- Set `sync_relay_log=1`, which instructs the replication receiver thread to synchronize the relay log to disk after each received transaction is written to it. This means the replica's record of the current position read from the source's binary log (in the applier metadata repository) is never ahead of the record of transactions saved in the relay log. Note that although this setting is the safest, it is also the slowest due to the number of disk writes involved. With `sync_relay_log > 1`, or `sync_relay_log=0` (where synchronization is handled by the operating system), in the event of an unexpected halt of a replica there might be committed transactions that have not been synchronized to disk. Such transactions can cause the recovery process to fail if the recovering replica, based on the information it has in the relay log as last synchronized to disk, tries to retrieve and apply the transactions again instead of skipping them. Setting `sync_relay_log=1` is particularly important for a multi-threaded replica, where the recovery process fails if gaps in the sequence of transactions cannot be filled using the information in the relay log. For a single-threaded replica, the recovery process only needs to use the relay log if the relevant information is not available in the applier metadata repository.
- Set `innodb_flush_log_at_trx_commit=1`, which synchronizes the InnoDB logs to disk before each transaction is committed. This setting, which is the default, ensures that InnoDB tables and the InnoDB logs are saved on disk so that there is no longer a requirement for the information in the relay log regarding the transaction. Combined with the setting `sync_relay_log=1`, this setting further ensures that the content of the InnoDB tables and the InnoDB logs is consistent with the content of the relay log at all times, so that purging the relay log files cannot cause unfillable gaps in the replica's history of transactions in the event of an unexpected halt.
- Set `relay_log_info_repository = TABLE`, which stores the replication SQL thread position in the InnoDB table `mysql.slave_relay_log_info`, and updates it together with the transaction commit to ensure a record that is always accurate. This setting is the default; `FILE` is deprecated. The system variable itself is also deprecated, so omit it and allow it to assume the default. If `FILE` is used, the information is stored in a file in the data directory that is updated after the transaction

has been applied. This creates a risk of losing synchrony with the source depending at which stage of processing a transaction the replica halts at, or even corruption of the file itself. With `relay_log_info_repository = FILE`, recovery is not guaranteed.

- Set `relay_log_recovery = ON`, which enables automatic relay log recovery immediately following server startup. This global variable defaults to `OFF` and is read-only at runtime, but you can set it to `ON` with the `--relay-log-recovery` option at replica startup following an unexpected halt of a replica. Note that this setting ignores the existing relay log files, in case they are corrupted or inconsistent. The relay log recovery process starts a new relay log file and fetches transactions from the source beginning at the replication SQL thread position recorded in the applier metadata repository. The previous relay log files are removed over time by the replica's normal purge mechanism.

For a multithreaded replica, setting `relay_log_recovery = ON` automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see [Section 19.5.1.35, “Replication and Transaction Inconsistencies”](#).) The relay log recovery process deals with gaps using the same method as the `START REPLICAS UNTIL SQL_AFTER_MTS_GAPS` statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the replication SQL thread position. When GTID-based replication is in use, a multithreaded replica checks first whether `SOURCE_AUTO_POSITION` is set to `ON`, and if it is, omits the step of calculating the transactions that should be skipped or not skipped, so that the old relay logs are not required for the recovery process.

### 19.4.3 Monitoring Row-based Replication

The current progress of the replication applier (SQL) thread when using row-based replication is monitored through Performance Schema instrument stages, enabling you to track the processing of operations and check the amount of work completed and work estimated. When these Performance Schema instrument stages are enabled the `events_stages_current` table shows stages for applier threads and their progress. For background information, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

To track progress of all three row-based replication event types (write, update, delete):

- Enable the three Performance Schema stages by issuing:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME LIKE 'stage/sql/Applying batch of row changes%';
```

- Wait for some events to be processed by the replication applier thread and then check progress by looking into the `events_stages_current` table. For example to get progress for `update` events issue:

```
mysql> SELECT WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
-> WHERE EVENT_NAME LIKE 'stage/sql/Applying batch of row changes (update)';
```

- If `binlog_rows_query_log_events` is enabled, information about queries is stored in the binary log and is exposed in the `processlist_info` field. To see the original query that triggered this event:

```
mysql> SELECT db, processlist_state, processlist_info FROM performance_schema.threads
-> WHERE processlist_state LIKE 'stage/sql/Applying batch of row changes%' AND thread_id = N;
```

### 19.4.4 Using Replication with Different Source and Replica Storage Engines

It does not matter for the replication process whether the original table on the source and the replicated table on the replica use different storage engine types. In fact, the `default_storage_engine` system variable is not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 19.4.5, “Using Replication for Scale-Out”](#)), you want to use [InnoDB](#) tables on the source to take advantage of the transactional functionality, but use [MyISAM](#) on the replicas where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the [Archive](#) storage engine on the replica.

Configuring different engines on the source and replica depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your source, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the replica before using the dump to build the data on the replica. For example, you can add the `--skip-federated` option on your replica to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL uses the default engine type, usually `InnoDB`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the replica that supports only the engines you want.

- If you use raw data files (a binary backup) to set up the replica, it is not possible to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the replica has been started.
- For new source/replica replication setups where there are currently no tables on the source, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the replica from running replication updates:

```
mysql> STOP REPLICA;
```

This makes it possible to change engine types without interruption.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the replication process again:

```
mysql> START REPLICA;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification are replicated to the replica correctly. If, in the case of a `CSV` table, you execute this statement:

```
mysql> ALTER TABLE csvtable ENGINE='MyISAM';
```

This statement is replicated; the table's engine type on the replica is converted to `InnoDB`, even if you have previously changed the table type on the replica to an engine other than `CSV`. If you want to retain engine differences on the source and replica, you should be careful to use the `default_storage_engine` variable on the source when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable is ignored, and the `CREATE TABLE` statement executes on the replica using the replica's default engine.

### 19.4.5 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one source to one or more replicas, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replicas, while still enabling your web servers to communicate with the source when a write is required. You can see a sample replication layout for this scenario in [Figure 19.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 19.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the source, and to send reads to either the source or a replica. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a source/replica configuration, even one involving multiple replicas. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

## 19.4.6 Replicating Different Databases to Different Replicas

There may be situations where you have a single source server and want to replicate different databases to different replicas. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 19.2, “Replicating Databases to Separate Replicas”](#).

**Figure 19.2 Replicating Databases to Separate Replicas**

You can achieve this separation by configuring the source and replicas as normal, and then limiting the binary log statements that each replica processes by using the `--replicate-wild-do-table` configuration option on each replica.

**Important**

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's effects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 19.2, “Replicating Databases to Separate Replicas”](#), you should configure each replica as follows, before executing `START REPLICA`:

- Replica 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replica 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replica 3 should use `--replicate-wild-do-table=databaseC.%`.

Each replica in this configuration receives the entire binary log from the source, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that replica.

If you have data that must be synchronized to the replicas before replication starts, you have a number of choices:

- Synchronize all the data to each replica, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each replica.
- Use a raw data file dump and include only the specific files and databases that you need for each replica.

**Note**

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 19.4.7 Improving Replication Performance

As the number of replicas connecting to a source increases, the load, although minimal, also increases, as each replica uses a client connection to the source. Also, as each replica must receive a full copy of the source's binary log, the network load on the source may also increase and create a bottleneck.

If you are using a large number of replicas connected to one source, and that source is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the source to replicate to only one replica, and for the remaining replicas to connect to this primary replica for their individual replication requirements. A sample of this structure is shown in [Figure 19.3, “Using an Additional Replication Source to Improve Performance”](#).

**Figure 19.3 Using an Additional Replication Source to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Source 1 is the primary source where all changes and updates are written to the database. Binary logging is enabled on both source servers, which is the default.
- Source 2 is the replica to the server Source 1 that provides the replication functionality to the remainder of the replicas in the replication structure. Source 2 is the only machine permitted to connect to Source 1. Source 2 has the `--log-replica-updates` option enabled (the default). With this option, replication instructions from Source 1 are also written to Source 2's binary log so that they can then be replicated to the true replicas.
- Replica 1, Replica 2, and Replica 3 act as replicas to Source 2, and replicate the information from Source 2, which actually consists of the upgrades logged on Source 1.

The above solution reduces the client load and the network interface load on the primary source, which should improve the overall performance of the primary source when used as a direct database solution.

If your replicas are having trouble keeping up with the replication process on the source, there are a number of options available:

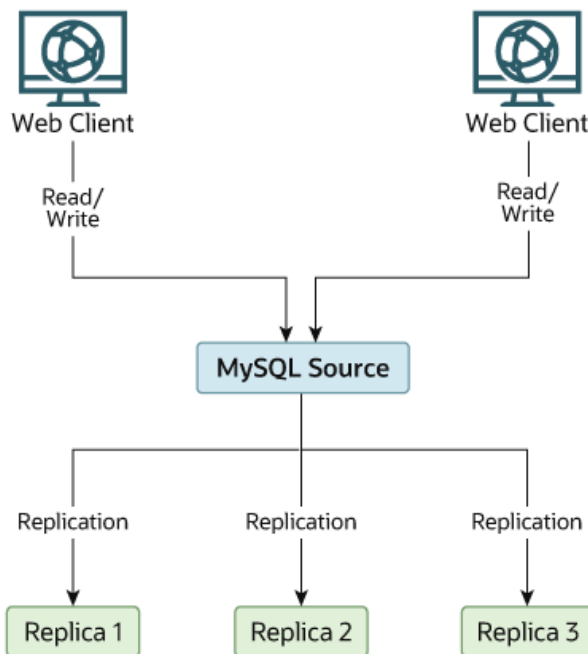

- If possible, put the relay logs and the data files on different physical drives. To do this, set the `relay_log` system variable to specify the location of the relay log.
- If heavy disk I/O activity for reads of the binary log file and relay log files is an issue, consider increasing the value of the `rpl_read_size` system variable. This system variable controls the minimum amount of data read from the log files, and increasing it might reduce file reads and I/O stalls when the file data is not currently cached by the operating system. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas. Setting a large value might therefore have an impact on memory consumption for servers.
- If the replicas are significantly slower than the source, you may want to divide up the responsibility for replicating different databases to different replicas. See [Section 19.4.6, “Replicating Different Databases to Different Replicas”](#).
- If your source makes use of transactions and you are not concerned about transaction support on your replicas, use `MyISAM` or another nontransactional engine on the replicas. See [Section 19.4.4, “Using Replication with Different Source and Replica Storage Engines”](#).
- If your replicas are not acting as sources, and you have a potential solution in place to ensure that you can bring up a source in the event of failure, then you can disable `log_replica_updates`. This prevents “dumb” replicas from also logging events they have executed into their own binary log.

## 19.4.8 Switching Sources During Failover

You can tell a replica to change to a new source using the `CHANGE REPLICATION SOURCE TO` statement. The replica does not check whether the databases on the source are compatible with those on the replica; it simply begins reading and executing events from the specified coordinates in the new source's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Replicas should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the replicas should also be run with `--log-replica-updates=OFF` (logging replica updates is the default). In this way, the replica is ready to become a source without restarting the replica `mysqld`. Assume that you have the structure shown in [Figure 19.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 19.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `Source` holds the source database, the `Replica*` hosts are replicas, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the replicas) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 19.4.5, “Using Replication for Scale-Out”](#).

Each MySQL replica (`Replica 1`, `Replica 2`, and `Replica 3`) is a replica running with binary logging enabled, and with `--log-replica-updates=OFF`. Because updates received by a replica from the source are not written to the binary log when `--log-replica-updates=OFF` is specified, the binary log on each replica is initially empty. If for some reason `Source` becomes unavailable, you can pick one of the replicas to become the new source. For example, if you pick `Replica 1`, all `Web Clients` should be redirected to `Replica 1`, which writes the updates to its binary log. `Replica 2` and `Replica 3` should then replicate from `Replica 1`.

The reason for running the replica with `--log-replica-updates=OFF` is to prevent replicas from receiving updates twice in case you cause one of the replicas to become the new source. If `Replica 1` has `--log-replica-updates` enabled, which is the default, it writes any updates that it receives from

`Source` in its own binary log. This means that, when `Replica 2` changes from `Source` to `Replica 1` as its source, it may receive updates from `Replica 1` that it has already received from `Source`.

Make sure that all replicas have processed any statements in their relay log. On each replica, issue `STOP REPLICIA IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all replicas, they can be reconfigured to the new setup. On the replica `Replica 1` being promoted to become the source, issue `STOP REPLICIA` and `RESET BINARY LOGS AND GTIDS`.

On the other replicas `Replica 2` and `Replica 3`, use `STOP REPLICIA` and `CHANGE REPLICATION SOURCE TO SOURCE_HOST='Replica1'` (where `'Replica1'` represents the real host name of `Replica 1`). To use `CHANGE REPLICATION SOURCE TO`, add all information about how to connect to `Replica 1` from `Replica 2` or `Replica 3` (`user, password, port`). When issuing the statement in this scenario, there is no need to specify the name of the `Replica 1` binary log file or log position to read from, since the first binary log file and position 4 are the defaults. Finally, execute `START REPLICIA` on `Replica 2` and `Replica 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Replica 1`. From that point on, all updates sent by `Web Client` to `Replica 1` are written to the binary log of `Replica 1`, which then contains every update sent to `Replica 1` since `Source` became unavailable.

The resulting server structure is shown in [Figure 19.5, “Redundancy Using Replication, After Source Failure”](#).

**Figure 19.5 Redundancy Using Replication, After Source Failure**

When `Source` becomes available again, you should make it a replica of `Replica 1`. To do this, issue on `Source` the same `CHANGE REPLICATION SOURCE TO` statement as that issued on `Replica 2` and `Replica 3` previously. `Source` then becomes a replica of `Replica 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Source` a source again, use the preceding procedure as if `Replica 1` were unavailable and `Source` were to be the new source. During this procedure, do not forget to run `RESET BINARY LOGS`

`AND GTIDS` on `Source` before making `Replica 1`, `Replica 2`, and `Replica 3` replicas of `Source`. If you fail to do this, the replicas may pick up stale writes from the `Web Client` applications dating from before the point at which `Source` became unavailable.

You should be aware that there is no synchronization between replicas, even when they share the same source, and thus some replicas might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all replicas should be relatively close together.

One way to keep applications informed about the location of the source is to have a dynamic DNS entry for the source host. With `BIND`, you can use `nsupdate` to update the DNS dynamically.

## 19.4.9 Switching Sources and Replicas with Asynchronous Connection Failover

You can use the asynchronous connection failover mechanism to establish an asynchronous (source-to-replica) replication connection to a new source automatically, after the existing connection from a replica to its source fails. The asynchronous connection failover mechanism can be used to keep a replica synchronized with multiple MySQL servers or groups of servers that share data. The list of potential source servers is stored on the replica, and in the event of a connection failure, a new source is selected from the list based on a weighted priority that you set.

The asynchronous connection failover mechanism also supports Group Replication topologies, by automatically monitoring changes to group membership and distinguishing between primary and secondary servers. When you add a group member to the source list and define it as part of a managed group, the asynchronous connection failover mechanism updates the source list to keep it in line with membership changes, adding and removing group members automatically as they join or leave. Only online group members that are in the majority are used for connections and obtaining status. The last remaining member of a managed group is not removed automatically even if it leaves the group, so that the configuration of the managed group is kept. However, you can delete a managed group manually if it is no longer needed.

The asynchronous connection failover mechanism also enables a replica that is part of a managed replication group to automatically reconnect to the sender if the current receiver (the primary of the group) fails. This feature works with Group Replication, on a group configured in single-primary mode, where the group's primary is a replica that has a replication channel using the mechanism. The feature is designed for a group of senders and a group of receivers to keep synchronized with each other even when some members are temporarily unavailable. It also synchronizes a group of receivers with one or more senders that are not part of a managed group. A replica that is not part of a replication group cannot use this feature.

The requirements for using the asynchronous connection failover mechanism are as follows:

- GTIDs must be in use on the source and the replica (`gtid_mode=ON`), and the `SOURCE_AUTO_POSITION` option of the `CHANGE REPLICATION SOURCE TO` statement must be enabled on the replica, so that GTID auto-positioning is used for the connection to the source.
- The same replication user account and password must exist on all the source servers in the source list for the channel. This account is used for the connection to each of the sources. You can set up different accounts for different channels.
- The replication user account must be given `SELECT` permissions on the Performance Schema tables, for example, by issuing `GRANT SELECT ON performance_schema.* TO 'repl_user';`
- The replication user account and password cannot be specified on the statement used to start replication, because they need to be available on the automatic restart for the connection to the

alternative source. They must be set for the channel using the `CHANGE REPLICATION SOURCE TO` statement on the replica, and recorded in the replication metadata repositories.

- If the channel where the asynchronous connection failover mechanism is in use is on the primary of a Group Replication single-primary mode group, asynchronous connection failover between replicas is also active by default. In this situation, the replication channel and the replication user account and password for the channel must be set up on all the secondary servers in the replication group, and on any new joining members. If the new servers are provisioned using MySQL's clone functionality, this all happens automatically.

### Important

If you do not want asynchronous connection failover to take place between replicas in this situation, disable it by disabling the member action `mysql_start_failover_channels_if_primary` for the group, using the `group_replication_disable_member_action` function. When the feature is disabled, you do not need to configure the replication channel on the secondary group members, but if the primary goes offline or into an error state, replication stops for the channel.

MySQL InnoDB ClusterSet is available to provide disaster tolerance for InnoDB Cluster deployments by linking a primary InnoDB Cluster with one or more replicas of itself in alternate locations, such as different datacenters. Consider using this solution instead to simplify the setup of a new multi-group deployment for replication, failover, and disaster recovery. You can adopt an existing Group Replication deployment as an InnoDB Cluster.

InnoDB ClusterSet and InnoDB Cluster are designed to abstract and simplify the procedures for setting up, managing, monitoring, recovering, and repairing replication groups. InnoDB ClusterSet automatically manages replication from a primary cluster to replica clusters using a dedicated ClusterSet replication channel. You can use administrator commands to trigger a controlled switchover or emergency failover between groups if the primary cluster is not functioning normally. Servers and groups can easily be added to or removed from the InnoDB ClusterSet deployment after the initial setup when demand changes. For more information, see [MySQL InnoDB ClusterSet](#).

## 19.4.9.1 Asynchronous Connection Failover for Sources

To activate asynchronous connection failover for a replication channel set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in a `CHANGE REPLICATION SOURCE TO` statement for this channel. GTID auto-positioning must be in use for the channel (`SOURCE_AUTO_POSITION = 1`).

### Important

When the existing connection to a source fails, the replica first retries the same connection the number of times specified by the `SOURCE_RETRY_COUNT` option of the `CHANGE REPLICATION SOURCE TO`. The interval between attempts is set by the `SOURCE_CONNECT_RETRY` option. When these attempts are exhausted, the asynchronous connection failover mechanism takes over. Note that the defaults for these options, which were designed for a connection to a single source, make the replica retry the same connection for 60 days. To ensure that the asynchronous connection failover mechanism can be activated promptly, set `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` to minimal numbers that just allow a few retry attempts with the same source, in case the connection failure is caused by a transient network outage. Suitable values are `SOURCE_RETRY_COUNT=3` and `SOURCE_CONNECT_RETRY=10`, which make the replica retry the connection 3 times with 10-second intervals between.

You also need to set the source list for the replication channel, to specify the sources that are available for failover. You set and manage source lists using the `asynchronous_connection_failover_add_source` and `asynchronous_connection_failover_delete_source` functions to add and remove single replication source servers. To add and remove managed groups of servers, use the `asynchronous_connection_failover_add_managed` and `asynchronous_connection_failover_delete_managed` functions instead.

The functions name the relevant replication channel and specify the host name, port number, network namespace, and weighted priority (1-100, with 100 being the highest priority) of a MySQL instance to add to or delete from the channel's source list. For a managed group, you also specify the type of managed service (currently only Group Replication is available), and the identifier of the managed group (for Group Replication, this is the value of the `group_replication_group_name` system variable). When you add a managed group, you only need to add one group member, and the replica automatically adds the rest from the current group membership. When you delete a managed group, you delete the entire group together.

The asynchronous connection failover mechanism also fails over the connection if another available server on the source list has a higher priority (weight) setting. This feature ensures that the replica stays connected to the most suitable source server at all times, and it applies to both managed groups and single (non-managed) servers. For a managed group, a source's weight is assigned depending on whether it is a primary or a secondary server. So assuming that you set up the managed group to give a higher weight to a primary and a lower weight to a secondary, when the primary changes, the higher weight is assigned to the new primary, so the replica changes over the connection to it. The asynchronous connection failover mechanism additionally changes connection if the currently connected managed source server leaves the managed group, or is no longer in the majority in the managed group.

When failing over a connection, the source with the highest priority (weight) setting among the alternative sources listed in the source list for the channel is chosen for the first connection attempt. The replica checks first that it can connect to the source server, or in the case of a managed group, that the source server has `ONLINE` status in the group (not `RECOVERING` or unavailable). If the highest weighted source is not available, the replica tries with all the listed sources in descending order of weight, then starts again from the highest weighted source. If multiple sources have the same weight, the replica orders them randomly. If the replica needs to start working through the list again, it includes and retries the source to which the original connection failure occurred.

The source lists are stored in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables, and can be viewed in the Performance Schema `replication_asynchronous_connection_failover` and `replication_asynchronous_connection_failover_managed` tables. The replica uses a monitor thread to track the membership of managed groups and update the source list (`thread/sql/replica_monitor`). The setting for the `SOURCE_CONNECTION_AUTO_FAILOVER` option of the `CHANGE REPLICATION SOURCE TO` statement, and the source list, are transferred to a clone of the replica during a remote cloning operation.

### 19.4.9.2 Asynchronous Connection Failover for Replicas

Asynchronous connection failover for replicas is activated automatically for a replication channel on a Group Replication primary when you set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in the `CHANGE REPLICATION SOURCE TO` statement for the channel. The feature is designed for a group of senders and a group of receivers to keep synchronized with each other even when some members are temporarily unavailable. When the feature is active and correctly configured, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected.

The new primary uses the source list for the channel to select the source with the highest priority (weight) setting, which might not be the same as the original source.

To configure this feature, the replication channel and the replication user account and password for the channel must be set up on all the member servers in the replication group, and on any new joining members. Ensure that `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` are set to minimal numbers that just allow a few retry attempts, for example 3 and 10. You can set up the replication channel using `CHANGE REPLICATION SOURCE TO`, or if the new servers are provisioned using MySQL's clone functionality, this all happens automatically. The `SOURCE_CONNECTION_AUTO_FAILOVER` setting for the channel is broadcast to group members from the primary when they join. If you later disable `SOURCE_CONNECTION_AUTO_FAILOVER` for the channel on the primary, this is also broadcast to the secondary servers, and they change the status of the channel to match.

Asynchronous connection failover for replicas is activated and deactivated using the Group Replication member action `mysql_start_failover_channels_if_primary`, which is enabled by default. You can disable it for the whole group by disabling that member action on the primary, using the `group_replication_disable_member_action` function, as in this example:

```
mysql> SELECT group_replication_disable_member_action("mysql_start_failover_channels_if_primary", "AFTER_P
```

The function can only be changed on a primary, and must be enabled or disabled for the whole group, so you cannot have some members providing failover and others not. When the `mysql_start_failover_channels_if_primary` member action is disabled, the channel does not need to be configured on secondary members, but if the primary goes offline or into an error state, replication stops for the channel. Note that if there is more than one channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1`, the member action covers all the channels, so they cannot be individually enabled and disabled by that method. Set `SOURCE_CONNECTION_AUTO_FAILOVER=0` on the primary to disable an individual channel.

The source list for a channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1` is broadcast to all group members when they join, and also when it changes. This is the case whether the sources are a managed group for which the membership is updated automatically, or whether they are added or changed manually using `asynchronous_connection_failover_add_source()`, `asynchronous_connection_failover_delete_source()`, `asynchronous_connection_failover_add_managed()`, or `asynchronous_connection_failover_delete_managed()`. All group members receive the current source list as recorded in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables. Because the sources do not have to be in a managed group, you can set up the function to synchronize a group of receivers with one or more alternative standalone senders, or even a single sender. A standalone replica that is not part of a replication group cannot use this feature.

## 19.4.10 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 9.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The source writes events to its binary log and replicas request them when they are ready. The source does not know whether or when a replica has retrieved and processed the transactions, and there is no guarantee that any event ever reaches any replica. With asynchronous replication, if the source crashes, transactions that it has committed might not have been transmitted to any replica. Failover from source to replica in this case might result in failover to a server that is missing transactions relative to the source.

With fully synchronous replication, when a source commits a transaction, all replicas have also committed the transaction before the source returns to the session that performed the transaction. Fully synchronous replication means failover from the source to any replica is possible at any time. The drawback of fully synchronous replication is that there might be a lot of delay to complete a transaction.

Semisynchronous replication falls between asynchronous and fully synchronous replication. The source waits until at least one replica has received and logged the events (the required number of replicas is configurable), and then commits the transaction. The source does not wait for all replicas to acknowledge receipt, and it requires only an acknowledgement from the replicas, not that the events have been fully executed and committed on the replica side. Semisynchronous replication therefore guarantees that if the source crashes, all the transactions that it has committed have been transmitted to at least one replica.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity, because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous source receives acknowledgment from the required number of replicas, the transaction is on hold and not committed.

Compared to fully synchronous replication, semisynchronous replication is faster, because it can be configured to balance your requirements for data integrity (the number of replicas acknowledging receipt of the transaction) with the speed of commits, which are slower due to the need to wait for replicas.

### Important

With semisynchronous replication, if the source crashes and a failover to a replica is carried out, the failed source should not be reused as the replication source, and should be discarded. It could have transactions that were not acknowledged by any replica, which were therefore not committed before the failover.

If your goal is to implement a fault-tolerant replication topology where all the servers receive the same transactions in the same order, and a server that crashes can rejoin the group and be brought up to date automatically, you can use Group Replication to achieve this. For information, see [Chapter 20, Group Replication](#).

The performance impact of semisynchronous replication compared to asynchronous replication is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the replica and wait for the acknowledgment of receipt by the replica. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks. Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from source to replica. When one user is too busy, this slows it down, which can be useful in some deployment situations.

Semisynchronous replication between a source and its replicas operates as follows:

- A replica indicates whether it is semisynchronous-capable when it connects to the source.
- If semisynchronous replication is enabled on the source side and there is at least one semisynchronous replica, a thread that performs a transaction commit on the source blocks and waits until at least one semisynchronous replica acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The replica acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any replica having acknowledged the transaction, the source reverts to asynchronous replication. When at least one semisynchronous replica catches up, the source returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the source and replica sides. If semisynchronous replication is disabled on the source, or enabled on the source but on no replicas, the source uses asynchronous replication.

While the source is blocking (waiting for acknowledgment from a replica), it does not return to the session that performed the transaction. When the block ends, the source returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the source side, and receipt of its events has been acknowledged by at least one replica. The number of replica acknowledgments the source must receive per transaction before returning to the session is configurable, and defaults to one acknowledgement (see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#)).

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to replicas.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the source blocks for each such statement, just as it does for explicit transaction commits.

By default, the source waits for replica acknowledgment of the transaction receipt after syncing the binary log to disk, but before committing the transaction to the storage engine. As an alternative, you can configure the source so that the source waits for replica acknowledgment after committing the transaction to the storage engine, using the `rpl_semi_sync_source_wait_point` system variable. This setting affects the replication characteristics and the data that clients can see on the source. For more information, see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#).

You can improve the performance of semisynchronous replication by enabling the system variables `replication_sender_observe_commit_only`, which limits callbacks, and `replication_optimize_for_static_plugin_config`, which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.

### 19.4.10.1 Installing Semisynchronous Replication

Semisynchronous replication is implemented using plugins, which must be installed on the source and on the replicas to make semisynchronous replication available on the instances. There are different plugins for a source and for a replica. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are available only when the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 19.1, “Configuring Replication”](#).

- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 19.2.2, “Replication Channels”](#).

MySQL 9.7 supplies versions of the plugins that implement semisynchronous replication—one for the source server and one for the replica—which replace the terms “master” and “slave” with “source” and “replica” in system variables and status variables; you must install these versions instead of the old ones (which have now been removed). Replication topologies that still use the old semisynchronous plugins must be upgraded to use the new plugins. For more information, see [Upgrading Replication Topologies to Use New Semisynchronous Replication Plugins](#).

The file name suffix for the plugin library files differs per platform (for example, `.so` for Unix and Unix-like systems, and `.dll` for Windows). The plugin and library file names are as follows:

- Source server: `rpl_semi_sync_source` plugin (`semisync_source.so` or `semisync_source.dll` library)
- Replica: `rpl_semi_sync_replica` plugin (`semisync_replica.so` or `semisync_replica.dll` library)

To be usable by a source or replica server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup. The source plugin library file must be present in the plugin directory of the source server. The replica plugin library file must be present in the plugin directory of each replica server.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP REPLICATION`, and `START REPLICATION` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege).

To load the plugins, use the `INSTALL PLUGIN` statement on the source and on each replica that is to be semisynchronous, adjusting the `.so` suffix for your platform as necessary.

On the source:

```
INSTALL PLUGIN rpl_semi_sync_source SONAME 'semisync_source.so';
```

On each replica:

```
INSTALL PLUGIN rpl_semi_sync_replica SONAME 'semisync_replica.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_source SONAME 'semisync_source.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_source.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <https://dev.mysql.com/downloads/os-linux.html>.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_source | ACTIVE |
+-----+-----+
```

```
+-----+-----+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the source side and the replica side to enable semisynchronous replication. If only one side is enabled, replication is asynchronous. To enable the plugins, set the appropriate system variable either at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file. For example:

```
SET GLOBAL rpl_semi_sync_source_enabled = 1;
```

```
SET GLOBAL rpl_semi_sync_replica_enabled = 1;
```

If you enable semisynchronous replication on a replica at runtime, you must also start the replication I/O (receiver) thread (stopping it first if it is already running) to cause the replica to connect to the source and register as a semisynchronous replica:

```
STOP REPLICATION IO_THREAD;
START REPLICATION IO_THREAD;
```

If the replication I/O (receiver) thread is already running and you do not restart it, the replica continues to use asynchronous replication.

A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the source and replica servers as follows. On the source:

```
[mysqld]
rpl_semi_sync_source_enabled=1
```

On each replica:

```
[mysqld]
rpl_semi_sync_replica_enabled=1
```

You can configure the behavior of the semisynchronous replication plugins using the system variables that become available when you install the plugins. For information on key system variables, see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#).

## Upgrading Replication Topologies to Use New Semisynchronous Replication Plugins

In replication topologies that still use the old semisynchronous plugins, the MySQL instances must first be reconfigured to use the new semisynchronous replication plugins. To reconfigure the MySQL instances:

1. Stop replication on each replica and source instances.
2. Uninstall the old `rpl_semi_sync_master` and `rpl_semi_sync_slave` plugins.
3. Install the new `rpl_semi_sync_source` and `rpl_semi_sync_slave` plugins.
4. Enable semisynchronous replication again.

The replication topology upgrade must then be performed in the standard manner, starting with replicas and then proceeding to the source. For more information, see [Section 19.5.3, “Upgrading or Downgrading a Replication Topology”](#).

### 19.4.10.2 Configuring Semisynchronous Replication

When you install the source and replica plugins for semisynchronous replication (see [Section 19.4.10.1, “Installing Semisynchronous Replication”](#)), system variables become available to control plugin behavior.

To check the current values of the status variables for semisynchronous replication, use `SHOW VARIABLES:`

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

All the `rpl_semi_sync_XXX` system variables are described at [Section 19.1.6.2, “Replication Source Options and Variables”](#) and [Section 19.1.6.3, “Replica Server Options and Variables”](#). Some key system variables are:

`rpl_semi_sync_source_enabled` Controls whether semisynchronous replication is enabled on the source server. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

`rpl_semi_sync_replica_enabled` Controls whether semisynchronous replication is enabled on the replica.

`rpl_semi_sync_source_timeout` A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

`rpl_semi_sync_source_wait_replicas` Controls the number of replica acknowledgments the source must receive per transaction before returning to the session. The default is 1, meaning that the source only waits for one replica to acknowledge receipt of the transaction's events.

The `rpl_semi_sync_source_wait_point` system variable controls the point at which a semisynchronous source server waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time, which is after it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source and failover to the replica is lossless because the replica is up to date. As noted above, the source should not be reused after the failover.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source exit and failover to the replica, it is possible for such clients to see a loss of data relative to what they saw on the source.

You can improve the performance of semisynchronous replication by enabling the system variables `replication_sender_observe_commit_only`, which limits callbacks, and `replication_optimize_for_static_plugin_config`, which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.

### 19.4.10.3 Semisynchronous Replication Monitoring

The plugins for semisynchronous replication expose a number of status variables that enable you to monitor their operation. To check the current values of the status variables, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

All `Rpl_semi_sync_xxx` status variables are described at [Section 7.1.10, “Server Status Variables”](#). Some examples are:

- `Rpl_semi_sync_source_clients`

The number of semisynchronous replicas that are connected to the source server.

- `Rpl_semi_sync_source_status`

Whether semisynchronous replication currently is operational on the source server. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_source_no_tx`

The number of commits that were not acknowledged successfully by a replica.

- `Rpl_semi_sync_source_yes_tx`

The number of commits that were acknowledged successfully by a replica.

- `Rpl_semi_sync_replica_status`

Whether semisynchronous replication currently is operational on the replica. This is 1 if the plugin has been enabled and the replication I/O (receiver) thread is running, 0 otherwise.

When the source switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a replica catching up, it sets the value of the `Rpl_semi_sync_source_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the source means that it is possible for the `rpl_semi_sync_source_enabled` system variable to have a value of 1 on the source side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_source_status` status variable to determine whether the source currently is using asynchronous or semisynchronous replication.

### 19.4.11 Delayed Replication

MySQL supports delayed replication such that a replica server deliberately executes transactions later than the source by at least a specified amount of time. This section describes how to configure a replication delay on a replica, and how to monitor replication delay.

In MySQL 9.7, the method of delaying replication depends on two timestamps, `immediate_commit_timestamp` and `original_commit_timestamp` (see [Replication Delay](#)

[Timestamps](#)); delayed replication is measured using these timestamps. If either the immediate source or replica is not using these timestamps, the implementation of delayed replication from MySQL 5.7 is used (see [Delayed Replication](#)). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use a `CHANGE REPLICATION SOURCE TO SOURCE_DELAY=N` statement to set the delay to *N* seconds. A transaction received from the source is not executed until at least *N* seconds later than its commit on the immediate source. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

### Note

`START REPLICHA` and `STOP REPLICHA` take effect immediately and ignore any delay. `RESET REPLICHA` resets the delay to 0.

The `replication_applier_configuration` Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `SOURCE_DELAY` option. The `replication_applier_status` Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the source. With a delay you can roll back a delayed replica to the time just before the mistake.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the replica. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging replica.
- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a replica with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed replica can be inspected.

## Replication Delay Timestamps

MySQL 9.7 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- `original_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original source.
- `immediate_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate source.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined time zone for better readability. For example:

```
#170404 10:48:05 server id 1 end_log_pos 233 CRC32 0x016ce647 GTID last_committed=0
\ sequence_number=1 original_committed_timestamp=1491299285661130 immediate_commit_timestamp=14912992858
# original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
# immediate_commit_timestamp=1491299285843771 (2017-04-04 10:48:05.843771 WEST)
/*!80001 SET @@SESSION.original_commit_timestamp=1491299285661130/*!*/;
SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:1'/*!*/;
```

---

# at 233

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In source-replica replication, the `original_commit_timestamp` of a transaction in the (original) source's binary log is always the same as its `immediate_commit_timestamp`. In the replica's relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the source's binary log; whereas in its own binary log, the transaction's `immediate_commit_timestamp` corresponds to when the replica committed the transaction.

In a Group Replication setup, when the original source is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original source and its write set is ready to be sent to all members of the group for certification. When the original source is a server outside the group, the `original_commit_timestamp` is preserved. The same `original_commit_timestamp` for a particular transaction is replicated to all servers in the group, and to any replica outside the group that is replicating from a member. Each recipient of the transaction also stores the local commit time in its binary log using `immediate_commit_timestamp`.

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each group member but share the same GTID (so, they are not first executed in a source and then replicated to the group, but all members of the group execute and apply the same transaction). Group members set local timestamp values for transactions associated with view change events.

## Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW REPLICICA STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional source-replica setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the source, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multithreaded replica, provides information on the last transaction buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering.
- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the source, provides information about the transactions applied by the replication SQL thread, or by each worker thread when using a multithreaded replica.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction's GTID
- a transaction's `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the replica's relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW REPLICA STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE REPLICATION SOURCE TO SOURCE_DELAY=N`, where *N* is measured in seconds.
- `SQL_Remaining_Delay`: When `Replica_SQL_Running_State` is `Waiting until SOURCE_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Replica_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Replica_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the replication SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until SOURCE_DELAY seconds after master executed event`.

## 19.5 Replication Notes and Tips

### 19.5.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the source and replica. In other words, successful statement-based replication requires that any SQL features used be supported by both the source and the replica servers. If you use a feature on the source server that is available only in the current version of MySQL, you cannot replicate to a replica that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 9.7 and a previous MySQL release series, it is a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 27.9, “Stored Program Binary Logging”](#). For more information about row-based logging and row-based replication, see [Section 7.4.4.1, “Binary Logging Formats”](#), and [Section 19.2.1, “Replication Formats”](#).

For additional information specific to replication and `InnoDB`, see [Section 17.19, “InnoDB and MySQL Replication”](#). For information relating to replication with NDB Cluster, see [Section 25.7, “NDB Cluster Replication”](#).

#### 19.5.1.1 Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is carried out subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)
- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an [AUTO\\_INCREMENT](#) column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an [AUTO\\_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

### Important

To guarantee the same ordering on both source and replica, the [ORDER BY](#) clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of [CREATE TABLE ... LIKE](#): Foreign key definitions are ignored, as are the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If a table definition includes any of those characteristics, create `t2` using a [CREATE TABLE](#) statement that is identical to the one used to create `t1`, but with the addition of the [AUTO\\_INCREMENT](#) column.

Regardless of the method used to create and populate the copy having the [AUTO\\_INCREMENT](#) column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.3.6.1, “Problems with ALTER TABLE”](#).

## 19.5.1.2 Replication and BLACKHOLE Tables

The [BLACKHOLE](#) storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting [BLACKHOLE](#) tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the [BLACKHOLE](#) storage engine that you have the [binlog\\_format](#) server variable set to [STATEMENT](#), and not to either [ROW](#) or [MIXED](#).

## 19.5.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the source has databases with a character set different from the global [character\\_set\\_server](#) value, you should design your [CREATE TABLE](#) statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in [CREATE TABLE](#) statements.

## 19.5.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

### 19.5.1.5 Replication of `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER`

The statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 19.5.1.6 Replication of `CREATE ... IF NOT EXISTS` Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the source.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the source. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 19.5.1.7, “Replication of `CREATE TABLE ... SELECT` Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the source.
- `CREATE USER` is written to the binary log only if successful. If the statement includes `IF NOT EXISTS`, it is considered successful, and is logged as long as at least one user named in the statement is created; in such cases, the statement is logged as written; this includes references to existing users that were not created. See [CREATE USER Binary Logging](#), for more information.
- `CREATE PROCEDURE IF NOT EXISTS`, `CREATE FUNCTION IF NOT EXISTS`, or `CREATE TRIGGER IF NOT EXISTS`, if successful, is written in its entirety to the binary log (including the `IF NOT EXISTS` clause), whether or not the statement raised a warning because the object (procedure, function, or trigger) already existed.

### 19.5.1.7 Replication of `CREATE TABLE ... SELECT` Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 15.3.3, “Statements That Cause an Implicit Commit”](#)).
- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

With storage engines that support atomic DDL, the statement is logged as one transaction. For more information, see [Section 15.1.1, “Atomic Data Definition Statement Support”](#).

- If the `CREATE TABLE ... SELECT` statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.
- If the destination table exists and `IF NOT EXISTS` is given, MySQL 9.7 ignores the statement completely; nothing is inserted or logged.

MySQL 9.7 does not allow a `CREATE TABLE . . . SELECT` statement to make any changes in tables other than the table that is created by the statement.

### 19.5.1.8 Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the source and the replica when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the source is replicated to the replica as metadata, and the replica applies the statement to the current user named in the metadata, rather than to the current user on the replica.

### 19.5.1.9 Replication with Differing Table Definitions on Source and Replica

Source and target tables for replication do not have to be identical. A table on the source can have more or fewer columns than the replica's copy of the table. In addition, corresponding table columns on the source and the replica can use different data types, subject to certain conditions.

#### Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 19.5.1.25, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the source and the replica. Additional conditions are discussed, with examples, in the following two sections.

#### Replication with More Columns on Source or Replica

You can replicate a table from the source to the replica such that the source and replica copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the source and the replica. (This is true even if both tables have the same number of columns.)
- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the replica where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the source and the replica, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  c1 INT,
  c2 INT,
  c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the replica:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the replica because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the replica without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the replica of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 13.6, “Data Type Default Values”](#)).

In addition, when the replica's copy of the table has more columns than the source's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the source.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the replica than they are on the source:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the source appears before the definitions of the columns common to both versions of the table:

```
source> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the replica.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the source and the replica:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the replica's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the replica's version of the table has additional columns compared to the source's version, and the two versions of the table use different data types for the common column `c2`:

```
source> CREATE TABLE t1 (c1 INT, c2 BIGINT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the source's and the replica's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the source) to a column having a different data type (on the replica); when the data type of the source's version of the column is promoted to a type that is the same size or larger on the replica, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the source or the replica. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the replica's copy of the table cannot contain more columns than the source's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the source would also execute successfully on the replica, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the replica, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the replica's copy of a table to `BIGINT`, any insert into that column on the source that succeeds should also succeed on the replica, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

**Row-based replication: attribute promotion and demotion.** Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes.** The global value of the system variable `replica_type_conversions` controls the type conversion mode used on the replica. This variable takes a set of values from the following list, which describes the effects of each mode on the replica’s type-conversion behavior:

ALL_LOSSY	In this mode, type conversions that would mean loss of information are permitted.  This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the replica.
ALL_NON_LOSSY	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.  Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code> , then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code> ) causes the replica to stop with an error.
ALL_LOSSY,ALL_NON_LOSSY	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
ALL_SIGNED	Treat promoted integer types as signed values (the default behavior).
ALL_UNSIGNED	Treat promoted integer types as unsigned values.
ALL_SIGNED,ALL_UNSIGNED	Treat promoted integer types as signed if possible, otherwise as unsigned.
[empty]	When <code>replica_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.  This mode is the default.

When an integer type is promoted, its signedness is not preserved. By default, the replica treats all such values as signed. You can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. `ALL_SIGNED` tells the replica to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the replica to treat the value as signed if possible,

otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the replica with the new `replica_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M' - D') \geq (M - D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 14.25.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` characters of the string on the replica, where `N` is the width of the target column.

#### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` bytes of the string on the replica, where `N` is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the `M` bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

### 19.5.1.10 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the source server, the table option is also used on the replica. This can cause problems if no corresponding directory exists in the replica host file system or if it exists but is not accessible to the replica MySQL server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the replica, which causes the replica to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 7.1.11, “Server SQL Modes”](#).

### 19.5.1.11 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the source. This is to ensure that the object to be dropped no longer exists on either the source or the replica, once the replica has caught up with the source.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the source.

### 19.5.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on source and replica servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 14.3, “Type Conversion in Expression Evaluation”](#), and [Section B.3.4.8, “Problems with Floating-Point Values”](#).

### 19.5.1.13 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a replica: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 15.7.8.3, “FLUSH Statement”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to replicas. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the replicas to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the replicas. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 19.5.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the replica unless row-based replication is enabled. (See [Section 19.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 19.5.1.8, “Replication of CURRENT\\_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the source* is replicated to the replica. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both source and replica. For more information, see [Section 19.5.1.34, “Replication and Time Zones”](#).

To explain the potential problems when replicating between servers which are in different time zones, suppose that the source is located in New York, the replica is located in Stockholm, and both servers are using local time. Suppose further that, on the source, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the replica at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the replica's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the replica's copy of `mytable`, you obtain exactly the same result as on the source:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the source and the replica to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the source and the replica.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 19.5.1.34, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle

user-level locks are replicated without the replica knowing the concurrency context on the source. Therefore, these functions should not be used to insert into a source table because the content on the replica would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK( . . . ))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT . . . INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the replica correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

### 19.5.1.15 Replication and Fractional Seconds Support

MySQL 9.7 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 13.2.6, “Fractional Seconds in Time Values”](#).

### 19.5.1.16 Replication of Invoked Features

Replication of invoked features such as loadable functions and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a loadable function with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the function is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `REPLICA_SIDE_DISABLED` on the replica regardless of the state specified (this does not apply to `DROP EVENT`).
  - The source on which the event was created is identified on the replica by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` stores this information. See [Section 15.7.7.20, “SHOW EVENTS Statement”](#), for more information.
- The feature implementation resides on the replica in a renewable state so that if the source fails, the replica can be used as the source without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a source), query the Information Schema `EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED';
```

When promoting a replica having such events to a source, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event\_name* is the name of the event.

If more than one source was involved in creating events on this replica, and you wish to identify events that were created only on a given source having the server ID *source\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED'
AND ORIGINATOR = 'source_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED'
AND ORIGINATOR = 'source_id'
```

#### Note

`REPLICA_SIDE_DISABLED` replaces `SLAVESIDE_DISABLED`, which is deprecated.

Before enabling events that were replicated from the source, you should disable the MySQL Event Scheduler on the replica (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the replica afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new source back to being a replica, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replica, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 19.5.1.17 Replication of JSON Documents

In MySQL 9.7, it is possible to log partial updates to JSON documents (see [Partial Updates of JSON Values](#)). The logging behavior depends on the format used, as described here:

**Statement-based replication.** JSON partial updates are always logged as partial updates. This cannot be disabled when using statement-based logging.

**Row-based replication.** JSON partial updates are not logged as such by default, but instead are logged as complete documents. To enable logging of partial updates, set `binlog_row_value_options=PARTIAL_JSON`. If a replication source has this variable set, partial updates received from that source are handled and applied by a replica regardless of the replica's own setting for the variable.

### 19.5.1.18 Replication and JavaScript Stored Programs

MySQL Replication is compatible with JavaScript stored programs, provided that the MLE component is installed on each and every server in the topology, due to the following issues:

- A replica without the component installed accepts `CREATE FUNCTION` and `CREATE PROCEDURE` statements containing JavaScript code from the source, but the replica cannot execute the stored programs thus created.
- A JavaScript stored program created on a server without the component installed is not checked for validity.
- The following SQL statements cannot be executed successfully on a replica that does not have the component installed:
  - `CREATE LIBRARY`
  - `DROP LIBRARY`
  - A `CREATE FUNCTION` or `CREATE PROCEDURE` statement which contains a `USING` clause

On a server without the MLE component, each of the statements just shown is rejected with a syntax error.

This means that, when a `CREATE FUNCTION` or `CREATE PROCEDURE` statement without `USING`, and which contains invalid JavaScript code, is executed on a server without the MLE component installed, the statement succeeds, and thus is replicated. If the replica has the MLE component installed, an error is raised when the replica attempts to execute such a statement, leading to a break in replication.

In addition, when `CREATE LIBRARY`, `DROP LIBRARY`, `CREATE FUNCTION ... USING`, or `CREATE PROCEDURE ... USING` is executed on a server without the MLE component installed, the statement is always rejected because the server does not support the syntax.

For installing (or uninstalling) the MLE component on MySQL servers used in replication, it is recommended that you stop replication, install (or uninstall) the component on every server in the topology, and only then allow replication to resume. Replicating between servers in a mixed setting (that is, in which some servers have the MLE component installed and some do not) is not supported for the reasons stated in the previous paragraph.

For more information about JavaScript stored programs in MySQL, see [Section 27.3, “JavaScript Stored Programs”](#). For information about the MLE component, see [Section 7.5.7, “Multilingual Engine Component \(MLE\)”](#).

### 19.5.1.19 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 19.5.1.20 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see [Section 19.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

If you use `LOAD DATA` with `binlog_format=STATEMENT`, each replica on which the changes are to be applied creates a temporary file containing the data. The replica then uses a `LOAD DATA` statement to apply the changes. This temporary file is not encrypted, even if binary log encryption is active on the source. If encryption is required, use row-based or mixed binary logging format instead, for which replicas do not create the temporary file.

If a `PRIVILEGE_CHECKS_USER` account has been used to help secure the replication channel (see [Section 19.3.3, “Replication Privilege Checks”](#)), it is strongly recommended that you log `LOAD DATA` operations using row-based binary logging (`binlog_format=ROW`). If `REQUIRE_ROW_FORMAT` is set for the channel, row-based binary logging is required. With this logging format, the `FILE` privilege is not needed to execute the event, so do not give the `PRIVILEGE_CHECKS_USER` account this privilege. If you need to recover from a replication error involving a `LOAD DATA INFILE` operation logged in statement format, and the replicated event is trusted, you could grant the `FILE` privilege to the `PRIVILEGE_CHECKS_USER` account temporarily, removing it after the replicated event has been applied.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

### 19.5.1.21 Replication and max\_allowed\_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replicas. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the source, the source fails with an error, and the replica shuts down the replication I/O (receiver) thread. If `max_allowed_packet` is too small on the replica, this also causes the replica to stop the I/O thread.

Row-based replication sends all columns and column values for updated rows from the source to the replica, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded replica, ensure that the system variable `replica_pending_jobs_size_max` is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the source. The default setting for `replica_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the source can send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.

The replica actually accepts packets up to the limit set by its `replica_max_allowed_packet` setting, which default to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `replica_pending_jobs_size_max` controls the memory that is made available on the replica to hold incoming packets. The specified memory is shared among all the replica worker queues.

The value of `replica_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the replica workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `replica_pending_jobs_size_max` can be processed, the delay to clear the queues of all the replica workers and the wait to queue subsequent transactions can cause lag on the replica and decreased concurrency of the replica workers. `replica_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

### 19.5.1.22 Replication and MEMORY Tables

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `DELETE` or `TRUNCATE TABLE` statement for that table to the binary log. This generated event is identifiable by a comment in the binary log, and if GTIDs are in use on the server, it has a GTID assigned. The statement is always logged in statement format, even if the binary logging format is set to `ROW`, and it is written even if `read_only` or `super_read_only` mode is set on the server. Note that the replica still has outdated data in a `MEMORY` table during the interval between the source's restart and its first use of the table. To avoid this interval when a direct query to the replica could return stale data, you can set the `init_file` system variable to name a file containing statements that populate the `MEMORY` table on the source at startup.

When a replica server shuts down and restarts, its `MEMORY` tables become empty. This causes the replica to be out of synchrony with the source and may lead to other failures or cause the replica to stop:

- Row-format updates and deletes received from the source may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the source and replica.

The replica also writes a `DELETE` or `TRUNCATE TABLE` statement to its own binary log, which is passed on to any downstream replicas, causing them to empty their own `MEMORY` tables.

The safe way to restart a replica that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the source and wait until those changes have replicated to the replica. Then it is safe to restart the replica.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the replica from stopping if you set `replica_exec_mode=IDEMPOTENT` before you start the replica again. This allows the replica to continue to replicate, but its `MEMORY` tables still differ from those on the source. This is acceptable if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `replica_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `replica_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 19.5.1.40, "Replication and Variables"](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the source without doing so on the replica, it becomes possible for a table on the source to grow larger than its counterpart on the replica, leading to inserts that succeed on the source but fail on the replica with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the replica as well as on the

source, then restart replication. It is also recommended that you restart both the source and replica MySQL servers, to ensure that the new value takes complete (global) effect on each of them.

See [Section 18.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

### 19.5.1.23 Replication of the `mysql` System Schema

Data modification statements made to tables in the `mysql` schema are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to replicas using statement-based replication.

### 19.5.1.24 Replication and the Query Optimizer

It is possible for the data on the source and replica to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 19.5.1.19, “Replication and LIMIT”](#), for a detailed discussion of these.

### 19.5.1.25 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure, except where an exception is specifically allowed (see [Section 19.5.1.9, “Replication with Differing Table Definitions on Source and Replica”](#)).

Replication between tables that have different partitioning is generally not supported. This is because statements (such as `ALTER TABLE ... DROP PARTITION`) that act directly on partitions in such cases might produce different results on the source and the replica. In the case where a table is partitioned on the source but not on the replica, any statements that operate on partitions on the source's copy of the replica fail on the replica. When the replica's copy of the table is partitioned but the source's copy is not, statements that act directly on partitions cannot be run on the source without causing errors there. To avoid stopping replication or creating inconsistencies between the source and replica, always ensure that a table on the source and the corresponding replicated table on the replica are partitioned in the same way.

### 19.5.1.26 Replication and `REPAIR TABLE`

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause source and replica to lose synchronization. For this reason, in the event that a table on the source becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the source's and replica's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 19.5.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older source to a newer replica and you make use of identifiers on the source that are reserved words in the newer MySQL version running on the replica. For example, a table column named `rank` on a MySQL 5.7 source that is replicating to a MySQL 9.7 replica could cause a problem because `RANK` became a reserved word in MySQL 8.0.

Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication`. This is due to the fact that each SQL event must be parsed by

the replica prior to execution, so that the replica knows which database object or objects would be affected. Only after the event is parsed can the replica apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the source which would be regarded as reserved words by the replica, do one of the following:

- Use one or more `ALTER TABLE` statements on the source to change the names of any database objects where these names would be considered reserved words on the replica, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Keywords and Reserved Words in MySQL 8.0](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 11.2, “Schema Object Names”](#).

### 19.5.1.28 Replication and Row Searches

When a replica using row-based replication format applies an `UPDATE` or `DELETE` operation, it must search the relevant table for the matching rows. The algorithm used to carry out this process uses one of the table's indexes to carry out the search as the first choice, and a hash table if there are no suitable indexes.

The algorithm first assesses the available indexes in the table definition to see if there is any suitable index to use, and if there are multiple possibilities, which index is the best fit for the operation. The algorithm ignores the following types of index:

- Fulltext indexes.
- Hidden indexes.
- Generated indexes.
- Multi-valued indexes.
- Any index where the before-image of the row event does not contain all the columns of the index.

If there are no suitable indexes after ruling out these index types, the algorithm does not use an index for the search. If there are suitable indexes, one index is selected from the candidates, in the following priority order:

1. A primary key.
2. A unique index where every column in the index has a NOT NULL attribute. If more than one such index is available, the algorithm chooses the leftmost of these indexes.
3. Any other index. If more than one such index is available, the algorithm chooses the leftmost of these indexes.

If the algorithm is able to select a primary key or a unique index where every column in the index has a `NOT NULL` attribute, it uses this index to iterate over the rows in the `UPDATE` or `DELETE` operation. For each row in the row event, the algorithm looks up the row in the index to locate the table record to update. If no matching record is found, it returns the error `ER_KEY_NOT_FOUND` and stops the replication applier thread.

If the algorithm was not able to find a suitable index, or was only able to find an index that was non-unique or contained nulls, a hash table is used to assist in identifying the table records. The algorithm creates a hash table containing the rows in the `UPDATE` or `DELETE` operation, with the key as the full before-

image of the row. The algorithm then iterates over all the records in the target table, using the selected index if it found one, or else performing a full table scan. For each record in the target table, it determines whether that row exists in the hash table. If the row is found in the hash table, the record in the target table is updated, and the row is deleted from the hash table. When all the records in the target table have been checked, the algorithm verifies whether the hash table is now empty. If there are any unmatched rows remaining in the hash table, the algorithm returns the error `ER_KEY_NOT_FOUND` and stops the replication applier thread.

### 19.5.1.29 Replication and Source or Replica Shutdowns

It is safe to shut down a replication source server and restart it later. When a replica loses its connection to the source, the replica tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE REPLICATION SOURCE TO` statement. A replica also is able to deal with network connectivity outages. However, the replica notices the network outage only after receiving no data from the source for `replica_net_timeout` seconds. If your outages are short, you may want to decrease the value of `replica_net_timeout`. See [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

An unclean shutdown (for example, a crash) on the source side can result in the source's binary log having a final position less than the most recent position read by the replica, due to the source's binary log file not being flushed. This can cause the replica not to be able to replicate when the source comes back up. Setting `sync_binlog=1` in the source server's `my.cnf` file helps to minimize this problem because it causes the source to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the InnoDB redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a replica cleanly is safe because it keeps track of where it left off. However, be careful that the replica does not have temporary tables open; see [Section 19.5.1.32, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the replica commits and then updates `relay-log.info`. If an unexpected exit occurs between these two operations, relay log processing proceeds further than the information file indicates and the replica re-executes the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the replica updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the replica `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 19.5.1.30 Replica Errors During Replication

If a statement produces the same error (identical error code) on both the source and the replica, the error is logged, but replication continues.

If a statement produces different errors on the source and the replica, the replication SQL thread terminates, and the replica writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the source or the replica, but not both. To address the issue, connect to the replica manually and determine the cause

of the problem. `SHOW REPLICA STATUS` is useful for this. Then fix the problem and run `START REPLICA`. For example, you might need to create a nonexistent table before you can start the replica again.

**Note**

If a temporary error is recorded in the replica's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the replication SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the replica, unless the replication SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--replica-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the source, the replica expects execution of the statement to result in the same error code. If it does not, the replication SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the source and replica, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the source might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the replica would produce no such error, causing replication to stop.

Replication filter rules are applied first, prior to making any privilege or row format checks, making it possible to filter out any transactions that fail validation; no checks are performed and thus no errors are raised for transactions which have been filtered out. This means that the replica can accept only that part of the database to which a given user has been granted access (as long as any updates to this part of the database use the row-based replication format). This may be helpful when performing an upgrade or when migrating to a system or application that uses administration tables to which the inbound replication user does not have access. See also [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

### 19.5.1.31 Replication and Server SQL Mode

Using different server SQL mode settings on the source and the replica may cause the same `INSERT` statements to be handled differently on the source and the replica, leading the source and replica to diverge. For best results, you should always use the same server SQL mode on the source and on the replica. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the source and the replica is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the source's and replica's copies of a given table. It may also cause inserts into partitioned tables that succeed on the source to fail on the replica.

For more information, see [Section 7.1.11, “Server SQL Modes”](#).

### 19.5.1.32 Replication and Temporary Tables

In MySQL 9.7, when `binlog_format` is set to `ROW` or `MIXED`, statements that exclusively use temporary tables are not logged on the source, and therefore the temporary tables are not replicated. Statements that involve a mix of temporary and nontemporary tables are logged on the source only for the operations on nontemporary tables, and the operations on temporary tables are not logged. This means that there are never any temporary tables on the replica to be lost in the event of an unplanned shutdown by the

replica. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

When `binlog_format` is set to `STATEMENT`, operations on temporary tables are logged on the source and replicated on the replica, provided that the statements involving temporary tables can be logged safely using statement-based format. In this situation, loss of replicated temporary tables on the replica can be an issue. In statement-based replication mode, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements cannot be used inside a transaction, procedure, function, or trigger when GTIDs are in use on the server (that is, when the `enforce_gtid_consistency` system variable is set to `ON`). They can be used outside these contexts when GTIDs are in use, provided that `autocommit=1` is set.

Because of the differences in behavior between row-based or mixed replication mode and statement-based replication mode regarding temporary tables, you cannot switch the replication format at runtime, if the change applies to a context (global or session) that contains any open temporary tables. For more details, see the description of the `binlog_format` option.

**Safe replica shutdown when using temporary tables.** In statement-based replication mode, temporary tables are replicated except in the case where you stop the replica server (not just the replication threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the replica. If you stop the replica server, the temporary tables needed by those updates are no longer available when the replica is restarted. To avoid this problem, do not shut down the replica while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP REPLICATION SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Replica_open_temp_tables` status variable.
3. If the value is not 0, restart the replication SQL thread with `START REPLICATION SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the replica.

**Temporary tables and replication options.** By default, with statement-based replication, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replica always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

### 19.5.1.33 Replication Retries and Timeouts

The global value of the system variable `replica_transaction_retries` sets the maximum number of times for applier threads on a single-threaded or multithreaded replica to automatically retry failed transactions before stopping. Transactions are automatically retried when the SQL thread fails to execute them because of an `InnoDB` deadlock, or when the transaction's execution time exceeds the `InnoDB innodb_lock_wait_timeout` value. If a transaction has a non-temporary error that prevents it from succeeding, it is not retried.

The default setting for `replica_transaction_retries` is 10, meaning that a failing transaction with an apparently temporary error is retried 10 times before the applier thread stops. Setting the variable

to 0 disables automatic retrying of transactions. On a multithreaded replica, the specified number of transaction retries can take place on all applier threads of all channels. The Performance Schema table `replication_applier_status` shows the total number of transaction retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

The process of retrying transactions can cause lag on a replica or on a Group Replication group member, which can be configured as a single-threaded or multithreaded replica. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by the applier threads on a single-threaded or multithreaded replica. This data includes timestamps showing how long it took the applier thread to apply the last transaction from start to finish (and when the transaction currently in progress was started), and how long this was after the commit on the original source and the immediate source. The data also shows the number of retries for the last transaction and the transaction currently in progress, and enables you to identify the transient errors that caused the transactions to be retried. You can use this information to see whether transaction retries are the cause of replication lag, and investigate the root cause of the failures that led to the retries.

### 19.5.1.34 Replication and Time Zones

By default, source and replica servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both source and replica. Otherwise, statements depending on the local time on the source are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions.

Verify that your combination of settings for the system time zone (`system_time_zone`), server current time zone (the global value of `time_zone`), and per-session time zones (the session value of `time_zone`) on the source and replica is producing the correct results. In particular, if the `time_zone` system variable is set to the value `SYSTEM`, indicating that the server time zone is the same as the system time zone, this can cause the source and replica to apply different time zones. For example, a source could write the following statement in the binary log:

```
SET @@session.time_zone='SYSTEM' ;
```

If this source and its replica have a different setting for their system time zones, this statement can produce unexpected results on the replica, even if the replica's global `time_zone` value has been set to match the source's. For an explanation of MySQL Server's time zone settings, and how to change them, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

See also [Section 19.5.1.14, “Replication and System Functions”](#).

### 19.5.1.35 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap in the externalized transaction set appears when, given an ordered sequence of transactions, a transaction that is later in the sequence is applied before some other transaction that is prior in the sequence. Gaps can only appear when using a multithreaded replica.

To avoid gaps occurring on a multithreaded replica, set `replica_preserve_commit_order=ON`. This is the default, because all replicas are multithreaded by default.

Binary logging and replica update logging are not required on the replica to set `replica_preserve_commit_order=ON`, and can be disabled if wanted.

In some specific situations, as listed in the description for `replica_preserve_commit_order`, setting `replica_preserve_commit_order=ON` cannot preserve commit order on the replica, so in these cases gaps might still appear in the sequence of transactions that have been executed from the replica's relay log.

Setting `replica_preserve_commit_order=ON` does not prevent source binary log position lag.

- *Source binary log position lag.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. In this situation, `Exec_master_log_pos` is a “low-water mark” of the transactions applied, and lags behind the position of the most recently applied transaction. This can only happen on multithreaded replicas. Enabling `replica_preserve_commit_order` does not prevent source binary log position lag.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and source binary log position lag:

1. While replication threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded replica, the coordinator thread when using a multithreaded replica). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded replica, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP REPLICIA` when using a multithreaded replica. After issuing `STOP REPLICIA`, the replica waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or source binary log position lag, unless any of the cases above applies, in other words, before `STOP REPLICIA` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP REPLICIA` returns successfully.
6. If the last transaction in the relay log is only half-received and the multithreaded replica's coordinator thread has started to schedule the transaction to a worker, then `STOP REPLICIA` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP REPLICIA` when the ongoing transaction updates transactional tables only, in which case it is rolled back and `STOP REPLICIA` stops immediately. If the ongoing transaction is mixed, `STOP REPLICIA` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global setting for the system variable `rpl_stop_replica_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP REPLICIA` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The replica database is in a state that may never have existed on the source.

2. The field `Exec_master_log_pos` in `SHOW REPLICATION STATUS` is only a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE REPLICATION SOURCE TO` statements for that channel fail with an error, unless the applier threads are running and the statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-replica`, it does not record the existence of gaps; thus it prints `CHANGE REPLICATION SOURCE TO` with `RELAY_LOG_POS` set to the “low-water mark” position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-replica`).

If a replication channel has source binary log position lag but no gaps, cases 2 to 5 above apply, but case 1 does not.

The source binary log position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START REPLICATION [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `START REPLICATION` is used with `UNTIL`. `START REPLICATION UNTIL SQL_AFTER_MTS_GAPS` applies only as many transactions as needed in order to fill in the gaps. If `START REPLICATION` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

### Warning

`RESET REPLICATION` removes the relay logs and resets the replication position. Thus issuing `RESET REPLICATION` on a multithreaded replica with gaps means the replica loses any information about the gaps, without correcting the gaps. In this situation, if binary log position based replication is in use, the recovery process fails.

When GTID-based replication is in use (`GTID_MODE=ON`) and `SOURCE_AUTO_POSITION` is set for the replication channel using the `CHANGE REPLICATION SOURCE TO` statement, the old relay logs are not required for the recovery process. Instead, the replica can use GTID auto-positioning to calculate what transactions it is missing compared to the source. The process used for binary log position based replication to resolve gaps on a multithreaded replica is skipped entirely when GTID-based replication is in use. When the process is skipped, a `START REPLICATION UNTIL SQL_AFTER_MTS_GAPS` statement behaves differently, and does not attempt to check for gaps in the sequence of transactions. You can also issue `CHANGE REPLICATION SOURCE TO` statements, which are not permitted on a non-GTID replica where there are gaps.

## 19.5.1.36 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In MySQL 9.6 (and later), transactions that update both transactional tables and tables which are nontransactional or noncomposable are deprecated, and causes a deprecation warning to be written to both the client and the error log. In MySQL 9.6 only the `InnoDB` and `BLACKHOLE` storage engines are transactional and composable; `NDBCLUSTER` is transactional but not composable. This means that the only combinations of storage engines that do *not* raise the deprecation warning are those listed here:

- `InnoDB` and `BLACKHOLE`
- `MyISAM` and `Merge`

- `performance_schema` and any other storage engine
- `TempTable` and any other storage engine

In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

#### Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates *any* of the tables involved is considered a “mixed” statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is `OFF`

For more information, see [Section 19.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

#### Note

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on source and replica.** It is possible to replicate transactional tables on the source using nontransactional tables on the replica. For example, you can replicate an `InnoDB` source table as a `MyISAM` replica table. However, if you do this, there are problems if the replica is stopped in the middle of a `BEGIN ... COMMIT` block because the replica restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the source to transactional tables, such as tables that use the `InnoDB` storage engine, on the replica. In such cases, an `AUTOCOMMIT=1` statement issued on the source is replicated, thus enforcing `AUTOCOMMIT` mode on the replica.

When the storage engine type of the replica is nontransactional, transactions on the source that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the source transactional table and the replica nontransactional table. That is, such transactions can lead to source storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this, so extra care should be taken when replicating transactional tables from the source to nontransactional tables on the replicas.

**Changing the binary logging format within transactions.** The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

#### Note

For restrictions that apply specifically to XA transactions, see [Section 15.3.8.3, “Restrictions on XA Transactions”](#).

### 19.5.1.37 Replication and Triggers

With statement-based replication, triggers executed on the source also execute on the replica. With row-based replication, triggers executed on the source do not execute on the replica. Instead, the row changes on the source resulting from trigger execution are replicated and applied on the replica.

This behavior is by design. If under row-based replication the replica applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

If you want triggers to execute on both the source and the replica, perhaps because you have different triggers on the source and replica, you must use statement-based replication. However, to enable replica-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 9.7 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Multiple triggers are not supported in versions earlier than MySQL 5.7. If you upgrade servers in a replication topology that use a version earlier than MySQL 5.7, upgrade the replicas first and then upgrade the source. If an upgraded replication source server still has old replicas using MySQL versions

that do not support multiple triggers, an error occurs on those replicas if a trigger is created on the source for a table that already has a trigger with the same trigger event and action time.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see the Table Trigger Storage section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

### 19.5.1.38 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replicas still follow the rules described in [Section 15.1.42, "TRUNCATE TABLE Statement"](#) governing such tables. (Bug #36763)

### 19.5.1.39 Replication and User Name Length

The maximum length for user names in MySQL 9.7 is 32 characters. Replication of user names longer than 16 characters fails when the replica runs a version of MySQL previous to 5.7, because those versions support only shorter user names. This occurs only when replicating from a newer source to an older replica, which is not a recommended configuration.

### 19.5.1.40 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`

- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 7.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the replica always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the source. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the source without doing so on the replica can lead eventually to `Table is full` errors on the replica when trying to execute `INSERT` statements on a `MEMORY` table on the source that is thus permitted to grow larger than its counterpart on the replica. For more information, see [Section 19.5.1.22, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements does not insert the same data on the source and the replica:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 19.2.1, “Replication Formats”](#).

The following session variables are written to the binary log and honored by the replica when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both source and replica, especially when you are running MySQL on platforms with case-sensitive file systems. The `lower_case_table_names` setting can only be configured when initializing the server.

### 19.5.1.41 Replication and Views

Views are always replicated to replicas. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the replica even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

## 19.5.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from an older source to a newer replica for version combinations where we support upgrades from the source version to the replica version as described at [Section 1.3, “MySQL Releases: Innovation and LTS”](#) and [Section 3.2, “Upgrade Paths”](#). However, you might encounter difficulties when replicating from an older source to a newer replica if the source uses statements or relies on behavior no longer supported in the version of MySQL used on the replica.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple sources, regardless of the number of source or replica MySQL servers. For example, if you are using a

chained or circular replication setup, you cannot use MySQL X.Y.1, MySQL X.Y.2, and MySQL X.Y.3 concurrently, although you could use any two of these releases together.

### Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade sources and replicas that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

The server version is recorded in the binary log for each transaction for the server that originally committed the transaction (`original_server_version`), and for the server that is the immediate source of the current server in the replication topology (`immediate_server_version`).

Replication from newer sources to older replicas might be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. A source might also have optional features enabled that are not understood by older replicas, such as binary log transaction compression, where the resulting compressed transaction payloads cannot be read by a replica from a release prior to MySQL 8.0.20.

This also has significant implications for upgrading replication servers; see [Section 19.5.3, “Upgrading or Downgrading a Replication Topology”](#), for more information.

- **SQL incompatibilities.** You cannot replicate from a newer source to an older replica using statement-based replication if the statements to be replicated use SQL features available on the source but not on the replica.

However, if both the source and the replica support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the source but not on the replica, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the source is not supported on the replica.

For more information about row-based replication, see [Section 19.2.1, “Replication Formats”](#).

For more information on potential replication issues, see [Section 19.5.1, “Replication Features and Issues”](#).

## 19.5.3 Upgrading or Downgrading a Replication Topology

When you upgrade servers that participate in a replication topology, you need to take into account each server's role in the topology and look out for issues specific to replication. For general information and instructions for upgrading a MySQL Server instance, see [Chapter 3, \*Upgrading MySQL\*](#).

As explained in [Section 19.5.2, “Replication Compatibility Between MySQL Versions”](#), MySQL supports replication from an older source to a newer replica for version combinations where we support upgrades from the source version to the replica version as described at [Section 1.3, “MySQL Releases: Innovation and LTS”](#) and [Section 3.2, “Upgrade Paths”](#), but does not support replication from a source running a later release to a replica running an earlier release. A replica at an earlier release might not have the required capability to process transactions that can be handled by the source at a later release. You must therefore upgrade all of the replicas in a replication topology to the target MySQL Server release, before you upgrade the source server to the target release. In this way you will never be in the situation where a replica still at the earlier release is attempting to handle transactions from a source at the later release.

In a replication topology where there are multiple sources (multi-source replication), the use of more than two MySQL Server versions is not supported, regardless of the number of source or replica MySQL servers. For example, you cannot use MySQL X.Y.1, MySQL X.Y.2, and MySQL X.Y.3 concurrently in such a setup, although you could use any two of these releases together.

### Pre-Check Servers before Upgrade

It is possible to encounter replication difficulties when replicating from a source at an earlier release that has not yet been upgraded, to a replica at a later release that has been upgraded. This can happen if the source uses statements or relies on behavior that is no longer supported in the later release installed on the replica. You can use the MySQL Shell upgrade checker utility `util.checkForServerUpgrade()` to check MySQL 8.0 server instances for upgrade to a MySQL 8.4 release. This utility identifies configuration and stored data that is known to potentially cause upgrade problems, including features and behaviors that are no longer available in the later release. See [Upgrade Checker Utility](#) for information on the upgrade checker utility.

### Standard Upgrade Procedure

To upgrade a replication topology, follow the instructions in [Chapter 3, Upgrading MySQL](#) for each individual MySQL Server instance, using this overall procedure:

1. Upgrade the replicas first. On each replica instance:
  - Carry out the preliminary checks and steps described in [Section 3.6, “Preparing Your Installation for Upgrade”](#).
  - Shut down MySQL Server.
  - Upgrade the MySQL Server binaries or packages.
  - Restart MySQL Server.
  - MySQL Server performs the entire MySQL upgrade procedure automatically, disabling binary logging during the upgrade.
  - Restart replication using a `START REPLICAS`.
2. If there are multiple layers of replicas (replicas-of-replicas) start upgrading the replicas that are farthest away from the source, performing the upgrade in a bottom-up fashion.
3. When all replicas have upgraded and only the source remains, perform a switch-over to one of the replicas. In other words, stop client updates on the source, wait for at least one replica to apply all changes, reconfigure the replication topology so that replica becomes the source and that the source is left outside the replication topology. Upgrade the old source according to the procedure for a single server, and then reinsert it into the topology.

If you need to downgrade the servers in a replication topology, the source must be downgraded before the replicas are downgraded. On the replicas, you must ensure that the binary log and relay log have been fully processed, and purge them before proceeding with the downgrade.

### Rolling Downgrade Procedure

1. Stop the updates.
2. Wait for replicas to receive all updates. It is not necessary to wait for them to apply all changes. If they have not applied all changes, leave their applier running so they can process the received transactions in the background.

3. Downgrade the source server, following the instructions for single server downgrade.
4. Insert the downgraded source server in the topology again.
5. Allow updates again.
6. Wait until all replicas have applied all remaining transactions from the previous primary.
7. For each replica, take out the replica from the topology, wait for it to apply all its relay log, downgrade it following the instructions for a single server downgrade, and reinsert it back into the topology. If there are multiple levels of replicas (replicas-of-replicas) then downgrade top-down starting with the replicas nearest to the source server.

## 19.5.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the source has binary logging enabled by issuing a `SHOW BINARY LOG STATUS` statement. Binary logging is enabled by default. If binary logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are not running the source with any settings that disable binary logging, such as the `--skip-log-bin` option.
- Verify that the `server_id` system variable was set at startup on both the source and replica and that the ID value is unique on each server.
- Verify that the replica is running. Use `SHOW REPLICA STATUS` to check whether the `Replica_IO_Running` and `Replica_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the replica server. For example, `--skip-replica-start` prevents the replication threads from starting until you issue a `START REPLICA` statement.
- If the replica is running, check whether it established a connection to the source. Use `SHOW PROCESSLIST`, find the I/O (receiver) and SQL (applier) threads and check their `State` column to see what they display. See [Section 19.2.3, “Replication Threads”](#). If the receiver thread state says `Connecting to master`, check the following:
  - Verify the privileges for the replication user on the source.
  - Check that the host name of the source is correct and that you are using the correct port to connect to the source. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check the configuration file to see whether the `skip_networking` system variable has been enabled on the source or replica to disable networking. If so, comment the setting or remove it.
  - If the source has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the source by using `ping` or `traceroute/tracert` to reach the host.
- If the replica was running previously but has stopped, the reason usually is that some statement that succeeded on the source failed on the replica. This should never happen if you have taken a proper snapshot of the source, and never modified the data on the replica outside of the replication threads. If the replica stops unexpectedly, it is a bug or you have encountered one of the known

replication limitations described in [Section 19.5.1, “Replication Features and Issues”](#). If it is a bug, see [Section 19.5.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.

- If a statement that succeeded on the source refuses to run on the replica, try the following procedure if it is not feasible to do a full database resynchronization by deleting the replica's databases and copying a new snapshot from the source:

1. Determine whether the affected table on the replica is different from the source table. Try to understand how this happened. Then make the replica's table identical to the source's and run `START REPLICA`.
2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the source.
3. If you decide that the replica can skip the next statement from the source, issue the following statements:

```
mysql> SET GLOBAL sql_replica_skip_counter = N;  
mysql> START REPLICA;
```

The value of *N* should be 1 if the next statement from the source does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the source.

4. If you are sure that the replica started out perfectly synchronized with the source, and that no one has updated the tables involved outside of the replication threads, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 19.5.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the replica outside of the replication threads, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the replication thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Ensure that the replica is running with binary logging enabled (the `log_bin` system variable), and with the `--log-replica-updates` option enabled, which causes the replica to log the updates that it receives from the source into its own binary logs. These settings are the defaults.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the source

- All binary log files from the replica
  - The output of `SHOW BINARY LOG STATUS` from the source at the time you discovered the problem
  - The output of `SHOW REPLICATION STATUS` from the replica at the time you discovered the problem
  - Error logs from the source and the replica
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW REPLICATION STATUS`.

```
$> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

---

This chapter explains Group Replication in MySQL 9.7, and how to install, configure and monitor groups. MySQL Group Replication enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

Group Replication guarantees that the database service is continuously available. However, it is important to understand that if one of the group members becomes unavailable, the clients connected to that group member must be redirected, or failed over, to a different server in the group, using a connector, load balancer, router, or some form of middleware. Group Replication does not have an inbuilt method to do this. For example, see [MySQL Router 9.7](#).

Group Replication is provided as a plugin to MySQL Server. You can follow the instructions in this chapter to configure the plugin on each of the server instances that you want in the group, start up the group, and monitor and administer the group. An alternative way to deploy a group of MySQL server instances is by using InnoDB Cluster.

#### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

MySQL 9.7 and later support a number of MySQL components for use with MySQL Group Replication. See [Section 7.5.6, “Replication Components”](#), for more information.

This chapter is structured as follows:

- [Section 20.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.
- [Section 20.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 20.3, “Requirements and Limitations”](#) explains architecture and setup requirements and limitations for Group Replication.
- [Section 20.4, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 20.5, “Group Replication Operations”](#) explains how to work with a group.
- [Section 20.6, “Group Replication Security”](#) explains how to secure a group.
- [Section 20.7, “Group Replication Performance and Troubleshooting”](#) explains how to fine tune performance for a group.

- [Section 20.8, “Upgrading Group Replication”](#) explains how to upgrade a group.
- [Section 20.9, “Group Replication Variables”](#) is a reference for the system variables specific to Group Replication.
- [Section 20.10, “Frequently Asked Questions”](#) provides answers to some technical questions about deploying and operating Group Replication.

## 20.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

### 20.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

### 20.1.1.1 Source to Replica Replication

Traditional MySQL [Replication](#) provides a simple source to replica approach to replication. The source is the primary, and there are one or more replicas, which are secondaries. The source applies transactions, commits them and then they are later (thus asynchronously) sent to the replicas to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

**Figure 20.1 MySQL Asynchronous Replication**

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the primary waits, at apply time, for the secondary to acknowledge that it has *received* the transaction. Only then does the primary resume the commit operation.

**Figure 20.2 MySQL Semisynchronous Replication**

**Key**  
 ACK = Acknowledged

In the two pictures there is a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). The arrows between the different instances represent messages exchanged between servers or messages exchanged between servers and the client application.

### 20.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. A replication group is a set of servers, each of which has a complete copy of the data (a shared-nothing replication scheme), which interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-source update everywhere replication protocol. A replication group is formed by multiple servers; each server in the group may execute transactions independently at any time. Read/write transactions commit only after they have been approved by the group. In other words, for any read/write transaction the group needs to decide whether it commits or not, so the commit operation is not a unilateral decision from the originating server. Read-only transactions need no coordination within the group and commit immediately.

When a read/write transaction is ready to commit at the originating server, the server atomically broadcasts the write values (the rows that were changed) and the corresponding write set (the unique identifiers of the rows that were updated). Because the transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. All servers therefore receive the same set of transactions in the same order, and a global total order is established for the transactions.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting and comparing the write sets of two different and concurrent transactions, in a process called *certification*. During certification, conflict detection is carried out at row level: if two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The conflict resolution procedure states that the transaction that was ordered first commits on all servers, and the transaction ordered second aborts, and is therefore rolled back on the originating server and dropped by the other servers in the group. For example, if t1 and t2 execute concurrently at different sites, both changing the same row, and t2 is ordered before t1, then t2 wins the conflict and t1 is rolled back. This is in fact a distributed first commit wins rule. Note that if two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server, where they have a chance to synchronize on the local lock manager instead of being rolled back as a result of certification.

For applying and externalizing the certified transactions, Group Replication permits servers to deviate from the agreed order of the transactions if this does not break consistency and validity. Group Replication is an eventual consistency system, meaning that as soon as the incoming traffic slows down or stops, all group members have the same data content. While traffic is flowing, transactions can be externalized in a slightly different order, or externalized on some members before the others. For example, in multi-primary mode, a local transaction might be externalized immediately following certification, although a remote transaction that is earlier in the global order has not yet been applied. This is permitted when the certification process has established that there is no conflict between the transactions. In single-primary mode, on the primary server, there is a small chance that concurrent, non-conflicting local transactions might be committed and externalized in a different order from the global order agreed by Group Replication. On the secondaries, which do not accept writes from clients, transactions are always committed and externalized in the agreed order.

The following figure depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

Figure 20.3 MySQL Group Replication Protocol

## 20.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server failover, and the multi-source update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of an unexpected server exit, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see [MySQL Router 9.7](#).

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

## Example Use Cases

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to asynchronous Source-Replica replication* - In certain situations, using a single source server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

### 20.1.3 Multi-Primary and Single-Primary Modes

Group Replication operates either in single-primary mode or in multi-primary mode. The group's mode is a group-wide configuration setting, specified by the `group_replication_single_primary_mode` system variable, which must be the same on all members. `ON` means single-primary mode, which is the default mode, and `OFF` means multi-primary mode. It is not possible to have members of the group deployed in different modes, for example one member configured in multi-primary mode while another member is in single-primary mode.

You cannot change the value of `group_replication_single_primary_mode` manually while Group Replication is running. You can use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to move a group from one mode to another while Group Replication is still running. These functions manage the process of changing the group's mode and ensure the safety and consistency of your data. In earlier releases, to change the group's mode you must stop Group Replication and change the value of `group_replication_single_primary_mode` on all members. Then carry out a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) to implement the change to the new operating configuration. You do not need to restart the servers.

Regardless of the deployed mode, Group Replication does not handle client-side failover. That must be handled by a middleware framework such as [MySQL Router 9.7](#), a proxy, a connector, or the application itself.

#### 20.1.3.1 Single-Primary Mode

In single-primary mode (`group_replication_single_primary_mode=ON`) the group has a single primary server that is set to read/write mode. All the other members in the group are set to read-only mode (with `super_read_only=ON`). The primary typically bootstraps the entire group. All other servers that join the group learn about the primary server and are automatically set to read-only mode.

In single-primary mode, Group Replication enforces that only a single server writes to the group, so compared to multi-primary mode, consistency checking can be less strict and DDL statements do not need to be handled with any extra care. The option `group_replication_enforce_update_everywhere_checks` enables or disables strict consistency checks for a group. When deploying in single-primary mode, or changing the group to single-primary mode, this system variable must be set to `OFF`.

The member that is designated as the primary server can change in the following ways:

- If the existing primary leaves the group, whether voluntarily or unexpectedly, a new primary is elected automatically.

- You can appoint a specific member as the new primary using the `group_replication_set_as_primary()` function.
- If you use the `group_replication_switch_to_single_primary_mode()` function to change a group that was running in multi-primary mode to run in single-primary mode, a new primary is elected automatically, or you can appoint the new primary by specifying it with the function.

When a new primary server is elected (automatically or manually), it is automatically set to read/write, and the other group members remain as secondaries, and as such, read-only. The following diagram shows this process:

**Figure 20.4 New Primary Election**

When a new primary is chosen, it might have a backlog of changes that had been applied on the old primary but have not yet been applied on the new one. In this case, until the new primary catches up with the old one, read/write transactions might result in conflicts and be rolled back, and read-only transactions might result in stale reads. The Group Replication flow control mechanism minimizes the difference between fast and slow members, and so reduces the chances of this happening if it is activated and properly tuned. For more information, see [Section 20.7.2, “Flow Control”](#). You can also use the `group_replication_consistency` system variable to set the group's level of transaction consistency to prevent this issue. Setting this variable to `BEFORE_ON_PRIMARY_FAILOVER` (the default) or any higher consistency level holds new transactions on a newly elected primary until the backlog has been applied.

For more information on transaction consistency, see [Section 20.5.3, “Transaction Consistency Guarantees”](#). If flow control and transaction consistency guarantees are not used for a group, it is a good practice to wait for the new primary to apply its replication-related relay log before re-routing client applications to it.

## Primary Election Algorithm

The automatic primary member election process involves each member looking at the new view of the group, ordering the potential new primary members, and choosing the member that qualifies as the most suitable. Each member makes its own decision locally, following the primary election algorithm in its MySQL Server release. Because all members must reach the same decision, members adapt their primary election algorithm if other group members are running lower MySQL Server versions, so that they have the same behavior as the member with the lowest MySQL Server version in the group.

The factors considered by members when electing a primary, in order, are as follows:

1. The first factor considered is which member or members are running the lowest MySQL Server version. All group members are first ordered by the patch version of their release.
2. If more than one member is running the lowest MySQL Server version, the second factor considered is the member weight of each of those members, as specified by the `group_replication_member_weight` system variable on the member.

The `group_replication_member_weight` system variable specifies a number in the range 0-100. All members default to a weight of 50, so set a weight below this to lower their ordering, and a weight above it to increase their ordering. You can use this weighting function to prioritize the use of better hardware or to ensure failover to a specific member during scheduled maintenance of the primary.

3. If more than one member is running the lowest MySQL Server version, and more than one of those members has the highest member weight (or member weighting is being ignored), the third factor considered is the lexicographical order of the generated server UUIDs of each member, as specified by the `server_uuid` system variable. The member with the lowest server UUID is chosen as the primary. This factor acts as a guaranteed and predictable tie-breaker so that all group members reach the same decision if it cannot be determined by any important factors.

## Finding the Primary

To find out which server is currently the primary when deployed in single-primary mode, use the `MEMBER_ROLE` column in the `performance_schema.replication_group_members` table. For example:

```
mysql> SELECT MEMBER_HOST, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

MEMBER_HOST	MEMBER_ROLE
remote1.example.com	PRIMARY
remote2.example.com	SECONDARY
remote3.example.com	SECONDARY

### 20.1.3.2 Multi-Primary Mode

In multi-primary mode (`group_replication_single_primary_mode=OFF`) no member has a special role. Any member that is compatible with the other group members is set to read/write mode when joining the group, and can process write transactions, even if they are issued concurrently.

If a member stops accepting write transactions, for example, in the event of an unexpected server exit, clients connected to it can be redirected, or failed over, to any other member that is in read/write mode. Group Replication does not handle client-side failover itself, so you need to arrange this using a middleware framework such as [MySQL Router 9.7](#), a proxy, a connector, or the application itself. [Figure 20.5, “Client Failover”](#) shows how clients can reconnect to an alternative group member if a member leaves the group.

Figure 20.5 Client Failover

Group Replication is an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. While traffic is flowing, transactions can be externalized on some members before the others, especially if some members have less write throughput than others, creating the possibility of stale reads. In multi-primary mode, slower members can also build up an excessive backlog of transactions to certify and apply, leading to a greater risk of conflicts and certification failure. To limit these issues, you can activate and tune Group Replication's flow control mechanism to minimize the difference between fast and slow members. For more information on flow control, see [Section 20.7.2, "Flow Control"](#).

If you want transaction consistency guaranteed for every transaction in the group, you can do this using the `group_replication_consistency` system variable. You can choose a setting that suits the workload of your group and your priorities for data reads and writes, taking into account the performance impact of the synchronization required to increase consistency. You can also set the system variable for individual sessions to protect particularly concurrency-sensitive transactions. For more information on transaction consistency, see [Section 20.5.3, "Transaction Consistency Guarantees"](#).

## Transaction Checks

When a group is deployed in multi-primary mode, transactions are checked to ensure they are compatible with the mode. The following strict consistency checks are made when Group Replication is deployed in multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then its commit fails when synchronizing itself with the group.

The checks are controlled by the `group_replication_enforce_update_everywhere_checks` system variable. In multi-primary mode, the system variable should normally be set to `ON`, but the checks can optionally be deactivated by setting the system variable to `OFF`. When deploying in single-primary mode, the system variable must be set to `OFF`.

## Data Definition Statements

In a Group Replication topology in multi-primary mode, care needs to be taken when executing data definition statements, also commonly known as data definition language (DDL).

MySQL 9.7 supports atomic Data Definition Language (DDL) statements, where the complete DDL statement is either committed or rolled back as a single atomic transaction. DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a `COMMIT` before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as `START TRANSACTION ... COMMIT`, or combined with other statements within the same transaction.

Group Replication is based on an optimistic replication paradigm, where statements are optimistically executed and rolled back later if necessary. Each server executes without securing group agreement first. Therefore, more care needs to be taken when replicating DDL statements in multi-primary mode. If you make schema changes (using DDL) and changes to the data that an object contains (using DML) for the same object, the changes need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency when operations are interrupted or only partially completed. If the group is deployed in single-primary mode this issue does not occur, because all changes are performed through the same server, the primary.

For more information about atomic DDL support, see [Section 15.1.1, “Atomic Data Definition Statement Support”](#).

## Version Compatibility

For optimal compatibility and performance, all members of a group should run the same version of MySQL Server and therefore of Group Replication. In multi-primary mode, this is more significant because all members would normally join the group in read/write mode. If a group includes members running more than one MySQL Server version, there is a potential for some members to be incompatible with others, because they support functions others do not, or lack functions others have. To guard against this, when a new member joins (including a former member that has been upgraded and restarted), the member carries out compatibility checks against the rest of the group.

One result of these compatibility checks is particularly important in multi-primary mode. If a joining member is running a higher MySQL Server version than the lowest version that the existing group members are running, it joins the group but remains in read-only mode. (In a group that is running in single-primary mode, new members default to read-only in any case.) Members take into account the major.minor.release version of the MySQL software (and thus, of the Group Replication plugin) when checking their compatibility.

In a group running in multi-primary mode with members that use different MySQL Server versions, Group Replication automatically manages their read/write and read-only status. If a member leaves the group, the members running the version that is now the lowest are automatically set to read/write mode. When you change a group that was running in single-primary mode to run in multi-primary mode, using the function `group_replication_switch_to_multi_primary_mode()`, Group Replication automatically sets members to the correct mode. Members are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group, and members running the lowest version are placed in read/write mode.

For full information on version compatibility in a group and how this influences the behavior of a group during an upgrade process, see [Section 20.8.1, “Combining Different Member Versions in a Group”](#).

## 20.1.4 Group Replication Services

This section introduces some of the services that Group Replication builds on.

### 20.1.4.1 Group Membership

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically.

Group Replication has a group membership service that defines which servers are online and participating in the group. The list of online servers is referred to as a *view*. Every server in the group has a consistent view of which servers are the members participating actively in the group at a given moment in time.

Group members must agree not only on transaction commits, but also on which is the current view. If existing members agree that a new server should become part of the group, the group is reconfigured to integrate that server in it, which triggers a view change. If a server leaves the group, either voluntarily or not, the group dynamically rearranges its configuration and a view change is triggered.

In the case where a member leaves the group voluntarily, it first initiates a dynamic group reconfiguration, during which all members have to agree on a new view without the leaving server. However, if a member leaves the group involuntarily, for example because it has stopped unexpectedly or the network connection is down, it cannot initiate the reconfiguration. In this situation, Group Replication's failure detection mechanism recognizes after a short period of time that the member has left, and a reconfiguration of the group without the failed member is proposed. As with a member that leaves voluntarily, the reconfiguration requires agreement from the majority of servers in the group. However, if the group is not able to reach agreement, for example because it partitioned in such a way that there is no majority of servers online, the system is not able to dynamically change the configuration, and blocks to prevent a split-brain situation. This situation requires intervention from an administrator.

It is possible for a member to go offline for a short time, then attempt to rejoin the group again before the failure detection mechanism has detected its failure, and before the group has been reconfigured to remove the member. In this situation, the rejoining member forgets its previous state, but if other members send it messages that are intended for its pre-crash state, this can cause issues including possible data inconsistency. If a member in this situation participates in XCom's consensus protocol, it could potentially cause XCom to deliver different values for the same consensus round, by making a different decision before and after failure.

To counter this possibility, MySQL Group Replication checks for the situation where a new incarnation of the same server is trying to join the group while its old incarnation (with the same address and port number) is still listed as a member. The new incarnation is blocked from joining the group until the old incarnation can be removed by a reconfiguration. Note that if a waiting period has been added by the `group_replication_member_expel_timeout` system variable to allow additional time for members to reconnect with the group before they are expelled, a member under suspicion can become active in the group again as its current incarnation if it reconnects to the group before the suspicion times out. When a member exceeds the expel timeout and is expelled from the group, or when Group Replication is stopped on the server by a `STOP GROUP_REPLICATION` statement or a server failure, it must rejoin as a new incarnation.

### 20.1.4.2 Failure Detection

Group Replication's failure detection mechanism is a distributed service which is able to identify that a server in the group is not communicating with the others, and is therefore suspected of being out of service. If the group's consensus is that the suspicion is probably true, the group takes a coordinated decision to expel the member. Expelling a member that is not communicating is necessary because the group needs a majority of its members to agree on a transaction or view change. If a member is not

participating in these decisions, the group must remove it to increase the chance that the group contains a majority of correctly working members, and can therefore continue to process transactions.

In a replication group, each member has a point-to-point communication channel to each other member, creating a fully connected graph. These connections are managed by the group communication engine (XCom, a Paxos variant) and use TCP/IP sockets. One channel is used to send messages to the member and the other channel is used to receive messages from the member. If a member does not receive messages from another member for 5 seconds, it suspects that the member has failed, and lists the status of that member as `UNREACHABLE` in its own Performance Schema table `replication_group_members`. Usually, two members will suspect each other of having failed because they are each not communicating with the other. It is possible, though less likely, that member A suspects member B of having failed but member B does not suspect member A of having failed - perhaps due to a routing or firewall issue. A member can also create a suspicion of itself. A member that is isolated from the rest of the group suspects that all the others have failed.

If a suspicion lasts for more than 10 seconds, the suspecting member tries to propagate its view that the suspect member is faulty to the other members of the group. A suspecting member only does this if it is a notifier, as calculated from its internal XCom node number. If a member is actually isolated from the rest of the group, it might attempt to propagate its view, but that will have no consequences as it cannot secure a quorum of the other members to agree on it. A suspicion only has consequences if a member is a notifier, and its suspicion lasts long enough to be propagated to the other members of the group, and the other members agree on it. In that case, the suspect member is marked for expulsion from the group in a coordinated decision, and is expelled after the waiting period set by the `group_replication_member_expel_timeout` system variable expires and the expelling mechanism detects and implements the expulsion.

Where the network is unstable and members frequently lose and regain connection to each other in different combinations, it is theoretically possible for a group to end up marking all its members for expulsion, after which the group would cease to exist and have to be set up again. To counter this possibility, the Group Replication Group Communication System (GCS) tracks the group members that have been marked for expulsion, and treats them as if they were in the group of suspected members when deciding if there is a majority. This ensures at least one member remains in the group and the group can continue to exist. When an expelled member has actually been removed from the group, GCS removes its record of having marked the member for expulsion, so that the member can rejoin the group if it is able to do so.

For information on the Group Replication system variables that you can configure to specify the responses of working group members to failure situations, and the actions taken by group members that are suspected of having failed, see [Section 20.7.7, “Responses to Failure Detection and Network Partitioning”](#).

### 20.1.4.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers ( $n$ ) needed to tolerate  $f$  failures is then  $n = 2 \times f + 1$ .

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

---

Group Size	Majority	Instant Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2
7	4	3

#### 20.1.4.4 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through Performance Schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 20.4, “Monitoring Group Replication”](#).

#### 20.1.5 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

Figure 20.6 Group Replication Plugin Block Diagram

The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions

on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, managing the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.

The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see [Section 20.1, “Group Replication Background”](#)). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

## 20.2 Getting Started

MySQL Group Replication is provided as a plugin for the MySQL server; each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three members.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

### 20.2.1 Deploying Group Replication in Single-Primary Mode

Each of the MySQL server instances in a group can run on an independent physical host machine, which is the recommended way to deploy Group Replication. This section explains how to create a replication group with three MySQL Server instances, each running on a different host machine. See [Section 20.2.2, “Deploying Group Replication Locally”](#) for information about deploying multiple MySQL server instances running Group Replication on the same host machine, for example for testing purposes.

Figure 20.7 Group Architecture

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

### 20.2.1.1 Deploying Instances for Group Replication

The first step is to deploy at least three instances of MySQL Server, this procedure demonstrates using multiple hosts for the instances, named s1, s2, and s3. It is assumed that MySQL Server is installed on each host (see [Chapter 2, \*Installing MySQL\*](#)). The Group Replication plugin is provided with MySQL Server 9.7; no additional software is required, although the plugin must be installed in the running MySQL server. See [Section 20.2.1.1, “Deploying Instances for Group Replication”](#); for additional information, see [Section 7.6, “MySQL Server Plugins”](#).

In this example, three instances are used for the group, which is the minimum number of instances to create a group. Adding more instances increases the fault tolerance of the group. For example if the group consists of three members, in event of failure of one instance the group can continue. But in the event of another failure the group can no longer continue processing write transactions. By adding more instances, the number of servers which can fail while the group continues to process transactions also

increases. The maximum number of instances which can be used in a group is nine. For more information see [Section 20.1.4.2, “Failure Detection”](#).

### 20.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 20.3, “Requirements and Limitations”](#).

- [Storage Engines](#)
- [Replication Framework](#)
- [Group Replication Settings](#)

#### Storage Engines

For Group Replication, data must be stored in the InnoDB transactional storage engine (for details of why, see [Section 20.3.1, “Group Replication Requirements”](#)). The use of other storage engines, including the temporary `MEMORY` storage engine, might cause errors in Group Replication. Set the `disabled_storage_engines` system variable as follows to prevent their use:

```
disabled_storage_engines="MyISAM, BLACKHOLE, FEDERATED, ARCHIVE, MEMORY"
```

#### Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
```

These settings configure the server to use the unique identifier number 1, to enable [Section 19.1.3, “Replication with Global Transaction Identifiers”](#), and to allow execution of only statements that can be safely logged using a GTID.

This setting disables checksums for events written to the binary log, which default to being enabled. Group Replication in MySQL 9.7 supports the presence of checksums in the binary log and can use them to verify the integrity of events on some channels, so you can use the default setting. For more details, see [Section 20.3.2, “Group Replication Limitations”](#).

See also [Section 20.3.1, “Group Replication Requirements”](#).

#### Group Replication Settings

At this point the option file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s1:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group=off
```

- `plugin-load-add` adds the Group Replication plugin to the list of plugins which the server loads at startup. This is preferable in a production deployment to installing the plugin manually.
- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa".

The value of `group_replication_group_name` must be a valid UUID. You can use `SELECT UUID()` to generate one. This UUID forms part of the GTIDs that are used when transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

- Configuring the `group_replication_start_on_boot` variable to `off` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to `on` so that Group Replication starts automatically upon server boot.
- Configuring `group_replication_local_address` sets the network address and port which the member uses for internal communication with other members in the group. Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant).

#### Important

The group replication local address must be different to the host name and port used for SQL client connections, which are defined by MySQL Server's `hostname` and `port` system variables. It must not be used for client applications. It must be only be used for internal communication between the members of the group while running Group Replication.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses; a group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

The recommended port for `group_replication_local_address` is 33061. This is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, as demonstrated in this tutorial. Alternatively you can use the same host name or IP address for all members as long as the ports are all different, for example as shown in [Section 20.2.2, “Deploying Group Replication Locally”](#).

The connection that an existing member offers to a joining member for Group Replication's distributed recovery process is not the network address configured by `group_replication_local_address`. Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port`; they may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For more details, see [Section 20.5.4.1, “Connections for Distributed Recovery”](#).

#### Important

Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema

table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server's `report_host` system variable to configure a unique host name to be externalized by each of the servers.

- Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed in the Performance Schema table `replication_group_members`. Usually the `group_replication_group_seeds` list contains the `hostname:port` of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

### Important

The `hostname:port` listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the `hostname:port` used for SQL client connections, which is shown for example in the Performance Schema table `replication_group_members`.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

### Warning

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they might not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It might work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

A joining member must communicate with a seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not. In this case, even though s1 is the first member of the group we set this variable to off in the option file. Instead we configure `group_replication_bootstrap_group` when the instance is running, to ensure that only one member actually bootstraps the group.

**Important**

The `group_replication_bootstrap_group` variable must only be enabled on one server instance belonging to a group at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Always set `group_replication_bootstrap_group=off` after the first server instance comes online.

The system variables described in this tutorial are the required configuration settings to start a new member, but further system variables are also available to configure group members. These are listed in [Section 20.9, “Group Replication Variables”](#).

**Important**

A number of system variables, some specific to Group Replication and others not, are group-wide configuration settings that must have the same value on all group members. If the group members have a value set for one of these system variables, and a joining member has a different value set for it, the joining member cannot join the group and an error message is returned. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group. These system variables are all identified in [Section 20.9, “Group Replication Variables”](#).

### 20.2.1.3 User Credentials For Distributed Recovery

Group Replication uses a distributed recovery process to synchronize group members when joining them to the group. Distributed recovery involves transferring transactions from a donor's binary log to a joining member using a replication channel named `group_replication_recovery`. You must therefore set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role too. For a complete description of distributed recovery, see [Section 20.5.4, “Distributed Recovery”](#).

The same replication user must be used for distributed recovery on every group member. The process of creating the replication user for distributed recovery can be captured in the binary log, and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging before creating the replication user, and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. If you do this, ensure you re-enable binary logging once you have configured the user.

**Important**

If distributed recovery connections for your group use SSL, the replication user must be created on each server *before* the joining member connects to the donor. For instructions to set up SSL for distributed recovery connections and create a replication user that requires SSL, see [Section 20.6.3, “Securing Distributed Recovery Connections”](#)

### Important

By default, users created in MySQL 8 use [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#). If the replication user for distributed recovery uses the caching SHA-2 authentication plugin, and you are *not* using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. You can either copy the public key of the replication user to the joining member, or configure the donors to provide the public key when requested. For instructions to do this, see [Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

To create the replication user for distributed recovery, follow these steps:

1. Start the MySQL server instance, then connect a client to it.
2. If you want to disable binary logging in order to create the replication user separately on each instance, do so by issuing the following statement:

```
mysql> SET SQL_LOG_BIN=0;
```

3. Create a MySQL user with the following privileges:
  - `REPLICATION SLAVE`, which is required for making a distributed recovery connection to a donor to retrieve data.
  - `CONNECTION_ADMIN`, which ensures that Group Replication connections are not terminated if one of the servers involved is placed in offline mode.
  - `BACKUP_ADMIN`, if the servers in the replication group are set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)). This privilege is required for a member to act as the donor in a cloning operation for distributed recovery.
  - `GROUP_REPLICATION_STREAM`, if the MySQL communication stack is in use for the replication group (see [Section 20.6.1, “Communication Stack for Connection Security Management”](#)). This privilege is required for the user account to be able to establish and maintain connections for Group Replication using the MySQL communication stack.

In this example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password:

```
mysql> CREATE USER rpl_user@%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

4. If you disabled binary logging, enable it again as soon as you have created the user, by issuing the following statement:

```
mysql> SET SQL_LOG_BIN=1;
```

5. When you have created the replication user, you must supply the user credentials to the server for use with distributed recovery. You can do this by setting the user credentials as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement. Alternatively, you can specify the user credentials for distributed recovery in a `START GROUP_REPLICATION` statement.
  - User credentials set using `CHANGE REPLICATION SOURCE TO` are stored in plain text in the replication metadata repositories on the server. They are applied whenever Group Replication is

started, including automatic starts if the `group_replication_start_on_boot` system variable is set to `ON`.

- User credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. You must issue a `START GROUP_REPLICATION` statement to provide the credentials again, so you cannot start Group Replication automatically with these credentials. This method of specifying the user credentials helps to secure the Group Replication servers against unauthorized access.

For more information on the security implications of each method of providing the user credentials, see [Providing Replication User Credentials Securely](#). If you choose to provide the user credentials using a `CHANGE REPLICATION SOURCE TO` statement, issue the following statement on the server instance now, replacing `rpl_user` and `password` with the values used when creating the user:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

### 20.2.1.4 Launching Group Replication

It is first necessary to ensure that the Group Replication plugin is installed on server `s1`. If you used `plugin_load_add='group_replication.so'` in the option file then the Group Replication plugin is already installed, and you can proceed to the next step. Otherwise, you must install the plugin manually; to do this, connect to the server using the `mysql` client, and issue the SQL statement shown here:

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name                | Status | Type                | Library                | License                |
+-----+-----+-----+-----+-----+
| binlog              | ACTIVE | STORAGE ENGINE     | NULL                   | PROPRIETARY           |
| (...)
| group_replication  | ACTIVE | GROUP REPLICATION | group_replication.so  | PROPRIETARY           |
+-----+-----+-----+-----+-----+
```

### 20.2.1.5 Bootstrapping the Group

The process of starting a group for the first time is called bootstrapping. You use the `group_replication_bootstrap_group` system variable to bootstrap a group. The bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the `group_replication_bootstrap_group` option was not stored in the instance's option file. If it is saved in the option file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`. Therefore to safely bootstrap the group, connect to `s1` and issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Or if you are providing user credentials for distributed recovery in the `START GROUP_REPLICATION` statement, issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
```

## Deploying Group Replication in Single-Primary Mode

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
+-----+-----+-----+-----+-----+
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | s1 | 3306 | ONLINE |
+-----+-----+-----+-----+-----+
1 row in set (0.0108 sec)
```

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `s1` listening for client connections on port `3306`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | Luis |
+-----+-----+

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info |
+-----+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 1 | 123 | Server ver: 9.7.0-log, Binlog ver: 4 |
| binlog.000001 | 123 | Previous_gtid | 1 | 150 | |
| binlog.000001 | 150 | Gtid | 1 | 211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 211 | Query | 1 | 270 | BEGIN |
| binlog.000001 | 270 | View_change | 1 | 369 | view_id=14724817264259180:1 |
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT |
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 495 | Query | 1 | 585 | CREATE DATABASE test |
| binlog.000001 | 585 | Gtid | 1 | 646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 646 | Query | 1 | 770 | use `test`; CREATE TABLE t1 (c1 INT PRIMARY |
| binlog.000001 | 770 | Gtid | 1 | 831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 831 | Query | 1 | 899 | BEGIN |
| binlog.000001 | 899 | Table_map | 1 | 942 | table_id: 108 (test.t1) |
| binlog.000001 | 942 | Write_rows | 1 | 984 | table_id: 108 flags: STMT_END_F |
| binlog.000001 | 984 | Xid | 1 | 1011 | COMMIT /* xid=38 */ |
+-----+-----+-----+-----+-----+-----+-----+
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log, so it can be used for distributed recovery by state transfer from a donor's binary log.

### 20.2.1.6 Adding Instances to the Group

At this point, the group has one member in it, server `s1`, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

## Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the `server_id`.

```
[mysqld]

#
# Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
# Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON

#
# Group Replication configuration
#
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s2:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server. Then configure the distributed recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. This member needs to have the same replication user configured in [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#). If you are relying on distributed recovery to configure the user on all members, when s2 connects to the seed s1 the replication user is replicated or cloned to s1. If you did not have binary logging enabled when you configured the user credentials on s1, and a remote cloning operation is not used for state transfer, you must create the replication user on s2. In this case, connect to s2 and issue:

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

If you are providing user credentials using a `CHANGE REPLICATION SOURCE TO`, issue the following statement after that:

```
CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user', SOURCE_PASSWORD='password' \
FOR CHANNEL 'group_replication_recovery';
```

### Tip

If you are using the caching SHA-2 authentication plugin (the default), see [Replication User With The Caching SHA-2 Authentication Plugin](#).

If necessary, install the Group Replication plugin, see [Section 20.2.1.4, “Launching Group Replication”](#).

Start Group Replication and s2 starts the process of joining the group.

```
mysql> START GROUP_REPLICATION;
```

If you are providing user credentials for distributed recovery as part of `START GROUP_REPLICATION`, you can do so like this:

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

Unlike the previous steps that were the same as those executed on `s1`, here there is a difference in that you do *not* need to bootstrap the group because the group already exists. In other words on `s2` `group_replication_bootstrap_group` is set to `OFF`, and you do not issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server `s1`. At this point server `s2` only needs to be added to the already existing group.

### Tip

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to `ON` in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as a read/write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when `super_read_only` is set to `ON` then it is set to `OFF` upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two `ONLINE` servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	s1	3306	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	s2	3306	ONLINE

When `s2` attempted to join the group, [Section 20.5.4, “Distributed Recovery”](#) ensured that `s2` applied the same transactions which `s1` had applied. Once this process completed, `s2` could join the group as a member, and at this point it is marked as `ONLINE`. In other words it must have already caught up with server `s1` automatically. Once `s2` is `ONLINE`, it then begins to process transactions with the group. Verify that `s2` has indeed synchronized with server `s1` as follows.

```
mysql> SHOW DATABASES LIKE 'test';
```

```
+-----+
| Database (test) |
+-----+
| test           |
+-----+
```

```
mysql> SELECT * FROM test.t1;
```

```
+-----+
| c1 | c2 |
+-----+
| 1  | Luis |
+-----+
```

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	2	123	Server ver: 9.7.0-log, Binlog ver: 4
binlog.000001	123	Previous_gtids	2	150	

binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa'
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa'
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa'
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa'
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=30 */
binlog.000001	1002	Gtid	1	1063	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa'
binlog.000001	1063	Query	1	1122	BEGIN
binlog.000001	1122	View_change	1	1261	view_id=14724832985483517:2
binlog.000001	1261	Query	1	1326	COMMIT

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. In other words, the transactions applied on s1 up to the point in time that s2 joined the group have been replicated to s2.

### Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file.

```
[mysqld]

#
# Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON

#
# Group Replication configuration
#
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s3:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off
```

2. Start the server and connect to it. Create the replication user for distributed recovery.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

## Deploying Group Replication in Single-Primary Mode

If you are providing user credentials using a `CHANGE REPLICATION SOURCE TO` statement, issue the following statement after that:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

3. Install the Group Replication plugin if necessary, like this:

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

4. Start Group Replication:

```
mysql> START GROUP_REPLICATION;
```

If you are providing user credentials for distributed recovery in the `START GROUP_REPLICATION` statement, you can do so like this:

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	s1	3306	ONLINE
group_replication_applier	7eb217ff-6df3-11e6-966c-00212844f856	s3	3306	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	s2	3306	ONLINE

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has caught up:

```
mysql> SHOW DATABASES LIKE 'test';
```

```
+-----+
| Database (test) |
+-----+
| test           |
+-----+
```

```
mysql> SELECT * FROM test.t1;
```

```
+-----+
| c1 | c2 |
+-----+
| 1 | Luis |
+-----+
```

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	3	123	Server ver: 9.7.0-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	3	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa

binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=29 */

## 20.2.2 Deploying Group Replication Locally

The most common way to deploy Group Replication is using multiple server instances, to provide high availability. It is also possible to deploy Group Replication locally, for example for testing purposes. This section explains how you can deploy Group Replication locally.

### Important

Group Replication is usually deployed on multiple hosts because this ensures that high-availability is provided. The instructions in this section are not suitable for production deployments because all MySQL server instances are running on the same single host. In the event of failure of this host, the whole group fails. Therefore this information should be used for testing purposes and it should not be used in a production environments.

This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently. This procedure assumes that MySQL Server was downloaded and unpacked into the directory named `mysql-9.7`. Each MySQL server instance requires a specific data directory. Create a directory named `data`, then in that directory create a subdirectory for each server instance, for example `s1`, `s2` and `s3`, and initialize each one.

```
mysql-9.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.7 --datadir=$PWD/data/s1
mysql-9.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.7 --datadir=$PWD/data/s2
mysql-9.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.7 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.9.1, “Initializing the Data Directory”](#).

### Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 20.6, “Group Replication Security”](#).

## Configuration of Local Group Replication Members

When you are following [Section 20.2.1.2, “Configuring an Instance for Group Replication”](#), you need to add configuration for the data directories added in the previous section. For example:

```
[mysqld]
# server configuration
```

```
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-9.7/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

### Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Then each member needs to be able to connect to the other members on their `group_replication_local_address`. For example in the option file of member s1 add:

```
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
```

This configures s1 to use port 24901 for internal group communication with seed members. For each server instance you want to add to the group, make these changes in the option file of the member. For each member you must ensure a unique address is specified, so use a unique port per instance for `group_replication_local_address`. Usually you want all members to be able to serve as seeds for members that are joining the group and have not got the transactions processed by the group. In this case, add all of the ports to `group_replication_group_seeds` as shown above.

The remaining steps of [Section 20.2.1, “Deploying Group Replication in Single-Primary Mode”](#) apply equally to a group which you have deployed locally in this way.

## 20.3 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

### 20.3.1 Group Replication Requirements

- [Infrastructure](#)
- [Server Instance Configuration](#)

Server instances that you want to use for Group Replication must satisfy the following requirements.

#### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the [InnoDB](#) transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, [InnoDB](#) provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication. The use of other storage engines, including the temporary [MEMORY](#) storage engine,

might cause errors in Group Replication. Convert any tables in other storage engines to use [InnoDB](#) before using the instance with Group Replication. You can prevent the use of other storage engines by setting the `disabled_storage_engines` system variable on group members, for example:

```
disabled_storage_engines="MyISAM, BLACKHOLE, FEDERATED, ARCHIVE, MEMORY"
```

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified. Group Replication has its own built-in set of checks for primary keys or primary key equivalents, and does not use the checks carried out by the `sql_require_primary_key` system variable. You may set `sql_require_primary_key=ON` for a server instance where Group Replication is running, and you may set the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement to `ON` for a Group Replication channel. However, be aware that you might find some transactions that are permitted under Group Replication's built-in checks are not permitted under the checks carried out when you set `sql_require_primary_key=ON` or `REQUIRE_TABLE_PRIMARY_KEY_CHECK=ON`.
- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

You can use a network infrastructure based on IPv4, IPv6, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

Where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

## Server Instance Configuration

The following options must be configured as shown on server instances that are members of a group.

- **Unique Server Identifier.** Use the `server_id` system variable to configure the server with a unique server ID, as required for all servers in replication topologies. The server ID must be a positive integer between 1 and  $(2^{32})-1$ , and it must be different from every other server ID in use by any other server in the replication topology.
- **Binary Log Active.** In MySQL 9.7, binary logging is enabled by default. You can optionally specify the names of the binary log files using `--log-bin[=log_file_name]`. Group Replication replicates the binary log's contents, therefore the binary log needs to be on for it to operate. See [Section 7.4.4, "The Binary Log"](#).
- **Replica Updates Logged.** Set `log_replica_updates=ON` if it is not already enabled. (In MySQL 9.7, this is the default.) Group members need to log transactions that are received from their donors at joining time and applied through the replication applier, and to log all transactions that they receive and apply from the group. This enables Group Replication to carry out distributed recovery by state transfer from an existing group member's binary log.

- **Binary Log Row Format.** Set `binlog_format=ROW` if necessary; in MySQL 9.7, this is the default. Group Replication relies on the row-based replication format to propagate changes consistently among the servers in the group, and extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. The setting for `REQUIRE_ROW_FORMAT` is automatically added to Group Replication's channels to enforce the use of row-based replication when the transactions are applied. See [Section 19.2.1, “Replication Formats”](#) and [Section 19.3.3, “Replication Privilege Checks”](#).
- **Global Transaction Identifiers On.** Set `gtid_mode=ON` and `enforce_gtid_consistency=ON`. These settings are not the defaults. GTID-based replication is required for Group Replication, which uses global transaction identifiers to track the transactions that have been committed on every server instance in the group. See [Section 19.1.3, “Replication with Global Transaction Identifiers”](#).

In addition, if you need to set the value of `gtid_purged`, you must do so while Group Replication is not running.

- **Default Table Encryption.** Set `default_table_encryption` to the same value on all group members. Default schema and tablespace encryption can be either enabled (`ON`) or disabled (`OFF`, the default) as long as the setting is the same on all members.

The value of `default_table_encryption` cannot be changed while Group Replication is running.

- **Lower Case Table Names.** Set `lower_case_table_names` to the same value on all group members. A setting of 1 is correct for the use of the `InnoDB` storage engine, which is required for Group Replication. Note that this setting is not the default on all platforms.
- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded replicas, enabling transactions to be applied in parallel. All replicas are configured as multithreaded by default. The default is 4 parallel applier threads; up to 1024 parallel applier threads can be specified. For a multithreaded replica, the following is also required:

`replica_preserve_commit_order=ON` This setting is required to ensure that the final commit of parallel transactions is in the same order as the original transactions. Group Replication relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transactions in the same order.

- **Detached XA transactions.** MySQL 9.7 and later supports detached XA transactions. A detached transaction is one which, once prepared, is no longer connected to the current session. This happens automatically as part of executing `XA PREPARE`. The prepared XA transaction can be committed or rolled back by another connection, and the current session can then initiate another XA transaction or local transaction without waiting for the transaction that was just prepared to complete.

When detached XA transaction support is enabled (`xa_detach_on_prepare = ON`) it is possible for any connection to this server to list (using `XA RECOVER`), roll back, or commit any prepared XA transaction. In addition, you cannot use temporary tables within detached XA transactions.

You can disable support for detached XA transactions by setting `xa_detach_on_prepare` to `OFF`, but this is not recommended. In particular, if this server is being set up as an instance in MySQL group replication, you should leave this variable set to its default value (`ON`).

See [Section 15.3.8.2, “XA Transaction States”](#), for more information.

## 20.3.2 Group Replication Limitations

- [Limit on Group Size](#)

- [Limits on Transaction Size](#)

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

#### Tip

Group Replication is built on GTID based replication, therefore you should also be aware of [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#).

- **--upgrade=MINIMAL option.** Group Replication cannot be started following a MySQL Server upgrade that uses the MINIMAL option (`--upgrade=MINIMAL`), which does not upgrade system tables on which the replication internals depend.
- **Gap Locks.** Group Replication's certification process for concurrent transactions does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

#### Note

For a group in multi-primary mode, unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication. For a group in single-primary mode, only the primary accepts writes, so the [READ COMMITTED](#) isolation level is not important to Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 15.3.6, “LOCK TABLES and UNLOCK TABLES Statements”](#)) or named locks (see [GET\\_LOCK\(\)](#)).
- **Binary Log Checksums.** Group Replication in MySQL 9.7 supports checksums, so group members may use the default setting `binlog_checksum=CRC32`. The setting for `binlog_checksum` does not have to be the same for all members of a group.

When checksums are available, Group Replication does not use them to verify incoming events on the `group_replication_applier` channel, because events are written to that relay log from multiple sources and before they are actually written to the originating server's binary log, which is when a checksum is generated. Checksums are used to verify the integrity of events on the `group_replication_recovery` channel and on any other replication channels on group members.

- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables

with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting [group\\_replication\\_enforce\\_update\\_everywhere\\_checks=ON](#) on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, [SELECT .. FOR UPDATE](#) statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.
- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the [group\\_replication\\_applier](#) or [group\\_replication\\_recovery](#) channels.
- **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL, provided that it was compiled using OpenSSL 1.1.1 or higher. Group Replication supports TLSv1.3, where it can be used for group communication connections and distributed recovery connections.

[group\\_replication\\_recovery\\_tls\\_version](#) and [group\\_replication\\_recovery\\_tls\\_ciphersuites](#) can be used to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired. See [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- **Cloning Operations.** Group Replication initiates and manages cloning operations for distributed recovery, but group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the [DATA DIRECTORY](#) clause if Group Replication is running. See [Cloning for Other Purposes](#).

### Limit on Group Size

The maximum number of MySQL servers that can be members of a single replication group is 9. If further members attempt to join the group, their request is refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

### Limits on Transaction Size

If an individual transaction results in message contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

- If unnecessary expulsions occur due to large messages, use the system variable [group\\_replication\\_member\\_expel\\_timeout](#) to allow additional time before a member under suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection

period before a suspect member is expelled from the group. An additional 5 seconds is allowed by default.

- Where possible, try and limit the size of your transactions before they are handled by Group Replication. For example, split up files used with `LOAD DATA` into smaller chunks.
- Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group accepts. The default maximum transaction size is 150000000 bytes (approximately 143 MB); transactions above this size are rolled back and are not sent to Group Replication's Group Communication System (GCS) for distribution to the group. Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.
- Use the system variable `group_replication_compression_threshold` to specify a message size above which compression is applied. This system variable defaults to 1000000 bytes (1 MB), so large messages are automatically compressed. Compression is carried out by Group Replication's Group Communication System (GCS) when it receives a message that was permitted by the `group_replication_transaction_size_limit` setting but exceeds the `group_replication_compression_threshold` setting. For more information, see [Section 20.7.4, "Message Compression"](#).
- Use the system variable `group_replication_communication_max_message_size` to specify a message size above which messages are fragmented. This system variable defaults to 10485760 bytes (10 MiB), so large messages are automatically fragmented. GCS carries out fragmentation after compression if the compressed message still exceeds the `group_replication_communication_max_message_size` limit. For more information, see [Section 20.7.5, "Message Fragmentation"](#).

The maximum transaction size, message compression, and message fragmentation can all be deactivated by specifying a zero value for the relevant system variable. If you have deactivated all these safeguards, the upper size limit for a message that can be handled by the applier thread on a member of a replication group is the value of the member's `replica_max_allowed_packet` system variable, which has a default and maximum value of 1073741824 bytes (1 GB). A message that exceeds this limit fails when the receiving member attempts to handle it. The upper size limit for a message that a group member can originate and attempt to transmit to the group is 4294967295 bytes (approximately 4 GB). This is a hard limit on the packet size that is accepted by the group communication engine for Group Replication (XCom, a Paxos variant), which receives messages after GCS has handled them. A message that exceeds this limit fails when the originating member attempts to broadcast it.

## 20.4 Monitoring Group Replication

You can use the MySQL [Performance Schema](#) to monitor Group Replication. These Performance Schema tables display information specific to Group Replication:

- `replication_group_member_stats`: See [Section 20.4.4, "The replication\\_group\\_member\\_stats Table"](#).
- `replication_group_members`: See [Section 20.4.3, "The replication\\_group\\_members Table"](#).
- `replication_group_communication_information`: See [Section 29.12.11.14, "The replication\\_group\\_communication\\_information Table"](#).

These Performance Schema replication tables also show information relating to Group Replication:

- `replication_connection_status` shows information regarding Group Replication, such as transactions received from the group and queued in the applier queue (relay log).

- `replication_applier_status` shows the states of channels and threads relating to Group Replication. These can also be used to monitor what individual worker threads are doing.

Replication channels created by the Group Replication plugin are listed here:

- `group_replication_recovery`: Used for replication changes related to distributed recovery.
- `group_replication_applier`: Used for the incoming changes from the group, to apply transactions coming directly from the group.

For information about system variables affecting Group Replication, see [Section 20.9.1, “Group Replication System Variables”](#). See [Section 20.9.2, “Group Replication Status Variables”](#), for status variables providing information about Group Replication.

Messages relating to Group Replication lifecycle events other than errors are classified as system messages; these are always written to the replication group member's error log. You can use this information to review the history of a given server's membership in a replication group.

Some lifecycle events that affect the whole group are logged on every group member, such as a new member entering `ONLINE` status in the group or a primary election. Other events are logged only on the member where they take place, such as super read only mode being enabled or disabled on the member, or the member leaving the group. A number of lifecycle events that can indicate an issue if they occur frequently are logged as warning messages, including a member becoming unreachable and then reachable again, and a member starting distributed recovery by state transfer from the binary log or by a remote cloning operation.

#### Note

If you are monitoring one or more secondary instances using `mysqladmin`, you should be aware that a `FLUSH STATUS` statement executed by this utility creates a GTID event on the local instance which may impact future group operations.

User of MySQL Enterprise Edition can also use the advanced monitoring capabilities built into the MySQL components listed here:

- *Replication Applier Metrics*: Adds tables to the MySQL Performance Schema (`replication_applier_metrics` and `replication_applier_progress_by_worker`) that contain detailed information about applier and worker performance. See [Section 7.5.6.1, “Replication Applier Metrics Component”](#), as well as the descriptions of the Performance Schema tables, for more information.
- *Group Replication Flow Control Statistics*: Provides additional global status variables which provide information on Group Replication flow control execution, that is, information about transaction throttling. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#).
- *Group Replication Resource Manager*: Monitors the applier channel, recovery channel, and system memory usage on each group member; expels group members which experience excessive channel lag or memory usage (and allows them to rejoin later). See [Section 7.5.6.3, “Group Replication Resource Manager Component”](#), for more information.

## 20.4.1 GTIDs and Group Replication

Group Replication uses GTIDs (global transaction identifiers) to track exactly which transactions have been committed on every server instance. The settings `gtid_mode=ON` and `enforce_gtid_consistency=ON` are required on all group members. Incoming transactions from clients are assigned a GTID by the group member that receives them. Any replicated transactions that are

received by group members on asynchronous replication channels from source servers outside the group retain the GTIDs that they have when they arrive on the group member.

The GTIDs that are assigned to incoming transactions from clients use the group name specified by the `group_replication_group_name` system variable as the UUID part of the identifier, rather than the server UUID of the individual group member that received the transaction. All the transactions received directly by the group can therefore be identified and are grouped together in GTID sets, and it does not matter which member originally received them. Each group member has a block of consecutive GTIDs reserved for its use, and when these are consumed it reserves more. The `group_replication_gtid_assignment_block_size` system variable sets the size of the blocks, with a default of 1 million GTIDs in each block.

View change events (`View_change_log_event`), which are generated by the group itself when a new member joins, are given GTIDs when they are recorded in the binary log. By default, the GTIDs for these events also use the group name specified by the `group_replication_group_name` system variable as the UUID part of the identifier. You can set the Group Replication system variable `group_replication_view_change_uuid` to use an alternative UUID in the GTIDs for view change events, so that they are easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The alternative UUID must be different from the server UUIDs of the members. It must also be different from any UUIDs in the GTIDs applied to anonymous transactions using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement.

`GTID_ONLY=1`, `REQUIRE_ROW_FORMAT = 1`, and `SOURCE_AUTO_POSITION = 1` are applied for the Group Replication channels `group_replication_applier` and `group_replication_recovery`. The settings are made automatically on the Group Replication channels when they are created, or when a member server in a replication group is upgraded. These options are normally set using a `CHANGE REPLICATION SOURCE TO` statement, but note that you cannot disable them for a Group Replication channel. With these options set, the group member does not persist file names and file positions in the replication metadata repositories for these channels. GTID auto-positioning and GTID auto-skip are used to locate the correct receiver and applier positions when necessary.

## Extra Transactions

If a joining member has transactions in its GTID set that are not present on the existing members of the group, it is not allowed to complete the distributed recovery process, and cannot join the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor's binary log was carried out, these transactions could conflict with the group's transactions.

Extra transactions might be present on a member if an administrative transaction is carried out on the instance while Group Replication is stopped. To avoid introducing new transactions in that way, always set the value of the `sql_log_bin` system variable to `OFF` before issuing administrative statements, and back to `ON` afterwards:

```
SET SQL_LOG_BIN=0;
<administrator action>
SET SQL_LOG_BIN=1;
```

Setting this system variable to `OFF` means that the transactions that occur from that point until you set it back to `ON` are not written to the binary log and do not have GTIDs assigned to them.

If an extra transaction is present on a joining member, check the binary log for the affected server to see what the extra transaction actually contains. The safest method to reconcile the joining member's data and GTID set with the members currently in the group is to use MySQL's cloning functionality to transfer the

content from a server in the group to the affected server. For instructions to do this, see [Section 7.6.6.3, “Cloning Remote Data”](#). If the transaction is required, rerun it after the member has successfully rejoined.

## 20.4.2 Group Replication Server States

The state of a Group Replication group member shows its current role in the group. The Performance Schema table `replication_group_members` shows the state for each member in a group. If the group is fully functional and all members are communicating properly, all members report the same state for all other members. However, a member that has left the group or is part of a network partition cannot report accurate information on the other servers. In this situation, the member does not attempt to guess the status of the other servers, and instead reports them as unreachable.

A group member can be in the following states:

<code>ONLINE</code>	The server is an active member of a group and in a fully functioning state. Other group members can connect to it, as can clients if applicable. A member is only fully synchronized with the group, and participating in it, when it is in the <code>ONLINE</code> state.
<code>RECOVERING</code>	The server has joined a group and is in the process of becoming an active member. Distributed recovery is currently taking place, where the member is receiving state transfer from a donor using a remote cloning operation or the donor's binary log. This state is  For more information, see <a href="#">Section 20.5.4, “Distributed Recovery”</a> .
<code>OFFLINE</code>	The Group Replication plugin is loaded but the member does not belong to any group. This status may briefly occur while a member is joining or rejoining a group.
<code>ERROR</code>	The member is in an error state and is not functioning correctly as a group member. A member can enter error state either while applying transactions or during the recovery phase. A member in this state does not participate in the group's transactions. For more information on possible reasons for error states, see <a href="#">Section 20.7.7, “Responses to Failure Detection and Network Partitioning”</a> .  Depending on the exit action set by <code>group_replication_exit_state_action</code> , the member is in read-only mode ( <code>super_read_only=ON</code> ) and could also be in offline mode ( <code>offline_mode=ON</code> ). Note that a server in offline mode following the <code>OFFLINE_MODE</code> exit action is displayed with <code>ERROR</code> status, not <code>OFFLINE</code> . A server with the exit action <code>ABORT_SERVER</code> shuts down and is removed from the view of the group. For more information, see <a href="#">Section 20.7.7.4, “Exit Action”</a> .  While a member is joining or rejoining a replication group, its status can be displayed as <code>ERROR</code> before the group completes the compatibility checks and accepts it as a member.
<code>UNREACHABLE</code>	The local failure detector suspects that the member cannot be contacted, because the group's messages are timing out. This can happen if a member is disconnected involuntarily, for example. If you see this status for other servers, it can also mean that the member where you query this table is part of a partition, where a subset of the group's servers can contact each other but cannot contact the

other servers in the group. For more information, see [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#).

See [Section 20.4.3, “The replication\\_group\\_members Table”](#) for an example of the Performance Schema table contents.

### 20.4.3 The replication\_group\_members Table

The `performance_schema.replication_group_members` table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:

```
SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	d391e9ee-2691-11ec-bf61-00059a3c7a00	example1	4410	ONLINE
group_replication_applier	e059ce5c-2691-11ec-8632-00059a3c7a00	example2	4420	ONLINE
group_replication_applier	ecd9ad06-2691-11ec-91c7-00059a3c7a00	example3	4430	ONLINE

3 rows in set (0.0007 sec)

Based on this result we can see that the group consists of three members. Shown in the table is each member's `server_uuid`, as well as the member's host name and port number, which clients use to connect to it. The `MEMBER_STATE` column shows one of the [Section 20.4.2, “Group Replication Server States”](#), in this case it shows that all three members in this group are `ONLINE`, and the `MEMBER_ROLE` column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The `MEMBER_VERSION` column can be useful when you are upgrading a group and are combining members running different MySQL versions. The `MEMBER_COMMUNICATION_STACK` column shows the communication stack used for the group.

For more information about the `MEMBER_HOST` value and its impact on the distributed recovery process, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#).

### 20.4.4 The replication\_group\_member\_stats Table

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The `performance_schema.replication_group_member_stats` table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made. To use this table to monitor a Group Replication member, issue the following statement:

```
mysql> SELECT * FROM performance_schema.replication_group_member_stats\G
```

You can also use the following statement:

```
mysql> TABLE performance_schema.replication_group_member_stats\G
```

These columns are important for monitoring the performance of the members connected in the group. Suppose that one of the group's members always reports a large number of transactions in its queue compared to other members. This means that the member is delayed and is not able to keep up to date with the other members of the group. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin, see [Section 20.7.2, “Flow Control”](#).

## 20.5 Group Replication Operations

This section explains common operations for managing groups.

### 20.5.1 Configuring an Online Group

You can configure an online group while Group Replication is running by using a set of functions, which rely on a group action coordinator. These functions are installed by the Group Replication plugin. This section describes how changes are made to a running group, and the available functions.

#### Important

For the coordinator to be able to configure group wide actions on a running group, all members must have the functions installed.

To use the functions, connect to a member of the running group and invoke the function with the `SELECT` statement. The Group Replication plugin processes the action and its parameters and the coordinator sends it to all members which are visible to the member where you invoked the function. If the action is accepted, all members execute the action and send a termination message when completed. Once all members declare the action as finished, the invoking member returns the result to the client.

When configuring a whole group, the distributed nature of the operations means that they interact with many processes of the Group Replication plugin, and therefore you should observe the following:

**You can issue configuration operations everywhere.** If you want to make member A the new primary you do not need to invoke the operation on member A. All operations are sent and executed in a coordinated way on all group members. Also, this distributed execution of an operation has a different ramification: if the invoking member dies, any already running configuration process continues to run on other members. In the unlikely event that the invoking member dies, you can still use the monitoring features to ensure other members complete the operation successfully.

**All members must be online.** To simplify the migration or election processes and guarantee they are as fast as possible, the group must not contain any member currently in the distributed recovery process, otherwise the configuration action is rejected by the member where you issue the statement.

**No members can join a group during a configuration change.** Any member that attempts to join the group during a coordinated configuration change leaves the group and cancels its join process.

**Only one configuration at once.** A group which is executing a configuration change cannot accept any other group configuration change, because concurrent configuration operations could lead to member divergence.

#### 20.5.1.1 Changing the Primary

This section explains how to change which member of a single-primary group is the primary, using the `group_replication_set_as_primary()` function, which can be run on any member of the group. When this is done, the current primary becomes a read-only secondary, and the specified group member becomes the read/write primary; this replaces the usual primary election process (see [Section 20.1.3.1, “Single-Primary Mode”](#)).

If a standard source-to-replica replication channel is running on the existing primary member in addition to the Group Replication channels, you must stop that replication channel before you can change the primary member. You can identify the current primary using the `MEMBER_ROLE` column in the Performance Schema `replication_group_members` table.

If all members are not running the same MySQL Server version, you can specify a new primary member that is running the lowest MySQL Server version in the group only. This safeguard is applied to ensure the group maintains compatibility with new functions.

Any uncommitted transactions that the group is waiting on must be committed, rolled back, or terminated before the operation can complete. You can specify a timeout from 1 to 3600 seconds (60 minutes) for transactions that are running when you use the function. Specify 0 for no timeout (or do not specify a timeout value), in which case the group waits indefinitely. If you do not set the timeout, there is no upper limit to the wait time, and new transactions can start during that time.

When the timeout expires, for any transactions that did not yet reach their commit phase, the client session is disconnected so that the transaction does not proceed. Transactions that reached their commit phase are allowed to complete. When you set a timeout, it also prevents new transactions starting on the primary from that point on. Explicitly defined transactions (with a `START TRANSACTION` or `BEGIN` statement) are subject to the timeout, disconnection, and incoming transaction blocking even if they do not modify any data. To allow inspection of the primary while the function is operating, single statements that do not modify data, as listed in [Permitted Queries Under Consistency Rules](#), are permitted to proceed.

Pass in the `server_uuid` of the member which you want to become the new primary of the group by issuing the following statement:

```
SELECT group_replication_set_as_primary(member_uuid);
```

You can add a timeout as shown here:

```
SELECT group_replication_set_as_primary('00371d66-3c45-11ea-804b-080027337932', 300)
```

To check the status of the timeout, use the `PROCESSLIST_INFO` column in the Performance Schema `threads` table, like this:

```
mysql> SELECT NAME, PROCESSLIST_INFO FROM performance_schema.threads
-> WHERE NAME="thread/group_rpl/THD_transaction_monitor"\G
***** 1. row *****
      NAME: thread/group_rpl/THD_transaction_monitor
PROCESSLIST_INFO: Group replication transaction monitor: Stopped client connections
```

The status shows when the transaction monitoring thread has been created, when new transactions have been stopped, when the client connections with uncommitted transactions have been disconnected, and finally, when the process is complete and new transactions are allowed again.

While the action runs, you can check its progress by issuing the statement shown here:

```
mysql> SELECT event_name, work_completed, work_estimated
-> FROM performance_schema.events_stages_current
-> WHERE event_name LIKE "%stage/group_rpl%\G
```

```
***** 1. row *****
EVENT_NAME: stage/group_rpl/Primary Election: Waiting for members to turn on super_read_only
WORK_COMPLETED: 3
WORK_ESTIMATED: 5
```

### 20.5.1.2 Changing the Group Mode

This section explains how to change the mode which a group is running in, either single or multi-primary. The functions used to change a group's mode can be run on any member.

#### Changing to Single-Primary Mode

Use the `group_replication_switch_to_single_primary_mode()` function to change a group running in multi-primary mode to single-primary mode by issuing:

```
SELECT group_replication_switch_to_single_primary_mode()
```

When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (`group_replication_enforce_update_everywhere_checks=OFF`).

If no string is passed in, the election of the new primary in the resulting single-primary group follows the election policies described in [Section 20.1.3.1, "Single-Primary Mode"](#). To override the election process and configure a specific member of the multi-primary group as the new primary in the process, get the `server_uuid` of the member and pass it to `group_replication_switch_to_single_primary_mode()`. For example, issue:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

#### Changing to Multi-Primary Mode

Use the `group_replication_switch_to_multi_primary_mode()` function to change a group running in single-primary mode to multi-primary mode by issuing:

```
SELECT group_replication_switch_to_multi_primary_mode()
```

After some coordinated group operations to ensure the safety and consistency of your data, all members which belong to the group become primaries.

When you change a group from single-primary mode to multi-primary mode, members are automatically placed in read-only mode if they are running a later MySQL server version than the lowest version present in the group.

While the action runs, you can check its progress by issuing the following `SELECT` statement:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name = 'stage/group_rpl/Multi-primary Switch: applying buffered transactions'
```

event_name	work_completed	work_estimated
stage/group_rpl/Multi-primary Switch: applying buffered transactions	0	1

### 20.5.1.3 Using Group Replication Group Write Consensus

This section explains how to inspect and configure the maximum number of consensus instances at any time for a group. This maximum is referred to as the event horizon for a group, and is the maximum number of consensus instances that the group can execute in parallel. This enables you to fine tune the

performance of your Group Replication deployment. For example, the default value of 10 is suitable for a group running on a LAN, but for groups operating over a slower network such as a WAN, increase this number to improve performance.

## Inspecting a Group's Write Concurrency

Use the `group_replication_get_write_concurrency()` function to inspect a group's event horizon value at runtime by issuing:

```
SELECT group_replication_get_write_concurrency();
```

## Configuring a Group's Write Concurrency

Use the `group_replication_set_write_concurrency()` function to set the maximum number of consensus instances that the system can execute in parallel by issuing:

```
SELECT group_replication_set_write_concurrency(instances);
```

where *instances* is the new maximum number of consensus instances. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function.

### 20.5.1.4 Setting a Group's Communication Protocol Version

Group Replication in MySQL 9.7 uses the concept of a group communication protocol whose version can be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. This enables groups to be formed from members using different MySQL Server versions while ensuring backward compatibility.

- MySQL 5.7.14 and later allows compression of messages (see [Section 20.7.4, “Message Compression”](#)).
- MySQL 8.0.16 and later also allows fragmentation of messages (see [Section 20.7.5, “Message Fragmentation”](#)).
- MySQL 8.0.27 and later also allow the group communication engine to operate with a single consensus leader when the group is in single-primary mode and `group_replication_paxos_single_leader` is set to true (see [Section 20.7.3, “Single Consensus Leader”](#)).

All members of the group must use the same communication protocol version, so that group members can be at different MySQL Server releases but only send messages that can be understood by all group members.

A MySQL server at version X can only join and reach `ONLINE` status in a replication group if the group's communication protocol version is less than or equal to X. When a new member joins a replication group, it checks the communication protocol version that is announced by the existing members of the group. If the joining member supports that version, it joins the group and uses the communication protocol that the group has announced, even if the member supports additional communication capabilities. If the joining member does not support the communication protocol version, it is expelled from the group.

If two members attempt to join in the same membership change event, they can only join if the communication protocol version for both members is already compatible with the group's communication protocol version. Members with different communication protocol versions from the group must join in isolation. For example:

- One MySQL Server 8.0.16 instance can successfully join a group that uses the communication protocol version 5.7.24.

- One MySQL Server 5.7.24 instance cannot successfully join a group that uses the communication protocol version 8.0.16.
- Two MySQL Server 8.0.16 instances cannot simultaneously join a group that uses the communication protocol version 5.7.24.
- Two MySQL Server 8.0.16 instances can simultaneously join a group that uses the communication protocol version 8.0.16.

You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` function, which returns the oldest MySQL Server version that the group supports. All existing members of the group return the same communication protocol version. For example:

```
SELECT group_replication_get_communication_protocol();
+-----+
| group_replication_get_communication_protocol() |
+-----+
| 8.0.16 |
+-----+
```

Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` function, and from the MySQL Server version that is installed on the member where you use the function.

If you need to change the communication protocol version of a group so that members at earlier releases can join, use the `group_replication_set_communication_protocol()` function to specify the MySQL Server version of the oldest member that you want to allow. This makes the group fall back to a compatible communication protocol version if possible. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function, and all existing group members must be online when you issue the statement, with no loss of majority. For example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

If you upgrade all the members of a replication group to a new MySQL Server release, the group's communication protocol version is not automatically upgraded to match.

If you no longer need to support members at earlier releases, you can use the `group_replication_set_communication_protocol()` function to set the communication protocol version to the new MySQL Server version to which you have upgraded the members. For example:

```
SELECT group_replication_set_communication_protocol("8.0.16");
```

The `group_replication_set_communication_protocol()` function is implemented as a group action, so it is executed at the same time on all members of the group. The group action starts buffering messages and waits for delivery of any outgoing messages that were already in progress to complete, then changes the communication protocol version and sends the buffered messages. If a member attempts to join the group at any time after you change the communication protocol version, the group members announce the new protocol version.

MySQL InnoDB cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. An InnoDB cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it. For details, see [InnoDB Cluster and Group Replication Protocol](#).

### 20.5.1.5 Configuring Member Actions

Group Replication has the ability to set actions for the members of a group to take in specified situations. Member actions can be enabled and disabled individually using functions. The member actions configuration for a server can also be reset to the default after it has left the group.

Administrators (with the `GROUP_REPLICATION_ADMIN` privilege) can configure a member action on the group's primary using the `group_replication_enable_member_action` or `group_replication_disable_member_action` function. The member actions configuration, consisting of all the member actions and whether they are enabled or disabled, is then propagated to other group members and joining members using Group Replication's group messages. All group members therefore have the same member actions configuration. You can also configure member actions on a server that is not part of a group, as long as the Group Replication plugin is installed. In that case, the member actions configuration is not propagated to any other servers.

If the server where you use the functions to configure a member action is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The configuration change is tracked internally by Group Replication, but it is not given a GTID and is not written to the binary log, so it is not propagated to any servers outside the group, such as downstream replicas. Group Replication increments the version number for its member actions configuration each time a member action is enabled or disabled.

The member actions configuration is propagated to members as follows:

- When starting a group, the member actions configuration of the server that bootstraps the group becomes the configuration for the group.
- If a group's lowest MySQL Server version supports member actions, joining members receive the group's member actions configuration during the state exchange process that takes place when they join. In that case, the joining member replaces its own member actions configuration with the group's.
- If a joining member that supports member actions joins a group where the lowest MySQL Server version does not support member actions, it does not receive a member actions configuration when it joins. In that case, the joining member resets its own configuration to the default.

A member that does not support member actions cannot join a group that has a member actions configuration, because its MySQL Server version is lower than the lowest version that the existing group members are running.

The Performance Schema table `replication_group_member_actions` lists the member actions that are available in the configuration, the events that trigger them, and whether or not they are currently enabled. Member actions have a priority from 1 to 100, with lower values being actioned first. If an error occurs when the member action is being carried out, the failure of the member action can be logged but otherwise ignored. If the failure of the member action is considered critical, it can be handled according to the policy specified by the `group_replication_exit_state_action` system variable.

The `mysql.replication_group_configuration_version` table, which can be viewed using the Performance Schema table `replication_group_configuration_version`, records the current version of the member actions configuration. Whenever a member action is enabled or disabled using the functions, the version number is incremented.

The `group_replication_reset_member_actions` function can only be used on a server that is not part of a group. It resets the member actions configuration to the default settings, and resets its version number to 1. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed. You can use this function to remove the member actions configuration that a server used when it was part of a group, if you intend to use it as a standalone server with no member actions or different member actions.

The member action `mysql_disable_super_read_only_if_primary` can be set so that a group in single-primary mode stay in super read-only mode when a new primary is elected; this means that the group accepts replicated transactions only, and does not accept any direct writes from clients. This setup means that when a group's is intended to provide a secondary backup to another group for disaster tolerance, you can ensure that the secondary group remains synchronized with the first.

By default, super read-only mode is disabled on the primary when it is elected, so that the primary becomes read/write, and accepts updates from a replication source server and from clients. This is the situation when the member action `mysql_disable_super_read_only_if_primary` is enabled, which is its default setting. If you set the action to disabled using the `group_replication_disable_member_action()` function, the primary remains in super read-only mode after election. In this state, it does not accept updates from any clients, even users who have the `CONNECTION_ADMIN` or `SUPER` privilege. It does continue to accept updates performed by replication threads.

### 20.5.2 Restarting a Group

Group Replication is designed to ensure that the database service is continuously available, even if some of the servers that form the group are currently unable to participate in it due to planned maintenance or unplanned issues. As long as the remaining members are a majority of the group they can elect a new primary and continue to function as a group. However, if every member of a replication group leaves the group, and Group Replication is stopped on every member by a `STOP GROUP_REPLICATION` statement or system shutdown, the group now only exists in theory, as a configuration on the members. In that situation, to re-create the group, it must be started by bootstrapping as if it was being started for the first time.

The difference between bootstrapping a group for the first time and doing it for the second or subsequent times is that in the latter situation, the members of a group that was shut down might have different transaction sets from each other, depending on the order in which they were stopped or failed. A member cannot join a group if it has transactions that are not present on the other group members. For Group Replication, this includes both transactions that have been committed and applied, which are in the `gtid_executed` GTID set, and transactions that have been certified but not yet applied, which are in the `group_replication_applier` channel. The exact point at which a transaction is committed depends on the transaction consistency level that is set for the group (see [Section 20.5.3, "Transaction Consistency Guarantees"](#)). However, a Group Replication group member never removes a transaction that has been certified, which is a declaration of the member's intent to commit the transaction.

The replication group must therefore be restarted beginning with the most up to date member, that is, the member that has the most transactions executed and certified. The members with fewer transactions can then join and catch up with the transactions they are missing through distributed recovery. It is not correct to assume that the last known primary member of the group is the most up to date member of the group, because a member that was shut down later than the primary might have more transactions. You must therefore restart each member to check the transactions, compare all the transaction sets, and identify the most up to date member. This member can then be used to bootstrap the group.

Follow this procedure to restart a replication group safely after every member shuts down.

1. For each group member in turn, in any order:
  - a. Connect a client to the group member. If Group Replication is not already stopped, issue a `STOP GROUP_REPLICATION` statement and wait for Group Replication to stop.
  - b. Edit the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems) and set the system variable `group_replication_start_on_boot=OFF`. This setting prevents Group Replication from starting when MySQL Server is started, which is the default.

If you cannot change that setting on the system, you can just allow the server to attempt to start Group Replication, which will fail because the group has been fully shut down and not yet bootstrapped. If you take that approach, do not set `group_replication_bootstrap_group=ON` on any server at this stage.

- c. Start the MySQL Server instance, and verify that Group Replication has not been started (or has failed to start). Do not start Group Replication at this stage.
- d. Collect the following information from the group member:
  - The contents of the `gtid_executed` GTID set. You can get this by issuing the following statement:

```
mysql> SELECT @@GLOBAL.GTID_EXECUTED
```

- The set of certified transactions on the `group_replication_applier` channel. You can get this by issuing the following statement:

```
mysql> SELECT received_transaction_set FROM \
performance_schema.replication_connection_status WHERE \
channel_name="group_replication_applier";
```

2. When you have collected the transaction sets from all the group members, compare them to find which member has the biggest transaction set overall, including both the executed transactions (`gtid_executed`) and the certified transactions (on the `group_replication_applier` channel). You can do this manually by looking at the GTIDs, or you can compare the GTID sets using stored functions, as described in [Section 19.1.3.8, “Stored Function Examples to Manipulate GTIDs”](#).
3. Use the member that has the biggest transaction set to bootstrap the group, by connecting a client to the group member and issuing the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

It is important not to store the setting `group_replication_bootstrap_group=ON` in the configuration file, otherwise when the server is restarted again, a second group with the same name is set up.

4. To verify that the group now exists with this founder member in it, issue this statement on the member that bootstrapped it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

5. Add each of the other members back into the group, in any order, by issuing a `START GROUP_REPLICATION` statement on each of them:

```
mysql> START GROUP_REPLICATION;
```

6. To verify that each member has joined the group, issue this statement on any member:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

7. When the members have rejoined the group, if you edited their configuration files to set `group_replication_start_on_boot=OFF`, you can edit them again to set `ON` (or remove the system variable, since `ON` is the default).

## 20.5.3 Transaction Consistency Guarantees

One of the major implications of a distributed system such as Group Replication is the consistency guarantees that it provides as a group. In other words, the consistency of the global synchronization of transactions distributed across the members of the group. This section describes how Group Replication handles consistency guarantees depending on the events that occur in a group, and how to best configure your group's consistency guarantees.

### 20.5.3.1 Understanding Transaction Consistency Guarantees

In terms of distributed consistency guarantees, either in normal or failure repair operations, Group Replication has always been an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. The events that relate to the consistency of a system can be split into control operations, either manual or automatically triggered by failures; and data flow operations.

For Group Replication, the control operations that can be evaluated in terms of consistency are:

- a member joining or leaving, which is covered by Group Replication's [Section 20.5.4, “Distributed Recovery”](#) and write protection.
- network failures, which are covered by the fencing modes.
- in single-primary groups, primary failover, which can also be an operation triggered by `group_replication_set_as_primary()`.

### Consistency Guarantees and Primary Failover

In a single-primary group, in the event of a primary failover when a secondary is promoted to primary, the new primary can either be made available to application traffic immediately, regardless of how large the replication backlog is, or alternatively access to it can be restricted until the backlog has been applied.

With the first approach, the group takes the minimum time possible to secure a stable group membership after a primary failure by electing a new primary and then allowing data access immediately while it is still applying any possible backlog from the old primary. Write consistency is ensured, but reads can temporarily retrieve stale data while the new primary applies the backlog. For example, if client C1 wrote `A=2 WHERE A=1` on the old primary just before its failure, when client C1 is reconnected to the new primary it could potentially read `A=1` until the new primary applies its backlog and catches up with the state of the old primary before it left the group.

With the second alternative, the system secures a stable group membership after the primary failure and elects a new primary in the same way as the first alternative, but in this case the group then waits until the new primary applies all backlog and only then does it permit data access. This ensures that in a situation as described previously, when client C1 is reconnected to the new primary it reads `A=2`. However, the trade-off is that the time required to failover is then proportional to the size of the backlog, which on a correctly configured group should be small .

You can determine the level of transaction consistency guarantees provided by members during primary failover using the `group_replication_consistency` variable. See [Impact of Consistency on Primary Election](#).

### Data Flow Operations

Data flow is relevant to group consistency guarantees due to the reads and writes executed against a group, especially when these operations are distributed across all members. Data flow operations apply to both modes of Group Replication: single-primary and multi-primary, however to make this explanation clearer it is restricted to single-primary mode. The usual way to split incoming read or write transactions

across a single-primary group's members is to route writes to the primary and evenly distribute reads to the secondaries. Since the group should behave as a single entity, it is reasonable to expect that writes on the primary are instantaneously available on the secondaries. Although Group Replication is written using Group Communication System (GCS) protocols that implement the Paxos algorithm, some parts of Group Replication are asynchronous, which implies that data is asynchronously applied to secondaries. This means that a client C2 can write `B=2 WHERE B=1` on the primary, immediately connect to a secondary and read `B=1`. This is because the secondary is still applying backlog, and has not applied the transaction which was applied by the primary.

## Transaction Synchronization Points

You configure a group's consistency guarantee based on the point at which you want to synchronize transactions across the group. To help you understand the concept, this section simplifies the points of synchronizing transactions across a group to be at the time of a read operation or at the time of a write operation. If data is synchronized at the time of a read, the current client session waits until a given point, which is the point in time that all preceding update transactions have been applied, before it can start executing. With this approach, only this session is affected, all other concurrent data operations are not affected.

If data is synchronized at the time of write, the writing session waits until all secondaries have written their data. Group Replication uses a total order on writes, and therefore this implies waiting for this and all preceding writes that are in secondaries' queues to be applied. Therefore when using this synchronization point, the writing session waits for all secondaries queues to be applied.

Any alternative ensures that in the situation described for client C2 would always read `B=2` even if immediately connected to a secondary. Each alternative has its advantages and disadvantages, which are directly related to your system workload. The following examples describe different types of workloads and advise which point of synchronization is appropriate.

Imagine the following situations:

- You want to load-balance reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much less common than group reads.
- For a group that has predominantly read-only data, you want read/write transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes the latest write. This ensures that you do not pay the synchronization cost for every read-only transaction, but only for read/write transactions.

In these cases, you should choose to synchronize on writes.

Imagine the following situations:

- You want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much more common than group reads.
- You want specific transactions in your workload to always read up-to-date data from the group, for example whenever sensitive data is updated (such as credentials for a file or similar data) and you want to enforce that reads retrieve the most up to date value.

In these cases, you should choose to synchronize on reads.

### 20.5.3.2 Configuring Transaction Consistency Guarantees

Although the [Transaction Synchronization Points](#) section explains that conceptually there are two synchronization points from which you can choose: on read or on write, these terms were a simplification

and the terms used in Group Replication are: *before* and *after* transaction execution. The consistency level can have different effects on read-only and read/write transactions processed by the group as demonstrated in this section.

- [How to Choose a Consistency Level](#)
- [Impacts of Consistency Levels](#)
- [Impact of Consistency on Primary Election](#)
- [Permitted Queries Under Consistency Rules](#)

The following list shows the possible consistency levels that you can configure in Group Replication using the `group_replication_consistency` variable, in order of increasing transaction consistency guarantee:

- `EVENTUAL`

Neither read-only nor read/write transactions wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before the `group_replication_consistency` variable was added. A read/write transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new read-only and read/write transactions before the previous primary transactions are all applied. Read-only transactions could result in outdated values, read/write transactions could result in a rollback due to conflicts.

- `BEFORE_ON_PRIMARY_FAILOVER`

New read-only or read/write transactions with a newly elected primary that is applying a backlog from the old primary are not applied until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but it does depend on the size of the backlog.

- `BEFORE`

A read/write transaction waits for all preceding transactions to complete before being applied. A read-only transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every read/write transaction, by ensuring synchronization is used only on read-only transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `AFTER`

A read/write transaction waits until its changes have been applied to all of the other members. This value has no effect on read-only transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly read-only operations to ensure that applied read/write transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every read-only transaction, by ensuring synchronization is used only on read/write transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `BEFORE_AND_AFTER`

A read/write transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A read-only transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

The [BEFORE](#) and [BEFORE\\_AND\\_AFTER](#) consistency levels can be used on both read-only and read/write transactions. The [AFTER](#) consistency level has no impact on read-only transactions, because they do not generate changes.

## How to Choose a Consistency Level

The different consistency levels provide flexibility to both DBAs, who can use them to set up their infrastructure; and to developers who can use the consistency level that best suits their application's requirements. The following scenarios show how to choose a consistency guarantee level based on how you use your group:

- *Scenario 1:* You want to balance reads without being concerned about stale reads, and group write operations are considerably fewer than group read operations. In this case, you should choose [AFTER](#).
- *Scenario 2:* For a data set that applies many writes, you want to perform occasional reads without concerns about reading stale data. In this case, you should choose [BEFORE](#).
- *Scenario 3:* You want specific transactions to read only up-to-date data from the group, so that whenever sensitive data such as credentials for a file is updated, reads always use the most recent value. In this case, you should choose [BEFORE](#).
- *Scenario 4:* For a group that has predominantly read-only data, you want read/write transactions to be applied everywhere once they commit, so that subsequent reads are done on data that includes your latest writes and you do not incur the cost of synchronization for every read-only transaction, but only for read/write transactions. In this case, you should choose [AFTER](#).
- *Scenario 5:* For a group that works predominantly with read-only data, you want read/write transactions to read up-to-date data from the group and to be applied everywhere once they commit, so that subsequent reads are performed on data that includes the latest write and you do not incur the cost of synchronization for every read-only transaction, but only for read/write transactions. In this case, you should choose [BEFORE\\_AND\\_AFTER](#).

You can choose the scope for which the consistency level is enforced by setting [group\\_replication\\_consistency](#) with session or global scope. This is important because consistency levels can have a negative impact on group performance they apply globally.

To enforce the consistency level for the current session, use session scope, like this:

```
> SET @@SESSION.group_replication_consistency= 'BEFORE';
```

To enforce the consistency level for all sessions, use global scope, as shown here:

```
> SET @@GLOBAL.group_replication_consistency= 'BEFORE';
```

The possibility of setting the consistency level on specific sessions enables you to take advantage of scenarios such as those listed here:

- *Scenario 6:* A given system handles several instructions that do not require a strong consistency level, but one kind of instruction does require strong consistency: managing access permissions to documents;. In this scenario, the system changes access permissions and it wants to be sure that all clients see the correct permission. You only need to [SET](#)

`@@SESSION.group_replication_consistency= 'AFTER'`, on those instructions and leave the other instructions to run with `EVENTUAL` set at the global scope.

- *Scenario 7:* On the same system as described in Scenario 6, a command that performs analytics needs to be executed daily, using the most up-to-date data. To achieve this, you need only run the SQL statement `SET @@SESSION.group_replication_consistency= 'BEFORE'` prior to executing the command.

In sum, you do not need to run all transactions with the same specific consistency level, especially if only some transactions actually require it.

You should be aware that all read/write transactions are always ordered in Group Replication, so even when you set the consistency level to `AFTER` for the current session, this transaction waits until its changes are applied on all members, which means waiting for this and all preceding transactions that could be in the secondaries' queues. In other words, the consistency level `AFTER` waits for everything up to and including this transaction.

### Impacts of Consistency Levels

Another way to classify the consistency levels is in terms of impact on the group, that is, the repercussions that the consistency levels have on the other members.

The `BEFORE` consistency level, apart from being ordered on the transaction stream, only impacts on the local member. That is, it does not require coordination with the other members and does not have repercussions on their transactions. In other words, `BEFORE` only impacts the transactions on which it is used.

The `AFTER` and `BEFORE_AND_AFTER` consistency levels do have side-effects on concurrent transactions executed on other members. These consistency levels make the other members transactions wait if transactions with the `EVENTUAL` consistency level start while a transaction with `AFTER` or `BEFORE_AND_AFTER` is executing. The other members wait until the `AFTER` transaction is committed on that member, even if the other member's transactions have the `EVENTUAL` consistency level. In other words, `AFTER` and `BEFORE_AND_AFTER` impact *all* `ONLINE` group members.

To illustrate this further, imagine a group with 3 members, M1, M2 and M3. On member M1 a client issues:

```
> SET @@SESSION.group_replication_consistency= AFTER;
> BEGIN;
> INSERT INTO t1 VALUES (1);
> COMMIT;
```

Then, while the above transaction is being applied, on member M2 a client issues:

```
> SET SESSION group_replication_consistency= EVENTUAL;
```

In this situation, even though the second transaction's consistency level is `EVENTUAL`, because it starts executing while the first transaction is already in the commit phase on M2, the second transaction has to wait for the first transaction to finish the commit and only then can it execute.

You can only use the consistency levels `BEFORE`, `AFTER` and `BEFORE_AND_AFTER` on `ONLINE` members, attempting to use them on members in other states causes a session error.

Transactions whose consistency level is not `EVENTUAL` hold execution until a timeout, configured by `wait_timeout` value is reached, which defaults to 8 hours. If the timeout is reached an `ER_GR_HOLD_WAIT_TIMEOUT` error is thrown.

### Impact of Consistency on Primary Election

This section describes how a group's consistency level impacts on a single-primary group that has elected a new primary. Such a group automatically detects failures and adjusts the view of the members that are active, in other words the membership configuration. Furthermore, if a group is deployed in single-primary mode, whenever the group's membership changes there is a check performed to detect if there is still a primary member in the group. If there is none, a new one is selected from the list of secondary members. Typically, this is known as the secondary promotion.

Given the fact that the system detects failures and reconfigures itself automatically, the user may also expect that once the promotion takes place, the new primary is in the exact state, data-wise, as that of the old one. In other words, the user may expect that there is no backlog of replicated transactions to be applied on the new primary once he is able to read from and write to it. In practical terms, the user may expect that once his application fails-over to the new primary, there would be no chance, even if temporarily, to read old data or write into old data records.

When flow control is activated and properly tuned on a group, there is only a small chance of transiently reading stale data from a newly elected primary immediately after the promotion, as there should not be a backlog, or if there is one it should be small. Moreover, you might have a proxy or middleware layers that govern application accesses to the primary after a promotion and enforce the consistency criteria at that level. You can specify the behavior of the new primary once it is promoted using the `group_replication_consistency` variable, which controls whether a newly elected primary blocks both reads and writes until after the backlog is fully applied. If the `group_replication_consistency` variable was set to `BEFORE_ON_PRIMARY_FAILOVER` on a newly elected primary which has backlog to apply, and transactions are issued against the new primary while it is still applying the backlog, incoming transactions are blocked until the backlog is fully applied. This prevents the following anomalies:

- No stale reads for read-only and read/write transactions. This prevents stale reads from being externalized to the application by the new primary.
- No spurious rollbacks for read/write transactions, due to write-write conflicts with replicated read/write transactions still in the backlog waiting to be applied.
- No read skew on read/write transactions, such as this one:

```
> BEGIN;
> SELECT x FROM t1; -- x=1 because x=2 is in the backlog;
> INSERT x INTO t2;
> COMMIT;
```

This query should not cause a conflict but writes outdated values.

To summarize, when `group_replication_consistency` is set to `BEFORE_ON_PRIMARY_FAILOVER` you are choosing to prioritize consistency over availability, because reads and writes are held whenever a new primary is elected. This is the trade-off you have to consider when configuring your group. It should also be remembered that if flow control is working correctly, backlog should be minimal. Note that the higher consistency levels `BEFORE`, `AFTER`, and `BEFORE_AND_AFTER` also include the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

To guarantee that the group provides the same consistency level regardless of which member is promoted to primary, all members of the group should have `BEFORE_ON_PRIMARY_FAILOVER` (or a higher consistency level) persisted to their configuration. For example, on each member issue:

```
> SET PERSIST group_replication_consistency='BEFORE_ON_PRIMARY_FAILOVER' ;
```

This ensures that the members all behave in the same way, and that the configuration is persisted after a restart of the member.

A transaction cannot be on-hold forever, and if the time held exceeds `wait_timeout` it returns an `ER_GR_HOLD_WAIT_TIMEOUT` error.

---

## Permitted Queries Under Consistency Rules

Although all writes are held when using `BEFORE_ON_PRIMARY_FAILOVER` consistency level, not all reads are blocked to ensure that you can still inspect the server while it is applying backlog after a promotion took place. This is useful for debugging, monitoring, observability and troubleshooting. Some queries that do not modify data are allowed, such as the following:

- `SHOW` statements: These are restricted to those that do not depend on data, only on status and configuration.

The `SHOW` statements that are allowed are `SHOW VARIABLES`, `SHOW PROCESSLIST`, `SHOW STATUS`, `SHOW ENGINE INNODB LOGS`, `SHOW ENGINE INNODB STATUS`, `SHOW ENGINE INNODB MUTEX`, `SHOW BINARY LOG STATUS`, `SHOW REPLICA STATUS`, `SHOW CHARACTER SET`, `SHOW COLLATION`, `SHOW BINARY LOGS`, `SHOW OPEN TABLES`, `SHOW REPLICAS`, `SHOW BINLOG EVENTS`, `SHOW WARNINGS`, `SHOW ERRORS`, `SHOW ENGINES`, `SHOW PRIVILEGES`, `SHOW PROCEDURE STATUS`, `SHOW FUNCTION STATUS`, `SHOW PLUGINS`, `SHOW EVENTS`, `SHOW PROFILE`, `SHOW PROFILES`, and `SHOW RELAYLOG EVENTS`.

- `SET` statements
- `DO` statements that do not use tables or loadable functions
- `EMPTY` statements
- `USE` statements
- Using `SELECT` statements against the `performance_schema` and `sys` databases
- Using `SELECT` statements against the `PROCESSLIST` table from the `infoschema` database
- `SELECT` statements that do not use tables or loadable functions
- `STOP GROUP_REPLICATION` statements
- `SHUTDOWN` statements
- `RESET PERSIST` statements

## 20.5.4 Distributed Recovery

Whenever a member joins or rejoins a replication group, it must catch up with the transactions that were applied by the group members before it joined, or while it was away. This process is called distributed recovery.

The joining member begins by checking the relay log for its `group_replication_applier` channel for any transactions that it already received from the group but did not yet apply. If the joining member was in the group previously, it might find unapplied transactions from before it left, in which case it applies these as a first step. A member that is new to the group does not have anything to apply.

After this, the joining member connects to an online existing member to carry out state transfer. The joining member transfers all the transactions that took place in the group before it joined or while it was away, which are provided by the existing member (called the *donor*). Next, the joining member applies the transactions that took place in the group while this state transfer was in progress. When this process is complete, the joining member has caught up with the remaining servers in the group, and it begins to participate normally in the group.

Group Replication uses a combination of these methods for state transfer during distributed recovery:

- A remote cloning operation using the clone plugin's function. To enable this method of state transfer, you must install the clone plugin on the group members and the joining member. Group Replication automatically configures the required clone plugin settings and manages the remote cloning operation.
- Replicating from a donor's binary log and applying the transactions on the joining member. This method uses a standard asynchronous replication channel named `group_replication_recovery` that is established between the donor and the joining member.

Group Replication automatically selects the best combination of these methods for state transfer after you issue `START GROUP_REPLICATION` on the joining member. To do this, Group Replication checks which existing members are suitable as donors, how many transactions the joining member needs from a donor, and whether any required transactions are no longer present in the binary log files on any group member. If the transaction gap between the joining member and a suitable donor is large, or if some required transactions are not in any donor's binary log files, Group Replication begins distributed recovery with a remote cloning operation. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.

- During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group applied while the remote cloning operation was in progress.
- During state transfer from a donor's binary log, the joining member replicates and applies the required transactions from the donor's binary log, applying the transactions as they are received, up to the point where the binary log records that the joining member joined the group (a view change event). While this is in progress, the joining member buffers the new transactions that the group applies. When state transfer from the binary log is complete, the joining member applies the buffered transactions.

When the joining member is up to date with all the group's transactions, it is declared online and can participate in the group as a normal member, and distributed recovery is complete.

#### Tip

State transfer from the binary log is Group Replication's base mechanism for distributed recovery, and if the donors and joining members in your replication group are not set up to support cloning, this is the only available option. As state transfer from the binary log is based on classic asynchronous replication, it might take a very long time if the server joining the group does not have the group's data at all, or has data taken from a very old backup image. In this situation, it is therefore recommended that before adding a server to the group, you should set it up with the group's data by transferring a fairly recent snapshot of a server already in the group. This minimizes the time taken for distributed recovery, and reduces the impact on donor servers, since they have to retain and transfer fewer binary log files.

### 20.5.4.1 Connections for Distributed Recovery

When a joining member connects to an online existing member for state transfer during distributed recovery, the joining member acts as a client on the connection and the existing member acts as a server. When state transfer from the donor's binary log is in progress over this connection (using the asynchronous replication channel `group_replication_recovery`), the joining member acts as the replica and the existing member acts as the source. When a remote cloning operation is in progress over this connection, the joining member acts as a recipient and the existing member acts as a donor. Configuration settings that apply to those roles outside the Group Replication context can apply for Group Replication also, unless they are overridden by a Group Replication-specific configuration setting or behavior.

The connection that an existing member offers to a joining member for distributed recovery is not the same connection that is used by Group Replication for communication between online members of the group.

- The connection used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances is specified by the `group_replication_local_address` system variable. This connection is used for TCP/IP messages between online members. Communication with the local instance is over an input channel using shared memory.
- For distributed recovery, by default, group members offer their standard SQL client connection to joining members, as specified by `hostname` and `port`. If an alternative port number is specified by `report_port`, that one is used instead.
- Group members may instead advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members, allowing you to control distributed recovery traffic separately from connections by regular client users of the member. A member transmits the list of distributed recovery endpoints specified by `group_replication_advertise_recovery_endpoints` to the group when it joins. By default, the member continues to offer the standard SQL client connection as in earlier releases.

### Important

Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server's `report_host` system variable to configure a unique host name to be externalized by each of the servers.

The steps for a joining member to establish a connection for distributed recovery are as follows:

1. When the member joins the group, it connects with one of the seed members included in the list in its `group_replication_group_seeds` system variable, initially using the `group_replication_local_address` connection as specified in that list. The seed members might be a subset of the group.
2. Over this connection, the seed member uses Group Replication's membership service to provide the joining member with a list of all the members that are online in the group, in the form of a view. The membership information includes the details of the distributed recovery endpoints or standard SQL client connection offered by each member for distributed recovery.
3. The joining member selects a suitable group member from this list to be its donor for distributed recovery, following the behaviors described in [Section 20.5.4.4, "Fault Tolerance for Distributed Recovery"](#).
4. The joining member then attempts to connect to the donor using the donor's advertised distributed recovery endpoints, trying each in turn in the order they are specified in the list. If the donor provides no endpoints, the joining member attempts to connect using the donor's standard SQL client connection. The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options described in [SSL and Authentication for Distributed Recovery](#).

