whether it produces any rows:

  NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)

  It is necessary to execute the original SELECT here, without any pushed-down equalities of the kind mentioned previously.

- **On the other hand**, when outer_expr **is not** NULL, it is absolutely essential that this comparison:

  outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)

  Be converted to this expression that uses a pushed-down condition:

  EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)

  Without this conversion, subqueries will be slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)

Is converted into:

EXISTS (SELECT 1 FROM ... WHERE subquery_where)
AND trigcond(outer_expr=inner_expr)

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

\( (oe_1, \ldots, oe_N) \text{ IN (SELECT } ie_1, \ldots, ie_N \text{ FROM ... WHERE subquery_where) } \)

And converts it to this expression:

EXISTS (SELECT 1 FROM ... WHERE subquery_where
    AND trigcond(oe_1=ie_1)
    AND ...
    AND trigcond(oe_N=ie_N)
)

Each \( \text{trigcond}(X) \) is a special function that evaluates to the following values:

- \( X \) when the “linked” outer expression \( oe_i \) is not NULL
- \( \text{TRUE} \) when the “linked” outer expression \( oe_i \) is NULL

Note
Trigger functions are not triggers of the kind that you create with \text{CREATE TRIGGER}.

Equalities that are wrapped within \( \text{trigcond}() \) functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any \( \text{trigcond}(X) \) to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- Reference optimizations: \( \text{trigcond}(X=Y \ [\text{OR } Y \text{ IS NULL}]) \) can be used to construct \text{ref}, \text{eq_ref}, or \text{ref_or_null} table accesses.
- Index lookup-based subquery execution engines: \( \text{trigcond}(X=Y) \) can be used to construct \text{unique_subquery} or \text{index_subquery} accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In \text{EXPLAIN} output, the fallback shows up as \text{Full scan on NULL key} in the \text{Extra} column:

```
mysql> EXPLAIN SELECT t1.col1,
                   t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1
G
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: t1
  ...                      
*************************** 2. row ***************************
  id: 2
  select_type: DEPENDENT SUBQUERY
  table: t2
  type: index_subquery
  possible_keys: key1
  key: key1
```
If you run `EXPLAIN` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
 Level: Note
 Code: 1003
 Message: select 'test'.'t1'.'col1' AS 'col1',
   <in_optimizer>('test'.'t1'.'col1',
   <exists>(<index_lookup>(<cache>('test'.'t1'.'col1') in t2
   on key1 checking NULL
   where ('test'.'t2'.'col2' = 'test'.'t1'.'col2') having
   trigcond(<is_not_null_test>('test'.'t2'.'key1'))) AS
   't1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)'
   from 'test'.'t1'
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` is particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as `NOT NULL` if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.

- If you need not distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

  ```
  outer_expr IN (SELECT inner_expr FROM ...)
  ```

  with this expression:

  ```
  (outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
  ```

  Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

  Another possible rewrite:

  ```
  EXISTS (SELECT inner_expr FROM ...
   WHERE inner_expr=outer_expr)
  ```

  This would apply when you need not distinguish `NULL` from `FALSE` subquery results, in which case you may actually want `EXISTS`.

The `subquery_materialization_cost_based` flag of the `optimizer_switch` system variable enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See Section 8.9.2, “Switchable Optimizations”.

---

1480
8.2.2.4 Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization

The optimizer can handle derived table references using two strategies (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

Example 1:

```
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging of the derived table `derived_t1`, that query is executed similar to:

```
SELECT * FROM t1;
```

Example 2:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

With merging of the derived table `derived_t2`, that query is executed similar to:

```
SELECT t1.*, t2.f1
FROM t1 JOIN t2 ON t1.f2=t2.f1
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are each treated as a separate table within their respective queries.

The optimizer handles derived tables, view references, and common table expressions the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see Section 8.2.2.2, “Optimizing Subqueries with Materialization”.)

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

The optimizer propagates an ORDER BY clause in a derived table or view reference to the outer query block if these conditions are all true:

- The outer query is not grouped or aggregated.
- The outer query does not specify DISTINCT, HAVING, or ORDER BY.
- The outer query has this derived table or view reference as the only source in the FROM clause.

Otherwise, the optimizer ignores the ORDER BY clause.

The following means are available to influence whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block:
• The **MERGE** and **NO_MERGE** optimizer hints can be used. They apply assuming that no other rule prevents merging. See Section 8.9.3, “Optimizer Hints”.

• Similarly, you can use the **derived_merge** flag of the **optimizer_switch** system variable. See Section 8.9.2, “Switchable Optimizations”. By default, the flag is enabled to permit merging. Disabling the flag prevents merging and avoids **ER_UPDATE_TABLE_USED** errors.

The **derived_merge** flag also applies to views that contain no **ALGORITHM** clause. Thus, if an **ER_UPDATE_TABLE_USED** error occurs for a view reference that uses an expression equivalent to the subquery, adding **ALGORITHM=TEMPTABLE** to the view definition prevents merging and takes precedence over the **derived_merge** value.

• It is possible to disable merging by using in the subquery any constructs that prevent merging, although these are not as explicit in their effect on materialization. Constructs that prevent merging are the same for derived tables, common table expressions, and view references:
  - Aggregate functions or window functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
  - **DISTINCT**
  - **GROUP BY**
  - **HAVING**
  - **LIMIT**
  - **UNION** or **UNION ALL**
  - Subqueries in the select list
  - Assignments to user variables
  - References only to literal values (in this case, there is no underlying table)

If the optimizer chooses the materialization strategy rather than merging for a derived table, it handles the query as follows:

• The optimizer postpones derived table materialization until its contents are needed during query execution. This improves performance because delaying materialization may result in not having to do it at all. Consider a query that joins the result of a derived table to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the derived table.

• During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following **EXPLAIN** statement, for a **SELECT** query that contains a derived table:

```sql
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the derived table by delaying it until the result is needed during **SELECT** execution. In this case, the query is not executed (because it occurs in an **EXPLAIN** statement), so the result is never needed.

Even for queries that are executed, delay of derived table materialization may enable the optimizer to avoid materialization entirely. When this happens, query execution is quicker by the time needed to perform materialization. Consider the following query, which joins the result of a derived table to another table:
Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

```sql
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the derived table need not be materialized.

For cases when a derived table requires materialization, the optimizer may add an index to the materialized table to speed up access to it. If such an index enables `ref` access to the table, it can greatly reduce amount of data read during query execution. Consider the following query:

```sql
SELECT *
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2
ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column `f1` from `derived_t2` if doing so would enable use of `ref` access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If `ref` access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

For optimizer trace output, a merged derived table or view reference is not shown as a node. Only its underlying tables appear in the top query’s plan.

What is true for materialization of derived tables is also true for common table expressions (CTEs). In addition, the following considerations pertain specifically to CTEs.

If a CTE is materialized by a query, it is materialized once for the query, even if the query references it several times.

A recursive CTE is always materialized.

If a CTE is materialized, the optimizer automatically adds relevant indexes if it estimates that indexing will speed up access by the top-level statement to the CTE. This is similar to automatic indexing of derived tables, except that if the CTE is referenced multiple times, the optimizer may create multiple indexes, to speed up access by each reference in the most appropriate way.

The `MERGE` and `NO_MERGE` optimizer hints can be applied to CTEs. Each CTE reference in the top-level statement can have its own hint, permitting CTE references to be selectively merged or materialized. The following statement uses hints to indicate that `cte1` should be merged and `cte2` should be materialized:

```sql
WITH
    cte1 AS (SELECT a, b FROM table1),
    cte2 AS (SELECT c, d FROM table2)
SELECT /*+ MERGE(cte1) NO_MERGE(cte2) */ cte1.b, cte2.d
FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

The `ALGORITHM` clause for `CREATE VIEW` does not affect materialization for any `WITH` clause preceding the `SELECT` statement in the view definition. Consider this statement:

```sql
CREATE ALGORITHM={TEMPTABLE|MERGE} VIEW v1 AS WITH ... SELECT ...
```

The `ALGORITHM` value affects materialization only of the `SELECT`, not the `WITH` clause.
Prior to MySQL 8.0.16, if `internal_tmp_disk_storage_engine=MYISAM`, an error occurred for any attempt to materialize a CTE using an on-disk temporary table, since for CTEs, the storage engine used for on-disk internal temporary tables could not be `MyISAM`. Beginning with MySQL 8.0.16, this is no longer an issue, since `TempTable` now always uses `InnoDB` for on-disk internal temporary tables.