5. If the joining member is not able to connect to the selected donor, it retries with other suitable donors, following the behaviors described in [Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”](#). Note that if the joining member exhausts the list of advertised endpoints without making a connection, it does not fall back to the donor's standard SQL client connection, but switches to another donor.
6. When the joining member establishes a distributed recovery connection with a donor, it uses that connection for state transfer as described in [Section 20.5.4, “Distributed Recovery”](#). The host and port for the connection that is used are shown in the joining member's log. Note that if a remote cloning operation is used, when the joining member has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log. This might be a connection to a different member from the original donor used for the remote cloning operation, or it might be a different connection to the original donor. In any case, the distributed recovery process continues in the same way as it would have with the original donor.

## Selecting addresses for distributed recovery endpoints

IP addresses supplied by the `group_replication_advertise_recovery_endpoints` system variable as distributed recovery endpoints do not have to be configured for MySQL Server (that is, they do not have to be specified by the `admin_address` system variable or in the list for the `bind_address` system variable). They do have to be assigned to the server. Any host names used must resolve to a local IP address. IPv4 and IPv6 addresses can be used.

The ports supplied for the distributed recovery endpoints do have to be configured for MySQL Server, so they must be specified by the `port`, `report_port`, or `admin_port` system variable. The server must listen for TCP/IP connections on these ports. If you specify the `admin_port`, the replication user for distributed recovery needs the `SERVICE_CONNECTION_ADMIN` privilege to connect. Selecting the `admin_port` keeps distributed recovery connections separate from regular MySQL client connections.

Joining members try each of the endpoints in turn in the order they are specified on the list. If `group_replication_advertise_recovery_endpoints` is set to `DEFAULT` rather than a list of endpoints, the standard SQL client connection is offered. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints, and is not offered as a fallback if the donor's list of endpoints is exhausted without a connection. If you want to offer the standard SQL client connection as one of a number of distributed recovery endpoints, you must include it explicitly in the list specified by `group_replication_advertise_recovery_endpoints`. You can put it in the last place so that it acts as a last resort for connection.

A group member's distributed recovery endpoints (or standard SQL client connection if endpoints are not provided) do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` system variable. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

The distributed recovery endpoints that you list are validated when the system variable is set and when a `START GROUP_REPLICATION` statement has been issued. If the list cannot be parsed correctly, or if any of the endpoints cannot be accessed on the host because the server is not listening on them, Group Replication logs an error and does not start.

## Compression for Distributed Recovery

You can optionally configure compression for distributed recovery by the method of state transfer from a donor's binary log. Compression can benefit distributed recovery where network bandwidth is limited and the donor has to transfer many transactions to the joining member. The `group_replication_recovery_compression_algorithms` and

`group_replication_recovery_zstd_compression_level` system variables determine permitted compression algorithms, and the `zstd` compression level used when carrying out state transfer from a donor's binary log. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

These compression settings do not apply to remote cloning operations. When a remote cloning operation is used for distributed recovery, the clone plugin's setting for `clone_enable_compression` applies.

## Replication User for Distributed Recovery

Distributed recovery requires a replication user that has the correct permissions so that Group Replication can establish direct member-to-member replication channels. The replication user must also have the correct permissions to act as the clone user on the donor for a remote cloning operation. The same replication user must be used for distributed recovery on every group member. For instructions to set up this replication user, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#). For instructions to secure the replication user credentials, see [Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

## SSL and Authentication for Distributed Recovery

SSL for distributed recovery is configured separately from SSL for normal group communications, which is determined by the server's SSL settings and the `group_replication_ssl_mode` system variable. For distributed recovery connections, dedicated Group Replication distributed recovery SSL system variables are available to configure the use of certificates and ciphers specifically for distributed recovery.

By default, SSL is not used for distributed recovery connections. To activate it, set `group_replication_recovery_use_ssl=ON`, and configure the Group Replication distributed recovery SSL system variables as described in [Section 20.6.3, “Securing Distributed Recovery Connections”](#). You need a replication user that is set up to use SSL.

When distributed recovery is configured to use SSL, Group Replication applies this setting for remote cloning operations, as well as for state transfer from a donor's binary log. Group Replication automatically configures the settings for the clone SSL options (`clone_ssl_ca`, `clone_ssl_cert`, and `clone_ssl_key`) to match your settings for the corresponding Group Replication distributed recovery options (`group_replication_recovery_ssl_ca`, `group_replication_recovery_ssl_cert`, and `group_replication_recovery_ssl_key`).

If you are not using SSL for distributed recovery (so `group_replication_recovery_use_ssl` is set to `OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default) or the `sha256_password` plugin (deprecated), RSA key pairs are used for password exchange. In this case, either use the `group_replication_recovery_public_key_path` system variable to specify the RSA public key file, or use the `group_replication_recovery_get_public_key` system variable to request the public key from the source, as described in [Replication User With The Caching SHA-2 Authentication Plugin](#).

### 20.5.4.2 Cloning for Distributed Recovery

If you want to use remote cloning operations for distributed recovery in a group, you must set up existing members and joining members beforehand to support this function. If you do not want to use this function in a group, do not set it up, in which case Group Replication only uses state transfer from the binary log.

To use cloning, at least one existing group member and the joining member must be set up beforehand to support remote cloning operations. As a minimum, you must install the clone plugin on the donor and joining member, grant the `BACKUP_ADMIN` permission to the replication user for distributed recovery, and

set the `group_replication_clone_threshold` system variable to an appropriate level. To ensure the maximum availability of donors, it is advisable to set up all current and future group members to support remote cloning operations.

Be aware that a remote cloning operation removes user-created tablespaces and data from the joining member before transferring the data from the donor. If the operation is stopped while in progress, the joining member might be left with partial data or no data. This can be repaired by retrying the remote cloning operation, which Group Replication does automatically.

## Prerequisites for Cloning

For full instructions to set up and configure the clone plugin, see [Section 7.6.6, “The Clone Plugin”](#). Detailed prerequisites for a remote cloning operation are covered in [Section 7.6.6.3, “Cloning Remote Data”](#). For Group Replication, note the following key points and differences:

- The donor (an existing group member) and the recipient (the joining member) must have the clone plugin installed and active. For instructions to do this, see [Section 7.6.6.1, “Installing the Clone Plugin”](#).
- The donor and the recipient must run on the same operating system, and must use the same MySQL Server release series. Cloning is therefore not suitable for groups where members run different minor MySQL Server versions, such as MySQL 8.0 and 8.4.
- The donor and the recipient must have the Group Replication plugin installed and active, and any other plugins that are active on the donor (such as a keyring plugin) must also be active on the recipient.
- If distributed recovery is configured to use SSL (`group_replication_recovery_use_ssl=ON`), Group Replication applies this setting for remote cloning operations. Group Replication automatically configures the settings for the clone SSL options (`clone_ssl_ca`, `clone_ssl_cert`, and `clone_ssl_key`) to match your settings for the corresponding Group Replication distributed recovery options (`group_replication_recovery_ssl_ca`, `group_replication_recovery_ssl_cert`, and `group_replication_recovery_ssl_key`).
- You do not need to set up a list of valid donors in the `clone_valid_donor_list` system variable for the purpose of joining a replication group. Group Replication configures this setting automatically for you after it selects a donor from the existing group members. Note that remote cloning operations use the server's SQL protocol hostname and port.
- The clone plugin has a number of system variables to manage the network load and performance impact of the remote cloning operation. Group Replication does not configure these settings, so you can review them and set them if you want to, or allow them to default. Note that when a remote cloning operation is used for distributed recovery, the clone plugin's `clone_enable_compression` setting applies to the operation, rather than the Group Replication compression setting.
- To invoke the remote cloning operation on the recipient, Group Replication uses the internal `mysql.session` user, which already has the `CLONE_ADMIN` privilege, so you do not need to set this up.
- As the clone user on the donor for the remote cloning operation, Group Replication uses the replication user that you set up for distributed recovery (which is covered in [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#)). You must therefore give the `BACKUP_ADMIN` privilege to this replication user on all group members that support cloning. Also give the privilege to the replication user on joining members when you are configuring them for Group Replication, because they can act as donors after they join the group. The same replication user is used for distributed recovery on every group member. To give this privilege to the replication user on existing members, you can issue this statement on each group member individually with binary logging disabled, or on one group member with binary logging enabled:

```
GRANT BACKUP_ADMIN ON *.* TO rpl_user'%';
```

- If you use `START GROUP_REPLICATION` to specify the replication user credentials on a server that previously supplied the user credentials using `CHANGE REPLICATION SOURCE TO`, ensure that you remove the user credentials from the replication metadata repositories before any remote cloning operations take place. Also ensure that `group_replication_start_on_boot=OFF` is set on the joining member. For instructions, see [Section 20.6.3, “Securing Distributed Recovery Connections”](#). If you do not unset the user credentials, they are transferred to the joining member during remote cloning operations. The `group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials on a `START GROUP_REPLICATION` command.

## Threshold for Cloning

When group members have been set up to support cloning, the `group_replication_clone_threshold` system variable specifies a threshold, expressed as a number of transactions, for the use of a remote cloning operation in distributed recovery. If the gap between the transactions on the donor and the transactions on the joining member is larger than this number, a remote cloning operation is used for state transfer to the joining member when this is technically possible. Group Replication calculates whether the threshold has been exceeded based on the `gtid_executed` sets of the existing group members. Using a remote cloning operation in the event of a large transaction gap lets you add new members to the group without transferring the group's data to the server manually beforehand, and also enables a member that is very out of date to catch up more efficiently.

The default setting for the `group_replication_clone_threshold` Group Replication system variable is extremely high (the maximum permitted sequence number for a transaction in a GTID), so it effectively deactivates cloning wherever state transfer from the binary log is possible. To enable Group Replication to select a remote cloning operation for state transfer where this is more appropriate, set the system variable to specify a number of transactions as the transaction gap above which you want cloning to take place.

### Warning

Do not use a low setting for `group_replication_clone_threshold` in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would expect to occur in the group during the time taken for the remote cloning operation.

Group Replication attempts to execute a remote cloning operation regardless of your threshold when state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary log on any existing group member. Group Replication identifies this based on the `gtid_purged` sets of the existing group members. You cannot use the `group_replication_clone_threshold` system variable to deactivate cloning when the required transactions are not available in any member's binary log files, because in that situation cloning is the only alternative to transferring data to the joining member manually.

## Cloning Operations

When group members and joining members are set up for cloning, Group Replication manages remote cloning operations for you. A remote cloning operation might take some time to complete, depending on

the size of the data. See [Section 7.6.6.10, “Monitoring Cloning Operations”](#) for information on monitoring the process.

### Note

When state transfer is complete, Group Replication restarts the joining member to complete the process. If `group_replication_start_on_boot=OFF` is set on the joining member, for example because you specify the replication user credentials on the `START GROUP_REPLICATION` statement, you must issue `START GROUP_REPLICATION` manually again following this restart. If `group_replication_start_on_boot=ON` and other settings required to start Group Replication were set in a configuration file or using a `SET PERSIST` statement, you do not need to intervene and the process continues automatically to bring the joining member online.

A remote cloning operation clones settings that are persisted in tables from the donor to the recipient, as well as the data. Group Replication manages the settings that relate specifically to Group Replication channels. Group Replication member settings that are persisted in configuration files, such as the group replication local address, are not cloned and are not changed on the joining member. Group Replication also preserves the channel settings that relate to the use of SSL, so these are unique to the individual member.

If the replication user credentials used by the donor for the `group_replication_recovery` replication channel have been stored in the replication metadata repositories using a `CHANGE REPLICATION SOURCE TO` statement, they are transferred to and used by the joining member after cloning, and they must be valid there. With stored credentials, all group members that received state transfer by a remote cloning operation therefore automatically receive the replication user and password for distributed recovery. If you specify the replication user credentials on the `START GROUP_REPLICATION` statement, these are used to start the remote cloning operation, but they are not transferred to and used by the joining member after cloning. If you do not want the credentials transferred to new joiners and recorded there, ensure that you unset them before remote cloning operations take place, as described in [Section 20.6.3, “Securing Distributed Recovery Connections”](#), and use `START GROUP_REPLICATION` to supply them instead.

If a `PRIVILEGE_CHECKS_USER` account has been used to help secure the replication appliers (see [Section 19.3.3.2, “Privilege Checks For Group Replication Channels”](#)), the `PRIVILEGE_CHECKS_USER` account and related settings from the donor are cloned to the joining member. If the joining member is set to start Group Replication on boot, it automatically uses the account for privilege checks on the appropriate replication channels.

## Cloning for Other Purposes

Group Replication initiates and manages cloning operations for distributed recovery. Group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. For example, you might want to create a new server instance by cloning from a group member as the donor, but you do not want the new server instance to join the group immediately, or maybe not ever.

In all releases that support cloning, you can initiate a cloning operation manually involving a group member on which Group Replication is stopped. Note that because cloning requires that the active plugins on a donor and recipient must match, the Group Replication plugin must be installed and active on the other server instance, even if you do not intend that server instance to join a group. You can install the plugin by issuing this statement:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the `DATA DIRECTORY` clause if Group Replication is running.

### 20.5.4.3 Configuring Distributed Recovery

Several aspects of Group Replication's distributed recovery process can be configured to suit your system.

#### Number of Connection Attempts

For state transfer from the binary log, Group Replication limits the number of attempts a joining member makes when trying to connect to a donor from the pool of donors. If the connection retry limit is reached without a successful connection, the distributed recovery procedure terminates with an error. Note that this limit specifies the total number of attempts that the joining member makes to connect to a donor. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes 2 attempts to connect to each of the donors before reaching the limit.

The default connection retry limit is 10. You can configure this setting using the `group_replication_recovery_retry_count` system variable. The following command sets the maximum number of attempts to connect to a donor to 5:

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 5;
```

For remote cloning operations, this limit does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

#### Sleep Interval for Connection Attempts

For state transfer from the binary log, the `group_replication_recovery_reconnect_interval` system variable defines how much time the distributed recovery process should sleep between donor connection attempts. Note that distributed recovery does not sleep after every donor connection attempt. As the joining member is connecting to different servers and not to the same one repeatedly, it can assume that the problem that affects server A does not affect server B. Distributed recovery therefore suspends only when it has gone through all the possible donors. Once the server joining the group has made one attempt to connect to each of the suitable donors in the group, the distributed recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` system variable. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes one attempt to connect to each of the donors, then sleeps for the connection retry interval, then makes one further attempt to connect to each of the donors before reaching the limit.

The default connection retry interval is 60 seconds, and you can change this value dynamically. The following command sets the distributed recovery donor connection retry interval to 120 seconds:

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

For remote cloning operations, this interval does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

#### Marking the Joining Member Online

When distributed recovery has successfully completed state transfer from the donor to the joining member, the joining member can be marked as online in the group and ready to participate. This is done after the new member has received and applied all the transactions that it missed prior to joining the group.

### 20.5.4.4 Fault Tolerance for Distributed Recovery

Group Replication's distributed recovery process has a number of built-in measures to ensure fault tolerance in the event of any problems during the process.

The donor for distributed recovery is selected randomly from the existing list of suitable online group members in the current view. Selecting a random donor means that there is a good chance that the same server is not selected more than once when multiple members enter the group. For state transfer from the binary log, the joiner selects a donor that is running a lower or equal patch version of MySQL Server compared to itself. For earlier releases, all of the online members are allowed to be a donor. For a remote cloning operation, the joiner selects a donor that is running the same patch version as itself. When the member joining has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log, which might be a different member from the original donor used for the remote cloning operation.

In the following situations, Group Replication detects an error in distributed recovery, automatically switches over to a new donor, and retries the state transfer:

- *Connection error* - There is an authentication issue or another problem with making the connection to a candidate donor.
- *Replication errors* - One of the replication threads (the receiver or applier threads) being used for state transfer from the binary log fails. Because this method of state transfer uses the existing MySQL replication framework, it is possible that some transient errors could cause errors in the receiver or applier threads.
- *Remote cloning operation errors* - A remote cloning operation fails or is stopped before it completes.
- *Donor leaves the group* - The donor leaves the group, or Group Replication is stopped on the donor, while state transfer is in progress.

The Performance Schema table `replication_applier_status_by_worker` displays the error that caused the last retry. In these situations, the new connection following the error is attempted with a new candidate donor. Selecting a different donor in the event of an error means that there is a chance the new candidate donor does not have the same error. If the clone plugin is installed, Group Replication attempts a remote cloning operation with each of the suitable online clone-supporting donors first. If all those attempts fail, Group Replication attempts state transfer from the binary log with all the suitable donors in turn, if that is possible.

#### Warning

For a remote cloning operation, user-created tablespaces and data on the recipient (the joining member) are dropped before the remote cloning operation begins to transfer the data from the donor. If the remote cloning operation starts but does not complete, the joining member might be left with a partial set of its original data files, or with no user data. Data transferred by the donor is removed from the recipient if the cloning operation is stopped before the data is fully cloned. This situation can be repaired by retrying the cloning operation, which Group Replication does automatically.

In the following situations, the distributed recovery process cannot be completed, and the joining member leaves the group:

- *Purged transactions* - Transactions that are required by the joining member are not present in any online group member's binary log files, and the data cannot be obtained by a remote cloning operation

(because the clone plugin is not installed, or because cloning was attempted with all possible donors but failed). The joining member is therefore unable to catch up with the group.

- *Extra transactions* - The joining member already contains some transactions that are not present in the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor's binary log was carried out, these transactions could conflict with the group's transactions. For advice on dealing with this situation, see [Extra Transactions](#).
- *Connection retry limit reached* - The joining member has made all the connection attempts allowed by the connection retry limit. You can configure this using the `group_replication_recovery_retry_count` system variable (see [Section 20.5.4.3, "Configuring Distributed Recovery"](#)).
- *No more donors* - The joining member has unsuccessfully attempted a remote cloning operation with each of the online clone-supporting donors in turn (if the clone plugin is installed), then has unsuccessfully attempted state transfer from the binary log with each of the suitable online donors in turn, if possible.
- *Joining member leaves the group* - The joining member leaves the group or Group Replication is stopped on the joining member while state transfer is in progress.

If the joining member left the group unintentionally, so in any situation listed above except the last, it proceeds to take the action specified by the `group_replication_exit_state_action` system variable.

### 20.5.4.5 How Distributed Recovery Works

When Group Replication's distributed recovery process is carrying out state transfer from the binary log, to synchronize the joining member with the donor up to a specific point in time, the joining member and donor make use of GTIDs (see [Section 19.1.3, "Replication with Global Transaction Identifiers"](#)). However, GTIDs only provide a means to realize which transactions the joining member is missing. They do not help marking a specific point in time to which the server joining the group must catch up, nor do they convey certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, supplying the joining member with missing certification-related data.

This topic explains the role of view changes and the view change identifier, and the steps to carry out state transfer from the binary log.

#### View and View Changes

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are functioning correctly and online in the group.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens.

At the group communication layer, view changes with their associated view identifiers mark boundaries between the data exchanged before and after a member joins. This concept is implemented through a binary log event: the "view change log event" (VCLE). The view identifier is recorded to demarcate transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: a randomly generated part, and a monotonically increasing integer. The randomly generated part is generated when the group is created, and remains unchanged while there is at least one member in the group. The integer is incremented every time a view change happens. Using these two different parts enables the view identifier to identify incremental group changes caused by members joining or leaving, and also to identify the situation where all members leave the group in a full group shutdown, so no information remains of what view the group was in. Randomly generating part of the identifier when the group is started from the beginning ensures that the data markers in the binary log remain unique, and an identical identifier is not reused after a full group shutdown, as this would cause issues with distributed recovery in the future.

### Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

Figure 20.8 Stable Group

### View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several

transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joining member selects a suitable donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a view change event to the binary log.

**Figure 20.9 A Member Joins**

### State Transfer: Catching Up

If group members and the joining member are set up with the clone plugin (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and the difference in transactions between the joining member and the group exceeds the threshold set for a remote cloning operation (`group_replication_clone_threshold`), Group Replication begins distributed recovery with a remote cloning operation. A remote cloning operation is also carried out if required transactions are no longer present in any group member's binary log files. During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group

applied while the remote cloning operation was in progress. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.

For state transfer from a donor's binary log, a connection is established between the joining member and the donor and state transfer begins. This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

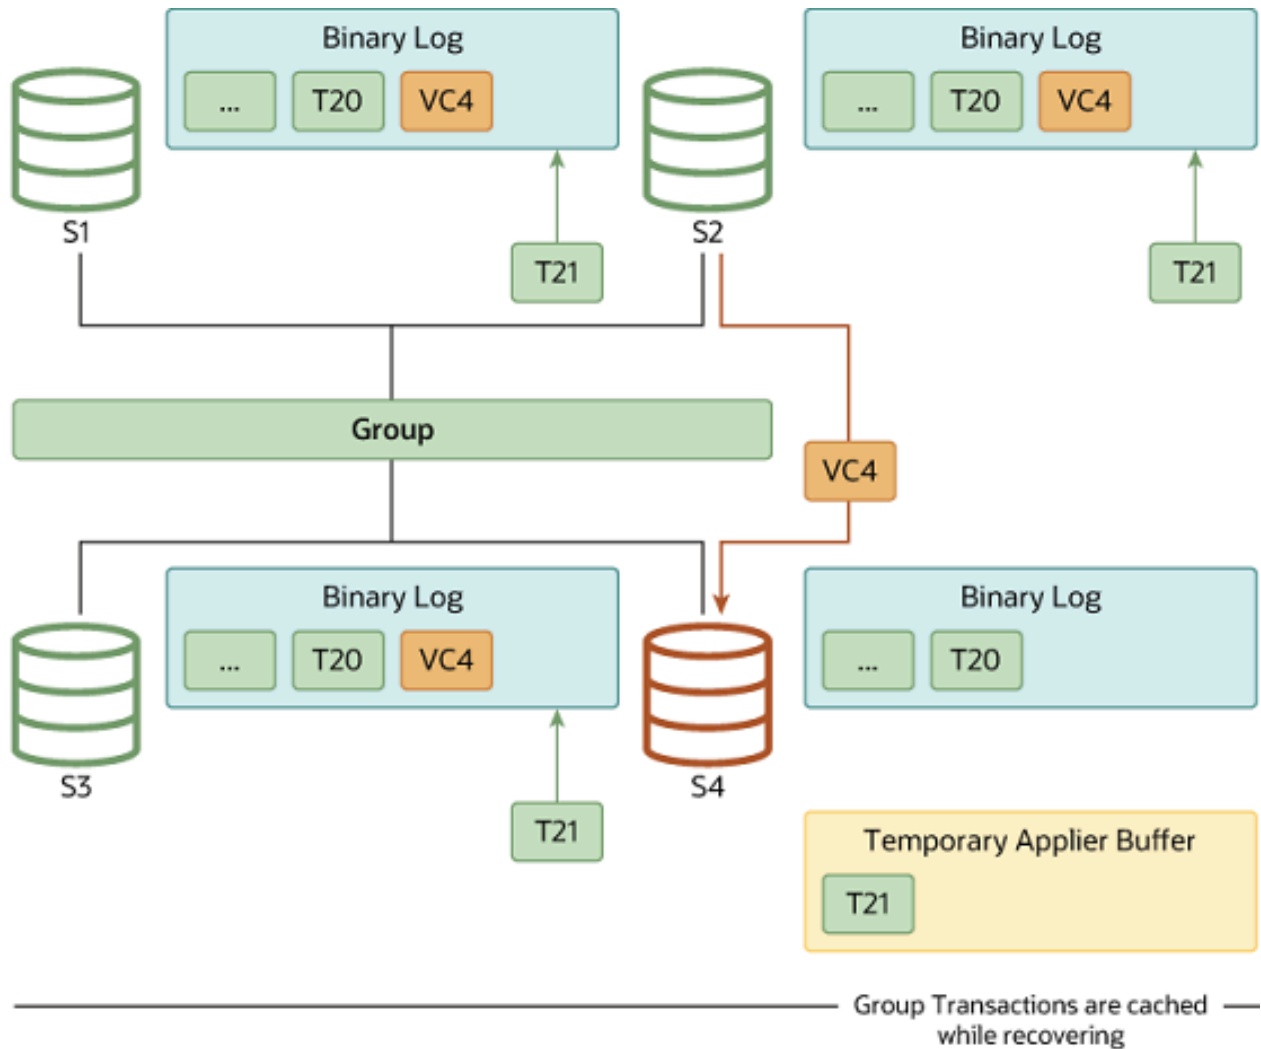

**Figure 20.10 State Transfer: Catching Up**

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view identifier clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 20.11 Queued Transactions

**Key**

- Transactions ■
- VCN-View Change Entry ■

### Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to this stage can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

**Figure 20.12 Instance Online**

## 20.5.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see [Section 7.1.13, “IPv6 Support”](#).

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address permissions for Group Replication (see [Section 20.6.4, "Group Replication IP Address Permissions"](#)), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` system variable on the other servers in the replication group.

A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and permit an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_allowlist` system variable on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```
group_replication_bootstrap_group=off
group_replication_local_address= "203.0.113.0/24:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B also has an alternative IPv6 address `2001:db8:8b0:40:3d9c:cc43:e006:19e8`. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A's allowlist, as in the following example:

```
group_replication_ip_allowlist=
"203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,
2001:db8:8b0:40:3d9c:cc43:e006:19e8"
```

As a best practice for Group Replication IP address permissions, Server B (and all other group members) should have the same allowlist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member

cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

IPv6 addresses can also be used as distributed recovery endpoints, which can be specified using the `group_replication_advertise_recovery_endpoints` system variable. The same rules apply to addresses used in this list. See [Section 20.5.4.1, “Connections for Distributed Recovery”](#).

## 20.5.6 Using MySQL Enterprise Backup with Group Replication

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

### Backing up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review [Backing Up a Database Server](#). Also note the requirements described in [Grant MySQL Privileges to Backup Administrator](#) and [Using MySQL Enterprise Backup with Group Replication](#).

Consider the following group with three members, `s1`, `s2`, and `s3`, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          | 3306        | ONLINE       |
| s2          | 3306        | ONLINE       |
| s3          | 3306        | ONLINE       |
+-----+-----+-----+
```

Using MySQL Enterprise Backup, create a backup of `s2` by issuing on its host, for example, the following command:

```
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
--backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p \
--host=127.0.0.1 backup-to-image
```

### Restoring a Failed Member

Assume one of the members (`s3` in the following example) is irreconcilably corrupted. The most recent backup of group member `s2` can be used to restore `s3`. Here are the steps for performing the restore:

1. *Copy the backup of `s2` onto the host for `s3`.* The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Preserve the two configuration files in the corrupted server's data directory, `auto.cnf` and `mysqld-auto.cnf` (if it exists), by copying them to a safe location outside of the data directory. This is for preserving the [server's UUID](#) and [Section 7.1.9.3, "Persisted System Variables"](#) (if used), which are needed in the steps below.

- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore backup of `s2` onto the host for `s3`:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
  --datadir=/var/lib/mysql \
  --backup-image=/backups/my.mbi_2206_1429 \
  --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

#### Note

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf \
  --datadir=/var/lib/mysql \
  --backup-image=/backups/my.mbi_2206_1429 \
  --log-bin=s3-bin --relay-log=s3-relay-bin \
  --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see [Rebuild the Failed Member to Rejoin as a New Member](#).

3. Restore the `auto.cnf` file for `s3`. To rejoin the replication group, the restored member *must* have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

#### Note

If you cannot supply the failed member's original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you must let the restored member join the group as a new member; see instructions in [Rebuild the Failed Member to Rejoin as a New Member](#) below on how to do that.

4. Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables). The settings for the [Section 7.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored member. These settings are to be found in the `mysqld-`

`auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

5. *Start the restored server.* For example, on Linux distributions that use `systemd`:

```
systemctl start mysqld
```

#### Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

6. *Restart Group Replication.* Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          |          3306 | ONLINE       |
| s2          |          3306 | ONLINE       |
| s3          |          3306 | RECOVERING   |
+-----+-----+-----+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          |          3306 | ONLINE       |
| s2          |          3306 | ONLINE       |
| s3          |          3306 | ONLINE       |
+-----+-----+-----+
```

#### Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

## Rebuild the Failed Member to Rejoin as a New Member

Sometimes, the steps outlined above in [Restoring a Failed Member](#) cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below,

we assume the rebuilt member is named `s3`, like the failed member, and that it runs on the same host as `s3`:

1. *Copy the backup of `s2` onto the host for `s3`.* The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use `systemd`:

```
s3> systemctl stop mysqld
```

- b. Preserve the configuration file `mysqld-auto.cnf`, if it is found in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the server's [Section 7.1.9.3, "Persisted System Variables"](#), which are needed later.

- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore the backup of `s2` onto the host of `s3`. With this approach, we are rebuilding `s3` as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` \
--skip-binlog --skip-relaylog \
copy-back-and-apply-log
```

#### Note

If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in [Restoring a Failed Member](#) above.

3. *Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables).* The settings for the [Section 7.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored server. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

#### Note

Do NOT restore the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt `s3` joins the group as a new member, it is going to be assigned a new server UUID.

4. *Start the restored server.* For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

#### Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

5. *Reconfigure the restored member to join Group Replication.* Connect to the restored server with a `mysql` client and reset the source and replica information with the following statements:

```
mysql> RESET BINARY LOGS AND GTIDS;
mysql> RESET REPLICA ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for [distributed recovery](#), configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member's data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Then, configure the [Group Replication user credentials](#) on the member using the SQL statements shown here:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

6. *Restart Group Replication.* Issue the following command to the restored server with your `mysql` client:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3          |          3306 | RECOVERING   |
| s2          |          3306 | ONLINE       |
| s1          |          3306 | ONLINE       |
+-----+-----+-----+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3          |          3306 | ONLINE       |
+-----+-----+-----+
```

s2	3306	ONLINE
s1	3306	ONLINE

**Note**

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

**Restoring Persisted System Variables.** `mysqlbackup` does not provide support for backing up or preserving [Section 7.1.9.3, “Persisted System Variables”](#)—the file `mysqld-auto.cnf` is not included in a backup. To start the restored member with its persisted variable settings, you need to do one of the following:

- Preserve a copy of the `mysqld-auto.cnf` file from the corrupted server, and copy it to the restored server's data directory.
- Copy the `mysqld-auto.cnf` file from another member of the group into the restored server's data directory, if that member has the same persisted system variable settings as the corrupted member.
- After the restored server is started and before you restart Group Replication, set all the system variables manually to their persisted values through a `mysql` client.

**Restoring a Primary Member.** If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication distributed recovery process. Depending on how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, *before starting the restored server*, configure the following system variables in the server option file:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

These settings ensure that the member becomes read-only at startup, and that the event scheduler is turned off while the member catches up with the group during the distributed recovery process. Adequate error handling must also be provided for on the clients, since they are unable to perform DML operations during this period on the member being restored.

Once the restoration process is fully completed and the restored member is synchronized with the rest of the group, you can revert these changes. First, restart the event scheduler using the statement shown here:

```
mysql> SET global event_scheduler=ON;
```

After this, you should set the following system variables in the member's option file, so that they have the necessary values for the next time that the member is started:

```
group_replication_start_on_boot=ON
super_read_only=OFF
event_scheduler=ON
```

## 20.6 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using an IP address allowlist.

## 20.6.1 Communication Stack for Connection Security Management

MySQL 9.7 Group Replication can secure group communication connections between members by one of the following methods:

- Using its own implementation of the security protocols, including TLS/SSL and the use of an allowlist for incoming Group Communication System (GCS) connections.
- Using MySQL Server's own connection security in place of Group Replication's implementation. Using the MySQL protocol means that standard methods of user authentication can be used for granting (or revoking) access to the group in place of the allowlist, and the latest functionality of the server's protocol is always available on release.

The choice is made by setting the system variable `group_replication_communication_stack` to `XCOM` to use Group Replication's own implementation (this is the default choice), or to `MYSQL` to use MySQL Server's connection security.

The following additional configuration is required for a replication group to use the MySQL communication stack. It is especially important to make sure these requirements are all fulfilled when you switch from using the XCom communication stack to the MySQL communication stack for your group.

### Group Replication Requirements For The MySQL Communication Stack

- The network address configured by the `group_replication_local_address` system variable for each group member must be set to one of the IP addresses and ports that MySQL Server is listening on, as specified by the `bind_address` system variable for the server. The combination of IP address and port for each member must be unique in the group. It is recommended that the `group_replication_group_seeds` system variable for each group member be configured to contain all the local addresses for all the group members.
- The MySQL communication stack supports network namespaces, which the XCom communication stack does not support. If network namespaces are used with the Group Replication local addresses for the group members (`group_replication_local_address`), these must be configured for each group member using the `CHANGE REPLICATION SOURCE TO` statement. Also, the `report_host` server system variable for each group member must be set to report the namespace. All group members must use the same namespace to avoid possible issues with address resolution during distributed recovery.
- The `group_replication_ssl_mode` system variable must be set to the required setting for group communications. This system variable controls whether TLS/SSL is enabled or disabled for group communications. When the MySQL communication stack is used, the TLS/SSL configuration is taken from Group Replication's distributed recovery settings. This setting should be the same on all the group members, to avoid potential conflicts.
- The `require_secure_transport` server system variable value should be the same on all the group members, to avoid potential conflicts. If `group_replication_ssl_mode` is set to `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`, use `require_secure_transport=ON`. If `group_replication_ssl_mode` is set to `DISABLED`, use `require_secure_transport=OFF`.
- If TLS/SSL is enabled for group communications, Group Replication's settings for securing distributed recovery must be configured if they are not already in place, or validated if they already are. The MySQL communication stack uses these settings not just for member-to-member distributed recovery connections, but also for TLS/SSL configuration in general group communications. `group_replication_recovery_use_ssl` and the other `group_replication_recovery_*` system variables are explained in [Section 20.6.3.2, "Secure Socket Layer \(SSL\) Connections for Distributed Recovery"](#).

- The Group Replication allowlist is not used when the group is using the MySQL communication stack, so the `group_replication_ip_allowlist` system variable is ignored and need not be set.
- The replication user account that Group Replication uses for distributed recovery, as configured using the `CHANGE REPLICATION SOURCE TO` statement, is used for authentication by the MySQL communication stack when setting up Group Replication connections. This user account, which is the same on all group members, must be given the following privileges:
  - `GROUP_REPLICATION_STREAM`. This privilege is required for the user account to be able to establish connections for Group Replication using the MySQL communication stack.
  - `CONNECTION_ADMIN`. This privilege is required so that Group Replication connections are not terminated if one of the servers involved is placed in offline mode. If the MySQL communication stack is in use without this privilege, a member that is placed in offline mode is expelled from the group.

These are in addition to the privileges `REPLICATION SLAVE` and `BACKUP_ADMIN` that all replication user accounts must have (see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#)). When you add the new privileges, ensure that you skip binary logging on each group member by issuing `SET SQL_LOG_BIN=0` before you issue the `GRANT` statements, and `SET SQL_LOG_BIN=1` after them, so that the local transaction does not interfere with restarting Group Replication.

`group_replication_communication_stack` is effectively a group-wide configuration setting, and the setting must be the same on all group members. However, this is not policed by Group Replication’s own checks for group-wide configuration settings. A member with a different value from the rest of the group cannot communicate with the other members at all, because the communication protocols are incompatible, so it cannot exchange information about its configuration settings.

This means that although the value of the system variable can be changed while Group Replication is running, and takes effect after you restart Group Replication on the group member, the member still cannot rejoin the group until the setting has been changed on all the members. You must therefore stop Group Replication on all of the members and change the value of the system variable on them all before you can restart the group. Because all of the members are stopped, a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) is required in order for the value change to take effect. You can make the other required changes to settings on the group members while they are stopped.

For a running group, follow this procedure to change the value of `group_replication_communication_stack` and the other required settings to migrate a group from the XCom communication stack to the MySQL communication stack, or from the MySQL communication stack to the XCom communication stack:

1. Stop Group Replication on each of the group members, using a `STOP GROUP_REPLICATION` statement. Stop the primary member last, so that you do not trigger a new primary election and have to wait for that to complete.
2. On each of the group members, set the system variable `group_replication_communication_stack` to the new communication stack, `MYSQL` or `XCOM` as appropriate. You can do this by editing the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems), or by using a `SET` statement. For example:

```
SET PERSIST group_replication_communication_stack="MYSQL";
```

3. If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, configure or reconfigure the required system variables to appropriate settings, as described in the listing above. For example, the

`group_replication_local_address` system variable must be set to one of the IP addresses and ports that MySQL Server is listening on. Also configure any network namespaces using a `CHANGE REPLICATION SOURCE TO` statement.

- If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, issue `GRANT` statements to give the replication user account the `GROUP_REPLICATION_STREAM` and `CONNECTION_ADMIN` privileges. You will need to take the group members out of the read-only state that is applied when Group Replication is stopped. Also ensure that you skip binary logging on each group member by issuing `SET SQL_LOG_BIN=0` before you issue the `GRANT` statements, and `SET SQL_LOG_BIN=1` after them, so that the local transaction does not interfere with restarting Group Replication. For example:

```
SET GLOBAL SUPER_READ_ONLY=OFF;
SET SQL_LOG_BIN=0;
GRANT GROUP_REPLICATION_STREAM ON *.* TO repl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO repl_user@'%';
SET SQL_LOG_BIN=1;
```

- If you are migrating the replication group from the MySQL communication stack back to the XCom communication stack, on each of the group members, reconfigure the system variables in the requirements listing above to settings suitable for the XCom communication stack. [Section 20.9, “Group Replication Variables”](#) lists the system variables with their defaults and requirements for the XCom communication stack.

#### Note

- The XCom communication stack does not support network namespaces, so the Group Replication local address (`group_replication_local_address` system variable) cannot use these. Unset them by issuing a `CHANGE REPLICATION SOURCE TO` statement.
  - When you move back to the XCom communication stack, the settings specified by `group_replication_recovery_use_ssl` and the other `group_replication_recovery_*` system variables are not used to secure group communications. Instead, the Group Replication system variable `group_replication_ssl_mode` is used to activate the use of SSL for group communication connections and specify the security mode for the connections, and the remainder of the configuration is taken from the server's SSL configuration. For details, see [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).
- To restart the group, follow the process in [Section 20.5.2, “Restarting a Group”](#), which explains how to safely bootstrap a group where transactions have been executed and certified. A bootstrap by a server with `group_replication_bootstrap_group=ON` is necessary to change the communication stack, because all of the members must be shut down.
  - Members now connect to each other using the new communication stack. Any server that has `group_replication_communication_stack` set (or defaulted, in the case of XCom) to the previous communication stack is no longer able to join the group. It is important to note that because Group Replication cannot even see the joining attempt, it does not check and reject the joining member with an error message. Instead, the attempted join fails silently when the previous communication stack gives up trying to contact the new one.

## 20.6.2 Securing Group Communication Connections with Secure Socket Layer (SSL)

Secure sockets can be used for group communication connections between members of a group.

The Group Replication system variable `group_replication_ssl_mode` is used to activate the use of SSL for group communication connections and specify the security mode for the connections. This value should be the same on all group members; if it differs, some members may not be able to join the group. The default setting means that SSL is not used. This variable has the following possible values:

**Table 20.1** `group_replication_ssl_mode` configuration values

Value	Description
<code>DISABLED</code>	Establish an unencrypted connection (the default).
<code>REQUIRED</code>	Establish a secure connection if the server supports secure connections.
<code>VERIFY_CA</code>	Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
<code>VERIFY_IDENTITY</code>	Like <code>VERIFY_CA</code> , but additionally verify that the server certificate matches the host to which the connection is attempted.

If SSL is used, the means for configuring the secure connection depends on whether the XCom or the MySQL communication stack is used for group communication.

**When using the XCom communication stack**

(`group_replication_communication_stack=XCOM`): The remainder of the configuration for Group Replication's group communication connections is taken from the server's SSL configuration. For more information on the options for configuring the server SSL, see [Command Options for Encrypted Connections](#). The server SSL options that are applied to Group Replication's group communication connections are as follows:

**Table 20.2** SSL Options

Server Configuration	Description
<code>ssl_key</code>	The path name of the SSL private key file in PEM format. On the client side, this is the client private key. On the server side, this is the server private key.
<code>ssl_cert</code>	The path name of the SSL public key certificate file in PEM format. On the client side, this is the client public key certificate. On the server side, this is the server public key certificate.
<code>ssl_ca</code>	The path name of the Certificate Authority (CA) certificate file in PEM format.
<code>ssl_cacpath</code>	The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format.
<code>ssl_crl</code>	The path name of the file containing certificate revocation lists in PEM format.
<code>ssl_crlpath</code>	The path name of the directory that contains certificate revocation list files in PEM format.

Server Configuration	Description
<code>ssl_cipher</code>	A list of permissible ciphers for encrypted connections.
<code>tls_version</code>	A list of the TLS protocols the server permits for encrypted connections.
<code>tls_ciphersuites</code>	Which TLSv1.3 ciphersuites the server permits for encrypted connections.

### Important

- Support for the TLSv1 and TLSv1.1 connection protocols was removed in MySQL 8.0. MySQL clients, including Group Replication server instances acting as clients, do not return warnings to the user if a deprecated TLS protocol version is used. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.
- MySQL 9.7 supports the TLSv1.3 protocol, provided that the MySQL Server was compiled using OpenSSL 1.1.1. The server checks the version of OpenSSL at startup; if it is lower than 1.1.1, TLSv1.3 is removed from the default values for all server system variables relating to TLS versions, including `group_replication_recovery_tls_version`.
- MySQL 9.7 Group Replication supports TLSv1.3.
- Use `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired.
- In the list of TLS protocols specified in the `tls_version` system variable, ensure the specified versions are contiguous (for example, `TLSv1.2, TLSv1.3`). If there are any gaps in the list of protocols (for example, if you specified `TLSv1, TLSv1.2`, omitting TLS 1.1) Group Replication might be unable to make group communication connections.

In a replication group, OpenSSL negotiates the use of the highest TLS protocol that is supported by all members. A joining member that is configured to use only TLSv1.3 (`tls_version=TLSv1.3`) cannot join a replication group where any existing member does not support TLSv1.3, because the group members in that case are using a lower TLS protocol version. To join the member to the group, you must configure the joining member to also permit the use of lower TLS protocol versions supported by the existing group members. Conversely, if a joining member does not support TLSv1.3, but the existing group members all do and are using that version for connections to each other, the member can join if the existing group members already permit the use of a suitable lower TLS protocol version, or if you configure them to do so. In that situation, OpenSSL uses a lower TLS protocol version for the connections from each member to the joining member. Each member's connections to other existing members continue to use the highest available protocol that both members support.

You can change the `tls_version` system variable at runtime to alter the list of permitted TLS protocol versions for the server. For Group Replication, the `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connection while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication on the member or members where you changed the `tls_version` system variable. Similarly, if you

want to make all members of a group change to using a higher or lower TLS protocol version, you must carry out a rolling restart of Group Replication on the members after changing the list of permitted TLS protocol versions, so that OpenSSL negotiates the use of the higher TLS protocol version when the rolling restart is completed. For instructions to change the list of permitted TLS protocol versions at runtime, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#) and [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

The following example shows a section from a `my.cnf` file that configures SSL on a server, and activates SSL for Group Replication group communication connections:

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

### Important

The `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connections while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication.

Connections made between a joining member and an existing member for distributed recovery are not covered by the options described above. These connections use Group Replication's dedicated distributed recovery SSL options, which are described in [Section 20.6.3.2, “Secure Socket Layer \(SSL\) Connections for Distributed Recovery”](#).

### When using the MySQL communication stack

**(`group_replication_communication_stack=MYSQL`):** The security settings for distributed recovery of the group are applied to the normal communications between group members. See [Section 20.6.3, “Securing Distributed Recovery Connections”](#) on how to configure the security settings.

## 20.6.3 Securing Distributed Recovery Connections

### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not just to distributed recovery connections, but to group communications between members in general.

When a member joins the group, distributed recovery is carried out using a combination of a remote cloning operation, if available and appropriate, and an asynchronous replication connection. For a full description of distributed recovery, see [Section 20.5.4, “Distributed Recovery”](#).

Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port` system variables, and may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For

more details, see [Section 20.5.4.1, “Connections for Distributed Recovery”](#). Notice that such connections offered to a joining member for distributed recovery is *not* the same connections that are used by Group Replication for communication between online members when the XCom communication stack is used for group communications (`group_replication_communication_stack=XCOM`).

To secure distributed recovery connections in the group, ensure that user credentials for the replication user are properly secured, and use SSL for distributed recovery connections if possible.

### 20.6.3.1 Secure User Credentials for Distributed Recovery

State transfer from the binary log requires a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. The same replication user is used for distributed recovery on all the group members. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role. For detailed instructions to set up this user, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#).

To secure the user credentials, you can require SSL for connections with the user account, and provide the user credentials when Group Replication is started, rather than storing them in the replica status tables. Also, if you are using caching SHA-2 authentication, you must set up RSA key-pairs on the group members.

#### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the recovery users must be properly set up, as they are also the users for group communications. Follow the instructions in [Replication User With SSL](#) and [Providing Replication User Credentials Securely](#).

### Replication User With The Caching SHA-2 Authentication Plugin

By default, users created in MySQL 8 use [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#). If the replication user you configure for distributed recovery uses the caching SHA-2 authentication plugin, and you are *not* using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. For more information on RSA key-pairs, see [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).

In this situation, you can either copy the public key of the `rpl_user` to the joining member, or configure the donors to provide the public key when requested. The more secure approach is to copy the public key of the replication user account to the joining member. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the joining member with the path to the public key for the replication user account.

The less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the replication user account to joining members. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

### Replication User With SSL

A replication user that requires an SSL connection must be created *before* the server joining the group (the joining member) connects to the donor. Typically, this is set up at the time you are provisioning a server to

join the group. To create a replication user for distributed recovery that requires an SSL connection, issue these statements on all servers that are going to participate in the group:

```
mysql> SET SQL_LOG_BIN=0;
mysql> CREATE USER 'rec_ssl_user'@'%' IDENTIFIED BY 'password' REQUIRE SSL;
mysql> GRANT REPLICATION_SLAVE ON *.* TO 'rec_ssl_user'@'%' ;
mysql> GRANT CONNECTION_ADMIN ON *.* TO 'rec_ssl_user'@'%' ;
mysql> GRANT BACKUP_ADMIN ON *.* TO 'rec_ssl_user'@'%' ;
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO 'rec_ssl_user'@'%' ;
mysql> FLUSH PRIVILEGES;
mysql> SET SQL_LOG_BIN=1;
```

### Note

The `GROUP_REPLICATION_STREAM` privilege is required when using both the MySQL communication stack (`group_replication_communication_stack=MYSQL`) and secure connections between members (`group_replication_ssl_mode` not set to `DISABLED`). See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

## Providing Replication User Credentials Securely

To supply the user credentials for the replication user, you can set them permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement. Alternatively, you can specify them in the `START GROUP_REPLICATION` statement each time Group Replication is started. User credentials specified in `START GROUP_REPLICATION` take precedence over any user credentials that have been set using a `CHANGE REPLICATION SOURCE TO` statement.

User credentials set using `CHANGE REPLICATION SOURCE TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable.

If you want to set the user credentials permanently using a `CHANGE REPLICATION SOURCE TO` statement, issue this statement on the member that is going to join the group:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rec_ssl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

To supply the user credentials on `START GROUP_REPLICATION`, issue this statement when starting Group Replication for the first time, or after a server restart:

```
mysql> START GROUP_REPLICATION USER='rec_ssl_user', PASSWORD='password';
```

### Important

If you switch to using `START GROUP_REPLICATION` to specify user credentials on a server that previously supplied the credentials using `CHANGE REPLICATION SOURCE TO`, you must complete the following steps to get the security benefits of this change.

1. Stop Group Replication on the group member using a `STOP GROUP_REPLICATION` statement. Although it is possible to take the following two steps while Group Replication is running, you need to restart Group Replication to implement the changes.

2. Set the value of the `group_replication_start_on_boot` system variable to `OFF` (the default is `ON`).
3. Remove the distributed recovery credentials from the replica status tables by issuing this statement:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='', SOURCE_PASSWORD=''
-> FOR CHANNEL 'group_replication_recovery';
```

4. Restart Group Replication on the group member using a `START GROUP_REPLICATION` statement that specifies the distributed recovery user credentials.

Without these steps, the credentials remain stored in the replica status tables, and can also be transferred to other group members during remote cloning operations for distributed recovery. The `group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials as part of `START GROUP_REPLICATION`.

### 20.6.3.2 Secure Socket Layer (SSL) Connections for Distributed Recovery

#### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not just to distributed recovery connections, but to group communications between members in general. See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

Whether the distributed recovery connection is made using the standard SQL client connection or a distributed recovery endpoint, to configure the connection securely, you can use Group Replication's dedicated distributed recovery SSL options. These options correspond to the server SSL options that are used for group communication connections, but they are only applied for distributed recovery connections. By default, distributed recovery connections do not use SSL, even if you activated SSL for group communication connections, and the server SSL options are not applied for distributed recovery connections. You must configure these connections separately.

If a remote cloning operation is used as part of distributed recovery, Group Replication automatically configures the clone plugin's SSL options to match your settings for the distributed recovery SSL options. (For details of how the clone plugin uses SSL, see [Configuring an Encrypted Connection for Cloning](#).)

The distributed recovery SSL options are as follows:

- `group_replication_recovery_use_ssl`: Set to `ON` to make Group Replication use SSL for distributed recovery connections, including remote cloning operations and state transfer from a donor's binary log. If the server you connect to does not use the default configuration for this (see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#)), use the other distributed recovery SSL options to determine which certificates and cipher suites to use.
- `group_replication_recovery_ssl_ca`: The path name of the Certificate Authority (CA) file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_ca` to match this.

`group_replication_recovery_ssl_capath`: The path name of a directory that contains trusted SSL certificate authority (CA) certificate files.

- `group_replication_recovery_ssl_cert`: The path name of the SSL public key certificate file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_key`: The path name of the SSL private key file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_verify_server_cert`: Makes the distributed recovery connection check the server's Common Name value in the donor sent certificate. Setting this option to `ON` is the equivalent for distributed recovery connections of setting `VERIFY_IDENTITY` for the `group_replication_ssl_mode` option for group communication connections.
- `group_replication_recovery_ssl_crl`: The path name of a file containing certificate revocation lists.
- `group_replication_recovery_ssl_crlpath`: The path name of a directory containing certificate revocation lists.
- `group_replication_recovery_ssl_cipher`: A list of permissible ciphers for connection encryption for the distributed recovery connection. Specify a list of one or more cipher names, separated by colons. For information about which encryption ciphers MySQL supports, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).
- `group_replication_recovery_tls_version`: A comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. The default for this system variable depends on the TLS protocol versions supported in the MySQL Server release. The group members involved in each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support.
- `group_replication_recovery_tls_ciphersuites`: A colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used.

## 20.6.4 Group Replication IP Address Permissions

When and only when the XCom communication stack is used for establishing group communications (`group_replication_communication_stack=XCOM`), the Group Replication plugin lets you specify an allowlist of hosts from which an incoming Group Communication System connection can be accepted. If you specify an allowlist on a server `s1`, then when server `s2` is establishing a connection to `s1` for the purpose of engaging group communication, `s1` first checks the allowlist before accepting the connection from `s2`. If `s2` is in the allowlist, then `s1` accepts the connection, otherwise `s1` rejects the connection attempt by `s2`. The system variable `group_replication_ip_allowlist` is used to specify the allowlist.

### Note

When the MySQL communication stack is used for establishing group communications (`group_replication_communication_stack=MYSQL`), the setting for `group_replication_ip_allowlist` is ignored. See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

If you do not specify an allowlist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks, together with the subnet mask that is configured for each interface. These addresses, and the `localhost` IP address for IPv4 and IPv6 are used to create an automatic Group Replication allowlist. The automatic allowlist therefore includes any IP addresses that are found for the host in the following ranges after the appropriate subnet mask has been applied:

```
IPv4 (as defined in RFC 1918)
10/8 prefix      (10.0.0.0 - 10.255.255.255) - Class A
172.16/12 prefix (172.16.0.0 - 172.31.255.255) - Class B
192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C

IPv6 (as defined in RFC 4193 and RFC 5156)
fc00::/7 prefix  - unique-local addresses
fe80::/10 prefix - link-local unicast addresses

127.0.0.1 - localhost for IPv4
::1       - localhost for IPv6
```

An entry is added to the error log stating the addresses that have been allowed automatically for the host.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify an allow list manually, use the `group_replication_ip_allowlist` system variable. You can change the list while Group Replication is running.

The allowlist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

IP addresses specified as distributed recovery endpoints, and the IP address for the member's standard SQL client connection if that is used for distributed recovery (which is the default), do not need to be added to the allowlist. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

In the allowlist, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses with CIDR notation (for example, `2001:db8:85a3:8d3::/64`)
- Host names (for example, `example.org`)
- Host names with CIDR notation (for example, `www.example.com/24`)

Host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can

use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

### Note

When a connection attempt from an IP address is refused because the address is not in the allowlist, the refusal message always prints the IP address in IPv6 format. IPv4 addresses are preceded by `::ffff:` in this format (an IPv4-mapped IPv6 address). You do not need to use this format to specify IPv4 addresses in the allowlist; use the standard IPv4 format for them.

A comma must separate each entry in the allowlist. For example:

```
mysql> SET GLOBAL group_replication_ip_allowlist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3
```

To join a replication group, a server needs to be permitted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only permitted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not permit it. To avoid this scenario entirely, specify the same allowlist for all servers that are members of the replication group.

### Note

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different allowlists to meet your security requirements, ensure that there is sufficient overlap between the allowlists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

### Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers,

are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

## 20.7 Group Replication Performance and Troubleshooting

Group Replication is designed to create fault-tolerant systems with built-in failure detection and automated recovery. If a member server instance leaves voluntarily or stops communicating with the group, the remaining members agree a reconfiguration of the group between themselves, and choose a new primary if needed. Expelled members automatically attempt to rejoin the group, and are brought up to date by distributed recovery. If a group experiences a level of difficulties such that it cannot contact a majority of its members in order to agree on a decision, it identifies itself as having lost quorum and stops processing transactions. Group Replication also has built-in mechanisms and settings to help the group adapt to and manage variations in workload and message size, and stay within the limitations of the underlying system and networking resources.

The default settings for Group Replication's system variables are designed to maximize a group's performance and autonomy. The information in this section is to help you configure a replication group to optimize the automatic handling of any recurring issues that you experience on your particular systems, such as transient network outages or workloads and transactions that exceed a server instance's resources.

If you find that group members are being expelled and rejoining the group more frequently than you would like, it is possible that Group Replication's default failure detection settings are too sensitive for your system. This might be the case on slower networks or machines, networks with a high rate of unexpected transient outages, or during planned network outages. For advice on dealing with that situation by adjusting the settings, see [Section 20.7.7, "Responses to Failure Detection and Network Partitioning"](#).

You should only need to intervene manually in a Group Replication setup if something happens that the group cannot deal with automatically. Some key issues that can require administrator intervention are when a member is in `ERROR` status and cannot rejoin the group, or when a network partition causes the group to lose quorum.

- If an otherwise correctly functioning and configured member is unable to join or rejoin the group using distributed recovery, and remains in `ERROR` status, [Section 20.5.4.4, "Fault Tolerance for Distributed Recovery"](#), explains the possible issues. One likely cause is that the joining member has extra transactions that are not present on the existing members of the group. For advice on dealing with that situation, see [Section 20.4.1, "GTIDs and Group Replication"](#).
- If a group has lost quorum, this may be due to a network partition that divides the group into two parts, or possibly due to the failure of the majority of the servers. For advice on dealing with that situation, see [Section 20.7.8, "Handling a Network Partition and Loss of Quorum"](#).

### 20.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

## 20.7.2 Flow Control

MySQL Group Replication ensures that a transaction commits only after a majority of the members in a group have received it and agreed on the relative order amongst all transactions sent concurrently. This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does, and some members have less write throughput than others—particularly less than the writer members—these members may start lagging behind the writers.

When some members lag behind the rest of the group, reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less of the replication context to be able to fulfil potential data transfer requests from the slow member.

The replication protocol provides a mechanism to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism, which has the following objectives:

1. To keep members close, to minimize buffering and desynchronization between them
2. To adapt quickly to changing conditions like different workloads or more writers in the group
3. To give each member a share of the available write capacity
4. Not to reduce throughput more than strictly necessary to avoid wasting resources

Given the design of Group Replication, the decision whether to throttle, or not, may be made taking into account two work queues, the certification queue, and the binary log applier queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered.

Flow control depends on two basic mechanisms:

1. Monitoring of members to collect statistics on throughput and queue sizes of all group members to make educated guesses concerning the maximum write pressure to which each member should be subjected
2. Throttling of members that are trying to write beyond their allotted shares of the available capacity at each moment in time

### Note

The Group Replication Flow Control Statistics Component supports status variables providing information on Group Replication flow control execution. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.

### 20.7.2.1 Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

### 20.7.2.2 Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota is enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

### 20.7.3 Single Consensus Leader

By default, the group communication engine for Group Replication (XCom, a Paxos variant) operates using every member of the replication group as a leader. The group communication engine can use a single leader to drive consensus when the group is in single-primary mode. Operating with a single consensus leader improves performance and resilience in single-primary mode, particularly when some of the group's secondary members are currently unreachable.

To use a single consensus leader, the group must be configured as follows:

- The group must be in single-primary mode.

- The `group_replication_paxos_single_leader` system variable must be set to `ON`. With the default setting `OFF`, the behavior is disabled. You must carry out a full reboot of the replication group (bootstrap) for Group Replication to pick up a change to this setting.
- The Group Replication communication protocol version must be set to 8.0.27 or later. Use the `group_replication_get_communication_protocol()` function to view the group's communication protocol version. If a lower version is in use, the group cannot use this behavior. You can use the `group_replication_set_communication_protocol()` function to set the group's communication protocol to a higher version if all group members support it. MySQL InnoDB Cluster manages the communication protocol version automatically. For more information, see [Section 20.5.1.4, “Setting a Group's Communication Protocol Version”](#).

When this configuration is in place, Group Replication instructs the group communication engine to use the group's primary as the single leader to drive consensus. When a new primary is elected, Group Replication tells the group communication engine to use it instead. If the primary is currently unhealthy, the group communication engine uses an alternative member as the consensus leader. The Performance Schema table `replication_group_communication_information` shows the current preferred and actual consensus leader, with the preferred leader being Group Replication's choice, and the actual leader being the one selected by the group communication engine.

If the group is in multi-primary mode, has a lower communication protocol version, or the behavior is disabled by the `group_replication_paxos_single_leader` setting, all members are used as leaders to drive consensus. In this situation, the Performance Schema table `replication_group_communication_information` shows all of the members as both the preferred and actual leaders.

The `WRITE_CONSENSUS_SINGLE_LEADER_CAPABLE` column of the Performance Schema `replication_group_communication_information` table shows whether the group supports the use of a single leader, even if `group_replication_paxos_single_leader` is currently set to `OFF` on the queried member. The column value is 1 if the group was started with `group_replication_paxos_single_leader` set to `ON`, and its communication protocol version is MySQL 8.0.27 or above. This information is returned only for group members in `ONLINE` or `RECOVERING` state.

### 20.7.4 Message Compression

For messages sent between online group members, Group Replication enables message compression by default. Whether a specific message is compressed depends on the threshold that you configure using the `group_replication_compression_threshold` system variable. Messages that have a payload larger than the specified number of bytes are compressed.

The default compression threshold is 1000000 bytes. You could use the following statements to increase the compression threshold to 2MB, for example:

```
STOP GROUP_REPLICATION;  
SET GLOBAL group_replication_compression_threshold = 2097152;  
START GROUP_REPLICATION;
```

If you set `group_replication_compression_threshold` to zero, message compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. The LZ4 maximum input size is therefore a practical limit for message compression, and transactions above this size cannot

be committed when message compression is enabled. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`.

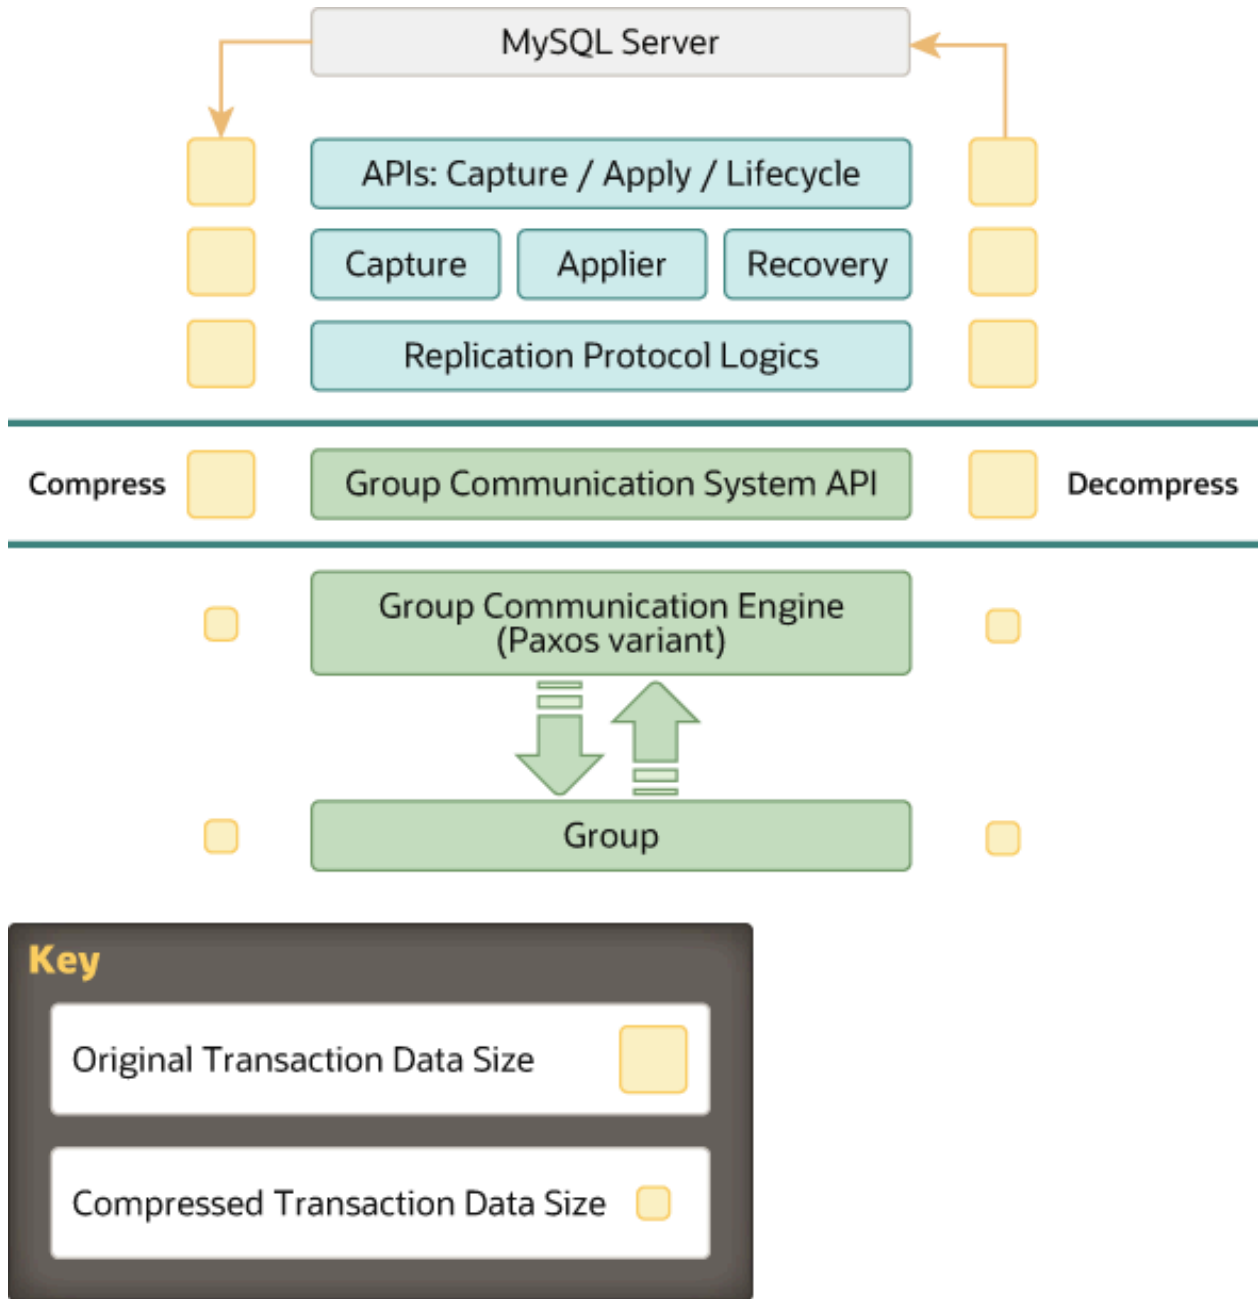

The value of `group_replication_compression_threshold` is not required by Group Replication to be the same on all group members. However, it is advisable to set the same value on all group members in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery.

You can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log. Compression for these messages, which are sent from a donor already in the group to a joining member, is controlled separately using the `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables. For more information, see [Section 6.2.8, "Connection Compression Control"](#).

Binary log transaction compression, enabled by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. The transaction payloads remain compressed when they are transferred between group members. If you use binary log transaction compression in combination with Group Replication's message compression, message compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see [Section 7.4.4.5, "Binary Log Transaction Compression"](#).

Compression for messages sent in the group happens at the group communication engine level, before the data is handed over to the group communication thread, so it takes place within the context of the `mysql` user session thread. If the message payload size exceeds the threshold set by `group_replication_compression_threshold`, the transaction payload is compressed before being sent out to the group, and decompressed when it is received. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer. This process is shown in the following figure.

Figure 20.13 Compression Support

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load. The TCP peer-to-peer nature of the interconnections between  $N$  participants in the group makes the sender send the same amount of data  $N$  times. Furthermore, binary logs are likely to exhibit a high compression ratio. This makes compression a compelling feature for Group Replication workloads that contain large transactions.

### 20.7.5 Message Fragmentation

When an abnormally large message is sent between Group Replication group members, it can result in some group members being reported as failed and expelled from the group. This is because the single

thread used by Group Replication's group communication engine (XCom, a Paxos variant) is occupied processing the message for too long, so some of the group members might report the receiver as failed. By default, large messages are automatically split into fragments that are sent separately and reassembled by the recipients.

The system variable `group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications, above which messages are fragmented. The default maximum message size is 10485760 bytes (10 MiB). The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` system variable (1 GB). `group_replication_communication_max_message_size` must be less than `replica_max_allowed_packet` because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

As with most other Group Replication system variables, you must restart the Group Replication plugin for the change to take effect. For example:

```
STOP GROUP_REPLICATION;  
SET GLOBAL group_replication_communication_max_message_size= 5242880;  
START GROUP_REPLICATION;
```

Message delivery for a fragmented message is considered complete when all the fragments of the message have been received and reassembled by all the group members. Fragmented messages include information in their headers that enables a member joining during message transmission to recover the earlier fragments that were sent before it joined. If the joining member fails to recover the fragments, it expels itself from the group.

The Group Replication communication protocol version in use by the group must allow fragmentation. You can obtain the communication protocol in use by a group using `group_replication_get_communication_protocol()`, which returns the oldest MySQL Server version that the group supports. If necessary, use `group_replication_set_communication_protocol()` to set the communication protocol version high enough (8.0.16 or above) to allow fragmentation. For more information, see [Section 20.5.1.4, "Setting a Group's Communication Protocol Version"](#).

If a replication group cannot use fragmentation because some members do not support it, the system variable `group_replication_transaction_size_limit` can be used to limit the maximum size of transactions the group accepts. Transactions above this size are rolled back. You can also use `group_replication_member_expel_timeout` to allow additional time (up to an hour) before a member under suspicion of having failed is expelled from the group.

## 20.7.6 XCom Cache Management

The group communication engine for Group Replication (XCom, a Paxos variant) includes a cache for messages (and their metadata) exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

A cache size limit can be set for XCom's message cache using the `group_replication_message_cache_size` system variable. If the cache size limit is reached, XCom removes the oldest entries that have been decided and delivered. The same cache size limit should be set on all group members, because an unreachable member that is attempting to reconnect selects any other member at random for recovery of missed messages. The same messages should therefore be available in each member's cache.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

When choosing the value for `group_replication_message_cache_size`, do so with regard to the expected volume of messages in the period before a member is expelled. The length of this period is controlled by the `group_replication_member_expel_timeout` system variable, which determines the waiting period (up to an hour) that is allowed *in addition to* the initial 5-second detection period for members to return to the group rather than being expelled. The timeout defaults to 5 seconds, so by default a member is not expelled until it has been absent for at least 10 seconds.

### 20.7.6.1 Increasing the cache size

If a member is absent for a period that is not long enough for it to be expelled from the group, it can reconnect and start participating in the group again by retrieving missed transactions from another member's XCom message cache. However, if the transactions that happened during the member's absence have been deleted from the other members' XCom message caches because their maximum size limit was reached, the member cannot reconnect in this way.

Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. This warning message is logged on all the active group members (only once for each unreachable member). Although the group members cannot know for sure what message was the last message seen by the unreachable member, the warning message indicates that the cache size might not be sufficient to support your chosen waiting period before a member is expelled.

In this situation, consider increasing the `group_replication_message_cache_size` limit with reference to the expected volume of messages in the time period specified by the `group_replication_member_expel_timeout` system variable plus the 5-second detection period, so that the cache contains all the missed messages required for members to return successfully. You can also consider increasing the cache size limit temporarily if you expect a member to become unreachable for an unusual period of time.

### 20.7.6.2 Reducing the cache size

The minimum setting for the XCom message cache size in MySQL 9.7 is 128 MB, which enables deployment on a host that has a restricted amount of available memory. Having a very low `group_replication_message_cache_size` setting is not recommended if the host is on an unstable network, because a smaller message cache makes it harder for group members to reconnect after a transient loss of connectivity.

If a reconnecting member cannot retrieve all the messages it needs from the XCom message cache, the member must leave the group and rejoin it, in order to retrieve the missing transactions from another member's binary log using distributed recovery. A member that has left a group makes three auto-rejoin attempts by default, so the process of rejoining the group can still take place without operator intervention. However, rejoining using distributed recovery is a significantly longer and more complex process than retrieving messages from an XCom message cache, so the member takes longer to become available and the performance of the group can be impacted. On a stable network, which minimizes the frequency and duration of transient losses of connectivity for members, the frequency of this occurrence should also be minimized, so the group might be able to tolerate a smaller XCom message cache size without a significant impact on its performance.

If you are considering reducing the cache size limit, you can query the Performance Schema table `memory_summary_global_by_event_name` using the following statement:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/group_rpl/GCS_XCom::xcom_cache';
```

This returns memory usage statistics for the message cache, including the current number of cached entries and current size of the cache. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. XCom might temporarily exceed the cache size limit while this removal process is ongoing.

## 20.7.7 Responses to Failure Detection and Network Partitioning

Group Replication's failure detection mechanism is designed to identify group members that are no longer communicating with the group, and expel them as and when it seems likely that they have failed. Having a failure detection mechanism increases the chance that the group contains a majority of correctly working members, and that requests from clients are therefore processed correctly.

Normally, all group members regularly exchange messages with all other group members. If a group member does not receive any messages from a particular fellow member for 5 seconds, when this detection period ends, it creates a suspicion of the fellow member. When a suspicion times out, the suspected member is assumed to have failed, and is expelled from the group. An expelled member is removed from the membership list seen by the other members, but it does not know that it has been expelled from the group, so it sees itself as online and the other members as unreachable. If the member has not in fact failed (for example, because it was just disconnected due to a temporary network issue) and it is able to resume communication with the other members, it receives a view containing the information that it has been expelled from the group.

The responses of group members, including the failed member itself, to these situations can be configured at a number of points in the process. By default, the following behaviors happen if a member is suspected of having failed:

1. In MySQL 9.7, when a suspicion is created, a waiting period of 5 seconds is added before the suspicion times out and the suspected member is liable for expulsion.
2. If an expelled member resumes communication and realises that it was expelled, it automatically makes three attempts to rejoin the group (with 5 minutes between each attempt); if this auto-rejoin procedure does not work, it then stops trying to rejoin the group.
3. When an expelled member is not trying to rejoin the group, it switches to super-read-only mode and awaits operator attention.

You can use the Group Replication configuration options described in this section to change these behaviors either permanently or temporarily, to suit your system's requirements and your priorities. If you are experiencing unnecessary expulsions caused by slower networks or machines, networks with a high rate of unexpected transient outages, or planned network outages, consider increasing the expel timeout and auto-rejoin attempts. While a member is undergoing any of the default behaviors described previously, although it does not accept writes, reads can still be performed if the member is still communicating with clients, with an increasing likelihood of stale reads over time. If avoiding stale reads is a higher priority for you than avoiding operator intervention, consider reducing the expel timeout and auto-rejoin attempts or setting them to zero.

Members that have not failed might lose contact with part, but not all, of the replication group due to a network partition. For example, in a group of 5 servers (S1, S2, S3, S4, S5), if there is a disconnection between (S1, S2) and (S3, S4, S5) there is a network partition. The first group (S1, S2) is now in a minority because it cannot contact more than half of the group. Any transactions that are processed by the members in the minority group are blocked, because the majority of the group is unreachable, therefore the group cannot achieve quorum. For a detailed description of this scenario, see [Section 20.7.8, "Handling a Network Partition and Loss of Quorum"](#). In this situation, the default behavior is for the members in both the

minority and the majority to remain in the group, continue to accept transactions (although they are blocked on the members in the minority), and wait for operator intervention. This behavior is also configurable.

Note that where group members are at an older MySQL Server release that does not support a relevant setting, or at a release with a different default, they act towards themselves and other group members according to the default behaviors stated above. For example, a member that does not support the `group_replication_member_expel_timeout` system variable expels other members as soon as an expired suspicion is detected, and this expulsion is accepted by other members even if they support the system variable and have a longer timeout set.

### 20.7.7.1 Expel Timeout

You can use the `group_replication_member_expel_timeout` system variable to allow additional time between the creation of a suspicion and the expulsion of the suspect member. A suspicion is created when one server does not receive messages from another server, as explained in [Section 20.1.4.2, “Failure Detection”](#).

There is an initial 5-second detection period before a Group Replication group member creates a suspicion of another member (or of itself). A group member is then expelled when another member's suspicion of it (or its own suspicion of itself) times out. A further short period of time might elapse after that before the expelling mechanism detects and implements the expulsion. `group_replication_member_expel_timeout` specifies the period of time in seconds, called the expel timeout, that a group member waits between creating a suspicion, and expelling the suspected member. Suspect members are listed as `UNREACHABLE` during this waiting period, but are not removed from the group's membership list.

- If a suspect member becomes active again before the suspicion times out at the end of the waiting period, the member applies all the messages that were buffered by the remaining group members in XCom's message cache and enters `ONLINE` state, without operator intervention. In this situation, the member is considered by the group as the same incarnation.
- If a suspect member becomes active only after the suspicion times out and is able to resume communications, it receives a view where it is expelled and at that point realises it was expelled. You can use `group_replication_autorejoin_tries` to make the member try to rejoin the group automatically at this point. This feature is active by default in MySQL 9.7, and the member makes three auto-rejoin attempts. If the auto-rejoin procedure does not succeed or is not attempted, the expelled member then follows the exit action specified by `group_replication_exit_state_action`.

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

If `group_replication_member_expel_timeout` is set to 0, there is no waiting period, and a suspected member is liable for expulsion immediately after the initial 5-second detection period ends. The default is 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period has expired. It is not mandatory for all members of a group to have the same setting for `group_replication_member_expel_timeout`, but it is recommended in order to avoid unexpected expulsions. Any member can create a suspicion of any other member, including itself, so the effective expel timeout is that of the member with the lowest setting.

Consider increasing the value of `group_replication_member_expel_timeout` from the default in the following scenarios:

- The network is slow and the default 5 or 10 seconds before expulsion is not long enough for group members to always exchange at least one message.

- The network sometimes has transient outages and you want to avoid unnecessary expulsions and primary member changes at these times.
- The network is not under your direct control and you want to minimize the need for operator intervention.
- A temporary network outage is expected and you do not want some or all of the members to be expelled due to this.
- An individual machine is experiencing a slowdown and you do not want it to be expelled from the group.

You can specify an expel timeout up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members cannot reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see [Section 20.7.6, "XCom Cache Management"](#).

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

If a replication group member stops unexpectedly and is immediately restarted (for example, because it was started with `mysqld_safe`), it automatically attempts to rejoin the group if `group_replication_start_on_boot=on` is set. In this situation, it is possible for the restart and rejoin attempt to take place before the member's previous incarnation has been expelled from the group, in which case the member cannot rejoin. Group Replication automatically uses a Group Communication System (GCS) feature to retry the rejoin attempt for the member 10 times, with a 5-second interval between each retry. This should cover most cases and allow enough time for the previous incarnation to be expelled from the group, letting the member rejoin. Note that if the `group_replication_member_expel_timeout` system variable is set to specify a longer waiting period before the member is expelled, the automatic rejoin attempts might still not succeed.

For alternative mitigation strategies to avoid unnecessary expulsions where the `group_replication_member_expel_timeout` system variable is not available, see [Section 20.3.2, "Group Replication Limitations"](#).

### 20.7.7.2 Unreachable Majority Timeout

By default, members that find themselves in a minority due to a network partition do not automatically leave the group. You can use the system variable `group_replication_unreachable_majority_timeout` to set a number of seconds for a member to wait after losing contact with the majority of group members, and then exit the group. Setting a timeout means you do not need to pro-actively monitor for servers that are in a minority group after a network partition, and you can avoid the possibility of creating a split-brain situation (with two versions of the group membership) due to inappropriate intervention.

When the timeout specified by `group_replication_unreachable_majority_timeout` elapses, all pending transactions that have been processed by the member and the others in the minority group are rolled back, and the servers in that group move to the `ERROR` state. You can use the `group_replication_autorejoin_tries` system variable to force the member to try to rejoin the group automatically at this point. This feature is active by default; the member makes three auto-rejoin

attempts. If the auto-rejoin procedure does not succeed or is not attempted, the minority member then follows the exit action specified by `group_replication_exit_state_action`.

Consider the following points when deciding whether or not to set an unreachable majority timeout:

- In a symmetric group, for example a group with two or four servers, if both partitions contain an equal number of servers, both groups consider themselves to be in a minority and enter the `ERROR` state. In this situation, the group has no functional partition.
- While a minority group exists, any transactions processed by the minority group are accepted, but blocked because the minority servers cannot reach quorum, until either `STOP GROUP_REPLICATION` is issued on those servers or the unreachable majority timeout is reached.
- If you do not set an unreachable majority timeout, the servers in the minority group never enter the `ERROR` state automatically, and you must stop them manually.
- Setting an unreachable majority timeout has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

If you do not use the `group_replication_unreachable_majority_timeout` system variable, the process for operator intervention in the event of a network partition is described in [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#). The process involves checking which servers are functioning and forcing a new group membership if necessary.

### 20.7.7.3 Auto-Rejoin

The `group_replication_autorejoin_tries` system variable makes a member that has been expelled or reached its unreachable majority timeout try to rejoin the group automatically. The default (3), means that the member automatically makes 3 attempts to rejoin the group, with 5 minutes between each attempt.

When auto-rejoin is not activated, a member accepts its expulsion as soon as it resumes communication, and proceeds to the action specified by the `group_replication_exit_state_action` system variable. After this, manual intervention is needed to bring the member back into the group. Using the auto-rejoin feature is appropriate if you can tolerate the possibility of stale reads and want to minimize the need for manual intervention, especially where transient network issues fairly often result in the expulsion of members.

With auto-rejoin, when the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. The auto-rejoin attempts and the time between them are called the auto-rejoin procedure. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and displays an `ERROR` state on its view of the replication group. During this time, the member does not accept writes. However, reads can still be made on the member, with an increasing likelihood of stale reads over time. If you do want to intervene to take the member offline during the auto-rejoin procedure, the member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. If you cannot tolerate the possibility of stale reads for any period of time, set the `group_replication_autorejoin_tries` system variable to 0.

You can monitor the auto-rejoin procedure using the Performance Schema. While an auto-rejoin procedure is taking place, the Performance Schema table `events_stages_current`

shows the event “Undergoing auto-rejoin procedure”, with the number of retries that have been attempted so far during this instance of the procedure (in the `WORK_COMPLETED` column). The `events_stages_summary_global_by_event_name` table shows the number of times the server instance has initiated the auto-rejoin procedure (in the `COUNT_STAR` column). The `events_stages_history_long` table shows the time each of these auto-rejoin procedures was completed (in the `TIMER_END` column). While a member is rejoining a replication group, its status can be displayed as `OFFLINE` or `ERROR` before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group's transactions, its status is `RECOVERING`.

#### 20.7.7.4 Exit Action

The `group_replication_exit_state_action` system variable specifies what Group Replication does when the member leaves the group unintentionally due to an error or problem, and either fails to auto-rejoin or does not try. Note that in the case of an expelled member, the member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

In order of impact, the exit actions are as follows:

1. If `READ_ONLY` is the exit action, the instance switches MySQL to super read only mode by setting the system variable `super_read_only` to `ON`. When the member is in super read only mode, clients cannot make any updates, even if they have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). However, clients can still read data, and because updates are no longer being made, there is a probability of stale reads which increases over time. With this setting, you therefore need to pro-actively monitor the servers for failures. This exit action is the default; after it is taken, the member's status is shown as `ERROR` in the view of the group.
2. If `OFFLINE_MODE` is the exit action, the instance switches MySQL to offline mode by setting the system variable `offline_mode` to `ON`. When the member is in offline mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege. This exit action prevents both updates and stale reads (with the exception of reads by client users with the stated privileges), and enables proxy tools such as MySQL Router to recognize that the server is unavailable and redirect client connections. It also leaves the instance running so that an administrator can attempt to resolve the issue without shutting down MySQL. After this exit action is taken, the member's status is displayed as `ERROR` in the view of the group (not `OFFLINE`, which means a member has Group Replication functionality available but does not currently belong to a group).
3. If `ABORT_SERVER` is the exit action, the instance shuts down MySQL. Instructing the member to shut itself down prevents all stale reads and client updates, but it means that the MySQL Server instance is unavailable and must be restarted, even if the issue could have been resolved without that step. After this exit action is taken, the member is removed from the listing of servers in the view of the group.

Bear in mind that operator intervention is required whatever exit action is set, as an ex-member that has exhausted its auto-rejoin attempts (or never had any) and has been expelled from the group is not allowed to rejoin without a restart of Group Replication. The exit action only influences whether or not clients can still read data on the server that was unable to rejoin the group, and whether or not the server stays running.

#### Important

If a failure occurs before the member has successfully joined the group, the exit action specified by `group_replication_exit_state_action` is *not taken*.

This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` statement.

If a failure occurs after the member has successfully joined the group, the specified exit action is taken. This is the case in the following situations:

1. *Applier error* - There is an error in the replication applier. This issue is not recoverable.
2. *Distributed recovery not possible* - There is an issue that means Group Replication's distributed recovery process (which uses remote cloning operations and state transfer from the binary log) cannot be completed. Group Replication retries distributed recovery automatically where this makes sense, but stops if there are no more options to complete the process. For details, see [Section 20.5.4.4, "Fault Tolerance for Distributed Recovery"](#).
3. *Group configuration change error* - An error occurred during a group-wide configuration change carried out using a function, as described in [Section 20.5.1, "Configuring an Online Group"](#).
4. *Primary election error* - An error occurred during election of a new primary member for a group in single-primary mode, as described in [Section 20.1.3.1, "Single-Primary Mode"](#).
5. *Unreachable majority timeout* - The member has lost contact with a majority of the group members so is in a minority, and a timeout that was set by the `group_replication_unreachable_majority_timeout` system variable has expired.
6. *Member expelled from group* - A suspicion has been raised on the member, and any timeout set by the `group_replication_member_expel_timeout` system variable has expired, and the member has resumed communication with the group and found that it has been expelled.
7. *Out of auto-rejoin attempts* - The `group_replication_autorejoin_tries` system variable was set to specify a number of auto-rejoin attempts after a loss of majority or expulsion, and the member completed this number of attempts without success.

The following table summarizes the failure scenarios and actions in each case:

**Table 20.3 Exit actions in Group Replication failure situations**

Failure situation	Group Replication started with <code>START GROUP_REPLICATION</code>	Group Replication started with <code>group_replication_start_on_boot=ON</code>
Member fails local configuration check	<code>super_read_only</code> and <code>offline_mode</code> unchanged	<code>super_read_only</code> and <code>offline_mode</code> unchanged
Mismatch between joining member and group configuration	MySQL continues running Set <code>super_read_only=ON</code> at startup to prevent updates	MySQL continues running

Failure situation	Group Replication started with <code>START GROUP_REPLICATION</code>	Group Replication started with <code>group_replication_start_on_boot=ON</code>
		Set <code>super_read_only=ON</code> at startup to prevent updates (Important)
Applier error on member	<code>super_read_only</code> set to <code>ON</code>	<code>super_read_only</code> set to <code>ON</code>
Distributed recovery not possible	OR	OR
Group configuration change error	<code>offline_mode</code> and <code>super_read_only</code> set to <code>ON</code>	<code>offline_mode</code> and <code>super_read_only</code> set to <code>ON</code>
Primary election error	OR	OR
Unreachable majority timeout	MySQL shuts down	MySQL shuts down
Member expelled from group		
Out of auto-rejoin attempts		

## 20.7.8 Handling a Network Partition and Loss of Quorum

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example, in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

### Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

For a group in single-primary mode, the primary might have transactions that are not yet present on other members at the time of the network partition. If you are considering excluding the primary from the new group, be aware that such transactions might be lost. A member with extra transactions cannot rejoin the group, and the attempt results in an error with the message `This member has more executed transactions than those present in the group`. Set the `group_replication_unreachable_majority_timeout` system variable for the group members to avoid this situation.

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

## Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 20.14 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT MEMBER_ID, MEMBER_STATE, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE	MEMBER_ROLE
1999b9fb-4aaf-11e6-bb54-28b2bd168d07	ONLINE	SECONDARY
199b2df7-4aaf-11e6-bb16-28b2bd168d07	ONLINE	PRIMARY
199bb88e-4aaf-11e6-babe-28b2bd168d07	ONLINE	SECONDARY
19ab72fc-4aaf-11e6-bb51-28b2bd168d07	ONLINE	SECONDARY
19b33846-4aaf-11e6-ba81-28b2bd168d07	ONLINE	SECONDARY

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several other members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE
1999b9fb-4aaf-11e6-bb54-28b2bd168d07	UNREACHABLE
199b2df7-4aaf-11e6-bb16-28b2bd168d07	ONLINE
199bb88e-4aaf-11e6-babe-28b2bd168d07	ONLINE
19ab72fc-4aaf-11e6-bb51-28b2bd168d07	UNREACHABLE
19b33846-4aaf-11e6-ba81-28b2bd168d07	UNREACHABLE

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

## Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 20.15 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shut down and if they are not, shut them down before proceeding.

### Warning

For a group in single-primary mode, the primary might have transactions that are not yet present on other members at the time of the network partition. If you are considering excluding the primary from the new group, be aware that such transactions might be lost. A member with extra transactions cannot rejoin the group, and the attempt results in an error with the message `This member has more executed transactions than those present in the group`. Set the `group_replication_unreachable_majority_timeout` system variable for the group members to avoid this situation.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE
1999b9fb-4aaf-11e6-bb54-28b2bd168d07	UNREACHABLE
199b2df7-4aaf-11e6-bb16-28b2bd168d07	ONLINE
199bb88e-4aaf-11e6-babe-28b2bd168d07	ONLINE
19ab72fc-4aaf-11e6-bb51-28b2bd168d07	UNREACHABLE
19b33846-4aaf-11e6-ba81-28b2bd168d07	UNREACHABLE

The first thing to do is to check what is the local address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
```

Once you know the group communication addresses of s1 (`127.0.0.1:10000`) and s2 (`127.0.0.1:10001`), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE
b5ffe505-4ab6-11e6-b04b-28b2bd168d07	ONLINE
b60907e7-4ab6-11e6-afb7-28b2bd168d07	ONLINE

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE
b5ffe505-4ab6-11e6-b04b-28b2bd168d07	ONLINE
b60907e7-4ab6-11e6-afb7-28b2bd168d07	ONLINE

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

## 20.7.9 Monitoring Group Replication Memory Usage with Performance Schema Memory Instrumentation

The MySQL [Performance Schema](#) provides instrumentation for performance monitoring of Group Replication memory usage. To view the available Group Replication instrumentation, issue the following query:

```
mysql> SELECT NAME,ENABLED FROM performance_schema.setup_instruments
        WHERE NAME LIKE 'memory/group_rpl/%';
```

NAME	ENABLED
memory/group_rpl/write_set_encoded	YES
memory/group_rpl/certification_data	YES
memory/group_rpl/certification_data_gc	YES
memory/group_rpl/certification_info	YES
memory/group_rpl/transaction_data	YES
memory/group_rpl/sql_service_command_data	YES
memory/group_rpl/mysql_thread_queued_task	YES
memory/group_rpl/message_service_queue	YES
memory/group_rpl/message_service_received_message	YES
memory/group_rpl/group_member_info	YES
memory/group_rpl/consistent_members_that_must_prepare_transaction	YES
memory/group_rpl/consistent_transactions	YES
memory/group_rpl/consistent_transactions_prepared	YES
memory/group_rpl/consistent_transactions_waiting	YES
memory/group_rpl/consistent_transactions_delayed_view_change	YES
memory/group_rpl/GCS_XCom::xcom_cache	YES
memory/group_rpl/Gcs_message_data::m_buffer	YES

For more information on Performance Schema's memory instrumentation and events, see [Section 29.12.20.10, "Memory Summary Tables"](#).

### Performance Schema Group Replication instruments memory allocation for Group Replication.

The `memory/group_rpl/` Performance Schema instrumentation contains the following instruments:

- `write_set_encoded`: Memory allocated to encode the write set before it is broadcast to the group members.
- `Gcs_message_data::m_buffer`: Memory allocated for the transaction data payload sent to the network.
- `certification_data`: Memory allocated for certification of incoming transactions.
- `certification_data_gc`: Memory allocated for the GTID\_EXECUTED sent by each member for garbage collection.
- `certification_info`: Memory allocated for storage of certification information allocated to resolve conflicts between concurrent transactions.
- `transaction_data`: Memory allocated for incoming transactions queued for the plugin pipeline.

- `message_service_received_message`: Memory allocated to receiving messages from Group Replication delivery message service.
- `sql_service_command_data`: Memory allocated for processing the queue of internal SQL service commands.
- `mysql_thread_queued_task`: Memory allocated when a MySQL-thread dependent task is added to the processing queue.
- `message_service_queue`: Memory allocated for queued messages of the Group Replication delivery message service.
- `GCS_XCom::xcom_cache`: Memory allocated to XCOM ache for messaging and metadata exchanged between group members as part of the consensus protocol.
- `consistent_members_that_must_prepare_transaction`: Memory allocated to hold list of members preparing transaction for Group Replication transaction consistency guarantees.
- `consistent_transactions`: Memory allocated to hold transaction and list of members that must prepare that transaction for Group Replication transaction consistency guarantees.
- `consistent_transactions_prepared`: Memory allocated to hold list of transaction's info prepared for the Group Replication Transaction Consistency Guarantees.
- `consistent_transactions_waiting`: Memory allocated to hold information on a list of transactions while preceding prepared transactions with consistency of `AFTER` and `BEFORE_AND_AFTER` are processed.
- `consistent_transactions_delayed_view_change`: Memory allocated to hold list of view change events (`view_change_log_event`) delayed by prepared consistent transactions waiting for prepare acknowledgement.
- `group_member_info`: Memory allocated to hold the group member properties. Properties such as hostname, port, member weight and role, and so on.

The following instruments in the `memory/sql/` grouping are also used to monitor Group Replication memory:

- `Log_event`: Memory allocated for encoding transaction data into the binary log format; this is the same format in which Group Replication transmits data.
- `write_set_extraction`: Memory allocated to the transaction's generated write set before it is committed.
- `Gtid_set::to_string`: Memory allocated to stored the string representation of a GTID set.
- `Gtid_set::Interval_chunk`: Memory allocated to store the GTID object.

### 20.7.9.1 Enabling or Disabling Group Replication Instrumentation

To enable all the Group Replication instrumentation from the command line, run the following in the SQL client of your choice:

```
UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
WHERE NAME LIKE 'memory/group_rpl/%';
```

To disable all the Group Replication instrumentation from the command line, run the following in the SQL client of your choice:

```
UPDATE performance_schema.setup_instruments SET ENABLED = 'NO'
```

```
WHERE NAME LIKE 'memory/group_rpl/%';
```

To enable all the Group Replication instrumentation at server startup, add the following to your option file:

```
[mysqld]
performance-schema-instrument='memory/group_rpl/%=ON'
```

To disable all the Group Replication instrumentation at server startup, add the following to your option file:

```
[mysqld]
performance-schema-instrument='memory/group_rpl/%=OFF'
```

To enable or disable individual instruments in that group, replace the wildcard (%) with the full name of the instrument.

For more information, see [Section 29.3, “Performance Schema Startup Configuration”](#) and [Section 29.4, “Performance Schema Runtime Configuration”](#).

### 20.7.9.2 Example Queries

This section describes sample queries using the instruments and events for monitoring Group Replication memory usage. The queries retrieve data from the `memory_summary_global_by_event_name` table.

The memory data can be queried for individual events, for example:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME = 'memory/group_rpl/write_set_encoded'\G

***** 1. row *****
      EVENT_NAME: memory/group_rpl/write_set_encoded
      COUNT_ALLOC: 1
      COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 45
SUM_NUMBER_OF_BYTES_FREE: 0
      LOW_COUNT_USED: 0
      CURRENT_COUNT_USED: 1
      HIGH_COUNT_USED: 1
      LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 45
      HIGH_NUMBER_OF_BYTES_USED: 45
```

See [Section 29.12.20.10, “Memory Summary Tables”](#) for more information on the columns.

You can also define queries which sum various events to provide overviews of specific areas of memory usage.

The following examples are described:

- [Memory Used to Capture Transactions](#)
- [Memory Used to Broadcast Transactions](#)
- [Total Memory Used in Group Replication](#)
- [Memory Used in Certification](#)
- [Memory Used in Certification](#)
- [Memory Used in Replication Pipeline](#)
- [Memory Used in Consistency](#)

- [Memory Used in Delivery Message Service](#)
- [Memory Used to Broadcast and Receive Transactions](#)

## Memory Used to Capture Transactions

The memory allocated to capture user transactions is a sum of the `write_set_encoded`, `write_set_extraction`, and `Log_event` event's values. For example:

```
SELECT * FROM (SELECT
  (CASE
    WHEN EVENT_NAME LIKE 'memory/group_rpl/write_set_encoded'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/write_set_extraction'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/Log_event'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
  END) AS EVENT_NAME,
  SUM(COUNT_ALLOC), SUM(COUNT_FREE),
  SUM(SUM_NUMBER_OF_BYTES_ALLOC),
  SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
  SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
  SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
  SUM(HIGH_NUMBER_OF_BYTES_USED)
  FROM performance_schema.memory_summary_global_by_event_name
  GROUP BY (CASE
    WHEN EVENT_NAME LIKE 'memory/group_rpl/write_set_encoded'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/write_set_extraction'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/sql/Log_event'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
  END)
) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
          EVENT_NAME: memory/group_rpl/memory_gr
          SUM(COUNT_ALLOC): 127
          SUM(COUNT_FREE): 117
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 54808
SUM(SUM_NUMBER_OF_BYTES_FREE): 52051
          SUM(LOW_COUNT_USED): 0
          SUM(CURRENT_COUNT_USED): 10
          SUM(HIGH_COUNT_USED): 35
          SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 2757
          SUM(HIGH_NUMBER_OF_BYTES_USED): 15630
```

## Memory Used to Broadcast Transactions

The memory allocated to broadcast transactions is a sum of the `Gcs_message_data::m_buffer`, `transaction_data`, and `GCS_XCom::xcom_cache` event values. For example:

```
SELECT * FROM (
  SELECT
    (CASE
      WHEN EVENT_NAME = 'memory/group_rpl/Gcs_message_data::m_buffer'
      THEN 'memory/group_rpl/memory_gr'
      WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
      THEN 'memory/group_rpl/memory_gr'
      WHEN EVENT_NAME = 'memory/group_rpl/transaction_data'
      THEN 'memory/group_rpl/memory_gr'
      ELSE 'memory_gr_rest'
    )
```

```

        END) AS EVENT_NAME,
        SUM(COUNT_ALLOC), SUM(COUNT_FREE),
        SUM(SUM_NUMBER_OF_BYTES_ALLOC),
        SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
        SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
        SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
        SUM(HIGH_NUMBER_OF_BYTES_USED)
FROM performance_schema.memory_summary_global_by_event_name
GROUP BY (CASE
            WHEN EVENT_NAME = 'memory/group_rpl/Gcs_message_data::m_buffer'
            THEN 'memory/group_rpl/memory_gr'
            WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
            THEN 'memory/group_rpl/memory_gr'
            WHEN EVENT_NAME = 'memory/group_rpl/transaction_data'
            THEN 'memory/group_rpl/memory_gr'
            ELSE 'memory_gr_rest'
          END)
) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
          EVENT_NAME: memory/group_rpl/memory_gr
          SUM(COUNT_ALLOC): 84
          SUM(COUNT_FREE): 31
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 1072324
SUM(SUM_NUMBER_OF_BYTES_FREE): 7149
          SUM(LOW_COUNT_USED): 0
          SUM(CURRENT_COUNT_USED): 53
          SUM(HIGH_COUNT_USED): 59
          SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 1065175
SUM(HIGH_NUMBER_OF_BYTES_USED): 1065809

```

## Total Memory Used in Group Replication

The memory allocation to sending and receiving transactions, certification, and all other major processes. It is calculated by querying all the events of the `memory/group_rpl/` group. For example:

```

SELECT * FROM (
  SELECT
    (CASE
      WHEN EVENT_NAME LIKE 'memory/group_rpl/%'
      THEN 'memory/group_rpl/memory_gr'
      ELSE 'memory_gr_rest'
    END) AS EVENT_NAME,
    SUM(COUNT_ALLOC), SUM(COUNT_FREE),
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),
    SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
    SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
    SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
    SUM(HIGH_NUMBER_OF_BYTES_USED)
  FROM performance_schema.memory_summary_global_by_event_name
  GROUP BY (CASE
            WHEN EVENT_NAME LIKE 'memory/group_rpl/%'
            THEN 'memory/group_rpl/memory_gr'
            ELSE 'memory_gr_rest'
          END)
) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
          EVENT_NAME: memory/group_rpl/memory_gr
          SUM(COUNT_ALLOC): 190
          SUM(COUNT_FREE): 127
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 1096370
SUM(SUM_NUMBER_OF_BYTES_FREE): 28675
          SUM(LOW_COUNT_USED): 0

```

```

SUM(CURRENT_COUNT_USED): 63
SUM(HIGH_COUNT_USED): 77
SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 1067695
SUM(HIGH_NUMBER_OF_BYTES_USED): 1069255

```

## Memory Used in Certification

The memory allocation in the certification process is a sum of the [certification\\_data](#), [certification\\_data\\_gc](#), and [certification\\_info](#) event values. For example:

```

SELECT * FROM (
  SELECT
    (CASE
      WHEN EVENT_NAME = 'memory/group_rpl/certification_data'
      THEN 'memory/group_rpl/certification'
      WHEN EVENT_NAME = 'memory/group_rpl/certification_data_gc'
      THEN 'memory/group_rpl/certification'
      WHEN EVENT_NAME = 'memory/group_rpl/certification_info'
      THEN 'memory/group_rpl/certification'
      ELSE 'memory_gr_rest'
    END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),
    SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
    SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
    SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
    SUM(HIGH_NUMBER_OF_BYTES_USED)
  FROM performance_schema.memory_summary_global_by_event_name
  GROUP BY (CASE
    WHEN EVENT_NAME = 'memory/group_rpl/certification_data'
    THEN 'memory/group_rpl/certification'
    WHEN EVENT_NAME = 'memory/group_rpl/certification_data_gc'
    THEN 'memory/group_rpl/certification'
    WHEN EVENT_NAME = 'memory/group_rpl/certification_info'
    THEN 'memory/group_rpl/certification'
    ELSE 'memory_gr_rest'
  )
) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
          EVENT_NAME: memory/group_rpl/certification
          SUM(COUNT_ALLOC): 80
          SUM(COUNT_FREE): 80
    SUM(SUM_NUMBER_OF_BYTES_ALLOC): 9442
    SUM(SUM_NUMBER_OF_BYTES_FREE): 9442
          SUM(LOW_COUNT_USED): 0
          SUM(CURRENT_COUNT_USED): 0
          SUM(HIGH_COUNT_USED): 66
          SUM(LOW_NUMBER_OF_BYTES_USED): 0
    SUM(CURRENT_NUMBER_OF_BYTES_USED): 0
          SUM(HIGH_NUMBER_OF_BYTES_USED): 6561

```

## Memory Used in Replication Pipeline

The memory allocation of the replication pipeline is the sum of the [certification\\_data](#) and [transaction\\_data](#) event values. For example:

```

SELECT * FROM (
  SELECT
    (CASE
      WHEN EVENT_NAME LIKE 'memory/group_rpl/certification_data'
      THEN 'memory/group_rpl/pipeline'
      WHEN EVENT_NAME LIKE 'memory/group_rpl/transaction_data'
      THEN 'memory/group_rpl/pipeline'
      ELSE 'memory_gr_rest'
    )

```

```

        END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
        SUM(SUM_NUMBER_OF_BYTES_ALLOC),
        SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
        SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
        SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
        SUM(HIGH_NUMBER_OF_BYTES_USED)
    FROM performance_schema.memory_summary_global_by_event_name
    GROUP BY (CASE
        WHEN EVENT_NAME LIKE 'memory/group_rpl/certification_data'
        THEN 'memory/group_rpl/pipeline'
        WHEN EVENT_NAME LIKE 'memory/group_rpl/transaction_data'
        THEN 'memory/group_rpl/pipeline'
        ELSE 'memory_gr_rest'
    END)
    ) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
        EVENT_NAME: memory/group_rpl/pipeline
        COUNT_ALLOC: 17
        COUNT_FREE: 13
        SUM_NUMBER_OF_BYTES_ALLOC: 2483
        SUM_NUMBER_OF_BYTES_FREE: 1668
        LOW_COUNT_USED: 0
        CURRENT_COUNT_USED: 4
        HIGH_COUNT_USED: 4
        LOW_NUMBER_OF_BYTES_USED: 0
        CURRENT_NUMBER_OF_BYTES_USED: 815
        HIGH_NUMBER_OF_BYTES_USED: 815

```

## Memory Used in Consistency

The memory allocation for transaction consistency guarantees is the sum of the [consistent\\_members\\_that\\_must\\_prepare\\_transaction](#), [consistent\\_transactions](#), [consistent\\_transactions\\_prepared](#), [consistent\\_transactions\\_waiting](#), and [consistent\\_transactions\\_delayed\\_view\\_change](#) event values. For example:

```

SELECT * FROM (
    SELECT
        (CASE
            WHEN EVENT_NAME = 'memory/group_rpl/consistent_members_that_must_prepare_transaction'
            THEN 'memory/group_rpl/consistency'
            WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions'
            THEN 'memory/group_rpl/consistency'
            WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_prepared'
            THEN 'memory/group_rpl/consistency'
            WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_waiting'
            THEN 'memory/group_rpl/consistency'
            WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_delayed_view_change'
            THEN 'memory/group_rpl/consistency'
            ELSE 'memory_gr_rest'
        END) AS EVENT_NAME, SUM(COUNT_ALLOC), SUM(COUNT_FREE),
        SUM(SUM_NUMBER_OF_BYTES_ALLOC),
        SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
        SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
        SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
        SUM(HIGH_NUMBER_OF_BYTES_USED)
    FROM performance_schema.memory_summary_global_by_event_name
    GROUP BY (CASE
        WHEN EVENT_NAME = 'memory/group_rpl/consistent_members_that_must_prepare_transaction'
        THEN 'memory/group_rpl/consistency'
        WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions'
        THEN 'memory/group_rpl/consistency'
        WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_prepared'
        THEN 'memory/group_rpl/consistency'
        WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_waiting'

```

```

        THEN 'memory/group_rpl/consistency'
        WHEN EVENT_NAME = 'memory/group_rpl/consistent_transactions_delayed_view_change'
        THEN 'memory/group_rpl/consistency'
        ELSE 'memory_gr_rest'
    END)
    ) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
      EVENT_NAME: memory/group_rpl/consistency
      COUNT_ALLOC: 16
      COUNT_FREE: 6
      SUM_NUMBER_OF_BYTES_ALLOC: 1464
      SUM_NUMBER_OF_BYTES_FREE: 528
      LOW_COUNT_USED: 0
      CURRENT_COUNT_USED: 10
      HIGH_COUNT_USED: 11
      LOW_NUMBER_OF_BYTES_USED: 0
      CURRENT_NUMBER_OF_BYTES_USED: 936
      HIGH_NUMBER_OF_BYTES_USED: 1024

```

## Memory Used in Delivery Message Service

### Note

This instrumentation applies only to data received, not data sent.

The memory allocation for the Group Replication delivery message service is the sum of the [message\\_service\\_received\\_message](#) and [message\\_service\\_queue](#) event values. For example:

```

SELECT * FROM (
    SELECT
      (CASE
        WHEN EVENT_NAME = 'memory/group_rpl/message_service_received_message'
        THEN 'memory/group_rpl/message_service'
        WHEN EVENT_NAME = 'memory/group_rpl/message_service_queue'
        THEN 'memory/group_rpl/message_service'
        ELSE 'memory_gr_rest'
      END) AS EVENT_NAME,
      SUM(COUNT_ALLOC), SUM(COUNT_FREE),
      SUM(SUM_NUMBER_OF_BYTES_ALLOC),
      SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
      SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
      SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
      SUM(HIGH_NUMBER_OF_BYTES_USED)
    FROM performance_schema.memory_summary_global_by_event_name
    GROUP BY (CASE
      WHEN EVENT_NAME = 'memory/group_rpl/message_service_received_message'
      THEN 'memory/group_rpl/message_service'
      WHEN EVENT_NAME = 'memory/group_rpl/message_service_queue'
      THEN 'memory/group_rpl/message_service'
      ELSE 'memory_gr_rest'
    END)
  ) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
      EVENT_NAME: memory/group_rpl/message_service
      COUNT_ALLOC: 2
      COUNT_FREE: 0
      SUM_NUMBER_OF_BYTES_ALLOC: 1048664
      SUM_NUMBER_OF_BYTES_FREE: 0
      LOW_COUNT_USED: 0
      CURRENT_COUNT_USED: 2
      HIGH_COUNT_USED: 2

```

```
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 1048664
HIGH_NUMBER_OF_BYTES_USED: 1048664
```

## Memory Used to Broadcast and Receive Transactions

The memory allocation for the broadcasting and receiving transactions to and from the network is the sum of the `wGcs_message_data::m_buffer` and `GCS_XCom::xcom_cache` event values. For example:

```
SELECT * FROM (
  SELECT
    (CASE
      WHEN EVENT_NAME = 'memory/group_rpl/Gcs_message_data::m_buffer'
      THEN 'memory/group_rpl/memory_gr'
      WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
      THEN 'memory/group_rpl/memory_gr'
      ELSE 'memory_gr_rest'
    END) AS EVENT_NAME,
    SUM(COUNT_ALLOC), SUM(COUNT_FREE),
    SUM(SUM_NUMBER_OF_BYTES_ALLOC),
    SUM(SUM_NUMBER_OF_BYTES_FREE), SUM(LOW_COUNT_USED),
    SUM(CURRENT_COUNT_USED), SUM(HIGH_COUNT_USED),
    SUM(LOW_NUMBER_OF_BYTES_USED), SUM(CURRENT_NUMBER_OF_BYTES_USED),
    SUM(HIGH_NUMBER_OF_BYTES_USED)
  FROM performance_schema.memory_summary_global_by_event_name
  GROUP BY (CASE
    WHEN EVENT_NAME = 'memory/group_rpl/Gcs_message_data::m_buffer'
    THEN 'memory/group_rpl/memory_gr'
    WHEN EVENT_NAME = 'memory/group_rpl/GCS_XCom::xcom_cache'
    THEN 'memory/group_rpl/memory_gr'
    ELSE 'memory_gr_rest'
  END)
) f
WHERE f.EVENT_NAME != 'memory_gr_rest'\G

***** 1. row *****
          EVENT_NAME: memory/group_rpl/memory_gr
          SUM(COUNT_ALLOC): 73
          SUM(COUNT_FREE): 20
SUM(SUM_NUMBER_OF_BYTES_ALLOC): 1070845
SUM(SUM_NUMBER_OF_BYTES_FREE): 5670
          SUM(LOW_COUNT_USED): 0
          SUM(CURRENT_COUNT_USED): 53
          SUM(HIGH_COUNT_USED): 56
          SUM(LOW_NUMBER_OF_BYTES_USED): 0
SUM(CURRENT_NUMBER_OF_BYTES_USED): 1065175
SUM(HIGH_NUMBER_OF_BYTES_USED): 1065175
```

## 20.8 Upgrading Group Replication

This section explains how to upgrade a Group Replication setup. The basic process of upgrading members of a group is the same as upgrading stand-alone instances, see [Chapter 3, Upgrading MySQL](#) for the actual process of doing upgrade and types available. Choosing between an in-place or logical upgrade depends on the amount of data stored in the group. Usually an in-place upgrade is faster, and therefore is recommended. You should also consult [Section 19.5.3, “Upgrading or Downgrading a Replication Topology”](#).

### Note

Before MySQL 8.4, a server would not join a group if it was running a lower MySQL Server version than the lowest group member's version. For example, for a group with S1 (8.0.30), S2 (8.0.31), and S3 (8.0.32), the joining member needs to be 8.0.30 or higher. As of MySQL 8.4, all versions within the same LTS series can join

a group. For example, an 8.4.0 server could join a group consisting of S1 (8.4.1) and S2 (8.4.2), and a 9.7.0 server could join a group consisting of S1 (9.7.1) and S2 (9.7.2).

As of MySQL 8.4, in-place downgrades of servers within groups are also supported within the same LTS series. For example, a member of a group running MySQL 9.7.2 can be downgraded to MySQL 9.7.0.

While you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Group Replication includes compatibility policies that enable you to safely combine members running different versions of MySQL in the same group during the upgrade procedure. Depending on your group, the effects of these policies might affect the order in which you should upgrade group members. For details, see [Section 20.8.1, “Combining Different Member Versions in a Group”](#).

If your group can be taken fully offline see [Section 20.8.2, “Group Replication Offline Upgrade”](#). If your group needs to remain online, as is common with production deployments, see [Section 20.8.3, “Group Replication Online Upgrade”](#) for the different approaches available for upgrading a group with minimal downtime.

## 20.8.1 Combining Different Member Versions in a Group

Group Replication is versioned according to the MySQL Server version that the Group Replication plugin was bundled with. For example, if a member is running MySQL 9.7.0 then that is the version of the Group Replication plugin. To check the version of MySQL Server on a group member issue:

```
SELECT MEMBER_HOST, MEMBER_PORT, MEMBER_VERSION FROM performance_schema.replication_group_members;
```

member_host	member_port	member_version
example.com	3306	9.7.0

For guidance on understanding the MySQL Server version and selecting a version, see [Section 2.1.2, “Which MySQL Version and Distribution to Install”](#).

For optimal compatibility and performance, all members of a group should run the same version of MySQL Server and therefore of Group Replication. However, while you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Depending on the changes made between the versions of MySQL, you could encounter incompatibilities in this situation. For example, if a feature has been deprecated between major versions, then combining the versions in a group might cause members that rely on the deprecated feature to fail. Conversely, writing to a member running a newer MySQL version while there are read/write members in the group running an older MySQL version might cause issues on members that lack functions introduced in the newer release.

To prevent such issues, Group Replication includes compatibility policies that enable you to combine members running different versions of MySQL in the same group safely. A member applies these policies to decide whether to join the group normally, or join in read-only mode, or not join the group, depending on which choice results in the safe operation of the joining member and of the existing members of the group. In an upgrade scenario, each server must leave the group, be upgraded, and rejoin the group with its new server version. At this point the member applies the policies for its new server version, which might have changed from the policies it applied when it originally joined the group.

As the administrator, you can instruct any server to attempt to join any group by configuring the server appropriately and issuing a `START GROUP_REPLICATION` statement. A decision to join or not join the group, or to join the group in read-only mode, is made and implemented by the joining member itself after

you attempt to add it to the group. The joining member receives information on the MySQL Server versions of the current group members, assesses its own compatibility with those members, and applies the policies used in its own MySQL Server version (*not* the policies used by the existing members) to decide whether it is compatible.

The compatibility policies that a joining member applies when attempting to join a group are as follows:

- A member joins a group normally if it is running the same or lower MySQL Server version as the lowest version that the existing group members are running.
- A member joins a group but remains in read-only mode if it is running a higher MySQL Server version than the lowest version that the existing group members are running. This behavior only makes a difference when the group is running in multi-primary mode, because in a group that is running in single-primary mode, newly added members default to being read-only in any case.

Members take into account the entire major.minor.release version of the software when checking compatibility.

In a multi-primary mode group with members that use different MySQL Server versions, Group Replication automatically manages members' read/write and read-only status. If a member leaves the group, the members running the version that is now the lowest are automatically set to read/write mode. When you change a group that was running in single-primary mode to run in multi-primary mode using `group_replication_switch_to_multi_primary_mode()`, Group Replication automatically sets each member to the correct mode. Members are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group, and members running the lowest version are placed in read/write mode.