As mentioned previously, a CTE, if materialized, is materialized once, even if referenced multiple times. To indicate one-time materialization, optimizer trace output contains an occurrence of `creating_tmp_table` plus one or more occurrences of `reusing_tmp_table`.

CTEs are similar to derived tables, for which the `materialized_from_subquery` node follows the reference. This is true for a CTE that is referenced multiple times, so there is no duplication of `materialized_from_subquery` nodes (which would give the impression that the subquery is executed multiple times, and produce unnecessarily verbose output). Only one reference to the CTE has a complete `materialized_from_subquery` node with the description of its subquery plan. Other references have a reduced `materialized_from_subquery` node. The same idea applies to `EXPLAIN` output in `TRADITIONAL` format: Subqueries for other references are not shown.

### 8.2.3 Optimizing INFORMATION_SCHEMA Queries

Applications that monitor databases may make frequent use of `INFORMATION_SCHEMA` tables. To write queries for these tables most efficiently, use the following general guidelines:

- Try to query only `INFORMATION_SCHEMA` tables that are views on data dictionary tables.
- Try to query only for static metadata. Selecting columns or using retrieval conditions for dynamic metadata along with static metadata adds overhead to process the dynamic metadata.

> **Note**

Comparison behavior for database and table names in `INFORMATION_SCHEMA` queries might differ from what you expect. For details, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

These `INFORMATION_SCHEMA` tables are implemented as views on data dictionary tables, so queries on them retrieve information from the data dictionary:

- `CHARACTER_SETS`
- `CHECK_CONSTRAINTS`
- `COLLATIONS`
- `COLLATION_CHARACTER_SET_APPLICABILITY`
- `COLUMNS`
- `EVENTS`
- `FILES`
- `INNODB_COLUMNS`
- `INNODB_DATAFILES`
- `INNODB_FIELDS`
- `INNODB_FOREIGN`
- `INNODB_FOREIGN_COLS`
- `INNODB_INDEXES`
- `INNODB_TABLES`
- `INNODB_TABLESPACES`
- `INNODB_TABLESPACES_BRIEF`
- `INNODB_TABLESTATS`
- `KEY_COLUMN_USAGE`
- `PARAMETERS`
- `PARTITIONS`
- `REFERENTIAL_CONSTRAINTS`
- `RESOURCE_GROUPS`
- `ROUTINES`
Some types of values, even for a non-view INFORMATION_SCHEMA table, are retrieved by lookups from the data dictionary. This includes values such as database and table names, table types, and storage engines.

Some INFORMATION_SCHEMA tables contain columns that provide table statistics:

<table>
<thead>
<tr>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATISTICS.CARDINALITY</td>
</tr>
<tr>
<td>TABLES.AUTO_INCREMENT</td>
</tr>
<tr>
<td>TABLES.AVG_ROW_LENGTH</td>
</tr>
<tr>
<td>TABLES.CHECKSUM</td>
</tr>
<tr>
<td>TABLES.CHECK_TIME</td>
</tr>
<tr>
<td>TABLES.CREATE_TIME</td>
</tr>
<tr>
<td>TABLES.DATA_FREE</td>
</tr>
<tr>
<td>TABLES.DATA_LENGTH</td>
</tr>
<tr>
<td>TABLES.INDEX_LENGTH</td>
</tr>
<tr>
<td>TABLES.MAX_DATA_LENGTH</td>
</tr>
<tr>
<td>TABLES.TABLE_ROWS</td>
</tr>
<tr>
<td>TABLES.UPDATE_TIME</td>
</tr>
</tbody>
</table>

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the mysql.index_stats and mysql.table_stats dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the mysql.index_stats and mysql.table_stats dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire.

The information_schema_stats_expiry session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use ANALYZE TABLE.

Querying statistics columns does not store or update statistics in the mysql.index_stats and mysql.table_stats dictionary tables under these circumstances:

- When cached statistics have not expired.
- When information_schema_stats_expiry is set to 0.
- When the server is started in read_only, super_read_only, transaction_read_only, or innodb_read_only mode.
- When the query also fetches Performance Schema data.

information_schema_stats_expiry is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.
Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

For `INFORMATION_SCHEMA` tables implemented as views on data dictionary tables, indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans. To see the choices made by the optimizer, use `EXPLAIN`. To also see the query used by the server to execute an `INFORMATION_SCHEMA` query, use `SHOW WARNINGS` immediately following `EXPLAIN`.

Consider this statement, which identifies collations for the `utf8mb4` character set:

```
mysql> SELECT COLLATION_NAME
           FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
           WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

```
+----------------------------+
| COLLATION_NAME             |
+----------------------------+
| utf8mb4_general_ci         |
| utf8mb4_bin                |
| utf8mb4_unicode_ci         |
| utf8mb4_icelandic_ci       |
| utf8mb4_latvian_ci         |
| utf8mb4_romanian_ci        |
| utf8mb4_slovenian_ci       |
| ...                        |
```

How does the server process that statement? To find out, use `EXPLAIN`:

```
mysql> EXPLAIN SELECT COLLATION_NAME
           FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
           WHERE CHARACTER_SET_NAME = 'utf8mb4'
```

```
 *************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: cs
partitions: NULL
type: const
possible_keys: PRIMARY,name
key: name
key_len: 194
ref: const
rows: 1
filtered: 100.00
Extra: Using index
```

```
 *************************** 2. row ***************************
id: 1
select_type: SIMPLE
table: col
partitions: NULL
type: ref
possible_keys: character_set_id
key: character_set_id
key_len: 8
ref: const
rows: 68
filtered: 100.00
Extra: NULL
```
To see the query used to satisfy that statement, use `SHOW WARNINGS`:

```sql
mysql> SHOW WARNINGS
```

```
*************************** 1. row ***************************
  Level: Note
  Code: 1003
Message: /* select#1 */ select `mysql`.`col`.`name` AS `COLLATION_NAME`
          from `mysql`.`character_sets` `cs`
          join `mysql`.`collations` `col`
          where ((`mysql`.`col`.`character_set_id` = '45')
          and ('utf8mb4' = 'utf8mb4'))
```

As indicated by `SHOW WARNINGS`, the server handles the query on `COLLATION_CHARACTER_SET_APPLICABILITY` as a query on the `character_sets` and `collations` data dictionary tables in the `mysql` system database.

### 8.2.4 Optimizing Performance Schema Queries

Applications that monitor databases may make frequent use of Performance Schema tables. To write queries for these tables most efficiently, take advantage of their indexes. For example, include a `WHERE` clause that restricts retrieved rows based on comparison to specific values in an indexed column.

Most Performance Schema tables have indexes. Tables that do not are those that normally contain few rows or are unlikely to be queried frequently. Performance Schema indexes give the optimizer access to execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables.

To see whether a given Performance Schema table has indexes and what they are, use `SHOW INDEX` or `SHOW CREATE TABLE`:

```sql
mysql> SHOW INDEX FROM performance_schema.accounts
```

```
Table: accounts
  Non_unique: 0
  Key_name: ACCOUNT
  Seq_in_index: 1
  Column_name: USER
  Collation: NULL
  Cardinality: NULL
  Sub_part: NULL
  Packed: NULL
  Null: YES
  Index_type: HASH
  Comment:
  Index_comment:
  Visible: YES
```
Optimizing Performance Schema Queries

Visible: YES