### 20.8.1.1 Member Versions During Upgrades

During an online upgrade procedure, if the group is in single-primary mode, all the servers that are not currently offline for upgrading function as they did before. The group elects a new primary whenever necessary, following the election policies described in [Section 20.1.3.1, “Single-Primary Mode”](#). Note that if you require the primary to remain the same throughout (except when it is being upgraded itself), you must first upgrade all of the secondaries to a version higher than or equal to the target primary member version, then upgrade the primary last. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary.

If the group is in multi-primary mode, fewer online members are available to perform writes during the upgrade procedure, because upgraded members join in read-only mode after their upgrade. When all members have been upgraded to the same release, they all change back to read/write mode automatically.

To deal with a problem situation, for example if you have to roll back an upgrade to a previous major version or add extra capacity to a group in an emergency, it is possible to allow a member to join an online group from a version that otherwise couldn't.

### 20.8.1.2 Group Replication Communication Protocol Version

A replication group uses a Group Replication communication protocol version that differs from the MySQL Server version of the members. To check the group's communication protocol version, issue the following statement on any member:

```
SELECT @@version, group_replication_get_communication_protocol();
+-----+-----+
| @@version | group_replication_get_communication_protocol() |
+-----+-----+
| 8.4.0     | 8.0.27                                         |
+-----+-----+
```

As demonstrated, the MySQL 8.4 LTS series uses the `8.0.27` communication protocol.

For more information, see [Section 20.5.1.4, “Setting a Group’s Communication Protocol Version”](#).

## 20.8.2 Group Replication Offline Upgrade

To perform an offline upgrade of a Group Replication group, you remove each member from the group, perform an upgrade of the member and then restart the group as usual. In a multi-primary group you can shutdown the members in any order. In a single-primary group, shutdown each secondary first and then finally the primary. See [Section 20.8.3.2, “Upgrading a Group Replication Member”](#) for how to remove members from a group and shutdown MySQL.

Once the group is offline, upgrade all of the members. See [Chapter 3, \*Upgrading MySQL\*](#) for how to perform an upgrade. When all members have been upgraded, restart the members.

If you upgrade all the members of a replication group when they are offline and then restart the group, the members join using the new release's Group Replication communication protocol version, so that becomes the group's communication protocol version. If you have a requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` function to downgrade the communication protocol version, specifying the MySQL Server version of the prospective group member that has the oldest installed server version.

## 20.8.3 Group Replication Online Upgrade

When you have a group running which you want to upgrade but you need to keep the group online to serve your application, you need to consider your approach to the upgrade. This section describes the different elements involved in an online upgrade, and various methods of how to upgrade your group.

### 20.8.3.1 Online Upgrade Considerations

When upgrading an online group you should consider the following points:

- Regardless of the way which you upgrade your group, it is important to disable any writes to group members until they are ready to rejoin the group.
- When a member is stopped, the `super_read_only` variable is set to on automatically, but this change is not persisted.

### 20.8.3.2 Upgrading a Group Replication Member

This section explains the steps required for upgrading a member of a group. This procedure is part of the methods described at [Section 20.8.3.3, “Group Replication Online Upgrade Methods”](#). The process of upgrading a member of a group is common to all methods and is explained first. The way which you join upgraded members can depend on which method you are following, and other factors such as whether the group is operating in single-primary or multi-primary mode. How you upgrade the server instance, using either the in-place or provision approach, does not impact on the methods described here.

The process of upgrading a member consists of removing it from the group, following your chosen method of upgrading the member, and then rejoining the upgraded member to a group. The recommended order of upgrading members in a single-primary group is to upgrade all secondaries, and then upgrade the primary last. If the primary is upgraded before a secondary, a new primary using the older MySQL version is chosen, but there is no need for this step.

To upgrade a member of a group:

- Connect a client to the group member and issue `STOP GROUP_REPLICATION`. Before proceeding, ensure that the member's status is `OFFLINE` by monitoring the `replication_group_members` table.

- Disable Group Replication from starting up automatically so that you can safely connect to the member after upgrading and configure it without it rejoining the group by setting `group_replication_start_on_boot=0`.

### Important

If an upgraded member has `group_replication_start_on_boot=1` then it could rejoin the group before you can perform the MySQL upgrade procedure and could result in issues. For example, if the upgrade fails and the server restarts again, then a possibly broken server could try to join the group.

- Stop the member, for example using `mysqladmin shutdown` or the `SHUTDOWN` statement. Any other members in the group continue running.
- Upgrade the member, using the in-place or provisioning approach. See [Chapter 3, \*Upgrading MySQL\*](#) for details. When restarting the upgraded member, because `group_replication_start_on_boot` is set to 0, Group Replication does not start on the instance, and therefore it does not rejoin the group.
- Once the MySQL upgrade procedure has been performed on the member, `group_replication_start_on_boot` must be set to 1 to ensure Group Replication starts correctly after restart. Restart the member.
- Connect to the upgraded member and issue `START GROUP_REPLICATION`. This rejoins the member to the group. The Group Replication metadata is in place on the upgraded server, therefore there is usually no need to reconfigure Group Replication. The server has to catch up with any transactions processed by the group while the server was offline. Once it has caught up with the group, it becomes an online member of the group.

### Note

The longer it takes to upgrade a server, the more time that member is offline and therefore the more time it takes for the server to catch up when added back to the group.

When an upgraded member joins a group which has any member running an earlier MySQL Server version, the upgraded member joins with `super_read_only=on`. This ensures that no writes are made to upgraded members until all members are running the newer version. In a multi-primary mode group, when the upgrade has been completed successfully and the group is ready to process transactions, members that are intended as writeable primaries must be set to read/write mode. When all members of a group have been upgraded to the same release, they all change back to read/write mode automatically.

### 20.8.3.3 Group Replication Online Upgrade Methods

Choose one of the following methods of upgrading a Group Replication group:

#### Rolling In-Group Upgrade

This method is supported provided that servers running a newer version are not generating workload to the group while there are still servers with an older version in it. In other words servers with a newer version can join the group only as secondaries. In this method there is only ever one group, and each server instance is removed from the group, upgraded and then rejoined to the group.

This method is well suited to single-primary groups. When the group is operating in single-primary mode, if you require the primary to remain the same throughout (except when it is being upgraded itself), it should be the last member to be upgraded. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary. If you do not mind

which member is the primary, the members can be upgraded in any order. The group elects a new primary whenever necessary from among the members running the lowest MySQL Server version, following the election policies described in [Section 20.1.3.1, “Single-Primary Mode”](#).

For groups operating in multi-primary mode, during a rolling in-group upgrade the number of primaries is decreased, causing a reduction in write availability. This is because if a member joins a group when it is running a higher MySQL Server version than the lowest version that the existing group members are running, it automatically remains in read-only mode (`super_read_only=ON`).

For full information on version compatibility in a group and how this influences the behavior of a group during an upgrade process, see [Section 20.8.1, “Combining Different Member Versions in a Group”](#).

## Rolling Migration Upgrade

In this method you remove members from the group, upgrade them and then create a second group using the upgraded members. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are upgrading the members, you need the group running the newer version to catch up with any transactions executed while the members were being upgraded. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see [Chapter 19, Replication](#). For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- remove members from the original group running the older server version one by one, see [Section 20.8.3.2, “Upgrading a Group Replication Member”](#)
- upgrade the server version running on the member, see [Chapter 3, Upgrading MySQL](#). You can either follow an in-place or provision approach to upgrading.
- create a new group with the upgraded members, see [Chapter 20, Group Replication](#). In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#). Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Before you can redirect your application to the new group, you must ensure that the new group has a suitable number of members, for example so that the group can handle the failure of a member. Issue `SELECT * FROM performance_schema.replication_group_members` and compare the initial group size and the new group size. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection and upgrade any missing members.

## Rolling Duplication Upgrade

In this method you create a second group consisting of members which are running the newer version, and the data missing from the older group is replicated to the newer group. This assumes that you have enough servers to run both groups simultaneously. Due to the fact that during this process the number of primaries is *not* decreased, for groups operating in multi-primary mode there is no reduction in write

availability. This makes rolling duplication upgrade well suited to groups operating in multi-primary mode. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are provisioning the members in the new group, you need the group running the newer version to catch up with any transactions executed while the members were being provisioned. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see [Chapter 19, Replication](#). For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- deploy a suitable number of members so that the group running the newer version can handle failure of a member
- take a backup of the existing data from a member of the group
- use the backup from the older member to provision the members of the new group, see [Section 20.8.3.4, “Group Replication Upgrade with `mysqlbackup`”](#) for one method.

#### Note

You must restore the backup to the same version of MySQL which the backup was taken from, and then perform an in-place upgrade. For instructions, see [Chapter 3, Upgrading MySQL](#).

- create a new group with the upgraded members, see [Chapter 20, Group Replication](#). In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#). Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Once the ongoing data missing from the newer group is small enough to be quickly transferred, you must redirect write operations to the new group. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection.

### 20.8.3.4 Group Replication Upgrade with `mysqlbackup`

As part of a provisioning approach you can use MySQL Enterprise Backup to copy and restore the data from a group member to new members. However you cannot use this technique to directly restore a backup taken from a member running an older version of MySQL to a member running a newer version of MySQL. The solution is to restore the backup to a new server instance which is running the same version of MySQL as the member which the backup was taken from, and then upgrade the instance. This process consists of:

- Take a backup from a member of the older group using `mysqlbackup`. See [Section 20.5.6, “Using MySQL Enterprise Backup with Group Replication”](#).
- Deploy a new server instance, which must be running the same version of MySQL as the older member where the backup was taken.
- Restore the backup from the older member to the new instance using `mysqlbackup`.

- Upgrade MySQL on the new instance, see [Chapter 3, Upgrading MySQL](#).

Repeat this process to create a suitable number of new instances, for example to be able to handle a failover. Then join the instances to a group based on the [Section 20.8.3.3, “Group Replication Online Upgrade Methods”](#).

## 20.9 Group Replication Variables

The next two sections contain information about MySQL server system and server status variables which are specific to the Group Replication plugin.

**Table 20.4 Group Replication Variable and Option Summary**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<a href="#">Gr_all_consensus_proposals_count</a>				Yes	Both	No
<a href="#">Gr_all_consensus_time_sum</a>				Yes	Both	No

## 20.9.1 Group Replication System Variables

This section lists the system variables that are specific to the Group Replication plugin.

The name of each Group Replication system variable is prefixed with `group_replication_`.

**Note**

InnoDB Cluster uses Group Replication, but the default values of the Group Replication system variables may differ from the defaults documented in this section. For example, in InnoDB Cluster, the default value of `group_replication_communication_stack` is `MYSQL`, not `XCOM` as it is for a default Group Replication implementation.

For more information, see [MySQL InnoDB Cluster](#).

Some system variables on a Group Replication group member, including some Group Replication-specific system variables and some general system variables, are group-wide configuration settings. These system variables must have the same value on all group members, and require a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to reboot a group where every member has been stopped, see [Section 20.5.2, “Restarting a Group”](#).

If a running group has a value set for a group-wide configuration setting, and a joining member has a different value set for that system variable, the joining member cannot join the group until the value is changed to match. If the group has a value set for one of these system variables, and the joining member does not support the system variable, it cannot join the group.

The following system variables are group-wide configuration settings:

- `group_replication_single_primary_mode`
- `group_replication_enforce_update_everywhere_checks`
- `group_replication_gtid_assignment_block_size`
- `group_replication_view_change_uuid` (deprecated)
- `group_replication_paxos_single_leader`
- `group_replication_communication_stack` (a special case not policed by Group Replication's own checks; see the system variable description for details)
- `default_table_encryption`
- `lower_case_table_names`

Group-wide configuration settings cannot be changed by the usual methods while Group Replication is running, but it is possible to use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the values of `group_replication_single_primary_mode` and `group_replication_enforce_update_everywhere_checks` while the group is still running. For more information, see [Section 20.5.1.2, “Changing the Group Mode”](#).

Most system variables for Group Replication can have different values on different group members. For the following system variables, it is advisable to set the same value on all members of a group in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery:

- `group_replication_auto_increment_increment`
- `group_replication_communication_max_message_size`
- `group_replication_compression_threshold`

- `group_replication_message_cache_size`
- `group_replication_transaction_size_limit`

The value of `group_replication_preemptive_garbage_collection` must be the same on all group members.

Most system variables for Group Replication are described as dynamic, and their values can be changed while the server is running. However, in most cases, the change takes effect only after you stop and restart Group Replication on the group member using a `STOP GROUP_REPLICATION` statement followed by a `START GROUP_REPLICATION` statement. Changes to the following system variables take effect without stopping and restarting Group Replication:

- `group_replication_advertise_recovery_endpoints`
- `group_replication_autorejoin_tries`
- `group_replication_consistency`
- `group_replication_elect_prefers_most_updated.enabled`
- `group_replication_exit_state_action`
- `group_replication_flow_control_applier_threshold`
- `group_replication_flow_control_certifier_threshold`
- `group_replication_flow_control_hold_percent`
- `group_replication_flow_control_max_quota`
- `group_replication_flow_control_member_quota_percent`
- `group_replication_flow_control_min_quota`
- `group_replication_flow_control_min_recovery_quota`
- `group_replication_flow_control_mode`
- `group_replication_flow_control_period`
- `group_replication_flow_control_release_percent`
- `group_replication_force_members`
- `group_replication_ip_allowlist`
- `group_replication_member_expel_timeout`
- `group_replication_member_weight`
- `group_replication_transaction_size_limit`
- `group_replication_unreachable_majority_timeout`

When you change the values of any Group Replication system variables, bear in mind that if there is a point where Group Replication is stopped on every member at once by a `STOP GROUP_REPLICATION` statement or system shutdown, the group must be restarted by bootstrapping as if it was being started for

the first time. For instructions on doing this safely, see [Section 20.5.2, “Restarting a Group”](#). In the case of group-wide configuration settings, this is required, but if you are changing other settings, try to ensure that at least one member is running at all times.

### Important

- A number of system variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These system variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control system variables. They are fully validated only after the server has started.
- System variables for Group Replication that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. Group Replication's Group Communication System (GCS) is not available to validate the values until that point.

Server system variables specific to the Group Replication plugin, along with descriptions of their function or purpose, are listed here:

- `group_replication_advertise_recovery_endpoints`

Command-Line Format	<code>--group-replication-advertise-recovery-endpoints=value</code>
System Variable	<code>group_replication_advertise_recovery_endpoints</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>DEFAULT</code>

The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the member. However, a joining member that already received the previous value of the system variable continues to use that value. Only members that join after the value change receive the new value.

`group_replication_advertise_recovery_endpoints` specifies how a joining member can establish a connection to an existing member for state transfer for distributed recovery. The connection is used for both remote cloning operations and state transfer from the donor's binary log.

A value of `DEFAULT`, which is the default setting, means joining members use the existing member's standard SQL client connection, as specified by MySQL Server's `hostname` and `port` system variables. If an alternative port number is specified by the `report_port` system variable, that one is used instead. The Performance Schema table `replication_group_members` shows this connection's address and port number in the `MEMBER_HOST` and `MEMBER_PORT` columns.

Instead of `DEFAULT`, you can specify one or more distributed recovery endpoints, which the existing member advertises to joining members for them to use. Offering distributed recovery endpoints lets administrators control distributed recovery traffic separately from regular MySQL client connections to the group members. Joining members try each of the endpoints in turn in the order they are specified on the list.

Specify the distributed recovery endpoints as a comma-separated list of IP addresses and port numbers, for example:

```
group_replication_advertise_recovery_endpoints= "127.0.0.1:3306,127.0.0.1:4567,[::1]:3306,localhost:3306"
```

IPv4 and IPv6 addresses and host names can be used in any combination. IPv6 addresses must be specified in square brackets. Host names must resolve to a local IP address. Wildcard address formats cannot be used, and you cannot specify an empty list. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints. If you want to use it as an endpoint, you must include it explicitly on the list.

For details of how to select IP addresses and ports as distributed recovery endpoints, and how joining members use them, see [Selecting addresses for distributed recovery endpoints](#). A summary of the requirements is as follows:

- The IP addresses do not have to be configured for MySQL Server, but they do have to be assigned to the server.
- The ports do have to be configured for MySQL Server using the `port`, `report_port`, or `admin_port` system variable.
- Appropriate permissions are required for the replication user for distributed recovery if the `admin_port` is used.
- The IP addresses do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` system variable.
- The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options.
- `group_replication_auto_increment_increment`

Command-Line Format	<code>--group-replication-auto-increment-increment=#</code>
System Variable	<code>group_replication_auto_increment_increment</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	7
Minimum Value	1
Maximum Value	65535

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

`group_replication_auto_increment_increment` determines the interval between successive values for auto-incremented columns for transactions that execute on this server instance. Adding an interval avoids the selection of duplicate auto-increment values for writes on group members, which

causes rollback of transactions. The default value of 7 represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members). If your group has more or fewer members, you can set this system variable to match the expected number of group members before Group Replication is started.

### Important

Setting `group_replication_auto_increment_increment` has no effect when `group_replication_single_primary_mode` is ON.

When Group Replication is started on a server instance, the value of the server system variable `auto_increment_increment` is changed to this value, and the value of the server system variable `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. The system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

- `group_replication_autorejoin_tries`

Command-Line Format	<code>--group-replication-autorejoin-tries=#</code>
System Variable	<code>group_replication_autorejoin_tries</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	2016

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when an issue occurs that means the behavior is needed.

`group_replication_autorejoin_tries` specifies the number of tries that a member makes to automatically rejoin the group if it is expelled, or if it is unable to contact a majority of the group before the `group_replication_unreachable_majority_timeout` setting is reached. When the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and does not accept writes, but reads can still be made on the member, with an increasing likelihood of stale reads over time. If you cannot tolerate the possibility of stale reads for any period of time, set `group_replication_autorejoin_tries` to 0. For more information on the auto-rejoin feature, and considerations when choosing a value for this option, see [Section 20.7.7.3, "Auto-Rejoin"](#).

- `group_replication_bootstrap_group`

Command-Line Format	<code>--group-replication-bootstrap-group[={OFF ON}]</code>
System Variable	<code>group_replication_bootstrap_group</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

`group_replication_bootstrap_group` configures this server to bootstrap the group. This system variable must *only* be set on one server, and *only* when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

For instructions to bootstrap a group for the first time, see [Section 20.2.1.5, “Bootstrapping the Group”](#). For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, “Restarting a Group”](#).

- `group_replication_clone_threshold`

Command-Line Format	<code>--group-replication-clone-threshold=#</code>
System Variable	<code>group_replication_clone_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>9223372036854775807</code>
Minimum Value	<code>1</code>
Maximum Value	<code>9223372036854775807</code>
Unit	transactions

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_clone_threshold` specifies the transaction gap, as a number of transactions, between the existing member (donor) and the joining member (recipient) that triggers the use of a remote cloning operation for state transfer to the joining member during the distributed recovery process. If the transaction gap between the joining member and a suitable donor exceeds the threshold, Group Replication begins distributed recovery with a remote cloning operation. If the transaction gap is below

the threshold, or if the remote cloning operation is not technically possible, Group Replication proceeds directly to state transfer from a donor's binary log.

### Warning

Do not use a low setting for `group_replication_clone_threshold` in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would expect to occur in the group during the time taken for the remote cloning operation.

To use this function, both the donor and the joining member must be set up beforehand to support cloning. For instructions, see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#). When a remote cloning operation is carried out, Group Replication manages it for you, including the required server restart, provided that `group_replication_start_on_boot=ON` is set. If not, you must restart the server manually. The remote cloning operation replaces the existing data dictionary on the joining member, but Group Replication checks and does not proceed if the joining member has additional transactions that are not present on the other group members, because these transactions would be erased by the cloning operation.

The default setting (which is the maximum permitted sequence number for a transaction in a GTID) means that state transfer from a donor's binary log is virtually always attempted rather than cloning. However, note that Group Replication always attempts to execute a cloning operation, regardless of your threshold, if state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary logs on any existing group member. If you do not want to use cloning at all in your replication group, do not install the clone plugin on the members.

- `group_replication_communication_debug_options`

Command-Line Format	<code>--group-replication-communication-debug-options=value</code>
System Variable	<code>group_replication_communication_debug_options</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>GCS_DEBUG_NONE</code>
Valid Values	<code>GCS_DEBUG_NONE</code> <code>GCS_DEBUG_BASIC</code> <code>GCS_DEBUG_TRACE</code> <code>XCOM_DEBUG_BASIC</code> <code>XCOM_DEBUG_TRACE</code> <code>GCS_DEBUG_ALL</code>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_communication_debug_options` configures the level of debugging messages to provide for the different Group Replication components, such as the Group Communication System (GCS) and the group communication engine (XCom, a Paxos variant). The debug information is stored in the `GCS_DEBUG_TRACE` file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- `GCS_DEBUG_NONE` disables all debugging levels for both GCS and XCom.
- `GCS_DEBUG_BASIC` enables basic debugging information in GCS.
- `GCS_DEBUG_TRACE` enables trace information in GCS.
- `XCOM_DEBUG_BASIC` enables basic debugging information in XCom.
- `XCOM_DEBUG_TRACE` enables trace information in XCom.
- `GCS_DEBUG_ALL` enables all debugging levels for both GCS and XCom.

Setting the debug level to `GCS_DEBUG_NONE` only has an effect when provided without any other option. Setting the debug level to `GCS_DEBUG_ALL` overrides all other options.

- `group_replication_communication_max_message_size`

Command-Line Format	<code>--group-replication-communication-max-message-size=#</code>
System Variable	<code>group_replication_communication_max_message_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10485760
Minimum Value	0
Maximum Value	1073741824
Unit	bytes

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

`group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications. Messages greater than this size are automatically split into fragments that are sent separately and reassembled by the recipients. For more information, see [Section 20.7.5, “Message Fragmentation”](#).

A maximum message size of 10485760 bytes (10 MiB) is set by default, which means that fragmentation is used by default. The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` system variable, which is 1073741824 bytes (1 GB). `group_replication_communication_max_message_size` must be less than

`replica_max_allowed_packet`, because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, set `group_replication_communication_max_message_size` to 0.

In order for members of a replication group to use fragmentation, the group's communication protocol version must be 8.0.16 or later. Use the `group_replication_get_communication_protocol()` function to view the group's communication protocol version. If a lower version is in use, group members do not fragment messages. You can use the `group_replication_set_communication_protocol()` function to set the group's communication protocol to a higher version if all group members support it. For more information, see [Section 20.5.1.4, “Setting a Group's Communication Protocol Version”](#).

- `group_replication_communication_stack`

System Variable	<code>group_replication_communication_stack</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>XCOM</code>
Valid Values	<code>XCOM</code> <code>MYSQL</code>

### Note

This system variable is effectively a group-wide configuration setting; although it can be set at runtime, a full reboot of the replication group is required for any change to take effect.

`group_replication_communication_stack` specifies whether the XCom communication stack or the MySQL communication stack is to be used to establish group communication connections between members. The XCom communication stack is Group Replication's own implementation, and does not support authentication or network namespaces. The MySQL communication stack is MySQL Server's native implementation, with support for authentication and network namespaces, and access to new security functions immediately on release. All members of a group must use the same communication stack.

When you use the MySQL communication stack in place of XCom, MySQL Server establishes each connection between group members using its own authentication and encryption protocols.

### Note

If you are using InnoDB Cluster, the default value of `group_replication_communication_stack` is `MYSQL`.

For more information, see [MySQL InnoDB Cluster](#).

Additional configuration is required when you set up a group to use MySQL's communication stack; see [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

`group_replication_communication_stack` is effectively a group-wide configuration setting, and the setting must be the same on all group members. However, this is not policed by Group Replication's

own checks for group-wide configuration settings. A member with a different value from the rest of the group cannot communicate with the other members at all, because the communication protocols are incompatible, so it cannot exchange information about its configuration settings.

This means that although the value of the system variable can be changed while Group Replication is running, and takes effect after you restart Group Replication on the group member, the member still cannot rejoin the group until the setting has been changed on all the members. You must therefore stop Group Replication on all of the members and change the value of the system variable on them all before you can restart the group. Because all of the members are stopped, a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) is required in order for the value change to take effect. For instructions to migrate from one communication stack to another, see [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

- `group_replication_components_stop_timeout`

Command-Line Format	<code>--group-replication-components-stop-timeout=#</code>
System Variable	<code>group_replication_components_stop_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	2
Maximum Value	31536000
Unit	seconds

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_components_stop_timeout` specifies the time, in seconds, for which Group Replication waits for each of its modules to complete ongoing processes while shutting down. The component timeout applies after a `STOP GROUP_REPLICATION` statement is issued, which happens automatically during server restart or auto-rejoin.

The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which might happen if a member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member. In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status.

The default value is 300 seconds, so that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and to rejoin.

- `group_replication_compression_threshold`

Command-Line Format	<code>--group-replication-compression-threshold=#</code>
System Variable	<code>group_replication_compression_threshold</code>

## Group Replication System Variables

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1000000
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

The threshold value in bytes above which compression is applied to messages sent between group members. If this system variable is set to zero, compression is disabled. The value of `group_replication_compression_threshold` should be the same on all group members.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`, because transactions above this size cannot be committed when message compression is enabled.

For more information, see [Section 20.7.4, “Message Compression”](#).

- `group_replication_consistency`

Command-Line Format	<code>--group-replication-consistency=value</code>
System Variable	<code>group_replication_consistency</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>BEFORE_ON_PRIMARY_FAILOVER</code>
Valid Values	<code>EVENTUAL</code>  <code>BEFORE_ON_PRIMARY_FAILOVER</code>  <code>BEFORE</code>  <code>AFTER</code>  <code>BEFORE_AND_AFTER</code>

`group_replication_consistency` is a server system variable rather than a Group Replication plugin-specific variable, so a restart of Group Replication is not required for the change to take effect. Changing the session value of the system variable takes effect immediately, and changing the global value takes effect for new sessions that start after the change. The `GROUP_REPLICATION_ADMIN` privilege is required to change the global setting for this system variable.

`group_replication_consistency` determines the transaction consistency guarantee which a group provides; this can be done globally, or per transaction. `group_replication_consistency` also

determines the fencing mechanism used by newly elected primaries in single primary groups. The effect of the variable must be considered both for read-only and for read/write transactions. The following list shows the possible values of this variable, in order of increasing transaction consistency guarantee:

- [EVENTUAL](#)

Neither read-only nor read/write transactions wait for preceding transactions to be applied before executing. (Before this variable was added, this was the default behavior.) A read/write transaction does not wait for other members to apply a transaction. This means that a transaction can be externalized on one member before the others. This also means that, in the event of a primary failover, the new primary can accept new read-only transactions before the previous primary transactions have all been applied, though read/write transactions are not allowed.

- [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#)

New read-only or read/write transactions with a newly elected primary that is applying a backlog from the old primary are not applied until any backlog has been applied. This ensures that, in the event of primary failover, clients always see the latest value on the primary, regardless of whether the failover is intentional. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. The length of this delay depends on the size of the backlog being processed, but is usually not great.

- [BEFORE](#)

A read/write transaction waits for all preceding transactions to complete before being applied. A read-only transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by affecting only the latency of the transaction. This reduces any overhead from synchronization, by ensuring it is used on read-only transactions only. This consistency level also includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

- [AFTER](#)

A read/write transaction waits until its changes have been applied to all of the other members. This value has no effect on read-only transactions, and ensures that, when a transaction is committed on the local member, any subsequent transaction reads the value written or a more recent value on any group member. This means that read-only transactions on the other members remain uncommitted until all preceding transactions are committed, increasing the latency of the affected transaction.

Use this mode with a group that is intended primarily for read-only operations to ensure that any read/write transactions are applied everywhere once they commit. This can be used by your application to ensure that subsequent reads fetch the latest data, including the latest writes. This reduces any overhead from synchronization, by ensuring that synchronization is used for read/write transactions only.

[AFTER](#) includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

- [BEFORE\\_AND\\_AFTER](#)

A read/write transaction waits for all preceding transactions to complete, and for all its changes to be applied on all other members, before being applied. A read-only transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

For more information, see [Section 20.5.3, “Transaction Consistency Guarantees”](#).

- `group_replication_elect_prefers_most_updated.enabled`

System Variable	<code>group_replication_elect_prefers_most_updated.enabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Whether the Group Replication Primary Election component is enabled on this server. All group members must have it enabled (set to `ON`) in order for the most-up-to-date primary selection mechanism to function properly. If any member has it disabled or if any member does not support, the primary selection is based on member weights.

Provided by the Group Replication Primary Election component. See [Section 7.5.6.4, “Group Replication Primary Election Component”](#), for more information.

- `group_replication_enforce_update_everywhere_checks`

Command-Line Format	<code>--group-replication-enforce-update-everywhere-checks[={OFF ON} ]</code>
System Variable	<code>group_replication_enforce_update_everywhere_checks</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

### Note

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_enforce_update_everywhere_checks` enables or disables strict consistency checks for multi-primary update everywhere. The default is that checks are disabled. In single-primary mode, this option must be disabled on all group members. In multi-primary mode, when this option is enabled, statements are checked as follows to ensure they are compatible with multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the

value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, “Restarting a Group”](#).

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the value of this system variable while the group is still running. For more information, see [Section 20.5.1.2, “Changing the Group Mode”](#).

- `group_replication_exit_state_action`

Command-Line Format	<code>--group-replication-exit-state-action=value</code>
System Variable	<code>group_replication_exit_state_action</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>OFFLINE_MODE</code>
Valid Values	<code>ABORT_SERVER</code> <code>OFFLINE_MODE</code> <code>READ_ONLY</code>

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when an issue occurs that means the behavior is needed.

`group_replication_exit_state_action` configures how Group Replication behaves when this server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable, and the timeout period for suspicions is set by the `group_replication_member_expel_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

When a group member is expelled due to a suspicion timing out or a loss of majority, if the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it first makes the specified number of attempts while in super read only mode, and then follows

the action specified by `group_replication_exit_state_action`. Auto-rejoin attempts are not made in case of an applier error, because these are not recoverable.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`).

When `group_replication_exit_state_action` is set to `OFFLINE_MODE`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to offline mode (by setting the system variable `offline_mode` to `ON`). In this mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege.

When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance shuts down MySQL.

**Important**

If a failure occurs before the member has successfully joined the group, the specified exit action *is not taken*. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, connections continue to be accepted, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` command.

For more information on using this option, and the full list of situations in which the exit action is taken, see [Section 20.7.7.4, “Exit Action”](#).

- `group_replication_flow_control_applier_threshold`

Command-Line Format	<code>--group-replication-flow-control-applier-threshold=#</code>
System Variable	<code>group_replication_flow_control_applier_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	0
Maximum Value	2147483647

Unit	transactions
------	--------------

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group\\_replication\\_flow\\_control\\_applier\\_threshold](#) specifies the number of waiting transactions in the applier queue that trigger flow control.

- [group\\_replication\\_flow\\_control\\_certifier\\_threshold](#)

Command-Line Format	<code>--group-replication-flow-control-certifier-threshold=#</code>
System Variable	<a href="#">group_replication_flow_control_certifier_thr</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	0
Maximum Value	2147483647
Unit	transactions

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group\\_replication\\_flow\\_control\\_certifier\\_threshold](#) specifies the number of waiting transactions in the certifier queue that trigger flow control.

- [group\\_replication\\_flow\\_control\\_hold\\_percent](#)

Command-Line Format	<code>--group-replication-flow-control-hold-percent=#</code>
System Variable	<a href="#">group_replication_flow_control_hold_percent</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	100
Unit	percentage

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group\\_replication\\_flow\\_control\\_hold\\_percent](#) defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

## Group Replication System Variables

- `group_replication_flow_control_max_quota`

Command-Line Format	<code>--group-replication-flow-control-max-quota=#</code>
System Variable	<code>group_replication_flow_control_max_quota</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_max_quota` defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. The value of this system variable cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

Command-Line Format	<code>--group-replication-flow-control-member-quota-percent=#</code>
System Variable	<code>group_replication_flow_control_member_quota_per</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100
Unit	percentage

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_member_quota_percent` defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

Command-Line Format	<code>--group-replication-flow-control-min-quota=#</code>
---------------------	---

System Variable	<a href="#">group_replication_flow_control_min_quota</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group\\_replication\\_flow\\_control\\_min\\_quota](#) controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than [group\\_replication\\_flow\\_control\\_max\\_quota](#).

- [group\\_replication\\_flow\\_control\\_min\\_recovery\\_quota](#)

Command-Line Format	<code>--group-replication-flow-control-min-recovery-quota=#</code>
System Variable	<a href="#">group_replication_flow_control_min_recovery_quota</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group\\_replication\\_flow\\_control\\_min\\_recovery\\_quota](#) controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than [group\\_replication\\_flow\\_control\\_max\\_quota](#).

- [group\\_replication\\_flow\\_control\\_mode](#)

Command-Line Format	<code>--group-replication-flow-control-mode=value</code>
System Variable	<a href="#">group_replication_flow_control_mode</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

## Group Replication System Variables

Type	Enumeration
Default Value	QUOTA
Valid Values	DISABLED QUOTA

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_mode` specifies the mode used for flow control.

- `group_replication_flow_control_period`

Command-Line Format	<code>--group-replication-flow-control-period=#</code>
System Variable	<code>group_replication_flow_control_period</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	60
Unit	seconds

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_period` defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

- `group_replication_flow_control_release_percent`

Command-Line Format	<code>--group-replication-flow-control-release-percent=#</code>
System Variable	<code>group_replication_flow_control_release_percent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	1000

Unit	percentage
------	------------

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_release_percent` defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- `group_replication_force_members`

Command-Line Format	<code>--group-replication-force-members=value</code>
System Variable	<code>group_replication_force_members</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

This system variable is used to force a new group membership. The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. You only need to set the value of the system variable on one of the group members that is to remain in the group. For details of the situation in which you might need to force a new group membership, and a procedure to follow when using this system variable, see [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#).

`group_replication_force_members` specifies a list of peer addresses as a comma separated list, such as `host1:port1,host2:port2`. Any existing members that are not included in the list do not receive a new view of the group and are blocked. For each existing member that is to continue as a member, you must include the IP address or host name and the port, as they are given in the `group_replication_local_address` system variable for each member. An IPv6 address must be specified in square brackets. For example:

```
"198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061,example.org:33061"
```

The group communication engine for Group Replication (XCom) checks that the supplied IP addresses are in a valid format, and checks that you have not included any group members that are currently unreachable. Otherwise, the new configuration is not validated, so you must be careful to include only online servers that are reachable members of the group. Any incorrect values or invalid host names in the list could cause the group to be blocked with an invalid configuration.

It is important before forcing a new membership configuration to ensure that the servers to be excluded have been shut down. If they are not, shut them down before proceeding. Group members that are still online can automatically form new configurations, and if this has already taken place, forcing a further new configuration could create an artificial split-brain situation for the group.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

- `group_replication_group_name`

Command-Line Format	<code>--group-replication-group-name=value</code>
System Variable	<code>group_replication_group_name</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable cannot be changed while Group Replication is running.

`group_replication_group_name` specifies the name of the group which this server instance belongs to, which must be a valid UUID. This UUID forms part of the GTIDs that are used when transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

### Important

A unique UUID must be used.

- `group_replication_group_seeds`

Command-Line Format	<code>--group-replication-group-seeds=value</code>
System Variable	<code>group_replication_group_seeds</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_group_seeds` is a list of group members to which a joining member can connect to obtain details of all the current group members. The joining member uses these details to select and connect to a group member to obtain the data needed for synchrony with the group. The list consists of a single internal network address or host name for each included seed member, as configured in the seed member's `group_replication_local_address` system variable (not the seed member's SQL client connection, as specified by MySQL Server's `hostname` and `port` system variables). The addresses of the seed members are specified as a comma separated list, such as `host1:port1,host2:port2`. An IPv6 address must be specified in square brackets. For example:

```
group_replication_group_seeds= "198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, example.or
```

Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when

starting Group Replication. If the list does not contain any valid member addresses, issuing `START GROUP_REPLICATION` fails.

When a server is joining a replication group, it attempts to connect to the first seed member listed in its `group_replication_group_seeds` system variable. If the connection is refused, the joining member tries to connect to each of the other seed members in the list in order. If the joining member connects to a seed member but does not get added to the replication group as a result (for example, because the seed member does not have the joining member's address in its allowlist and closes the connection), the joining member continues to try the remaining seed members in the list in order.

A joining member must communicate with the seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see [Section 20.6.4, "Group Replication IP Address Permissions"](#).

- `group_replication_gtid_assignment_block_size`

Command-Line Format	<code>--group-replication-gtid-assignment-block-size=#</code>
System Variable	<code>group_replication_gtid_assignment_block_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1000000
Minimum Value	1
Maximum Value (64-bit platforms)	9223372036854775807
Maximum Value (32-bit platforms)	4294967295

#### Note

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_gtid_assignment_block_size` specifies the number of consecutive GTIDs that are reserved for each group member. Each member consumes its own blocks and reserves more when needed.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, "Restarting a Group"](#).

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the

group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

- `group_replication_ip_allowlist`

Command-Line Format	<code>--group-replication-ip-allowlist=value</code>
System Variable	<code>group_replication_ip_allowlist</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>AUTOMATIC</code>

`group_replication_ip_allowlist` specifies which hosts are permitted to connect to the group. When the XCom communication stack is in use for the group (`group_replication_communication_stack=XCOM`), the allowlist is used to control access to the group. When the MySQL communication stack is in use for the group (`group_replication_communication_stack=MYSQL`), user authentication is used to control access to the group, and the allowlist is not used and is ignored if set.

The address that you specify for each group member in `group_replication_local_address` must be permitted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. The group communication engine for Group Replication (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 and IPv6 are used to create the Group Replication allowlist. For a list of the ranges from which addresses are automatically permitted, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private addresses are not added automatically, so if you use any of these, you must specify them explicitly. The `localhost` IP addresses are added automatically.

As the value of the `group_replication_ip_allowlist` option, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses using CIDR notation (for example, `2001:db8:85a3:8d3::/64`)
- Host names (for example, `example.org`)

- Host names with CIDR notation (for example, [www.example.com/24](#))

Host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but you should ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the allowlist. For example:

```
"192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.example.com"
```

If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). For more information, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do otherwise, use the same allowlist on all members of a group. For more details, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

### Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

Command-Line Format	<code>--group-replication-local-address=value</code>
System Variable	<code>group_replication_local_address</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_local_address` sets the network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be

reachable by all members of the group because it is used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances. If you are using the MySQL communication stack to establish group communication connections between members (`group_replication_communication_stack = MYSQL`), the address must be one of the IP addresses and ports where MySQL Server is listening on, as specified by the `bind_address` system variable for the server.

### Warning

Do not use this address to query or administer the databases on the member. This is not the SQL client connection host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. An IPv6 address must be specified in square brackets in order to distinguish the port number, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. For more information on Group Replication support for IPv6 networks and on replication groups with a mix of members using IPv4 and members using IPv6, see [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

If you are using the XCom communication stack to establish group communication connections between members (`group_replication_communication_stack = XCOM`), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` system variable on the other servers in the replication group. When the XCom communication stack is in use for the group, the allowlist is used to control access to the group. When the MySQL communication stack is in use for the group, user authentication is used to control access to the group, and the allowlist is not used and is ignored if set. If any of the seed members for the group are listed in `group_replication_group_seeds` with an IPv6 address when this member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for this member for the required protocol (or a host name that resolves to an address for that protocol). For more information, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

- `group_replication_member_expel_timeout`

Command-Line Format	<code>--group-replication-member-expel-timeout=#</code>
System Variable	<code>group_replication_member_expel_timeout</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	3600
Unit	seconds

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read whenever Group Replication checks the timeout. It is not mandatory for all members of a group to have the same setting, but it is recommended in order to avoid unexpected expulsions.

[group\\_replication\\_member\\_expel\\_timeout](#) specifies the period of time in seconds that a Group Replication group member waits after creating a suspicion, before expelling from the group the member suspected of having failed. The initial 5-second detection period before a suspicion is created does not count as part of this time. The value of [group\\_replication\\_member\\_expel\\_timeout](#) defaults to 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period.

Changing the value of [group\\_replication\\_member\\_expel\\_timeout](#) on a group member takes effect immediately for existing as well as future suspicions on that group member. You can therefore use this as a method to force a suspicion to time out and expel a suspected member, allowing changes to the group configuration. For more information, see [Section 20.7.7.1, “Expel Timeout”](#).

Increasing the value of [group\\_replication\\_member\\_expel\\_timeout](#) can help to avoid unnecessary expulsions on slower or less stable networks, or in the case of expected transient network outages or machine slowdowns. If a suspect member becomes active again before the suspicion times out, it applies all the messages that were buffered by the remaining group members and enters [ONLINE](#) state, without operator intervention. You can specify a timeout value up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members are unable to reconnect. You can adjust the cache size limit using the [group\\_replication\\_message\\_cache\\_size](#) system variable. For more information, see [Section 20.7.6, “XCom Cache Management”](#).

If the timeout is exceeded, the suspect member is liable for expulsion immediately after the suspicion times out. If the member is able to resume communications and receives a view where it is expelled, and the member has the [group\\_replication\\_autorejoin\\_tries](#) system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable [group\\_replication\\_exit\\_state\\_action](#).

For more information on using the [group\\_replication\\_member\\_expel\\_timeout](#) setting, see [Section 20.7.7.1, “Expel Timeout”](#). For alternative mitigation strategies to avoid unnecessary expulsions where this system variable is not available, see [Section 20.3.2, “Group Replication Limitations”](#).

- [group\\_replication\\_member\\_weight](#)

Command-Line Format	<code>--group-replication-member-weight=#</code>
System Variable	<code>group_replication_member_weight</code>

## Group Replication System Variables

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	100
Unit	percentage

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when a failover situation occurs.

[group\\_replication\\_member\\_weight](#) specifies a percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- [member-1](#): `group_replication_member_weight=30, server_uuid=aaaa`
- [member-2](#): `group_replication_member_weight=40, server_uuid=bbbb`
- [member-3](#): `group_replication_member_weight=40, server_uuid=cccc`
- [member-4](#): `group_replication_member_weight=40, server_uuid=dddd`

during election of a new primary the members above would be sorted as [member-2](#), [member-3](#), [member-4](#), and [member-1](#). This results in [member-2](#) being chosen as the new primary in the event of failover. For more information, see [Section 20.1.3.1, “Single-Primary Mode”](#).

- [group\\_replication\\_message\\_cache\\_size](#)

Command-Line Format	<code>--group-replication-message-cache-size=#</code>
System Variable	<a href="#">group_replication_message_cache_size</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1073741824 (1 GB)
Minimum Value	134217728 (128 MB)
Maximum Value (64-bit platforms)	18446744073709551615 (16 EiB)
Maximum Value (32-bit platforms)	315360004294967295 (4 GB)

Unit	bytes
------	-------

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect on each group member after you stop and restart Group Replication on the member. During this process, the value of the system variable is permitted to differ between group members, but members might be unable to reconnect in the event of a disconnection.

`group_replication_message_cache_size` sets the maximum amount of memory that is available for the message cache in the group communication engine for Group Replication (XCom). The XCom message cache holds messages (and their metadata) that are exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

The `group_replication_member_expel_timeout` system variable determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. The size of the XCom message cache should be set with reference to the expected volume of messages in this time period, so that it contains all the missed messages required for members to return successfully. The default is a 5-second waiting period after the 5-second detection period, for a total time period of 10 seconds.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of the server's other caches and object pools. The default setting is 1073741824 bytes (1 GB). The minimum setting of 134217728 bytes (128 MB) enables deployment on a host that has a restricted amount of available memory, and good network connectivity to minimize the frequency and duration of transient losses of connectivity for group members. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

The cache size limit can be increased or reduced dynamically at runtime. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. For more information on tuning the message cache size, see [Section 20.7.6, "XCom Cache Management"](#).

- `group_replication_paxos_single_leader`

Command-Line Format	<code>--group-replication-paxos-single-leader[={OFF ON}]</code>
System Variable	<code>group_replication_paxos_single_leader</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_paxos_single_leader` enables the group communication engine to operate with a single consensus leader when the group is in single-primary mode. With the default setting `OFF`, this behavior is disabled, and every member of the group is used as a leader, which is the behavior in releases before this system variable was available. When this variable is set to `ON`, the group communication engine can use a single leader to drive consensus. Operating with a single consensus leader improves performance and resilience in single-primary mode, particularly when some of the group's secondary members are currently unreachable. For more information, see [Section 20.7.3, "Single Consensus Leader"](#).

In order for the group communication engine to use a single consensus leader, the group's communication protocol version must be MySQL 8.0.27 or later. Use `group_replication_get_communication_protocol()` to obtain the group's communication protocol version. If a lower version is in use, the group cannot use this behavior. You can use `group_replication_set_communication_protocol()` to set the communication protocol to a higher version if all group members support it. For more information, see [Section 20.5.1.4, "Setting a Group's Communication Protocol Version"](#).

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, "Restarting a Group"](#).

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

The `WRITE_CONSENSUS_SINGLE_LEADER_CAPABLE` column of the Performance Schema `replication_group_communication_information` table shows whether the group supports the use of a single leader, even if `group_replication_paxos_single_leader` is currently set to `OFF` on the queried member. The column value is 1 if the group was started with `group_replication_paxos_single_leader` set to `ON`, and its communication protocol version is MySQL 8.0.27 or later.

- `group_replication_poll_spin_loops`

Command-Line Format	<code>--group-replication-poll-spin-loops=#</code>
System Variable	<code>group_replication_poll_spin_loops</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_poll_spin_loops` specifies the number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_preemptive_garbage_collection`

Command-Line Format	<code>--group-replication-preemptive-garbage-collection[=ON OFF]</code>
System Variable	<code>group_replication_preemptive_garbage_collect</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enable preemptive garbage collection in single-primary mode (only), keeping only the write sets for those transactions that have not yet been committed in the database.

In single-primary mode it is possible to clean up write sets for a given transaction earlier than in multi-primary mode; this is because conflicts are detected and handled by the database lock manager in the server while transactions are executing; thus, the write sets are useful only for calculating dependencies between transactions, and not for conflict detection. This means that write sets can be cleaned up as soon as the transaction to which they belong is tracked in the Group Replication transaction dependency and conflict detection module.

The aggressive purging of write sets which is performed when `group_replication_preemptive_garbage_collection` is enabled has the following effects:

- Reduction in memory used to keep write sets in memory
- Reduction of the impact of lagging secondaries on the tracking of write sets on the primary
- Reduction of the amount of time that the write set database lock is held per round of write set deletion, and thus a reduction of its impact on throughput

The value of `group_replication_preemptive_garbage_collection` can be changed only when Group Replication is not running, and has no effect on a group running in multi-primary mode. In

addition, when this system variable is enabled, it is not possible to change between multi-primary mode and single-primary mode (see [Section 20.5.1.2, “Changing the Group Mode”](#)).

`group_replication_preemptive_garbage_collection` must be set to the same value on all group members. A new joiner's `group_replication_preemptive_garbage_collection` value must be the same as those of all the group's current members, else it cannot join.

A group member running a version of MySQL previous to 8.4.0 sends no `group_replication_preemptive_garbage_collection` value; in such cases, the value is considered to be `OFF`.

- `group_replication_preemptive_garbage_collection_rows_threshold`

Command-Line Format	<code>--group-replication-preemptive-garbage-collection-rows-threshold=#</code>
System Variable	<code>group_replication_preemptive_garbage_collection_rows_threshold</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	100000
Minimum Value	10000
Maximum Value	100000000

When preemptive garbage collection in single-primary mode is enabled (`group_replication_preemptive_garbage_collection` is `ON`), this is the number of rows of certification information needed to trigger its use.

This variable has no effect on a group running in multi-primary mode.

- `group_replication_recovery_compression_algorithms`

Command-Line Format	<code>--group-replication-recovery-compression-algorithms=value</code>
System Variable	<code>group_replication_recovery_compression_algorithms</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Set
Default Value	<code>uncompressed</code>
Valid Values	<code>zlib</code> <code>zstd</code> <code>uncompressed</code>

`group_replication_recovery_compression_algorithms` specifies the compression algorithms permitted for Group Replication distributed recovery connections for state transfer from a donor's binary

log. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

This setting does not apply if the server has been set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)) and a remote cloning operation is used during distributed recovery. For this method of state transfer, the clone plugin's `clone_enable_compression` setting applies.

- `group_replication_recovery_get_public_key`

Command-Line Format	<code>--group-replication-recovery-get-public-key[={OFF ON}]</code>
System Variable	<code>group_replication_recovery_get_public_key</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_get_public_key` specifies whether to request from the source the public key required for RSA key pair-based password exchange. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (`group_replication_recovery_use_ssl=ON`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default). For more details, see [Replication User With The Caching SHA-2 Authentication Plugin](#).

- `group_replication_recovery_public_key_path`

Command-Line Format	<code>--group-replication-recovery-public-key-path=file_name</code>
System Variable	<code>group_replication_recovery_public_key_path</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	empty string

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_public_key_path` specifies the path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. If `group_replication_recovery_public_key_path` is set to a

valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (so `group_replication_recovery_use_ssl` is set to `OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default) or the `sha256_password` plugin (deprecated). (For `sha256_password`, setting `group_replication_recovery_public_key_path` applies only if MySQL was built using OpenSSL.) For more details, see [Replication User With The Caching SHA-2 Authentication Plugin](#).

- `group_replication_recovery_reconnect_interval`

Command-Line Format	<code>--group-replication-recovery-reconnect-interval=#</code>
System Variable	<code>group_replication_recovery_reconnect_interval</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	31536000
Unit	seconds

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_reconnect_interval` specifies the sleep time, in seconds, between reconnection attempts when no suitable donor was found in the group for distributed recovery.

- `group_replication_recovery_retry_count`

Command-Line Format	<code>--group-replication-recovery-retry-count=#</code>
System Variable	<code>group_replication_recovery_retry_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	31536000

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_retry_count` specifies the number of times that the member that is joining tries to connect to the available donors for distributed recovery before giving up.

- `group_replication_recovery_ssl_ca`

Command-Line Format	<code>--group-replication-recovery-ssl-ca=value</code>
System Variable	<code>group_replication_recovery_ssl_ca</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_ca` specifies the path to a file that contains a list of trusted SSL certificate authorities for distributed recovery connections. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_ca` to match your setting for `group_replication_recovery_ssl_ca`.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_capath`

Command-Line Format	<code>--group-replication-recovery-ssl-capath=value</code>
System Variable	<code>group_replication_recovery_ssl_capath</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_capath` specifies the path to a directory that contains trusted SSL certificate authority certificates for distributed recovery connections. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_cert`

Command-Line Format	<code>--group-replication-recovery-ssl-cert=value</code>
System Variable	<code>group_replication_recovery_ssl_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cert` specifies the name of the SSL certificate file to use for establishing a secure connection for distributed recovery. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_cert` to match your setting for `group_replication_recovery_ssl_cert`.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_cipher`

Command-Line Format	<code>--group-replication-recovery-ssl-cipher=value</code>
System Variable	<code>group_replication_recovery_ssl_cipher</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cipher` specifies the list of permissible ciphers for SSL encryption. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_crl`

Command-Line Format	<code>--group-replication-recovery-ssl-crl=value</code>
System Variable	<code>group_replication_recovery_ssl_crl</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crl` specifies the path to a directory that contains files containing certificate revocation lists. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_crlpath`

Command-Line Format	<code>--group-replication-recovery-ssl-crlpath=value</code>
System Variable	<code>group_replication_recovery_ssl_crlpath</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Directory name

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crlpath` specifies the path to a directory that contains files containing certificate revocation lists. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_key`

Command-Line Format	<code>--group-replication-recovery-ssl-key=value</code>
System Variable	<code>group_replication_recovery_ssl_key</code>
Scope	Global
Dynamic	Yes

## Group Replication System Variables

<code>SET_VAR</code> Hint Applies	No
Type	String

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_key` specifies the name of the SSL key file to use for establishing a secure connection. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_key` to match your setting for `group_replication_recovery_ssl_key`.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_ssl_verify_server_cert`

Command-Line Format	<code>--group-replication-recovery-ssl-verify-server-cert[={OFF ON}]</code>
System Variable	<code>group_replication_recovery_ssl_verify_server_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_verify_server_cert` specifies whether the distributed recovery connection should check the server's Common Name value in the certificate sent by the donor. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_tls_ciphersuites`

Command-Line Format	<code>--group-replication-recovery-tls-ciphersuites=value</code>
System Variable	<code>group_replication_recovery_tls_ciphersuites</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	String
Default Value	NULL

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_tls_ciphersuites` specifies a colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#), for information on configuring SSL for distributed recovery.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

- `group_replication_recovery_tls_version`

Command-Line Format	<code>--group-replication-recovery-tls-version=value</code>
System Variable	<code>group_replication_recovery_tls_version</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>TLSv1.2, TLSv1.3</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_tls_version` specifies a comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. The group members involved in each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support.

When the MySQL communication stack is in use for the group (`group_replication_communication_stack = MYSQL`), this setting is used for the TLS/SSL configuration for group communication connections, as well as for distributed recovery connections.

The default is “`TLSv1.2, TLSv1.3`”. Ensure that the specified protocol versions are contiguous, with no versions numbers skipped from the middle of the sequence.

### Important

- Support for the TLSv1.3 protocol is available in MySQL 9.7, provided that MySQL was compiled using OpenSSL 1.1.1. The server checks the version of

OpenSSL at startup, and if it is lower than 1.1.1, TLSv1.3 is removed from the default value for the system variable. In that case, the default is `TLSv1.2`.

- Group Replication supports TLSv1.3 with support for ciphersuite selection. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for more information.

See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_use_ssl`

Command-Line Format	<code>--group-replication-recovery-use-ssl[={OFF ON}]</code>
System Variable	<code>group_replication_recovery_use_ssl</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_use_ssl` specifies whether Group Replication distributed recovery connections between group members should use SSL or not. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and you set this option to `ON`, Group Replication uses SSL for remote cloning operations as well as for state transfer from a donor's binary log. If you set this option to `OFF`, Group Replication does not use SSL for remote cloning operations.

- `group_replication_recovery_zstd_compression_level`

Command-Line Format	<code>--group-replication-recovery-zstd-compression-level=#</code>
System Variable	<code>group_replication_recovery_zstd_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>3</code>
Minimum Value	<code>1</code>

Maximum Value	22
---------------	----

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_recovery_zstd_compression_level` specifies the compression level to use for Group Replication distributed recovery connections that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression. The default `zstd` compression level is 3. For distributed recovery connections that do not use `zstd` compression, this variable has no effect.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `group_replication_resource_manager.applier_channel_lag`

Command-Line Format	<code>--group-replication-resource-manager.applier-channel-lag=value</code>
System Variable	<code>group_replication_resource_manager.applier_channel_lag</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	3600
Minimum Value	0
Maximum Value	43200
Unit	seconds

Specifies the maximum allowed lag time for an applier on a Group Replication secondary. Provided by the Group Replication Resource Manager component.

The default value of this variable is equivalent to 1 hour; the maximum is equivalent to 12 hours. Setting `group_replication_resource_manager.applier_channel_lag` to 0 disables applier lag handling.

If the current lag by a secondary applier as shown by `Gr_resource_manager_applier_channel_lag` exceeds `group_replication_resource_manager.applier_channel_lag` 10 times in succession, the system initiates a graceful exit from the current group and sets the member's state to `ERROR`.

See [Section 7.5.6.3, “Group Replication Resource Manager Component”](#), for more information.

- `group_replication_resource_manager.memory_used_limit`

Command-Line Format	<code>--group-replication-resource-manager.memory-used-limit=value</code>
System Variable	<code>group_replication_resource_manager.memory_used_limit</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

## Group Replication System Variables

Type	Integer
Default Value	100
Minimum Value	0
Maximum Value	100
Unit	percent

Specifies the maximum allowed memory usage on a Group Replication secondary, as a percent of system memory. Provided by the Group Replication Resource Manager component.

Setting `group_replication_resource_manager.memory_used_limit` to 0 disables memory usage monitoring.

If the current memory usage on a group replication secondary as shown by `Gr_resource_manager_memory_used` exceeds `group_replication_resource_manager.memory_used_limit` 10 times in succession, the system initiates a graceful exit from the current group and sets the member's state to `ERROR`.

For more information, see [Section 7.5.6.3, “Group Replication Resource Manager Component”](#).

- `group_replication_resource_manager.quarantine_time`

Command-Line Format	<code>--group-replication-resource-manager.quarantine-time=value</code>
System Variable	<code>group_replication_resource_manager.quarantine_t</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3600
Minimum Value	0
Maximum Value	43200
Unit	seconds

Length of time, in seconds, to prevent the immediate re-ejection of a member attempting to join or rejoin a group after it has been expelled. Provided by the Group Replication Resource Manager component.

The default is equal to 1 hour.

See [Section 7.5.6.3, “Group Replication Resource Manager Component”](#), for more information.