```sql
mysql> SHOW CREATE TABLE performance_schema.rwlock_instances\G
*************************** 1. row ***************************
Table: rwlock_instances
Create Table: CREATE TABLE `rwlock_instances` (  
  `NAME` varchar(128) NOT NULL,
  `OBJECT_INSTANCE_BEGIN` bigint(20) unsigned NOT NULL,
  `WRITE_LOCKED_BY_THREAD_ID` bigint(20) unsigned DEFAULT NULL,
  `READ_LOCKED_BY_COUNT` int(10) unsigned NOT NULL,
  PRIMARY KEY (`OBJECT_INSTANCE_BEGIN`),
  KEY `NAME` (`NAME`),
  KEY `WRITE_LOCKED_BY_THREAD_ID` (`WRITE_LOCKED_BY_THREAD_ID`
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

To see the execution plan for a Performance Schema query and whether it uses any indexes, use `EXPLAIN`:

```sql
mysql> EXPLAIN SELECT * FROM performance_schema.accounts
                          WHERE (USER,HOST) = ('root','localhost')\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: accounts
partitions: NULL
type: const
possible_keys: ACCOUNT
  key: ACCOUNT
    key_len: 278
    ref: const,const
rows: 1
filtered: 100.00
Extra: NULL
```

The `EXPLAIN` output indicates that the optimizer uses the `accounts` table `ACCOUNT` index that comprises the `USER` and `HOST` columns.

Performance Schema indexes are virtual: They are a construct of the Performance Schema storage engine and use no memory or disk storage. The Performance Schema reports index information to the optimizer so that it can construct efficient execution plans. The Performance Schema in turn uses optimizer information about what to look for (for example, a particular key value), so that it can perform efficient lookups without building actual index structures. This implementation provides two important benefits:

- It entirely avoids the maintenance cost normally incurred for tables that undergo frequent updates.
- It reduces at an early stage of query execution the amount of data retrieved. For conditions on the indexed columns, the Performance Schema efficiently returns only table rows that satisfy the query conditions. Without an index, the Performance Schema would return all rows in the table, requiring that the optimizer later evaluate the conditions against each row to produce the final result.

Performance Schema indexes are predefined and cannot be dropped, added, or altered.

Performance Schema indexes are similar to hash indexes. For example:

- They are used only for equality comparisons that use the `=` or `<>` operators.
- They are unordered. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.

For additional information about hash indexes, see Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.
8.2.5 Optimizing Data Change Statements

This section explains how to speed up data change statements: **INSERT**, **UPDATE**, and **DELETE**. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for "extract-transform-load"), sometimes you use other SQL statements or external commands, that mimic the effects of **INSERT**, **UPDATE**, and **DELETE** statements.

8.2.5.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 \times \text{size of row})
- Inserting indexes: (1 \times \text{number of indexes})
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by \log N, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use **INSERT** statements with multiple **VALUES** lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row **INSERT** statements. If you are adding data to a nonempty table, you can tune the **bulk_insert_buffer_size** variable to make data insertion even faster. See Section 5.1.8, “Server System Variables”.

- When loading a table from a text file, use **LOAD DATA**. This is usually 20 times faster than using **INSERT** statements. See Section 13.2.7, “LOAD DATA Syntax”.

- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

- See Section 8.5.5, “Bulk Data Loading for InnoDB Tables” for tips specific to InnoDB tables.

- See Section 8.6.2, “Bulk Data Loading for MyISAM Tables” for tips specific to MyISAM tables.

8.2.5.2 Optimizing UPDATE Statements
An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 13.7.3.4, “OPTIMIZE TABLE Syntax”.

### 8.2.5.3 Optimizing DELETE Statements

The time required to delete individual rows in a MyISAM table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.

To delete all rows from a MyISAM table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 13.1.37, “TRUNCATE TABLE Syntax”.

### 8.2.6 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

### 8.2.7 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See Section 24.2, “Using Stored Routines” and Section 29.4, “Adding New Functions to MySQL” for more information.

- To fix any compression issues that occur with ARCHIVE tables, use `OPTIMIZE TABLE`. See Section 16.5, “The ARCHIVE Storage Engine”.

- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a BLOB column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.

- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents,
so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)

- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL InnoDB or MyISAM storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 17, Replication.

8.3 Optimization and Indexes

The best way to improve the performance of SELECT operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the WHERE clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes (PRIMARY KEY, UNIQUE, INDEX, and FULLTEXT) are stored in B-trees. Exceptions: Indexes on spatial data types use R-trees; MEMORY tables also support hash indexes; InnoDB uses inverted lists for FULLTEXT indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in MEMORY tables) are described in Section 8.3.9, “Comparison of B-Tree and Hash Indexes”.

MySQL uses indexes for these operations:

- To find the rows matching a WHERE clause quickly.

- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most selective index).

- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on (col1, col2, col3), you have indexed search capabilities on (col1), (col1, col2), and (col1, col2, col3). For more information, see Section 8.3.6, “Multiple-Column Indexes”.

- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, VARCHAR and CHAR are considered the same if they are declared as the same size. For example, VARCHAR(10) and CHAR(10) are the same size, but VARCHAR(10) and CHAR(15) are not.
For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a utf8 column with a latin1 column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as 1 in the numeric column, it might compare equal to any number of values in the string column such as '1', '1', '00001', or '01.e1'. This rules out use of any indexes for the string column.

• To find the MIN() or MAX() value for a specific indexed column key_col. This is optimized by a preprocessor that checks whether you are using WHERE key_part_N = constant on all key parts that occur before key_col in the index. In this case, MySQL does a single key lookup for each MIN() or MAX() expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```sql
SELECT MIN(key_part2), MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

• To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, ORDER BY key_part1, key_part2). If all key parts are followed by DESC, the key is read in reverse order. (Or, if the index is a descending index, the key is read in forward order.) See Section 8.2.1.15, “ORDER BY Optimization”, Section 8.2.1.16, “GROUP BY Optimization”, and Section 8.3.13, “Descending Indexes”.

• In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a covering index.) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```sql
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See Section 8.2.1.22, “Avoiding Full Table Scans” for details.

### 8.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the NOT NULL optimization, because it cannot include any NULL values. With the InnoDB storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

### 8.3.3 SPATIAL Index Optimization

MySQL permits creation of SPATIAL indexes on NOT NULL geometry-valued columns (see Section 11.5.10, “Creating Spatial Indexes”). The optimizer checks the SRID attribute for indexed columns to determine which spatial reference system (SRS) to use for comparisons, and uses calculations
appropriate to the SRS. (Prior to MySQL 8.0, the optimizer performs comparisons of SPATIAL index values using Cartesian calculations; the results of such operations are undefined if the column contains values with non-Cartesian SRIDs.)

For comparisons to work properly, each column in a SPATIAL index must be SRID-restricted. That is, the column definition must include an explicit SRID attribute, and all column values must have the same SRID.

The optimizer considers SPATIAL indexes only for SRID-restricted columns:

• Indexes on columns restricted to a Cartesian SRID enable Cartesian bounding box computations.

• Indexes on columns restricted to a geographic SRID enable geographic bounding box computations.

The optimizer ignores SPATIAL indexes on columns that have no SRID attribute (and thus are not SRID-restricted). MySQL still maintains such indexes, as follows:

• They are updated for table modifications (INSERT, UPDATE, DELETE, and so forth). Updates occur as though the index was Cartesian, even though the column might contain a mix of Cartesian and geographical values.

• They exist only for backward compatibility (for example, the ability to perform a dump in MySQL 5.7 and restore in MySQL 8.0). Because SPATIAL indexes on columns that are not SRID-restricted are of no use to the optimizer, each such column should be modified:

• Verify that all values within the column have the same SRID. To determine the SRIDs contained in a geometry column col_name, use the following query:

```sql
SELECT DISTINCT ST_SRID(col_name) FROM tbl_name;
```

If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

• Redefine the column to have an explicit SRID attribute.

• Recreate the SPATIAL index.

### 8.3.4 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 8.3.5 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as =, >, ≤, BETWEEN, IN, and so on, in a WHERE clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 15, *The InnoDB Storage Engine*, and Chapter 16, *Alternative Storage Engines*. All storage
Column Indexes

engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see Section 13.1.15, “CREATE INDEX Syntax”.

- Index Prefixes
- FULLTEXT Indexes
- Spatial Indexes
- Indexes in the MEMORY Storage Engine

Index Prefixes

With \textit{col_name}(N) syntax in an index specification for a string column, you can create an index that uses only the first \textit{N} characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a \texttt{BLOB} or \texttt{TEXT} column, you \textit{must} specify a prefix length for the index. For example:

\begin{verbatim}
CREATE TABLE test (blob_col BLOB, INDEX(blob_col BLOB, INDEX(blob_col(10)));
\end{verbatim}

Prefixes can be up to 767 bytes long for InnoDB tables that use the \texttt{REDUNDANT} or \texttt{COMPACT} row format. The prefix length limit is 3072 bytes for InnoDB tables that use the \texttt{DYNAMIC} or \texttt{COMPRESSED} row format. For MyISAM tables, the prefix length limit is 1000 bytes.

\begin{quote}
\textbf{Note}

Prefix limits are measured in bytes, whereas the prefix length in \texttt{CREATE TABLE}, \texttt{ALTER TABLE}, and \texttt{CREATE INDEX} statements is interpreted as number of characters for nonbinary string types (\texttt{CHAR}, \texttt{VARCHAR}, \texttt{TEXT}) and number of bytes for binary string types (\texttt{BINARY}, \texttt{VARBINARY}, \texttt{BLOB}). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
\end{quote}

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see Section 13.1.15, “CREATE INDEX Syntax”.

FULLTEXT Indexes

\texttt{FULLTEXT} indexes are used for full-text searches. Only the \texttt{InnoDB} and \texttt{MyISAM} storage engines support \texttt{FULLTEXT} indexes and only for \texttt{CHAR}, \texttt{VARCHAR}, and \texttt{TEXT} columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 12.9, “Full-Text Search Functions”.

Optimizations are applied to certain kinds of \texttt{FULLTEXT} queries against single \texttt{InnoDB} tables. Queries with these characteristics are particularly efficient:

- \texttt{FULLTEXT} queries that only return the document ID, or the document ID and the search rank.
- \texttt{FULLTEXT} queries that sort the matching rows in descending order of score and apply a \texttt{LIMIT} clause to take the top N matching rows. For this optimization to apply, there must be no \texttt{WHERE} clauses and only a single \texttt{ORDER BY} clause in descending order.
Multiple-Column Indexes

- **FULLTEXT** queries that retrieve only the `COUNT(*)` value of rows matching a search term, with no additional `WHERE` clauses. Code the `WHERE` clause as `WHERE MATCH(text) AGAINST ('other_text')`, without any > 0 comparison operator.

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that `EXPLAIN` for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

`EXPLAIN` for full-text queries may show `Select tables optimized away` in the `Extra` column due to matching occurring during optimization; in this case, no table access need occur during later execution.

**Spatial Indexes**

You can create indexes on spatial data types. **MyISAM** and **InnoDB** support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for **ARCHIVE**, which does not support spatial type indexing).

**Indexes in the MEMORY Storage Engine**

The **MEMORY** storage engine uses **HASH** indexes by default, but also supports **BTREE** indexes.

**8.3.6 Multiple-Column Indexes**

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see Section 8.3.5, “Column Indexes”).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

**Note**

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```sql
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1,val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```sql
CREATE TABLE test (
    id INT NOT NULL,
    last_name CHAR(30) NOT NULL,
);```
The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```sql
SELECT * FROM test WHERE last_name='Widenius';
SELECT * FROM test
  WHERE last_name='Widenius' AND first_name='Michael';
SELECT * FROM test
  WHERE last_name='Widenius'
  AND (first_name='Michael' OR first_name='Monty');
SELECT * FROM test
  WHERE last_name='Widenius'
  AND first_name >= 'M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```sql
SELECT * FROM test WHERE first_name='Michael';
SELECT * FROM test
  WHERE last_name='Widenius' OR first_name='Michael';
```