- `group_replication_resource_manager.recovery_channel_lag`

Command-Line Format	<code>--group-replication-resource-manager.recovery-channel-lag=value</code>
System Variable	<code>group_replication_resource_manager.recovery_cha</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	3600
Minimum Value	0
Maximum Value	43200
Unit	seconds

Specifies the maximum allowed lag time for a recovery thread on a Group Replication secondary. Provided by the Group Replication Resource Manager component.

The default value of this variable is equivalent to 1 hour; the maximum is equivalent to 12 hours. Setting `group_replication_resource_manager.recovery_channel_lag` to 0 disables recovery lag handling.

If the current lag by a recovery thread as shown by `Gr_resource_manager_recovery_channel_lag` exceeds `group_replication_resource_manager.recovery_channel_lag` 10 times in succession, the system initiates a graceful exit from the current group and sets the member's state to `ERROR`.

For more information, see [Section 7.5.6.3, “Group Replication Resource Manager Component”](#).

- `group_replication_single_primary_mode`

Command-Line Format	<code>--group-replication-single-primary-mode[={OFF ON}]</code>
System Variable	<code>group_replication_single_primary_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_single_primary_mode` instructs the group to pick a single server automatically to be the one that handles read/write workload. This server is the primary and all others are secondaries.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, “Restarting a Group”](#).

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the

group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Setting this variable `ON` causes any setting for `group_replication_auto_increment_increment` to be ignored.

Use the functions `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` to change the value of this system variable while the group is still running. For more information, see [Section 20.5.1.2, “Changing the Group Mode”](#).

- `group_replication_ssl_mode`

Command-Line Format	<code>--group-replication-ssl-mode=value</code>
System Variable	<code>group_replication_ssl_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>REQUIRED</code>
Valid Values	<code>DISABLED</code> <code>REQUIRED</code> <code>VERIFY_CA</code> <code>VERIFY_IDENTITY</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_ssl_mode` sets the security state of group communication connections between Group Replication members. The possible values are as follows:

<code>DISABLED</code>	Establish an unencrypted connection (the default).
<code>REQUIRED</code>	Establish a secure connection if the server supports secure connections.
<code>VERIFY_CA</code>	Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
<code>VERIFY_IDENTITY</code>	Like <code>VERIFY_CA</code> , but additionally verify that the server certificate matches the host to which the connection is attempted.

This variable should have the same value on all members of the group; otherwise, new members may be unable to join.

See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for group communication.

- `group_replication_start_on_boot`

Command-Line Format	<code>--group-replication-start-on-boot[={OFF ON}]</code>
System Variable	<code>group_replication_start_on_boot</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_start_on_boot` specifies whether the server should start Group Replication automatically (`ON`) or not (`OFF`) during server start. When you set this option to `ON`, Group Replication restarts automatically after a remote cloning operation is used for distributed recovery.

To start Group Replication automatically during server start, the user credentials for distributed recovery must be stored in the replication metadata repositories on the server using the `CHANGE REPLICATION SOURCE TO` statement. If you prefer to specify user credentials as part of `START GROUP_REPLICATION`, which stores the user credentials in memory only, ensure that `group_replication_start_on_boot` is set to `OFF`.

- `group_replication_tls_source`

Command-Line Format	<code>--group-replication-tls-source=value</code>
System Variable	<code>group_replication_tls_source</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>mysql_main</code>
Valid Values	<code>mysql_main</code> <code>mysql_admin</code>

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_tls_source` specifies the source of TLS material for Group Replication.

- `group_replication_transaction_size_limit`

Command-Line Format	<code>--group-replication-transaction-size-limit=#</code>
System Variable	<code>group_replication_transaction_size_limit</code>
Scope	Global
Dynamic	Yes

## Group Replication System Variables

<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	150000000
Minimum Value	0
Maximum Value	2147483647
Unit	bytes

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the group member, and applies from the next transaction started on that member. During this process, the value of the system variable is permitted to differ between group members, but some transactions might be rejected.

`group_replication_transaction_size_limit` configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. The default is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. The value of `group_replication_transaction_size_limit` should be the same on all group members. For further mitigation strategies for large transactions, see [Section 20.3.2, “Group Replication Limitations”](#).

- `group_replication_unreachable_majority_timeout`

Command-Line Format	<code>--group-replication-unreachable-majority-timeout=#</code>
System Variable	<code>group_replication_unreachable_majority_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000
Unit	seconds

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read when an issue occurs that means the behavior is needed.

`group_replication_unreachable_majority_timeout` specifies a number of seconds for which members that suffer a network partition and cannot connect to the majority wait before leaving the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot

contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. For a detailed description of this scenario, see [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#).

By default, `group_replication_unreachable_majority_timeout` is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If you set a timeout, when the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the `ERROR` state. If a member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

**Warning**

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter the `ERROR` state.

For more information on using this option, see [Section 20.7.7.2, “Unreachable Majority Timeout”](#).

- `group_replication_view_change_uuid`

Command-Line Format	<code>--group-replication-view-change-uuid=value</code>
Deprecated	Yes
System Variable	<code>group_replication_view_change_uuid</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>AUTOMATIC</code>

**Note**

This system variable is a group-wide configuration setting, and a full reboot of the replication group is required for a change to take effect.

`group_replication_view_change_uuid` specifies an alternative UUID to use as the UUID part of the identifier in the GTIDs for view change events generated by the group. The alternative UUID makes these internally generated transactions easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The default value for this system variable is `AUTOMATIC`, meaning that the GTIDs for view change events use the group name specified by the `group_replication_group_name` system variable, as transactions from clients do. Group members at a release that does not have this system variable are treated as having the value `AUTOMATIC`.

The alternative UUID must be different from the group name specified by the `group_replication_group_name` system variable, and it must be different from the server UUID of any group member. It must also be different from any UUIDs used in the GTIDs that are applied to anonymous transactions on replication channels anywhere in this topology, using the

`ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement.

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. For instructions to safely bootstrap a group where transactions have been executed and certified, see [Section 20.5.2, “Restarting a Group”](#).

If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

Logging of view change events is replaced by sharing of recovery metadata; thus, this variable is deprecated, and subject to removal in a future version of MySQL.

The previous list includes those system variables provided by the Group Replication Flow Control Statistics component and by the Group Replication Resource Manager component. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), and [Section 7.5.6.3, “Group Replication Resource Manager Component”](#), for more information about these components.

### 20.9.2 Group Replication Status Variables

This section describes the status variables providing information about Group Replication.

The status variables and their meanings are listed here:

- `Gr_all_consensus_proposals_count`

Sum of all proposals that were initiated and terminated on this node.

- `Gr_all_consensus_time_sum`

The total elapsed time for all consensus rounds started and finished on this node. By comparing this value with `Gr_all_consensus_proposals_count`, we can determine whether a given consensus time has an upward trend, which may signal a problem.

- `Gr_certification_garbage_collector_count`

The number of times certification garbage collection has been run.

- `Gr_certification_garbage_collector_time_sum`

Sum of the times in microseconds taken by certification garbage collection.

- `Gr_consensus_bytes_received_sum`

The sum of all socket-level bytes received from group nodes having this node as a destination.

- `Gr_consensus_bytes_sent_sum`

Sum of all socket-level bytes originating on this node that were sent to all (other) group nodes. More data is reported here than for sent messages, since they are multiplexed and sent to each member.

For example, if we have a group with three members and we send a 100-byte message, this value accounts for 300 bytes, since we send 100 bytes to each node.

- `Gr_control_messages_sent_count`

Number of control messages sent by this member.
- `Gr_control_messages_sent_bytes_sum`

Sum of the number of bytes used in control messages sent by this member; this is the on-the-wire size.
- `Gr_control_messages_sent_roundtrip_time_sum`

Sum of the round-trip times in microseconds for control messages sent by this member; a round trip is measured between the sending and the delivery of the message on the sender. This should provide the time between sending and delivery of control messages for the majority of the members of the group, including the sender.
- `Gr_data_messages_sent_count`

This is the number of transaction data messages sent by this member.
- `Gr_data_messages_sent_bytes_sum`

Sum in bytes used by data messages sent by this member; this is the on-the-wire size.
- `Gr_data_messages_sent_roundtrip_time_sum`

Sum of the round-trip times in microseconds for data messages sent by this member; a round trip is measured between the sending and the delivery of the message on the sender. This should provide the time between sending and delivery of data messages for the majority of the members of the group, including the sender.
- `Gr_empty_consensus_proposals_count`

Sum of all empty proposal rounds that were initiated and terminated on this node.
- `Gr_extended_consensus_count`

The number of full 3-phase rounds that this node has initiated. If this number grows over time, it means that at least one node is having problems answering to proposals, either due to something it to run slowly, or to network issues. Use this value together with the `count_member_failure_suspicious` column of the Performance Schema `replication_group_communication_information` table when diagnosing such issues.
- `Gr_flow_control_throttle_active_count`

The number of sessions currently being throttled by the Group Replication flow control mechanism.

Provided by the Group Replication Flow Control Statistics component. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.
- `Gr_flow_control_throttle_count`

The number of transactions which have throttled by flow control by the Group Replication flow control mechanism since the server was last restarted.

Provided by the Group Replication Flow Control Statistics component. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.
- `Gr_flow_control_throttle_last_throttle_timestamp`

A timestamp showing when a transaction was last throttled by the Group Replication flow control mechanism.

Provided by the Group Replication Flow Control Statistics component. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.

- `Gr_flow_control_throttle_time_sum`

The total amount of time that transactions have been throttled by the Group Replication flow control mechanism since the server was last restarted, in microseconds.

Provided by the Group Replication Flow Control Statistics component. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.

- `Gr_last_consensus_end_timestamp`

The time when the last consensus proposal was approved, in a timestamp format. This can be an indicator whether the group is making slow progress, or has halted.

- `Gr_latest_primary_election_by_most_uptodate_member_timestamp`

This timestamp is updated whenever a new primary is chosen using the most-up-to-date selection method.

Provided by the Group Replication Primary Election component. See [Section 7.5.6.4, “Group Replication Primary Election Component”](#), for more information.

- `Gr_latest_primary_election_by_most_uptodate_members_trx_delta`

The difference in the number of transactions between the new primary and secondary most up to date, when most-up-to-date primary selection was used. This is the backlog of transactions waiting to be processed by the indicated secondary.

Provided by the Group Replication Primary Election component. See [Section 7.5.6.4, “Group Replication Primary Election Component”](#), for more information.

- `Gr_resource_manager_applier_channel_eviction_timestamp`

Timestamp for the last time this member was evicted from the group due to issues with applier channel lag.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, “Group Replication Resource Manager Component”](#).

- `Gr_resource_manager_applier_channel_lag`

Time, in seconds, by which the applier channel currently lags. This is the length of the delay in applying changes to the system.

Provided by the Group Replication Resource Manager component. See [Section 7.5.6.3, “Group Replication Resource Manager Component”](#), for more information.

- `Gr_resource_manager_applier_channel_threshold_hits`

The number of samples which have exceeded `group_replication_resource_manager.applier_channel_lag`. This metric can help to identify frequent applier lag issues.

This value is reset to zero whenever the member is expelled.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, "Group Replication Resource Manager Component"](#).

- `Gr_resource_manager_channel_lag_monitoring_error_timestamp`

Timestamp for the last time this member encountered an error while trying to obtain a value for channel lag. Empty if no such error has occurred.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, "Group Replication Resource Manager Component"](#).

- `Gr_resource_manager_memory_eviction_timestamp`

The timestamp for the last eviction of this member caused by excessive memory usage.

Provided by the Group Replication Resource Manager component. See [Section 7.5.6.3, "Group Replication Resource Manager Component"](#), for more information.

- `Gr_resource_manager_memory_monitoring_error_timestamp`

Timestamp for the last time this member encountered an error while trying to obtain a value for system memory usage. Empty if no such error has occurred.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, "Group Replication Resource Manager Component"](#).

- `Gr_resource_manager_memory_threshold_hits`

The number of samples which have exceeded `group_replication_resource_manager.memory_used_limit` since the last time this member was evicted.

Provided by the Group Replication Resource Manager component. See [Section 7.5.6.3, "Group Replication Resource Manager Component"](#).

- `Gr_resource_manager_memory_used`

The percentage of available system memory currently in use.

Provided by the Group Replication Resource Manager component. See [Section 7.5.6.3, "Group Replication Resource Manager Component"](#), for more information.

- `Gr_resource_manager_recovery_channel_eviction_timestamp`

The timestamp for the last eviction caused by recovery channel lag.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, "Group Replication Resource Manager Component"](#).

- `Gr_resource_manager_recovery_channel_lag`

Number of seconds by which the recovery channel on this secondary currently lags behind the primary.

Provided by the Group Replication Resource Manager component. See [Section 7.5.6.3, "Group Replication Resource Manager Component"](#), for more information.

- `Gr_resource_manager_recovery_channel_threshold_hits`

The number of samples which have exceeded `group_replication_resource_manager.recovery_channel_lag`. This metric can help to identify frequent recovery channel lag issues.

If the member is ejected, this value is reset to 0.

Provided by the Group Replication Resource Manager component. For more information, see [Section 7.5.6.3, “Group Replication Resource Manager Component”](#).

- `Gr_total_messages_sent_count`

The number of high-level messages sent by this node to the group. These are the messages received from the API for proposing to the group. The XCom batching mechanism batches these messages and proposes them all together. The value shown for this variable reflects the number of messages prior to batching.

- `Gr_transactions_consistency_after_sync_count`

Number of transactions on secondaries that waited to start, while waiting for transactions from the primary with `group_replication_consistency` equal to `AFTER` or `BEFORE_AND_AFTER` to be committed.

- `Gr_transactions_consistency_after_sync_time_sum`

Sum of the times in microseconds that transactions on secondaries waited on transactions from the primary with `group_replication_consistency` equal to `AFTER` or `BEFORE_AND_AFTER` to be committed, before starting.

- `Gr_transactions_consistency_after_termination_count`

The number of transactions executed with `group_replication_consistency` equal to `AFTER` or `BEFORE_AND_AFTER`.

- `Gr_transactions_consistency_after_termination_time_sum`

Sum of the time in microseconds between delivery of the transaction executed with `group_replication_consistency` equal to `AFTER` or `BEFORE_AND_AFTER`, and acknowledgement by the other group members that the transaction is prepared.

This value does not include transaction send roundtrip time.

- `Gr_transactions_consistency_before_begin_count`

Number of transactions executed with `group_replication_consistency` equal to `BEFORE` or `BEFORE_AND_AFTER`.

- `Gr_transactions_consistency_before_begin_time_sum`

Sum of the time in microseconds that the member waited until its group replication applier channel was consumed before executing the transaction with `group_replication_consistency` equal to `BEFORE` or `BEFORE_AND_AFTER`.

These status variables all have member scope since they reflect what the local member observes. They are reset on group bootstrap, joining of a new member, automatic rejoin of an existing member, and server restart.

The list last shown includes status variables which are provided by the Group Replication Flow Control Statistics component and the Group Replication Resource Manager component. For more information about these, see [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), and [Section 7.5.6.3, “Group Replication Resource Manager Component”](#).

## 20.10 Frequently Asked Questions

This section provides answers to frequently asked questions.

### What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

### How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

### What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

### How do I set credentials for the distributed recovery process?

You can set the user credentials permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement. You can specify them in the `START GROUP_REPLICATION` statement each time Group Replication is started.

User credentials set using `CHANGE REPLICATION SOURCE TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable. For more information, see [Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

### Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

---

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

## Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

## Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then [Section 20.7.4, "Message Compression"](#) can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

### Warning

When the network round-trip time (RTT) between any group members is 5 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

## Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Two settings are available to increase the chances of a member remaining in or rejoining a group:

- `group_replication_member_expel_timeout` increases the time between the creation of a suspicion (which happens after an initial 5-second detection period) and the expulsion of the member. You can set a waiting period of up to 1 hour. A waiting period of 5 seconds is set by default.
- `group_replication_autorejoin_tries` makes a member try to rejoin the group after an expulsion or unreachable majority timeout. The member makes the specified number of auto-rejoin attempts five minutes apart. This feature is active by default; the member makes three auto-rejoin attempts.

If a server is expelled from the group and any auto-rejoin attempts do not succeed, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

## When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

## What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

## Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

## Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

## How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port. See [Setting the TCP Port Context for Group Replication](#).

## How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

## How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in asynchronous source to replica replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See [Section 19.2.4.1, “The Relay Log”](#) for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

## Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

## How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, Group Replication's distributed recovery process creates a connection to an existing group member using the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the joining member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

### Important

The assigned value is used directly and is not affected by the `skip_name_resolve` system variable.

To configure `MEMBER_PORT` on a server, specify it using the `report_port` system variable.

## Why did the auto increment setting on the server change?

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default auto increment value of 7 for Group Replication represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members).

The changes are made and reverted only if `auto_increment_increment` and `auto_increment_offset` each has its default value (1 in both cases). If their values have already been modified from the default, Group Replication does not alter them. The system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

## How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See [Finding the Primary](#)

---

## Chapter 21 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. MySQL Shell is a component that you can install separately.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at <https://dev.mysql.com/doc/mysql-shell/en/>.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables developers to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. This enables you to use MySQL as a Document Store, sometimes referred to as “using NoSQL”. For more information, see [Chapter 22, Using MySQL as a Document Store](#). For documentation on the concepts and usage of X DevAPI, which is implemented in MySQL Shell, see [X DevAPI User Guide](#).
- The AdminAPI enables database administrators to work with InnoDB Cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. The AdminAPI also includes support for InnoDB ReplicaSet, which enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. Additionally, the AdminAPI makes administration of MySQL Router easier, including integration with both InnoDB Cluster and InnoDB ReplicaSet. See [MySQL AdminAPI](#).

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

- X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 9.7. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see [Section 22.5, “X Plugin”](#).
- X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 9.7 Connectors.

- Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See [X DevAPI User Guide](#) for in-depth tutorials on using X DevAPI.

## 22.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

- The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
  - MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
  - Connector/C++
  - Connector/J
  - Connector/Node.js
  - Connector/NET
  - Connector/Python
- MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. [Installing MySQL Shell](#) has instructions to download and install MySQL Shell.
- The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.

The quick-start guide for JavaScript is here: [Section 22.3, “JavaScript Quick-Start Guide: MySQL Shell for Document Store”](#).

The quick-start guide for Python is here: [Section 22.4, “Python Quick-Start Guide: MySQL Shell for Document Store”](#).

- The *MySQL Shell User Guide* at [MySQL Shell 9.7](#) provides detailed information about configuring and using MySQL Shell.

## 22.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

- [JSON Document](#)
- [Collection](#)
- [CRUD Operations](#)

### JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the `world_x` schema (installed later in this chapter) contains this document:

```
{
  "GNP": 4834,
  "_id": "00005de917d8000000000000000023",
  "Code": "BWA",
  "Name": "Botswana",
  "IndepYear": 1966,
  "geography": {
    "Region": "Southern Africa",
    "Continent": "Africa",
    "SurfaceArea": 581730
  },
  "government": {
    "HeadOfState": "Festus G. Mogae",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 1622000,
    "LifeExpectancy": 39.29999923706055
  }
}
```

This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the `JSON` MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

## Collection

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

## CRUD Operations

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

## 22.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.

- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 9.7, and MySQL Shell to use as the client. [MySQL Shell 9.7](#) provides more in-depth information about MySQL Shell. The Document Store is accessed using X DevAPI, and MySQL Shell provides this API in both JavaScript and Python.

## Related Information

- [MySQL Shell 9.7](#) provides more in-depth information about MySQL Shell.
- See [Installing MySQL Shell](#) and [Section 22.5, “X Plugin”](#) for more information about the tools used in this quick-start guide.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI to develop applications which use Document Store.
- A [Python](#) quick-start guide is also available.

### 22.3.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. SQL is the default processing mode.

#### Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

#### Tip

If you connect to the instance using classic MySQL protocol, for example by using the default `port` of 3306 instead of the `mysqlx_port`, you *cannot* use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.
- `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.

- The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see [Section 22.3.2, “Download and Import world\\_x Database”](#).

For more information, see [Section 6.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”](#).

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is SQL.

```
MYSQL SQL>
```

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

## Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-js> \help \connect
```

## Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-js> \quit
```

## Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

## 22.3.2 Download and Import world\_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download [world\\_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.

3. Import the `world_x.sql` file to your server. You can either:

- Start MySQL Shell in SQL mode and import the file by issuing:

```
mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
Enter password: ****
```

- Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:

```
\sql
Switching to SQL mode... Commands end with ;
\source /tmp/world_x-db/world_x.sql
```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

## The world\_x Schema

The `world_x` example schema contains the following JSON collection and relational tables:

- Collection
  - `countryinfo`: Information about countries in the world.
- Tables
  - `country`: Minimal information about countries of the world.
  - `city`: Information about some of the cities in those countries.
  - `countrylanguage`: Languages spoken in each country.

## Related Information

- [MySQL Shell Sessions](#) explains session types.

## 22.3.3 Documents and Collections

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see [Section 22.3.2, “Download and Import world\\_x Database”](#).

## Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

```
{field1: "value", field2 : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript:

```
[{"Name": "Aruba", "Code": "ABW"}, {"Name": "Angola", "Code": "AGO"}]
```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

## Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.
<code>db.getCollections()</code>	<code>db.getCollections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

## Related Information

- See [Working with Collections](#) for a general overview.

- [CRUD EBNF Definitions](#) provides a complete list of operations.

### 22.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

#### Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-js> \use world_x
```

#### Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

#### List Collections

To display all collections in the `world_x` schema, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-js> db.getCollections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

#### Drop a Collection

To drop an existing collection from a schema, use the `db` object's `dropCollection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a schema.

#### Related Information

- See [Collection Objects](#) for more examples.

### 22.3.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection. Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

## Add a Document

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-js> db.countryinfo.add(
  {
    GNP: .6,
    IndepYear: 1967,
    Name: "Sealand",
    Code: "SEA",
    demographics: {
      LifeExpectancy: 79,
      Population: 27
    },
    geography: {
      Continent: "Europe",
      Region: "British Islands",
      SurfaceArea: 193
    },
    government: {
      GovernmentForm: "Monarchy",
      HeadOfState: "Michael Bates"
    }
  }
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{
  "GNP": 0.6,
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the `_id`. Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. Document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. MySQL sets an `_id` value if the document does not contain the `_id` field. For more information, see [Understanding Document IDs](#).

## Related Information

- See [CollectionAddFunction](#) for the full syntax definition.
- See [Understanding Document IDs](#).

### 22.3.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

### Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-js> db.countryinfo.find()
[
  {
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    },
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

### Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL [Chapter 14, Functions and Operators](#). You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-js> db.countryinfo.find("Name = 'Australia'")
[
  {
    "GNP": 351182,
    "Code": "AUS",
    "Name": "Australia",
    "IndepYear": 1901,
  }
]
```

```

    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  },
  "demographics": {
    "LifeExpectancy": 79.80000305175781,
    "Population": 18886000
  }
}
]

```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```

mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)

```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```

mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)

```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

#### Note

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.

```

mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0

```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```

mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
{
  "GNP": 1161755,
  "_id": "00005de917d8000000000000006a",
  "Code": "ITA",
  "Name": "Italy",
  "Airports": [],
  "IndepYear": 1861,
  "geography": {

```

```

    "Region": "Southern Europe",
    "Continent": "Europe",
    "SurfaceArea": 301316
  },
  "government": {
    "HeadOfState": "Carlo Azeglio Ciampi",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 57680000,
    "LifeExpectancy": 79
  }
}
1 document in set (0.01 sec)

```

### Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```

mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
{
  "GNP": 1424285,
  "_id": "00005de917d8000000000000000048",
  "Code": "FRA",
  "Name": "France",
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}
1 document in set (0.0028 sec)

mysql-js> myFind.bind('country', 'Germany')
{
  "GNP": 2133367,
  "_id": "00005de917d8000000000000000038",
  "Code": "DEU",
  "Name": "Germany",
  "IndepYear": 1955,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 357022
  },
  "government": {

```

```

    "HeadOfState": "Johannes Rau",
    "GovernmentForm": "Federal Republic"
  },
  "demographics": {
    "Population": 82164700,
    "LifeExpectancy": 77.4000015258789
  }
}
1 document in set (0.0026 sec)

```

## Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-js> db.countryinfo.find().fields(
mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).limit(2)
{
  "Name": "ARUBA",
  "GNPPerCapita": 8038.834951456311
}
{
  "Name": "AFGHANISTAN",
  "GNPPerCapita": 263.0281690140845
}

```

## Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```

mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)

```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

## Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

### 22.3.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

## Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-js> db.countryinfo.modify("Code = 'SEA']").set(
"demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-js> db.countryinfo.modify("Name = 'Sealand']").unset("GNP")
```

Use the `find()` method to verify the change.

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{
  "_id": "00005e2ff4af0000000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
}
```

```

    "government": {
      "HeadOfState": "Michael Bates",
      "GovernmentForm": "Monarchy"
    },
    "demographics": {
      "Population": 27,
      "LifeExpectancy": 79
    }
  }
}

```

## Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

### Caution

Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France']").arrayAppend("$.Airports", "ORY")
```

Use `find()` to see the change.

```

mysql-js> db.countryinfo.find("Name = 'France'")
{
  "GNP": 1424285,
  "_id": "00005de917d800000000000000048",
  "Code": "FRA",
  "Name": "France",
  "Airports": [
    "ORY"
  ],
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}

```

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-js> db.countryinfo.modify("Name = 'France']").arrayInsert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
```

## Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

### 22.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

#### Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-js> db.countryinfo.remove("Code = 'SEA'")
```

#### Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
```

#### Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

#### Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

#### Caution

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

## Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 22.3.2, “Download and Import world\\_x Database”](#) for instructions to recreate the `world_x` schema.

### 22.3.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see [Indexing Collections](#).

## Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `createIndex()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```
mysql-js> db.countryinfo.createIndex("popul", {fields:
[{"field": '$.demographics.Population', type: 'INTEGER'}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

## Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `createIndex()` method. This example shows a unique index created on the country name (`"Name"`), which is another common field in the `countryinfo` collection to index. In the index field description, `"TEXT(40)"` represents the number of characters to index, and `"required": True` specifies that the field is required to exist in the document.

```
mysql-js> db.countryinfo.createIndex("name",
{"fields": [{"field": "$.Name", "type": "TEXT(40)", "required": true}], "unique": true})
```

## Drop an Index

To drop an index, pass the name of the index to drop to the `dropIndex()` method. For example, you can drop the “popul” index as follows:

```
mysql-js> db.countryinfo.dropIndex("popul")
```

## Related Information

- See [Indexing Collections](#) for more information.
- See [Defining an Index](#) for more information on the JSON document that defines an index.
- See [Collection Index Management Functions](#) for the full syntax definition.

## 22.3.4 Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use [InnoDB](#) tables in the `world_x` schema.

### Confirm the Schema

To show the schema that is assigned to the `db` global variable, issue `db`.

```
mysql-js> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```
mysql-js> \use world_x
Schema `world_x` accessible through db.
```

### Show All Tables

To display all relational tables in the `world_x` schema, use the `getTables()` method on the `db` object.

```
mysql-js> db.getTables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

### Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The <code>insert()</code> method inserts one or more records into the named table.
<code>db.name.select()</code>	The <code>select()</code> method returns some or all records in the named table.
<code>db.name.update()</code>	The <code>update()</code> method updates records in the named table.
<code>db.name.delete()</code>	The <code>delete()</code> method deletes one or more records from the named table.

### Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 22.3.2, "Download and Import world\\_x Database"](#) for instructions on setting up the `world_x` schema sample.

#### 22.3.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

## Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` schema, insert the following record and press **Enter** twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").values(
None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

## Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").values(
None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

## Related Information

- See [TableInsertFunction](#) for the full syntax definition.

### 22.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (||)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

## Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

### Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-js> db.city.select()
+-----+-----+-----+-----+-----+
| ID   | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1    | Kabul     | AFG         | Kabul    | {"Population": 1780000}                 |
| 2    | Qandahar  | AFG         | Qandahar | {"Population": 237500}                  |
| 3    | Herat     | AFG         | Herat    | {"Population": 186800}                  |
| ...  | ...       | ...         | ...      | ...                                     |
| 4079 | Rafah     | PSE         | Rafah    | {"Population": 92020}                   |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

## Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-js> db.city.select(["Name", "CountryCode"])
```

Name	CountryCode
Kabul	AFG
Qandahar	AFG
Herat	AFG
Mazar-e-Sharif	AFG
Amsterdam	NLD
...	...
Rafah	PSE
Olympia	USA
Little Falls	USA
Happy Valley	USA

```
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
```

Name	CountryCode
Zaanstad	NLD
Zoetermeer	NLD
Zwolle	NLD
Zenica	BIH
Zagazig	EGY
Zaragoza	ESP
Zamboanga	PHL
Zahedan	IRN
Zanjan	IRN
Zabol	IRN
Zama	JPN
Zhezqazghan	KAZ
Zhengzhou	CHN
...	...
Zelevnogorsk	RUS

```
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%' "` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.city.select(["Name", "CountryCode"]).
  where("Name like :name").bind("name", "Z%")
```

### Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

## Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where(
  "Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name      | CountryCode |
+-----+-----+
| Zhengzhou | CHN         |
| Zibo      | CHN         |
| Zhangjiakou | CHN        |
| Zhuzhou   | CHN         |
| Zhangjiang | CHN         |
| Zigong    | CHN         |
| Zaozhuang | CHN         |
| ...       | ...         |
| Zhangjiagang | CHN        |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
  where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'")
+-----+-----+
| Name      | CountryCode |
+-----+-----+
| Zhengzhou | CHN         |
| Zibo      | CHN         |
| Zhangjiakou | CHN        |
| Zhuzhou   | CHN         |
| ...       | ...         |
| Zeleznogorsk | RUS        |
+-----+-----+
29 rows in set (0.01 sec)
```

## Limit, Order, and Offset Results

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-js> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name      |
+-----+-----+
| ABW  | Aruba     |
| AFG  | Afghanistan |
| AGO  | Angola    |
| AIA  | Anguilla  |
| ALB  | Albania   |
+-----+-----+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZWE  | Zimbabwe  |
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
| YEM  | Yemen     |
+-----+-----+
3 rows in set (0.00 sec)
```

## Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

### 22.3.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID  | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1891 | Beijing  | CHN         | Peking  | {"Population": 7472000}                 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

## Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

### 22.3.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

#### Delete Records Using Conditions

The following example passes search conditions to the `delete()` method. All records matching the condition are deleted from the `city` table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
```

#### Delete the First Record

To delete the first record in the `city` table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
```

#### Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

#### Caution

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

#### Drop a Table

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```
mysql-js> session.dropCollection("world_x", "citytest")
```

#### Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 22.3.2, “Download and Import world\\_x Database”](#) for instructions to recreate the `world_x` database.

## 22.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the `city` table in the `world_x` schema.

#### city Table Description

The `city` table has five columns (or fields).

Field	Type	Null	Key	Default	Extra

ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			
Info	json	YES		null	

## Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-js> db.city.insert().values(
None, "San Francisco", "USA", "California", '{"Population":830000}')
```

## Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where(
"CountryCode = :country and Info->'$.Population' > 1000000").bind(
'country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

9 rows in set (0.01 sec)

## Related Information

- See [Working with Relational Tables and Documents](#) for more information.
- See [Section 13.5, "The JSON Data Type"](#) for a detailed description of the data type.

## 22.4 Python Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 9.7, and MySQL Shell to use as the client. MySQL Shell includes X DevAPI, implemented in both JavaScript and Python, which enables you to connect to the MySQL server instance using X Protocol and use the server as a Document Store.

## Related Information

- [MySQL Shell 9.7](#) provides more in-depth information about MySQL Shell.
- See [Installing MySQL Shell](#) and [Section 22.5, “X Plugin”](#) for more information about the tools used in this quick-start guide.
- See [Supported Languages](#) for more information about the languages MySQL Shell supports.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI to develop applications which use MySQL as a Document Store.
- A [JavaScript](#) quick-start guide is also available.

### 22.4.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

#### Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

#### Tip

If you connect to the instance using classic MySQL protocol, for example by using the default `port` of 3306 instead of the `mysqlx_port`, you *cannot* use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.
- `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.
- The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see [Section 22.4.2, “Download and Import world\\_x Database”](#).

For more information, see [Section 6.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”](#).

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript. To switch MySQL Shell to Python mode, use the `\py` command.

```
mysql-js> \py
Switching to Python mode...
mysql-py>
```

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

## Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-py> \help \connect
```

## Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-py> \quit
```

## Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

## 22.4.2 Download and Import world\_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download [world\\_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your server. You can either:

- Start MySQL Shell in SQL mode and import the file by issuing:

```
mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
Enter password: ****
```

- Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:

```
\sql
Switching to SQL mode... Commands end with ;
\source /tmp/world_x-db/world_x.sql
```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

## The world\_x Schema

The `world_x` example schema contains the following JSON collection and relational tables:

- Collection
  - `countryinfo`: Information about countries in the world.
- Tables
  - `country`: Minimal information about countries of the world.
  - `city`: Information about some of the cities in those countries.
  - `countrylanguage`: Languages spoken in each country.

## Related Information

- [MySQL Shell Sessions](#) explains session types.

## 22.4.3 Documents and Collections

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see [Section 22.4.2, “Download and Import world\\_x Database”](#).

## Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2" : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for Python:

```
[{"Name": "Aruba", "Code": "ABW"}, {"Name": "Angola", "Code": "AGO"}]
```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

## Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable.
<code>db.get_collections()</code>	<code>db.get_collections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

## Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

### 22.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

#### Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-py> \use world_x
```

#### Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

#### List Collections

To display all collections in the `world_x` schema, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-py> db.get_collections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

#### Drop a Collection

To drop an existing collection from a schema, use the `db` object's `drop_collection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-py> db.drop_collection("flags")
```

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a schema.

#### Related Information

- See [Collection Objects](#) for more examples.

### 22.4.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection. Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

## Add a Document

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-py> db.countryinfo.add(
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "Code": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
  "GNP": 0.6,
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the `_id`. Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. Document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. MySQL sets an `_id` value if the document does not contain the `_id` field. For more information, see [Understanding Document IDs](#).

## Related Information

- See [CollectionAddFunction](#) for the full syntax definition.
- See [Understanding Document IDs](#).

### 22.4.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

#### Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find()
[
  {
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    },
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

#### Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL [Chapter 14, Functions and Operators](#). You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-py> db.countryinfo.find("Name = 'Australia'")
[
  {
    "GNP": 351182,
    "Code": "AUS",
    "Name": "Australia",
    "IndepYear": 1901,
  }
]
```

```

    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  },
  "demographics": {
    "LifeExpectancy": 79.80000305175781,
    "Population": 18886000
  },
}
]

```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```

mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)

```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```

mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)

```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

#### Note

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.

```

mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0

```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```

mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
{
  "GNP": 1161755,
  "_id": "00005de917d800000000000000006a",
  "Code": "ITA",
  "Name": "Italy",
  "Airports": [],
  "IndepYear": 1861,
  "geography": {

```

```

    "Region": "Southern Europe",
    "Continent": "Europe",
    "SurfaceArea": 301316
  },
  "government": {
    "HeadOfState": "Carlo Azeglio Ciampi",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 57680000,
    "LifeExpectancy": 79
  }
}
1 document in set (0.01 sec)

```

### Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```

mysql-py> myFind = db.countryinfo.find("Name = :country")
mysql-py> myFind.bind('country', 'France')
{
  "GNP": 1424285,
  "_id": "00005de917d800000000000000048",
  "Code": "FRA",
  "Name": "France",
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}
1 document in set (0.0028 sec)

mysql-py> myFind.bind('country', 'Germany')
{
  "GNP": 2133367,
  "_id": "00005de917d8000000000000000038",
  "Code": "DEU",
  "Name": "Germany",
  "IndepYear": 1955,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 357022
  },
  "government": {

```

```

      "HeadOfState": "Johannes Rau",
      "GovernmentForm": "Federal Republic"
    },
    "demographics": {
      "Population": 82164700,
      "LifeExpectancy": 77.4000015258789
    }
  }
}
1 document in set (0.0026 sec)

```

## Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-py> db.countryinfo.find().fields(
mysqlx.expr('{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).limit(2)
[
  {
    "Name": "ARUBA",
    "GNPPerCapita": 8038.834951456311
  }
  {
    "Name": "AFGHANISTAN",
    "GNPPerCapita": 263.0281690140845
  }
]

```

## Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```

mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)

```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

## Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

### 22.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

## Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-py> db.countryinfo.modify("Code = 'SEA']").set(
"demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand']").unset("GNP")
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
  "_id": "00005e2ff4af0000000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
}
```

```

"government": {
  "HeadOfState": "Michael Bates",
  "GovernmentForm": "Monarchy"
},
"demographics": {
  "Population": 27,
  "LifeExpectancy": 79
}
}

```

## Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

### Caution

Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.

```
mysql-py> db.countryinfo.modify("true").set("Airports", [])
```

With the Airports field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the Airports field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
```

Use `find()` to see the change.

```

mysql-py> db.countryinfo.find("Name = 'France'")
{
  "GNP": 1424285,
  "_id": "00005de917d8000000000000000048",
  "Code": "FRA",
  "Name": "France",
  "Airports": [
    "ORY"
  ],
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}

```

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
```

## Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

### 22.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

#### Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("Code = 'SEA'")
```

#### Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove("true").limit(1)
```

#### Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-py> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

#### Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

#### Caution

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

## Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 22.4.2, “Download and Import world\\_x Database”](#) for instructions to recreate the `world_x` schema.

## 22.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```
mysql-py> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see [Indexing Collections](#).

### Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `create_index()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```
mysql-py> db.countryinfo.createIndex("popul", {fields:
[{"field": '$.demographics.Population', type: 'INTEGER'}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

### Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `create_index()` method. This example shows a unique index created on the country name (“Name”), which is another common field in the `countryinfo` collection to index. In the index field description, “`TEXT(40)`” represents the number of characters to index, and “`required: True`” specifies that the field is required to exist in the document.

```
mysql-py> db.countryinfo.create_index("name",
{"fields": [{"field": "$.Name", "type": "TEXT(40)", "required": True}], "unique": True})
```

### Drop an Index

To drop an index, pass the name of the index to drop to the `drop_index()` method. For example, you can drop the “popul” index as follows:

```
mysql-py> db.countryinfo.drop_index("popul")
```

### Related Information

- See [Indexing Collections](#) for more information.
- See [Defining an Index](#) for more information on the JSON document that defines an index.

- See [Collection Index Management Functions](#) for the full syntax definition.

## 22.4.4 Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` schema.

### Confirm the Schema

To show the schema that is assigned to the `db` global variable, issue `db`.

```
mysql-py> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

### Show All Tables

To display all relational tables in the `world_x` schema, use the `get_tables()` method on the `db` object.

```
mysql-py> db.get_tables()
[
  <Table:city>,
  <Table:country>,
  <Table:countrylanguage>
]
```

## Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The <code>insert()</code> method inserts one or more records into the named table.
<code>db.name.select()</code>	The <code>select()</code> method returns some or all records in the named table.
<code>db.name.update()</code>	The <code>update()</code> method updates records in the named table.
<code>db.name.delete()</code>	The <code>delete()</code> method deletes one or more records from the named table.

### Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 22.4.2, "Download and Import world\\_x Database"](#) for instructions on setting up the `world_x` schema sample.

#### 22.4.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

### Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").values(
None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

### Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").values(
None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

### Related Information

- See [TableInsertFunction](#) for the full syntax definition.

## 22.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

### Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

#### Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-py> db.city.select()
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1 | Kabul | AFG | Kabul | {"Population": 1780000} |
| 2 | Qandahar | AFG | Qandahar | {"Population": 237500} |
| 3 | Herat | AFG | Herat | {"Population": 186800} |
... ..
```

```
| 4079 | Rafah      | PSE      | Rafah      | {"Population": 92020} |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

## Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(["Name", "CountryCode"])
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Kabul         | AFG         |
| Qandahar      | AFG         |
| Herat         | AFG         |
| Mazar-e-Sharif | AFG         |
| Amsterdam     | NLD         |
| ...          | ...         |
| Rafah        | PSE         |
| Olympia       | USA         |
| Little Falls  | USA         |
| Happy Valley  | USA         |
+-----+-----+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zaanstad      | NLD         |
| Zoetermeer    | NLD         |
| Zwolle        | NLD         |
| Zenica        | BIH         |
| Zagazig       | EGY         |
| Zaragoza      | ESP         |
| Zamboanga     | PHL         |
| Zahedan       | IRN         |
| Zanzan        | IRN         |
| Zabol         | IRN         |
| Zama          | JPN         |
| Zhezqazghan   | KAZ         |
| Zhengzhou     | CHN         |
| ...          | ...         |
| Zeleznogorsk  | RUS         |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%'"` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like :name").bind("name", "Z%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

**Project Results**

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| Zhangjiang   | CHN         |
| Zigong       | CHN         |
| Zaozhuang   | CHN         |
| ...         | ...         |
| Zhangjiagang | CHN         |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| ...         | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
29 rows in set (0.01 sec)
```

**Limit, Order, and Offset Results**

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name          |
+-----+-----+
| ABW  | Aruba         |
| AFG  | Afghanistan  |
```

```

| AGO | Angola      |
| AIA | Anguilla    |
| ALB | Albania     |
+-----+-----+
5 rows in set (0.00 sec)
    
```

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```

mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZWE  | Zimbabwe  |
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
    
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```

mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
| YEM  | Yemen     |
+-----+-----+
3 rows in set (0.00 sec)
    
```

## Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

### 22.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```

mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
    
```

Use the `select()` method to verify the change.

```

mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID   | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1891 | Beijing   | CHN         | Peking   | {"Population": 7472000}                 |
+-----+-----+-----+-----+-----+
    
```

```
+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

## Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

### 22.4.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

#### Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition are deleted from the `city` table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
```

#### Delete the First Record

To delete the first record in the `city` table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
```

#### Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

#### Caution

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

#### Drop a Table

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```
mysql-py> db.drop_collection("citytest")
```

## Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 22.4.2, “Download and Import world\\_x Database”](#) for instructions to recreate the `world_x` database.

### 22.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the `city` table in the `world_x` schema.

## city Table Description

The city table has five columns (or fields).

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			
Info	json	YES		null	

## Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-py> db.city.insert().values(
None, "San Francisco", "USA", "California", '{"Population":830000}')
```

## Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where(
"CountryCode = :country and Info->'$.Population' > 1000000").bind(
'country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

9 rows in set (0.01 sec)

## Related Information

- See [Working with Relational Tables and Documents](#) for more information.
- See [Section 13.5, “The JSON Data Type”](#) for a detailed description of the data type.

## 22.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

### 22.5.1 Checking X Plugin Installation

X Plugin is enabled by default in MySQL 8, therefore installing or upgrading to MySQL 8 makes the plugin available. You can verify X Plugin is installed on an instance of MySQL server by using the `SHOW plugins` statement to view the plugins list.

To use MySQL Shell to verify X Plugin is installed, issue:

```
$> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

To use MySQL Client to verify X Plugin is installed, issue:

```
$> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+-----+-----+-----+-----+-----+
| Name           | Status  | Type           | Library | License |
+-----+-----+-----+-----+-----+
...
| mysqlx         | ACTIVE  | DAEMON        | NULL   | GPL     |
...
+-----+-----+-----+-----+-----+
```

## 22.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `-DWITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

## 22.5.3 Using Encrypted Connections with X Plugin

This section explains how to configure X Plugin to use encrypted connections. For more background information, see [Section 8.3, “Using Encrypted Connections”](#).

To enable configuring support for encrypted connections, X Plugin has `mysqlx_ssl_xxx` system variables, which can have different values from the `ssl_xxx` system variables used with MySQL Server. For example, X Plugin can have SSL key, certificate, and certificate authority files that differ from those used for MySQL Server. These variables are described at [Section 22.5.6.2, “X Plugin Options and System Variables”](#). Similarly, X Plugin has its own `Mysqlx_ssl_xxx` status variables that correspond to the MySQL Server encrypted-connection `Ssl_xxx` status variables. See [Section 22.5.6.3, “X Plugin Status Variables”](#).

At initialization, X Plugin determines its TLS context for encrypted connections as follows:

- If all `mysqlx_ssl_xxx` system variables have their default values, X Plugin uses the same TLS context as the MySQL Server main connection interface, which is determined by the values of the `ssl_xxx` system variables.
- If any `mysqlx_ssl_xxx` variable has a nondefault value, X Plugin uses the TLS context defined by the values of its own system variables. (This is the case if any `mysqlx_ssl_xxx` system variable is set to a value different from its default.)

This means that, on a server with X Plugin enabled, you can choose to have MySQL Protocol and X Protocol connections share the same encryption configuration by setting only the `ssl_xxx` variables, or have separate encryption configurations for MySQL Protocol and X Protocol connections by configuring the `ssl_xxx` and `mysqlx_ssl_xxx` variables separately.

To have MySQL Protocol and X Protocol connections use the same encryption configuration, set only the `ssl_xxx` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To configure encryption separately for MySQL Protocol and X Protocol connections, set both the `ssl_XXX` and `mysqlx_ssl_XXX` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca1.pem
ssl_cert=server-cert1.pem
ssl_key=server-key1.pem

mysqlx_ssl_ca=ca2.pem
mysqlx_ssl_cert=server-cert2.pem
mysqlx_ssl_key=server-key2.pem
```

For general information about configuring connection-encryption support, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#). That discussion is written for MySQL Server, but the parameter names are similar for X Plugin. (The X Plugin `mysqlx_ssl_XXX` system variable names correspond to the MySQL Server `ssl_XXX` system variable names.)

The `tls_version` system variable that determines the permitted TLS versions for MySQL Protocol connections also applies to X Protocol connections. The permitted TLS versions for both types of connections are therefore the same.

Encryption per connection is optional, but a specific user can be required to use encryption for X Protocol and MySQL Protocol connections by including an appropriate `REQUIRE` clause in the `CREATE USER` statement that creates the user. For details, see [Section 15.7.1.3, “CREATE USER Statement”](#). Alternatively, to require all users to use encryption for X Protocol and MySQL Protocol connections, enable the `require_secure_transport` system variable. For additional information, see [Configuring Encrypted Connections as Mandatory](#).

## 22.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL user accounts created with the `caching_sha2_password` authentication plugin. For more information on this plugin, see [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#). You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the `caching_sha2_password` authentication plugin holds an authentication cache, this cache is not shared with X Plugin, so X Plugin uses its own authentication cache for `SHA256_MEMORY` authentication. The X Plugin authentication cache stores hashes of user account passwords, and cannot be accessed using SQL. If a user account is modified or removed, the relevant entries are removed from the cache. The X Plugin authentication cache is maintained by the `mysqlx_cache_cleaner` plugin, which is enabled by default, and has no related system variables or status variables.

Before you can use non-SSL X Protocol connections to authenticate an account that uses the `caching_sha2_password` authentication plugin, the account must have authenticated at least once over an X Protocol connection with SSL, to supply the password to the X Plugin authentication cache. Once this initial authentication over SSL has succeeded, non-SSL X Protocol connections can be used.

It is possible to disable the `mysqlx_cache_cleaner` plugin by starting the MySQL server with the option `--mysqlx_cache_cleaner=0`. If you do this, the X Plugin authentication cache is disabled, and therefore SSL must always be used for X Protocol connections when authenticating with `SHA256_MEMORY` authentication.

## 22.5.5 Connection Compression with X Plugin

X Plugin supports compression of messages sent over X Protocol connections. Connections can be compressed if the server and the client agree on a mutually supported compression algorithm. Enabling compression reduces the number of bytes sent over the network, but adds to the server and client an additional CPU cost for compression and decompression operations. The benefits of compression therefore occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

**Note**

Different MySQL clients implement support for connection compression differently; consult your client documentation for details. For example, for classic MySQL protocol connections, see [Section 6.2.8, “Connection Compression Control”](#).

- [Configuring Connection Compression for X Plugin](#)
- [Compressed Connection Characteristics for X Plugin](#)
- [Monitoring Connection Compression for X Plugin](#)

## Configuring Connection Compression for X Plugin

By default, X Plugin supports the zstd, LZ4, and Deflate compression algorithms. Compression with the Deflate algorithm is carried out using the zlib software library, so the `deflate_stream` compression algorithm setting for X Protocol connections is equivalent to the `zlib` setting for classic MySQL protocol connections.

On the server side, you can disallow any of the compression algorithms by setting the `mysqlx_compression_algorithms` system variable to include only those permitted. The algorithm names `zstd_stream`, `lz4_message`, and `deflate_stream` can be specified in any combination, and the order and lettercase are not important. If the system variable value is the empty string, no compression algorithms are permitted and connections are uncompressed.

The following table compares the characteristics of the different compression algorithms and shows their assigned priorities. By default, the server chooses the highest-priority algorithm permitted in common by the server and the client; clients may change the priorities as described later. The short form alias for the algorithms can be used by clients when specifying them.

**Table 22.1 X Protocol Compression Algorithm Characteristics**

Algorithm	Alias	Compression Ratio	Throughput	CPU Cost	Default Priority
<code>zsth_stream</code>	<code>zstd</code>	High	High	Medium	First
<code>lz4_message</code>	<code>lz4</code>	Low	High	Lowest	Second
<code>deflate_stream</code>	<code>deflate</code>	High	Low	Highest	Third

The X Protocol set of permitted compression algorithms (whether user-specified or default) is independent of the set of compression algorithms permitted by MySQL Server for classic MySQL protocol connections, which is specified by the `protocol_compression_algorithms` server system variable. If you do not specify the `mysqlx_compression_algorithms` system variable, X Plugin does not fall back to using compression settings for classic MySQL protocol connections. Instead, its default is to permit all algorithms shown in [Table 22.1, “X Protocol Compression Algorithm Characteristics”](#). This is unlike the situation for the TLS context, where MySQL Server settings are used if the X Plugin system variables are not set, as described in [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#). For information

about compression for classic MySQL protocol connections, see [Section 6.2.8, “Connection Compression Control”](#).

On the client side, an X Protocol connection request can specify several parameters for compression control:

- The compression mode.
- The compression level.
- The list of permitted compression algorithms in priority order.

**Note**

Some clients or Connectors might not support a given compression-control feature. For example, specifying compression level for X Protocol connections is supported only by MySQL Shell, not by other MySQL clients or Connectors. See the documentation for specific products for details about supported features and how to use them.

The connection mode has these permitted values:

- **disabled**: The connection is uncompressed.
- **preferred**: The server and client negotiate to find a compression algorithm they both permit. If no common algorithm is available, the connection is uncompressed. This is the default mode if not specified explicitly.
- **required**: Compression algorithm negotiation occurs as for **preferred** mode, but if no common algorithm is available, the connection request terminates with an error.

In addition to agreeing on a compression algorithm for each connection, the server and client can agree on a compression level from the numeric range that applies to the agreed algorithm. As the compression level for an algorithm increases, the data compression ratio increases, which reduces the network bandwidth and transfer time needed to send the message to the client. However, the effort required for data compression also increases, taking up time and CPU and memory resources on the server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

The client can request a specific compression level during capability negotiations with the server for an X Protocol connection.

The default compression levels used by X Plugin in MySQL 9.7 have been selected through performance testing as being a good trade-off between compression time and network transit time. These defaults are not necessarily the same as the library default for each algorithm. They apply if the client does not request a compression level for the algorithm. The default compression levels are initially set to 3 for zstd, 2 for LZ4, and 3 for Deflate. You can adjust these settings using the `mysqlx_zstd_default_compression_level`, `mysqlx_lz4_default_compression_level`, and `mysqlx_deflate_default_compression_level` system variables.

To prevent excessive resource consumption on the server, X Plugin sets a maximum compression level that the server permits for each algorithm. If a client requests a compression level that exceeds this setting, the server uses its maximum permitted compression level (compression level requests by a client are supported only by MySQL Shell). The maximum compression levels are initially set to 11 for zstd, 8 for LZ4, and 5 for Deflate. You can adjust these settings using the `mysqlx_zstd_max_client_compression_level`, `mysqlx_lz4_max_client_compression_level`, and `mysqlx_deflate_max_client_compression_level` system variables.

If the server and client permit more than one algorithm in common, the default priority order for choosing an algorithm during negotiation is shown in [Table 22.1, “X Protocol Compression Algorithm Characteristics”](#). For clients that support specifying compression algorithms, the connection request can include a list of algorithms permitted by the client, specified using the algorithm name or its alias. The order of these algorithms in the list is taken as a priority order by the server. The algorithm used in this case is the first of those in the client list that is also permitted on the server side. However, the option for compression algorithms is subject to the compression mode:

- If the compression mode is `disabled`, the compression algorithms option is ignored.
- If the compression mode is `preferred` but no algorithm permitted on the client side is permitted on the server side, the connection is uncompressed.
- If the compression mode is `required` but no algorithm permitted on the client side is permitted on the server side, an error occurs.

To monitor the effects of message compression, use the X Plugin status variables described in [Monitoring Connection Compression for X Plugin](#). You can use these status variables to calculate the benefit of message compression with your current settings, and use that information to tune your settings.

## Compressed Connection Characteristics for X Plugin

X Protocol connection compression operates with the following behaviors and boundaries:

- The `_stream` and `_message` suffixes in algorithm names refer to two different operational modes: In stream mode, all X Protocol messages in a single connection are compressed into a continuous stream and must be decompressed in the same manner—following the order they were compressed and without skipping any messages. In message mode, each message is compressed individually and independently, and need not be decompressed in the order in which they were compressed. Also, message mode does not require all compressed messages to be decompressed.
- Compression is not applied to any messages that are sent before authentication succeeds.
- Compression is not applied to control flow messages such as `MySQLx.Ok`, `MySQLx.Error`, and `MySQLx.Sql.StmtExecuteOk` messages.
- All other X Protocol messages can be compressed if the server and client agree on a mutually permitted compression algorithm during capability negotiation. If the client does not request compression at that stage, neither the client nor the server applies compression to messages.
- When messages sent over X Protocol connections are compressed, the limit specified by the `mysqlx_max_allowed_packet` system variable still applies. The network packet must be smaller than this limit after the message payload has been decompressed. If the limit is exceeded, X Plugin returns a decompression error and closes the connection.
- The following points pertain to compression level requests by clients, which is supported only by MySQL Shell:
  - Compression levels must be specified by the client as an integer. If any other type of value is supplied, the connection closes with an error.
  - If a client specifies an algorithm but not a compression level, the server uses its default compression level for the algorithm.
  - If a client requests an algorithm compression level that exceeds the server maximum permitted level, the server uses the maximum permitted level.

- If a client requests an algorithm compression level that is less than the server minimum permitted level, the server uses the minimum permitted level.

## Monitoring Connection Compression for X Plugin

You can monitor the effects of message compression using the X Plugin status variables. When message compression is in use, the session `Mysqlx_compression_algorithm` status variable shows which compression algorithm is in use for the current X Protocol connection, and `Mysqlx_compression_level` shows the compression level that was selected.

X Plugin status variables can be used to calculate the efficiency of the compression algorithms that are selected (the data compression ratio), and the overall effect of using message compression. Use the session value of the status variables in the following calculations to see what the benefit of message compression was for a specific session with a known compression algorithm. Or use the global value of the status variables to check the overall benefit of message compression for your server across all sessions using X Protocol connections, including all the compression algorithms that have been used for those sessions, and all sessions that did not use message compression. You can then tune message compression by adjusting the permitted compression algorithms, maximum compression level, and default compression level, as described in [Configuring Connection Compression for X Plugin](#).

When message compression is in use, the `Mysqlx_bytes_sent` status variable shows the total number of bytes sent out from the server, including compressed message payloads measured after compression, any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages. The `Mysqlx_bytes_sent_compressed_payload` status variable shows the total number of bytes sent as compressed message payloads, measured after compression, and the `Mysqlx_bytes_sent_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured before compression. The compression ratio, which shows the efficiency of the compression algorithm, can therefore be calculated using the following expression:

```
mysqlx_bytes_sent_uncompressed_frame / mysqlx_bytes_sent_compressed_payload
```

The effectiveness of compression for X Protocol messages sent by the server can be calculated using the following expression:

```
(mysqlx_bytes_sent - mysqlx_bytes_sent_compressed_payload + mysqlx_bytes_sent_uncompressed_frame) / mysqlx
```

For messages received by the server from clients, the `Mysqlx_bytes_received_compressed_payload` status variable shows the total number of bytes received as compressed message payloads, measured before decompression, and the `Mysqlx_bytes_received_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured after decompression. The `Mysqlx_bytes_received` status variable includes compressed message payloads measured before decompression, any uncompressed items in compressed messages, and any uncompressed messages.

## 22.5.6 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin, as well as the status variables available for monitoring purposes. If configuration values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

### 22.5.6.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, system variables, and status variables provided by X Plugin.

Table 22.2 X Plugin Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
mysqlx	Yes	Yes				
Mysqlx_aborted_clients				Yes	Global	No
Mysqlx_address				Yes	Global	No
mysqlx_bind_address	Yes	Yes	Yes		Global	No
Mysqlx_bytes_received				Yes	Both	No
Mysqlx_bytes_received_compressed_payload				Yes	Both	No
Mysqlx_bytes_received_uncompressed_frame				Yes	Both	No
Mysqlx_bytes_sent				Yes	Both	No
Mysqlx_bytes_sent_compressed_payload				Yes	Both	No
Mysqlx_bytes_sent_uncompressed_frame				Yes	Both	No
Mysqlx_compression_algorithm				Yes	Session	No
mysqlx_compression_algorithm	Yes	Yes	Yes		Global	Yes
Mysqlx_compression_level				Yes	Session	No
mysqlx_connect_timeout	Yes	Yes	Yes		Global	Yes
Mysqlx_connection_accept_errors				Yes	Both	No
Mysqlx_connection_errors				Yes	Both	No
Mysqlx_connections_accepted				Yes	Global	No

### 22.5.6.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx[=value]`

Command-Line Format	<code>--mysqlx[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON OFF

FORCE
FORCE_PLUS_PERMANENT

This option controls how the server loads X Plugin at startup. In MySQL 9.7, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`

Command-Line Format	<code>--mysqlx-bind-address=addr</code>
System Variable	<code>mysqlx_bind_address</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	*

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `bind_address` system variable; see that variable description for more information.

By default, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. If `mysqlx_bind_address` is specified, its value must satisfy these requirements:

- A single address value, which may specify a single non-wildcard IP address (either IPv4 or IPv6), or a host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`).
- A list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name. Wildcard address formats (`*`, `0.0.0.0`, or `::`) are not allowed in a list of values.
- The value may also include a network namespace specifier.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is `:::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.
- If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see [Section 7.1.14, “Network Namespace Support”](#).

### Important

Because X Plugin is not a mandatory plugin, it does not prevent server startup if there is an error in the specified address or list of addresses (as MySQL Server does for `bind_address` errors). With X Plugin, if one of the listed addresses cannot be parsed or if X Plugin cannot bind to it, the address is skipped, an error message is logged, and X Plugin attempts to bind to each of the remaining addresses. X Plugin's `Mysqlx_address` status variable displays only those addresses from the list for which the bind succeeded. If none of the listed addresses results in a successful bind, or if a single specified address fails, X Plugin logs the error message `ER_XPLUGIN_FAILED_TO_PREPARE_IO_INTERFACES` stating that X Protocol cannot be used. `mysqlx_bind_address` is not dynamic, so to fix any issues you must stop the server, correct the system variable value, and restart the server.

- `mysqlx_compression_algorithms`

Command-Line Format	<code>--mysqlx-compression-algorithms=value</code>
System Variable	<code>mysqlx_compression_algorithms</code>
Scope	Global

Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	<code>deflate_stream, lz4_message, zstd_stream</code>
Valid Values	<code>deflate_stream</code>  <code>lz4_message</code>  <code>zstd_stream</code>

The compression algorithms that are permitted for use on X Protocol connections. By default, the Deflate, LZ4, and zstd algorithms are all permitted. To disallow any of the algorithms, set `mysqlx_compression_algorithms` to include only the ones you permit. The algorithm names `deflate_stream`, `lz4_message`, and `zstd_stream` can be specified in any combination, and the order and case are not important. If you set the system variable to the empty string, no compression algorithms are permitted and only uncompressed connections are used. Use the algorithm-specific system variables to adjust the default and maximum compression level for each permitted algorithm. For more details, and information on how connection compression for X Protocol relates to the equivalent settings for MySQL Server, see [Section 22.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_connect_timeout`

Command-Line Format	<code>--mysqlx-connect-timeout=#</code>
System Variable	<code>mysqlx_connect_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	1000000000
Unit	seconds

The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of `connect_timeout`; see that variable description for more information.

- `mysqlx_deflate_default_compression_level`

Command-Line Format	<code>--mysqlx_deflate_default_compression_level=#</code>
System Variable	<code>mysqlx_deflate_default_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	1

Maximum Value	9
---------------	---

The default compression level that the server uses for the Deflate algorithm on X Protocol connections. Specify the level as an integer from 1 (the lowest compression effort) to 9 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see [Section 22.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_deflate_max_client_compression_level`

Command-Line Format	-- <code>mysqlx_deflate_max_client_compression_level=#</code>
System Variable	<code>mysqlx_deflate_max_client_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	1
Maximum Value	9

The maximum compression level that the server permits for the Deflate algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 5.

- `mysqlx_document_id_unique_prefix`

Command-Line Format	-- <code>mysqlx-document-id-unique-prefix=#</code>
System Variable	<code>mysqlx_document_id_unique_prefix</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See [Understanding Document IDs](#).

- `mysqlx_enable_hello_notice`

Command-Line Format	-- <code>mysqlx-enable-hello-notice[={OFF ON}]</code>
System Variable	<code>mysqlx_enable_hello_notice</code>

Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Controls messages sent to classic MySQL protocol clients that try to connect over X Protocol. When enabled, clients which do not support X Protocol that attempt to connect to the server X Protocol port receive an error explaining they are using the wrong protocol.

- `mysqlx_idle_worker_thread_timeout`

Command-Line Format	<code>--mysqlx-idle-worker-thread-timeout=#</code>
System Variable	<code>mysqlx_idle_worker_thread_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	3600
Unit	seconds

The number of seconds after which idle worker threads are terminated.

- `mysqlx_interactive_timeout`

Command-Line Format	<code>--mysqlx-interactive-timeout=#</code>
System Variable	<code>mysqlx_interactive_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value	2147483
Unit	seconds

The default value of the `mysqlx_wait_timeout` session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

- `mysqlx_lz4_default_compression_level`

Command-Line Format	<code>--mysqlx_lz4_default_compression_level=#</code>
---------------------	---

System Variable	<code>mysqlx_lz4_default_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	16

The default compression level that the server uses for the LZ4 algorithm on X Protocol connections. Specify the level as an integer from 0 (the lowest compression effort) to 16 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 2 as the default. For more information, see [Section 22.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_lz4_max_client_compression_level`

Command-Line Format	<code>--mysqlx_lz4_max_client_compression_level=#</code>
System Variable	<code>mysqlx_lz4_max_client_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0
Maximum Value	16

The maximum compression level that the server permits for the LZ4 algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 8.

- `mysqlx_max_allowed_packet`

Command-Line Format	<code>--mysqlx-max-allowed-packet=#</code>
System Variable	<code>mysqlx_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	67108864
Minimum Value	512
Maximum Value	1073741824
Unit	bytes

The maximum size of network packets that can be received by X Plugin. This limit also applies when compression is used for the connection, so the network packet must be smaller than this size after the message has been decompressed. This is the X Plugin equivalent of `max_allowed_packet`; see that variable description for more information.

- `mysqlx_max_connections`

Command-Line Format	<code>--mysqlx-max-connections=#</code>
System Variable	<code>mysqlx_max_connections</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value	65535

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable description for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- `mysqlx_min_worker_threads`

Command-Line Format	<code>--mysqlx-min-worker-threads=#</code>
System Variable	<code>mysqlx_min_worker_threads</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	100

The minimum number of worker threads used by X Plugin for handling client requests.

- `mysqlx_port`

Command-Line Format	<code>--mysqlx-port=port_num</code>
System Variable	<code>mysqlx_port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer

Default Value	33060
Minimum Value	1
Maximum Value	65535

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of `port`; see that variable description for more information.

- `mysqlx_port_open_timeout`

Command-Line Format	<code>--mysqlx-port-open-timeout=#</code>
System Variable	<code>mysqlx_port_open_timeout</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	120
Unit	seconds

The number of seconds X Plugin waits for a TCP/IP port to become free.

- `mysqlx_read_timeout`

Command-Line Format	<code>--mysqlx-read-timeout=#</code>
System Variable	<code>mysqlx_read_timeout</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	2147483
Unit	seconds

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, X Plugin closes the connection and returns a warning notice with the error code `ER_IO_READ_ERROR` to the client application.

- `mysqlx_socket`

Command-Line Format	<code>--mysqlx-socket=file_name</code>
System Variable	<code>mysqlx_socket</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	String
Default Value	<code>/tmp/mysqlx.sock</code>

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default `mysqlx_socket` path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the `mysqlx_socket` system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the `MYSQL_UNIX_ADDR` compile option, this does affect the default for the X Plugin socket file, which is formed by appending an `x` to the `MYSQL_UNIX_ADDR` file name. If you want to set a different default for the X Plugin socket file at compile time, use the `MYSQLX_UNIX_ADDR` compile option.

The `MYSQLX_UNIX_PORT` environment variable can also be used to set a default for the X Plugin socket file at server startup (see [Section 6.9, "Environment Variables"](#)). If you set this environment variable, it overrides the compiled `MYSQLX_UNIX_ADDR` value, but is overridden by the `mysqlx_socket` value.

- `mysqlx_ssl_ca`

Command-Line Format	<code>--mysqlx-ssl-ca=file_name</code>
System Variable	<code>mysqlx_ssl_ca</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The `mysqlx_ssl_ca` system variable is like `ssl_ca`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, "Using Encrypted Connections with X Plugin"](#).

- `mysqlx_ssl_capath`

Command-Line Format	<code>--mysqlx-ssl-capath=dir_name</code>
System Variable	<code>mysqlx_ssl_capath</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

The `mysqlx_ssl_capath` system variable is like `ssl_capath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_cert`

Command-Line Format	<code>--mysqlx-ssl-cert=file_name</code>
System Variable	<code>mysqlx_ssl_cert</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The `mysqlx_ssl_cert` system variable is like `ssl_cert`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_cipher`

Command-Line Format	<code>--mysqlx-ssl-cipher=name</code>
System Variable	<code>mysqlx_ssl_cipher</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

The `mysqlx_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crl`

Command-Line Format	<code>--mysqlx-ssl-crl=file_name</code>
System Variable	<code>mysqlx_ssl_crl</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

Default Value	NULL
---------------	------

The `mysqlx_ssl_crl` system variable is like `ssl_crl`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crlpath`

Command-Line Format	<code>--mysqlx-ssl-crlpath=dir_name</code>
System Variable	<code>mysqlx_ssl_crlpath</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	NULL

The `mysqlx_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_key`

Command-Line Format	<code>--mysqlx-ssl-key=file_name</code>
System Variable	<code>mysqlx_ssl_key</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The `mysqlx_ssl_key` system variable is like `ssl_key`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_wait_timeout`

Command-Line Format	<code>--mysqlx-wait-timeout=#</code>
System Variable	<code>mysqlx_wait_timeout</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	1
Maximum Value	2147483

Unit	seconds
------	---------

The number of seconds that X Plugin waits for activity on a connection. After this time, if the read operation is not successful, X Plugin closes the connection. If the client is noninteractive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- `mysqlx_write_timeout`

Command-Line Format	<code>--mysqlx-write-timeout=#</code>
System Variable	<code>mysqlx_write_timeout</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	2147483
Unit	seconds

The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, X Plugin closes the connection.

- `mysqlx_zstd_default_compression_level`

Command-Line Format	<code>--mysqlx_zstd_default_compression_level=#</code>
System Variable	<code>mysqlx_zstd_default_compression_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	-131072
Maximum Value	22

The default compression level that the server uses for the zstd algorithm on X Protocol connections. For versions of the zstd library from 1.4.0, you can set positive values from 1 to 22 (the highest compression effort), or negative values which represent progressively lower effort. A value of 0 is converted to a value of 1. For earlier versions of the zstd library, you can only specify the value 3. This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see [Section 22.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_zstd_max_client_compression_level`

Command-Line Format	<code>--mysqlx_zstd_max_client_compression_level=#</code>
---------------------	---

System Variable	<code>mysqlx_zstd_max_client_compression_level</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	11
Minimum Value	-131072
Maximum Value	22

The maximum compression level that the server permits for the zstd algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 11.

### 22.5.6.3 X Plugin Status Variables

The X Plugin status variables have the following meanings.

- `mysqlx_aborted_clients`

The number of clients that were disconnected because of an input or output error.

- `mysqlx_address`

The network address or addresses for which X Plugin accepts TCP/IP connections. If multiple addresses were specified using the `mysqlx_bind_address` system variable, `mysqlx_address` displays only those addresses for which the bind succeeded. If the bind has failed for every network address specified by `mysqlx_bind_address`, or if the `skip_networking` option has been used, the value of `mysqlx_address` is `UNDEFINED`. If X Plugin startup is not yet complete, the value of `mysqlx_address` is empty.

- `mysqlx_bytes_received`

The total number of bytes received through the network. If compression is used for the connection, this figure comprises compressed message payloads measured before decompression (`mysqlx_bytes_received_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- `mysqlx_bytes_received_compressed_payload`

The number of bytes received as compressed message payloads, measured before decompression.

- `mysqlx_bytes_received_uncompressed_frame`

The number of bytes received as compressed message payloads, measured after decompression.

- `mysqlx_bytes_sent`

The total number of bytes sent through the network. If compression is used for the connection, this figure comprises compressed message payloads measured after compression (`mysqlx_bytes_sent_compressed_payload`), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- `mysqlx_bytes_sent_compressed_payload`

The number of bytes sent as compressed message payloads, measured after compression.

- `Mysqlx_bytes_sent_uncompressed_frame`

The number of bytes sent as compressed message payloads, measured before compression.

- `Mysqlx_compression_algorithm`

(Session scope) The compression algorithm in use for the X Protocol connection for this session. The permitted compression algorithms are listed by the `mysqlx_compression_algorithms` system variable.

- `Mysqlx_compression_level`

(Session scope) The compression level in use for the X Protocol connection for this session.

- `Mysqlx_connection_accept_errors`

The number of connections which have caused accept errors.

- `Mysqlx_connection_errors`

The number of connections which have caused errors.

- `Mysqlx_connections_accepted`

The number of connections which have been accepted.

- `Mysqlx_connections_closed`

The number of connections which have been closed.

- `Mysqlx_connections_rejected`

The number of connections which have been rejected.

- `Mysqlx_crud_create_view`

The number of create view requests received.

- `Mysqlx_crud_delete`

The number of delete requests received.

- `Mysqlx_crud_drop_view`

The number of drop view requests received.

- `Mysqlx_crud_find`

The number of find requests received.

- `Mysqlx_crud_insert`

The number of insert requests received.

- `Mysqlx_crud_modify_view`

The number of modify view requests received.

- `Mysqlx_crud_update`  
The number of update requests received.
- `Mysqlx_cursor_close`  
The number of cursor-close messages received
- `Mysqlx_cursor_fetch`  
The number of cursor-fetch messages received
- `Mysqlx_cursor_open`  
The number of cursor-open messages received
- `Mysqlx_errors_sent`  
The number of errors sent to clients.
- `Mysqlx_errors_unknown_message_type`  
The number of unknown message types that have been received.
- `Mysqlx_expect_close`  
The number of expectation blocks closed.
- `Mysqlx_expect_open`  
The number of expectation blocks opened.
- `Mysqlx_init_error`  
The number of errors during initialisation.
- `Mysqlx_messages_sent`  
The total number of messages of all types sent to clients.
- `Mysqlx_notice_global_sent`  
The number of global notifications sent to clients.
- `Mysqlx_notice_other_sent`  
The number of other types of notices sent back to clients.
- `Mysqlx_notice_warning_sent`  
The number of warning notices sent back to clients.
- `Mysqlx_notified_by_group_replication`  
Number of Group Replication notifications sent to clients.
- `Mysqlx_port`  
The TCP port which X Plugin is listening to. If a network bind has failed, or if the `skip_networking` system variable is enabled, the value shows `UNDEFINED`.

- `Mysqlx_prep_deallocate`  
The number of prepared-statement-deallocate messages received
- `Mysqlx_prep_execute`  
The number of prepared-statement-execute messages received
- `Mysqlx_prep_prepare`  
The number of prepared-statement messages received
- `Mysqlx_rows_sent`  
The number of rows sent back to clients.
- `Mysqlx_sessions`  
The number of sessions that have been opened.
- `Mysqlx_sessions_accepted`  
The number of session attempts which have been accepted.
- `Mysqlx_sessions_closed`  
The number of sessions that have been closed.
- `Mysqlx_sessions_fatal_error`  
The number of sessions that have closed with a fatal error.
- `Mysqlx_sessions_killed`  
The number of sessions which have been killed.
- `Mysqlx_sessions_rejected`  
The number of session attempts which have been rejected.
- `Mysqlx_socket`  
The Unix socket which X Plugin is listening to.
- `Mysqlx_ssl_accept_renegotiates`  
The number of negotiations needed to establish the connection.
- `Mysqlx_ssl_accepts`  
The number of accepted SSL connections.
- `Mysqlx_ssl_active`  
If SSL is active.
- `Mysqlx_ssl_cipher`  
The current SSL cipher (empty for non-SSL connections).

- `Mysqlx_ssl_cipher_list`  
A list of possible SSL ciphers (empty for non-SSL connections).
- `Mysqlx_ssl_ctx_verify_depth`  
The certificate verification depth limit currently set in ctx.
- `Mysqlx_ssl_ctx_verify_mode`  
The certificate verification mode currently set in ctx.
- `Mysqlx_ssl_finished_accepts`  
The number of successful SSL connections to the server.
- `Mysqlx_ssl_server_not_after`  
The last date for which the SSL certificate is valid.
- `Mysqlx_ssl_server_not_before`  
The first date for which the SSL certificate is valid.
- `Mysqlx_ssl_verify_depth`  
The certificate verification depth for SSL connections.
- `Mysqlx_ssl_verify_mode`  
The certificate verification mode for SSL connections.
- `Mysqlx_ssl_version`  
The name of the protocol used for SSL connections.
- `Mysqlx_stmt_create_collection`  
The number of create collection statements received.
- `Mysqlx_stmt_create_collection_index`  
The number of create collection index statements received.
- `Mysqlx_stmt_disable_notices`  
The number of disable notice statements received.
- `Mysqlx_stmt_drop_collection`  
The number of drop collection statements received.
- `Mysqlx_stmt_drop_collection_index`  
The number of drop collection index statements received.
- `Mysqlx_stmt_enable_notices`  
The number of enable notice statements received.

- `Mysqlx_stmt_ensure_collection`  
The number of ensure collection statements received.
- `Mysqlx_stmt_execute_mysqlx`  
The number of StmtExecute messages received with namespace set to `mysqlx`.
- `Mysqlx_stmt_execute_sql`  
The number of StmtExecute requests received for the SQL namespace.
- `Mysqlx_stmt_execute_xplugin`  
This status variable is no longer used.
- `Mysqlx_stmt_get_collection_options`  
The number of get collection object statements received.
- `Mysqlx_stmt_kill_client`  
The number of kill client statements received.
- `Mysqlx_stmt_list_clients`  
The number of list client statements received.
- `Mysqlx_stmt_list_notices`  
The number of list notice statements received.
- `Mysqlx_stmt_list_objects`  
The number of list object statements received.
- `Mysqlx_stmt_modify_collection_options`  
The number of modify collection options statements received.
- `Mysqlx_stmt_ping`  
The number of ping statements received.
- `Mysqlx_worker_threads`  
The number of worker threads available.
- `Mysqlx_worker_threads_active`  
The number of worker threads currently used.

## 22.5.7 Monitoring X Plugin

For general X Plugin monitoring, use the status variables that it exposes. See [Section 22.5.6.3, “X Plugin Status Variables”](#). For information specifically about monitoring the effects of message compression, see [Monitoring Connection Compression for X Plugin](#).

## Monitoring SQL Generated by X Plugin

This section describes how to monitor the SQL statements which X Plugin generates when you run X DevAPI operations. When you execute a CRUD statement, it is translated into SQL and executed against the server. To be able to monitor the generated SQL, the Performance Schema tables must be enabled. The SQL is registered under the `performance_schema.events_statements_current`, `performance_schema.events_statements_history`, and `performance_schema.events_statements_history_long` tables. The following example uses the `world_x` schema, imported as part of the quickstart tutorials in this section. We use MySQL Shell in Python mode, and the `\sql` command which enables you to issue SQL statements without changing to SQL mode. This is important, because if you instead try to switch to SQL mode, the procedure shows the result of this operation rather than the X DevAPI operation. The `\sql` command is used in the same way if you are using MySQL Shell in JavaScript mode.

1. Check if the `events_statements_history` consumer is enabled. Issue:

```
mysql-py> \sql SELECT enabled FROM performance_schema.setup_consumers WHERE NAME = 'events_statements_h
+-----+
| enabled |
+-----+
| YES     |
+-----+
```

2. Check if all instruments report data to the consumer. Issue:

```
mysql-py> \sql SELECT NAME, ENABLED, TIMED FROM performance_schema.setup_instruments WHERE NAME LIKE 's
```

If this statement reports at least one row, you need to enable the instruments. See [Section 29.4, “Performance Schema Runtime Configuration”](#).

3. Get the thread ID of the current connection. Issue:

```
mysql-py> \sql SELECT thread_id INTO @id FROM performance_schema.threads WHERE processlist_id=connectio
```

4. Execute the X DevAPI CRUD operation for which you want to see the generated SQL. For example, issue:

```
mysql-py> db.CountryInfo.find("Name = :country").bind("country", "Italy")
```

You must not issue any further operations for the next step to show the correct result.

5. Show the last SQL query made by this thread ID. Issue:

```
mysql-py> \sql SELECT THREAD_ID, MYSQL_ERRNO,SQL_TEXT FROM performance_schema.events_statements_history
+-----+-----+-----+
| THREAD_ID | MYSQL_ERRNO | SQL_TEXT
+-----+-----+-----+
|          29 |           0 | SELECT doc FROM `world_x`.`CountryInfo` WHERE (JSON_EXTRACT(doc,'$.Name') =
```

The result shows the SQL generated by X Plugin based on the most recent statement, in this case the X DevAPI CRUD operation from the previous step.

## Chapter 23 InnoDB Cluster

This chapter introduces MySQL InnoDB Cluster, which combines MySQL technologies to enable you to deploy and administer a complete integrated high availability solution for MySQL. This content is a high-level overview of InnoDB Cluster, for full documentation, see [MySQL InnoDB Cluster](#).

### Important

InnoDB Cluster does not provide support for MySQL NDB Cluster. For more information about MySQL NDB Cluster, see [Chapter 25, MySQL NDB Cluster 9.7](#) and [Section 25.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#).

An InnoDB Cluster consists of at least three MySQL Server instances, and it provides high-availability and scaling features. InnoDB Cluster uses the following MySQL technologies:

- [MySQL Shell](#), which is an advanced client and code editor for MySQL.
- MySQL Server, and [Group Replication](#), which enables a set of MySQL instances to provide high-availability. InnoDB Cluster provides an alternative, easy to use programmatic way to work with Group Replication.
- [MySQL Router](#), a lightweight middleware that provides transparent routing between your application and InnoDB Cluster.

The following diagram shows an overview of how these technologies work together:

**Figure 23.1 InnoDB Cluster overview**

Being built on MySQL [Group Replication](#), provides features such as automatic membership management, fault tolerance, automatic failover, and so on. An InnoDB Cluster usually runs in a single-primary mode, with one primary instance (read-write) and multiple secondary instances (read-only). Advanced users can

---

also take advantage of a [multi-primary](#) mode, where all instances are primaries. You can even change the topology of the cluster while InnoDB Cluster is online, to ensure the highest possible availability.

You work with InnoDB Cluster using the [AdminAPI](#), provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB Cluster you need to [download](#) and [install](#) MySQL Shell. You need some hosts with MySQL Server instances [installed](#), and you can also [install](#) MySQL Router.

InnoDB Cluster supports [MySQL Clone](#), which enables you to provision instances simply. In the past, to provision a new instance before it joins a set of MySQL instances you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. Using InnoDB Cluster, you can simply [add an instance](#) to the cluster and it is automatically provisioned.

Similarly, InnoDB Cluster is tightly integrated with [MySQL Router](#), and you can use AdminAPI to [work with](#) them together. MySQL Router can automatically configure itself based on an InnoDB Cluster, in a process called [bootstrapping](#), which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB Cluster, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB Cluster using AdminAPI. InnoDB Cluster status information includes details about MySQL Routers bootstrapped against the cluster. Operations enable you to [create MySQL Router users](#) at the cluster level, to work with the MySQL Routers bootstrapped against the cluster, and so on.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from [Connectors and APIs](#).

---

## Chapter 24 InnoDB ReplicaSet

This chapter introduces MySQL InnoDB ReplicaSet, which combines MySQL technologies to enable you to deploy and administer [Chapter 19, Replication](#). This content is a high-level overview of InnoDB ReplicaSet, for full documentation, see [MySQL InnoDB ReplicaSet](#).

An InnoDB ReplicaSet consists of at least two MySQL Server instances, and it provides all of the MySQL Replication features you are familiar with, such as read scale-out and data security. InnoDB ReplicaSet uses the following MySQL technologies:

- [MySQL Shell](#), which is an advanced client and code editor for MySQL.
- MySQL Server, and [Chapter 19, Replication](#), which enables a set of MySQL instances to provide availability and asynchronous read scale-out. InnoDB ReplicaSet provides an alternative, easy to use programmatic way to work with Replication.
- [MySQL Router](#), a lightweight middleware that provides transparent routing between your application and InnoDB ReplicaSet.

The interface to an InnoDB ReplicaSet is similar to [MySQL InnoDB Cluster](#), you use MySQL Shell to work with MySQL Server instances as a ReplicaSet, and MySQL Router is also tightly integrated in the same way as InnoDB Cluster.

Being based on MySQL Replication, an InnoDB ReplicaSet has a single primary, which replicates to one or more secondary instances. An InnoDB ReplicaSet does not provide all of the features which InnoDB Cluster provides, such as automatic failover, or multi-primary mode. But, it does support features such as configuring, adding, and removing instances in a similar way. You can manually switch over or fail over to a secondary instance, for example in the event of a failure. You can even adopt an existing Replication deployment and then administer it as an InnoDB ReplicaSet.

You work with InnoDB ReplicaSet using the [AdminAPI](#), provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB ReplicaSet you need to [download](#) and [install](#) MySQL Shell. You need some hosts with MySQL Server instances [installed](#), and you can also [install](#) MySQL Router.

InnoDB ReplicaSet supports [MySQL Clone](#), which enables you to provision instances simply. In the past, to provision a new instance before it joined a MySQL Replication deployment, you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. You can simply [add an instance](#) to the replica set and it is automatically provisioned.

Similarly, InnoDB ReplicaSet is tightly integrated with [MySQL Router](#), and you can use AdminAPI to [work with](#) them together. MySQL Router can automatically configure itself based on an InnoDB ReplicaSet, in a process called [bootstrapping](#), which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB ReplicaSet, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB ReplicaSet using AdminAPI. InnoDB ReplicaSet status information includes details about MySQL Routers bootstrapped against the ReplicaSet. Operations enable you to [create MySQL Router users](#) at the ReplicaSet level, to work with the MySQL Routers bootstrapped against the ReplicaSet, and so on.

---

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from [Connectors and APIs](#).

# Chapter 25 MySQL NDB Cluster 9.7

## Table of Contents

25.1	General Information .....	4245
25.2	NDB Cluster Overview .....	4247
25.2.1	NDB Cluster Core Concepts .....	4248
25.2.2	NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions .....	4251
25.2.3	NDB Cluster Hardware, Software, and Networking Requirements .....	4254
25.2.4	What is New in MySQL NDB Cluster 9.7 .....	4256
25.2.5	Options, Variables, and Parameters Added, Deprecated or Removed in NDB 9.7 .....	4256
25.2.6	MySQL Server Using InnoDB Compared with NDB Cluster .....	4257
25.2.7	Known Limitations of NDB Cluster .....	4259
25.3	NDB Cluster Installation .....	4271
25.3.1	Installation of NDB Cluster on Linux .....	4274
25.3.2	Installing NDB Cluster on Windows .....	4282
25.3.3	Initial Configuration of NDB Cluster .....	4291
25.3.4	Initial Startup of NDB Cluster .....	4293
25.3.5	NDB Cluster Example with Tables and Data .....	4293
25.3.6	Safe Shutdown and Restart of NDB Cluster .....	4297
25.3.7	Upgrading and Downgrading NDB Cluster .....	4298
25.4	Configuration of NDB Cluster .....	4299
25.4.1	Quick Test Setup of NDB Cluster .....	4299
25.4.2	Overview of NDB Cluster Configuration Parameters, Options, and Variables .....	4301
25.4.3	NDB Cluster Configuration Files .....	4324
25.4.4	Using High-Speed Interconnects with NDB Cluster .....	4534
25.5	NDB Cluster Programs .....	4534
25.5.1	ndbd — The NDB Cluster Data Node Daemon .....	4535
25.5.2	ndbinfo_select_all — Select From ndbinfo Tables .....	4545
25.5.3	ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded) .....	4549
25.5.4	ndb_mgmd — The NDB Cluster Management Server Daemon .....	4550
25.5.5	ndb_mgm — The NDB Cluster Management Client .....	4561
25.5.6	ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables ....	4566
25.5.7	ndb_config — Extract NDB Cluster Configuration Information .....	4572
25.5.8	ndb_delete_all — Delete All Rows from an NDB Table .....	4583
25.5.9	ndb_desc — Describe NDB Tables .....	4588
25.5.10	ndb_drop_index — Drop Index from an NDB Table .....	4596
25.5.11	ndb_drop_table — Drop an NDB Table .....	4601
25.5.12	ndb_error_reporter — NDB Error-Reporting Utility .....	4605
25.5.13	ndb_import — Import CSV Data Into NDB .....	4606
25.5.14	ndb_index_stat — NDB Index Statistics Utility .....	4620
25.5.15	ndb_move_data — NDB Data Copy Utility .....	4627
25.5.16	ndb_perror — Obtain NDB Error Message Information .....	4632
25.5.17	ndb_print_backup_file — Print NDB Backup File Contents .....	4634
25.5.18	ndb_print_file — Print NDB Disk Data File Contents .....	4638

This chapter provides information about MySQL *NDB Cluster*, a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment, as well as information specific to NDB Cluster 8.4 (NDB 8.4.7), based on version 8.4 of the NDB storage engine. See [Section 25.2.4, “What is New in MySQL NDB Cluster 9.7”](#), for information about differences in NDB 8.4 as compared to earlier releases. See [MySQL NDB Cluster 8.0](#) for information about NDB Cluster 8.0. Both NDB 8.0 and NDB 8.4 are intended for use in production environments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production, although new deployments can and should use either of MySQL NDB Cluster 8.0 or 8.4.

*NDB Cluster 7.4 and older release series are no longer supported or maintained.*

## 25.1 General Information

MySQL NDB Cluster uses the MySQL server with the [NDB](#) storage engine. Support for the [NDB](#) storage engine is not included in standard MySQL Server 9.7 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster 9.7 users who build from source should use the sources provided for MySQL 9.7 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

### Important

MySQL NDB Cluster does not support InnoDB Cluster, which must be deployed using MySQL Server [InnoDB](#) storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server 9.7 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB Cluster, see [MySQL AdminAPI, Section 25.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#), discusses differences between the [NDB](#) and [InnoDB](#) storage engines.

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <https://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from <https://dev.mysql.com/downloads/cluster/>.

**Version strings used in NDB Cluster software.** The version string displayed by the `mysql` client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. Building from source using `-DWITH_NDB` or the equivalent adds the `-cluster` suffix to the version string. (See [Section 25.3.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).) You can see this format used in the `mysql` client, as shown here:

```
$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 9.4.0-cluster Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 9.4.0-cluster
1 row in set (0.00 sec)
```

The version string displayed by other NDB Cluster programs not normally included with the MySQL 9.7 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For NDB Cluster 9.7, this is `9.7.n`, where `n` is the release number. `ndb_engine_version` is

the version of the [NDB](#) storage engine used by this release of the NDB Cluster software. For NDB 9.7, this number is the same as the MySQL Server version. You can see this format used in the output of the [SHOW](#) command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @10.0.10.6  (mysql-9.5.0 ndb-9.5.0, Nodegroup: 0, *)
id=2      @10.0.10.8  (mysql-9.5.0 ndb-9.5.0, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3      @10.0.10.2  (mysql-9.5.0 ndb-9.5.0)

[mysqld(API)]   2 node(s)
id=4      @10.0.10.10  (mysql-9.5.0 ndb-9.5.0)
id=5      (not connected, accepting connect from any host)
```

**Compatibility with standard MySQL 9.7 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 25.2.7, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, [MyISAM](#) or [InnoDB](#)—to use the [NDB](#) storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without [NDB](#) support (that is, built without `-DWITH_NDB` or `-DWITH_NDBCLUSTER_STORAGE_ENGINE`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see [Section 2.8.5, “Installing MySQL Using a Development Source Tree”](#).

#### Note

As with MySQL Server 9.7, NDB Cluster 9.7 releases are built using [CMake](#).

NDB Cluster 9.7 is available as an Innovation release, with new features under development and intended for preview and testing. NDB Cluster 8.4 is the current LTS release series, and is recommended for new deployments (see [MySQL NDB Cluster 8.4](#)). NDB Cluster 8.0, 7.6, and 7.5 are previous GA releases still supported in production, although we recommend NDB Cluster 8.4 for new deployments intended for use in production.

Additional information regarding NDB Cluster can be found on the MySQL website at <https://www.mysql.com/products/cluster/>.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL 9.7 FAQ: NDB Cluster”](#).
- The NDB Cluster Forum: <https://forums.mysql.com/list.php?25>.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through [PlanetMySQL](#).

## 25.2 NDB Cluster Overview

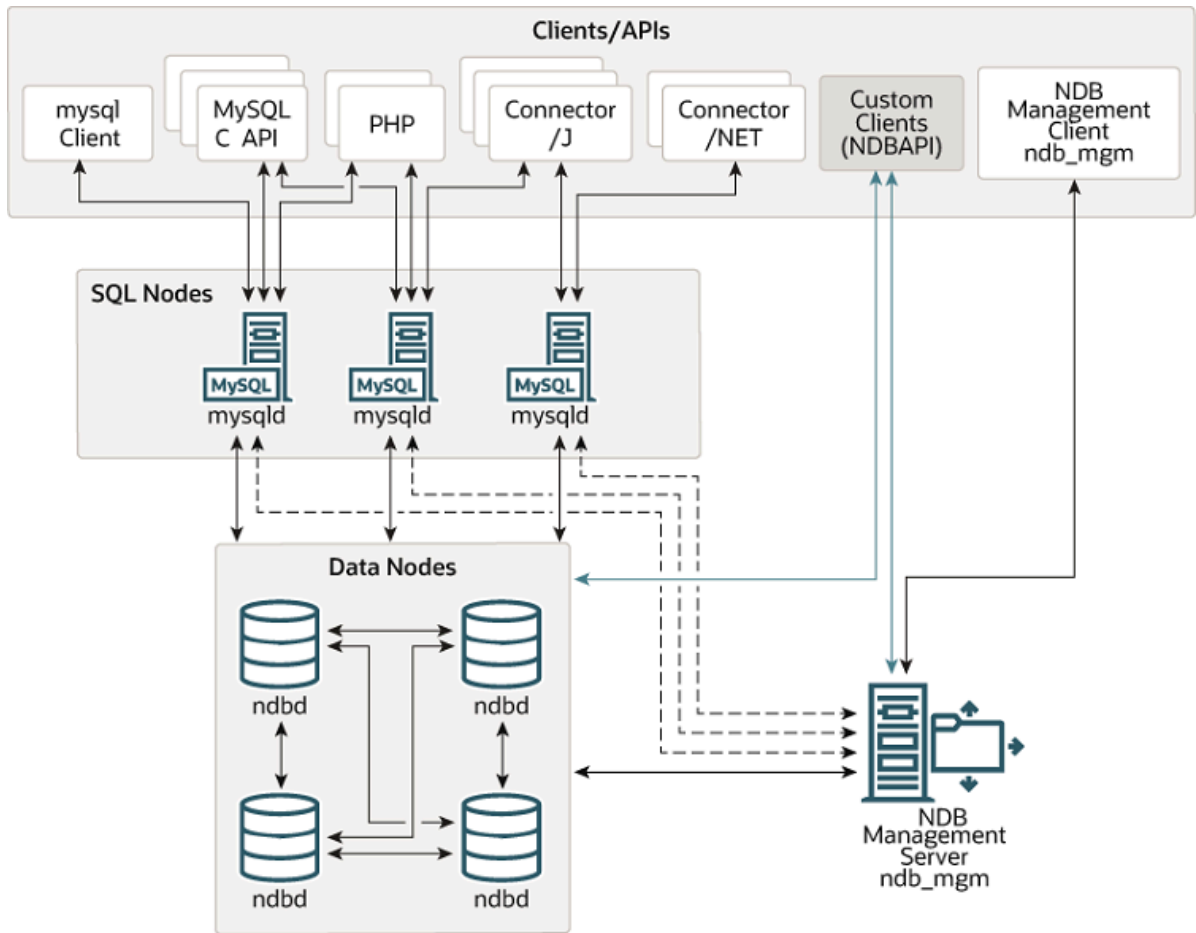

*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “Network DataBase”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 25.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see [Section 25.5, “NDB Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes.

Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

An NDB Cluster 9.7 SQL node uses the `mysqld` server daemon, which is the same as the `mysqld` supplied with MySQL Server 9.7 distributions. You should keep in mind that *an instance of `mysqld`, regardless of version, that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.*

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 25.6.7, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 25.6.8, “Online Backup of NDB Cluster”](#), and [Section 25.5.23, “ndb\\_restore — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 6.5.4, “mysqldump — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 25.2.1 NDB Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there are at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running

backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see [Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#)). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#)) or `ndbmtdd` (see [Section 25.5.3, “ndbmtdd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#), for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see [Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, and so on. Such client applications send SQL statements to and receive

responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

NDB-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see [Section 25.5.5, “ndb\\_mgm — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL Cluster Manager 9.7.0 User Manual](#), for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 25.6.3, “Event Reports Generated in NDB Cluster”](#). Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the

precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

NDB 9.7 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the [EnablePartialLcp](#) and [RecoveryWork](#) configuration parameters which enable partial LCPs and control the amount of storage they use.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory](#).

**Transporter.** We use the term *transporter* for the data transport mechanism employed between data nodes. MySQL NDB Cluster 9.7 supports three of these, which are listed here:

- *TCP/IP over Ethernet*. See [Section 25.4.3.10, “NDB Cluster TCP/IP Connections”](#).
- *Direct TCP/IP*. Uses machine-to-machine connections. See [Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

Although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster.

- *Shared memory (SHM)*. See [Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”](#).

Because it is ubiquitous, most users employ TCP/IP over Ethernet for NDB Cluster.

Regardless of the transporter used, NDB attempts to make sure that communication between data node processes is performed using chunks that are as large as possible since this benefits all types of data transmission.

## 25.2.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.** An `ndbd` or `ndbmt_d` process, which stores one or more *fragment replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmt_d` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of *fragment replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[# of node groups] = [# of data nodes] / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Fragment replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#).

### Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see [Section 25.6.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

**Partition.** This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

```
[# of partitions] = [# of data nodes] * [# of LDM threads]
```

When using data nodes running `ndbmttd`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmttd` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

**NDB and user-defined partitioning.** NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDB` table is  $8 * [\textit{number of LDM threads}] * [\textit{number of node groups}]$ , the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running `ndbd` for data node processes, setting the number of LDM threads has no effect (since `ThreadConfig` applies only to `ndbmttd`); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

See [Section 25.5.3, “ndbmttd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to NDB Cluster and user-defined partitioning, see [Section 25.2.7, “Known Limitations of NDB Cluster”](#), and [Section 26.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

**Fragment replica.** This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a *partition replica*. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

**Note**

Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

**Figure 25.2 NDB Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary fragment replica* (primary copy) is stored on node 1, and a *backup fragment replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 25.3 Nodes Required for a 2x2 NDB Cluster**

In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

### 25.2.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#), for more information about these.) You can obtain information about memory usage by data nodes by viewing the `ndbinfo.memoryusage` table, or the output of the `REPORT MemoryUsage` command in the `ndb_mgm` client. For information about memory used by NDB tables, you can query the `ndbinfo.memory_per_fragment` table.

Increasing the number of CPUs, using faster CPUs, or both, on the computers hosting data nodes can generally be expected to enhance the performance of NDB Cluster. Memory requirements for cluster processes other than the data nodes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at <https://dev.mysql.com/downloads/cluster/>.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole.

We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster; using a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster installation not only helps protect against unauthorized access to data stored in the cluster, but also ensures that cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

NDB supports encrypted live and backup files and file systems, as discussed in [Section 25.6.19.4, “File System Encryption for NDB Cluster”](#). [Section 25.6.19.5, “TLS Link Encryption for NDB Cluster”](#), provides information about enabling support for encrypted connections between nodes. Encrypted backups can be read by many NDB command-line programs including `ndb_restore`, `ndbxfrm`, `ndb_print_backup_file`, and `ndb_mgm`. See [Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for more information about creating encrypted backups.

NDB Cluster also supports encrypted network connections between nodes; see [Section 25.6.19.4, “File System Encryption for NDB Cluster”](#), for details.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100  $\mu$ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

## 25.2.4 What is New in MySQL NDB Cluster 9.7

The following sections describe changes in the implementation of MySQL NDB Cluster in NDB Cluster 9.7.0, as compared to earlier release series. NDB Cluster 9.7 is available as a Development release for preview and testing of new features currently under development. For production, please use NDB 8.4; for more information, see [MySQL NDB Cluster 8.4](#). NDB Cluster 8.0 and 7.6 are previous GA releases which are still supported in production, although we recommend that new deployments for production use MySQL NDB Cluster 8.4.

### What is New in NDB Cluster 9.7

Major changes and new features in NDB Cluster 9.7 which are likely to be of interest are listed here:

- **Ndb.cfg support removed.** Use of an `Ndb.cfg` configuration file in an NDB executable's startup directory was deprecated in MySQL 9.1, and is no longer supported as of NDB 9.5.0; such files are no longer read by any NDB Cluster executable.

See [Section 25.4.3.3, "NDB Cluster Connection Strings"](#), for more information.

MySQL Cluster Manager has an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See [MySQL Cluster Manager 9.7.0 User Manual](#), for more information.

## 25.2.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 9.7

- [Parameters Introduced in NDB 9.7](#)
- [Parameters Deprecated in NDB 9.7](#)
- [Parameters Removed in NDB 9.7](#)
- [Options and Variables Introduced in NDB 9.7](#)
- [Options and Variables Deprecated in NDB 9.7](#)
- [Options and Variables Removed in NDB 9.7](#)

The next few sections contain information about NDB node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 9.7.

### Parameters Introduced in NDB 9.7

No new node configuration parameters have been added in NDB 9.7.

### Parameters Deprecated in NDB 9.7

No node configuration parameters have been deprecated in NDB 9.7.

### Parameters Removed in NDB 9.7

No node configuration parameters have been removed in NDB 9.7.

### Options and Variables Introduced in NDB 9.7

No new system variables, status variables, or server options have been added in NDB 9.7.

### Options and Variables Deprecated in NDB 9.7

No system variables, status variables, or server options have been deprecated in NDB 9.7.

## Options and Variables Removed in NDB 9.7

No system variables, status variables, or options have been removed in NDB 9.7.

## 25.2.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both [NDB](#) and [InnoDB](#) can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see [NDB](#) as a possible alternative or upgrade to the default [InnoDB](#) storage engine in MySQL. While [NDB](#) and [InnoDB](#) share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the [NDB](#) storage engine used by NDB 9.7 with [InnoDB](#) used in MySQL 9.7. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for [NDB](#) as opposed to [InnoDB](#) back ends.

NDB Cluster 9.7 uses a `mysqld` based on MySQL 9.7, including support for [InnoDB](#) 1.1. While it is possible to use [InnoDB](#) tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 9.7 distribution with MySQL Server 9.7, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the [InnoDB](#) storage engine), there are some important architectural and implementation differences. [Section 25.2.6.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 25.2.6.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with [NDB](#) or [InnoDB](#). See [Section 25.2.6.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the [NDB](#) and [MEMORY](#) storage engines, see [When to Use MEMORY or NDB Cluster](#).

See [Chapter 18, Alternative Storage Engines](#), for additional information about MySQL storage engines.

### 25.2.6.1 Differences Between the NDB and InnoDB Storage Engines

The [NDB](#) storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from [InnoDB](#) in a number of ways. For those unaccustomed to working with [NDB](#), unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

**Table 25.1 Differences between InnoDB and NDB storage engines**

Feature	<a href="#">InnoDB (MySQL 9.7)</a>	<a href="#">NDB 9.7</a>
MySQL Server Version	9.7	9.7
<a href="#">InnoDB</a> Version	<a href="#">InnoDB 9.7.0</a>	<a href="#">InnoDB 9.7.0</a>
NDB Cluster Version	N/A	<a href="#">NDB 9.5.0/9.5.0</a>
Storage Limits	64TB	128TB
Foreign Keys	Yes	Yes
Transactions	All standard types	<a href="#">READ COMMITTED</a>

Feature	InnoDB (MySQL 9.7)	NDB 9.7
MVCC	Yes	No
Data Compression	Yes	No (NDB checkpoint and backup files can be compressed)
Large Row Support (> 14K)	Supported for <a href="#">VARBINARY</a> , <a href="#">VARCHAR</a> , <a href="#">BLOB</a> , and <a href="#">TEXT</a> columns	Supported for <a href="#">BLOB</a> and <a href="#">TEXT</a> columns only (Using these types to store very large amounts of data can lower NDB performance)
Replication Support	Asynchronous and semisynchronous replication using MySQL Replication; <a href="#">MySQL Group Replication</a>	Automatic synchronous replication within an NDB Cluster; asynchronous replication between NDB Clusters, using MySQL Replication (Semisynchronous replication is not supported)
Scaleout for Read Operations	Yes (MySQL Replication)	Yes (Automatic partitioning in NDB Cluster; NDB Cluster Replication)
Scaleout for Write Operations	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in NDB Cluster is transparent to applications)
High Availability (HA)	Built-in, from InnoDB cluster	Yes (Designed for 99.999% uptime)
Node Failure Recovery and Failover	From MySQL Group Replication	Automatic (Key element in NDB architecture)
Time for Node Failure Recovery	30 seconds or longer	Typically < 1 second
Real-Time Performance	No	Yes
In-Memory Tables	No	Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
NoSQL Access to Storage Engine	Yes	Yes (Multiple APIs, including Memcached, Java, JPA, C++, and HTTP/REST)
Concurrent and Parallel Writes	Yes	Up to 48 writers, optimized for concurrent writes
Conflict Detection and Resolution (Multiple Sources)	Yes (MySQL Group Replication)	Yes
Hash Indexes	No	Yes
Online Addition of Nodes	Read/write replicas using MySQL Group Replication	Yes (all node types)
Online Upgrades	Yes (using replication)	Yes
Online Schema Modifications	Yes, as part of MySQL 9.7	Yes

### 25.2.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing

well. A number of major differences in behavior between the [NDB](#) and [InnoDB](#) storage engines with regard to some common types of database-driven application workloads are shown in the following table::

**Table 25.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.**

Workload	InnoDB	NDB Cluster (NDB)
High-Volume OLTP Applications	Yes	Yes
DSS Applications (data marts, analytics)	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
Custom Applications	Yes	Yes
Packaged Applications	Yes	Limited (should be mostly primary key access); NDB Cluster 9.7 supports foreign keys
In-Network Telecoms Applications (HLR, HSS, SDP)	No	Yes
Session Management and Caching	Yes	Yes
E-Commerce Applications	Yes	Yes
User Profile Management, AAA Protocol	Yes	Yes

### 25.2.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of [InnoDB](#) with [NDB](#), some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

**Table 25.3 Supported application features according to the storage engine to which each feature is typically better suited**

Preferred application requirements for <a href="#">InnoDB</a>	Preferred application requirements for <a href="#">NDB</a>
<ul style="list-style-type: none"> <li>Foreign keys</li> </ul> <div style="display: flex; align-items: center; margin-top: 10px;">  <div> <p><b>Note</b></p> <p>NDB Cluster 9.7 supports foreign keys</p> </div> </div> <ul style="list-style-type: none"> <li>Full table scans</li> <li>Very large databases, rows, or transactions</li> <li>Transactions other than <a href="#">READ COMMITTED</a></li> </ul>	<ul style="list-style-type: none"> <li>Write scaling</li> <li>99.999% uptime</li> <li>Online addition of nodes and online schema operations</li> <li>Multiple SQL and NoSQL APIs (see <a href="#">NDB Cluster APIs: Overview and Concepts</a>)</li> <li>Real-time performance</li> <li>Limited use of <a href="#">BLOB</a> columns</li> <li>Foreign keys are supported, although their use may have an impact on performance at high throughput</li> </ul>

### 25.2.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the [MyISAM](#) and [InnoDB](#) storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). Any problem which we do not plan to fix in NDB Cluster 9.7, is added to the list.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in [Section 25.7.3, “Known Issues in NDB Cluster Replication”](#).

### 25.2.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with [NDB](#) tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the [NDB](#) storage engine or to alter an existing temporary table to use [NDB](#) fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an [NDB](#) table column whose width is greater than 3072 bytes is rejected with `ER_TOO_LONG_KEY: Specified key was too long; max key length is 3072 bytes`.

Attempting to create an index on an [NDB](#) table column whose width is greater than 3056 bytes succeeds with a warning. In such cases, statistical information is not generated, which means a nonoptimal execution plan may be selected. For this reason, you should consider making the index length shorter than 3056 bytes if possible.

- **TEXT and BLOB columns.** You cannot create indexes on [NDB](#) table columns that use any of the [TEXT](#) or [BLOB](#) data types.
- **FULLTEXT indexes.** The [NDB](#) storage engine does not support [FULLTEXT](#) indexes, which are possible for [MyISAM](#) and [InnoDB](#) tables only.

However, you can create indexes on [VARCHAR](#) columns of [NDB](#) tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an [NDB](#) column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 25.2.7.6, “Unsupported or Missing Features in NDB Cluster”](#), for additional information.)
- **BIT columns.** A [BIT](#) column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the [NDB](#) storage engine can handle a maximum of one [AUTO\\_INCREMENT](#) column per table, and this column must be indexed. However, in the case of an NDB table with no explicit primary key, an [AUTO\\_INCREMENT](#) column is automatically defined and used as a “hidden” primary key. For this reason, you cannot create an [NDB](#) table having an [AUTO\\_INCREMENT](#) column and no explicit primary key.

The following [CREATE TABLE](#) statements do not work, as shown here:

```
# No index on AUTO_INCREMENT column; table has no primary key
# Raises ER_WRONG_AUTO_KEY
mysql> CREATE TABLE n (
->   a INT,
->   b INT AUTO_INCREMENT
-> )
-> ENGINE=NDB;
ERROR 1075 (42000): Incorrect table definition; there can be only one auto
column and it must be defined as a key

# Index on AUTO_INCREMENT column; table has no primary key
# Raises NDB error 4335
mysql> CREATE TABLE n (
->   a INT,
->   b INT AUTO_INCREMENT,
->   KEY k (b)
-> )
-> ENGINE=NDB;
ERROR 1296 (HY000): Got error 4335 'Only one autoincrement column allowed per
table. Having a table without primary key uses an autoincr' from NDBCLUSTER
```

The following statement creates a table with a primary key, an [AUTO\\_INCREMENT](#) column, and an index on this column, and succeeds:

```
# Index on AUTO_INCREMENT column; table has a primary key
mysql> CREATE TABLE n (
->   a INT PRIMARY KEY,
->   b INT AUTO_INCREMENT,
->   KEY k (b)
-> )
-> ENGINE=NDB;
Query OK, 0 rows affected (0.38 sec)
```

- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 9.7 is comparable to that provided by [InnoDB](#), subject to the following restrictions:
  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
  - [ON UPDATE CASCADE](#) is not supported when the reference is to the parent table's primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the

NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

- `ON DELETE CASCADE` is also not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)
- `SET DEFAULT` is not supported. (Also not supported by `InnoDB`.)
- The `NO ACTION` keyword is accepted but treated as `RESTRICT`. `NO ACTION`, which is a standard SQL keyword, is the default in MySQL 9.7. (Also the same as with `InnoDB`.)
- In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see [Section 15.1.24.5, “FOREIGN KEY Constraints”](#), and [Section 1.7.3.2, “FOREIGN KEY Constraints”](#).

- **NDB Cluster and geometry data types.**

Geometry data types (`WKT` and `WKB`) are supported for `NDB` tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to `[LINEAR] KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see [User-defined partitioning and the NDB storage engine \(NDB Cluster\)](#).

**Default partitioning scheme.** All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the `NDB` storage engine is used instead. For additional discussion of these and related issues, see [Section 26.2.5, “KEY Partitioning”](#).

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

**Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can be defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group.

(See [Section 25.2.2](#), “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information about NDB Cluster node groups.

**DROP PARTITION not supported.** It is not possible to drop partitions from NDB tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for NDB tables, but use copying and so are not optimized. See [Section 26.3.1](#), “Management of RANGE and LIST Partitions” and [Section 15.1.11](#), “ALTER TABLE Statement”.

**Partition selection.** Partition selection is not supported for NDB tables. See [Section 26.5](#), “Partition Selection”, for more information.

- **JSON data type.** The MySQL `JSON` data type is supported for NDB tables in the `mysqlld` supplied with NDB 9.7.

An NDB table can have a maximum of 3 `JSON` columns.

The NDB API has no special provision for working with `JSON` data, which it views simply as `BLOB` data. Handling data as `JSON` must be performed by the application.

### 25.2.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 25.6.5](#), “Performing a Rolling Restart of an NDB Cluster”.

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

#### Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 15.1.42](#), “TRUNCATE TABLE Statement”.

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 25.4.3](#), “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:
  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 25.4.3.6](#), “Defining NDB Cluster Data Nodes”, for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters [MaxNoOfConcurrentOperations](#) and [MaxNoOfLocalOperations](#).

**Note**

Bulk loading, [TRUNCATE TABLE](#), and [ALTER TABLE](#) are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by [MaxNoOfOrderedIndexes](#), and the maximum number of ordered indexes per table is 16.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
  - The maximum number of data nodes is 144. (In NDB 7.6 and earlier, this was 48.)  
A data node must have a node ID in the range of 1 to 144, inclusive.  
Management and API nodes may use node IDs in the range 1 to 255, inclusive.
  - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
  - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

### 25.2.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The [NDBCLUSTER](#) storage engine supports only the [READ COMMITTED](#) transaction isolation level. ([InnoDB](#), for example, supports [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#).) You should keep in mind that [NDB](#) implements [READ COMMITTED](#) on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using [SELECT ... LOCK IN SHARE MODE](#). In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by [MaxNoOfConcurrentOperations](#)

NDB uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

See [Section 25.6.8.4, “NDB Cluster Backup Troubleshooting”](#), for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:
  1. For any `SELECT` from an NDB Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
  2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b INT NOT NULL,
  c INT NOT NULL,
  d TEXT,
  INDEX i(b),
  UNIQUE KEY u(c)
) ENGINE = NDB,
```

The following query on `t` causes a shared read lock, because it uses a unique key lookup:

```
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Unique key lookups and transaction isolation.** Unique indexes are implemented in [NDB](#) using a hidden index table which is maintained internally. When a user-created [NDB](#) table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created [NDB](#) table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) [NDB](#) table must wait for the update to complete. This is true even when the transaction level of the read operation is [READ COMMITTED](#).

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the [IGNORE INDEX](#) index hint as part of the [SELECT](#) statement reading the table (see [Section 10.9.4, “Index Hints”](#)). Because the MySQL server creates a shadowing ordered index for every unique index created in [NDB](#), this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as [InnoDB](#) that may roll back individual statements.

- **Transactions and memory usage.**

As noted elsewhere in this chapter, [NDB Cluster](#) does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

- [TRUNCATE TABLE](#) is not transactional when used on [NDB](#) tables. If a [TRUNCATE TABLE](#) fails to empty the table, then it must be re-run until it is successful.
- [DELETE FROM](#) (even with no [WHERE](#) clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several [DELETE FROM ... LIMIT ...](#) statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use [TRUNCATE TABLE](#) instead.
- **LOAD DATA statements.** [LOAD DATA](#) is not transactional when used on [NDB](#) tables.

#### Important

When executing a [LOAD DATA](#) statement, the [NDB](#) engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an [NDB](#) table as part of an [ALTER TABLE](#), the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the replica. In other words, when performing on the source a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the replica may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

#### 25.2.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 25.2.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#).

#### 25.2.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Number of database objects.** The maximum number of *all* NDB database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 30000 bytes.

Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total; this includes `JSON` columns. See [String Type Storage Requirements](#), as well as [JSON Storage Requirements](#), for more information relating to these types.

In addition, the maximum offset for a fixed-width column of an NDB table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 `Maximum offset for fixed-size columns exceeded`. For memory-based columns, you can work around this limitation by using a variable-width column type such as `VARCHAR` or defining the column as `COLUMN_FORMAT=DYNAMIC`; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the `CREATE TABLE` statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as `CHAR` or `VARCHAR`; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all `BIT` columns used in a given NDB table is 4096.

- **FIXED column storage.** NDB Cluster supports a maximum of 128 TB per fragment of data in [FIXED](#) columns.

### 25.2.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for [NDB](#) tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by [NDB](#), must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for [NDB](#) tables. If a prefix is used as part of an index specification in a statement such as [CREATE TABLE](#), [ALTER TABLE](#), or [CREATE INDEX](#), the prefix is not created by [NDB](#).

A statement containing an index prefix, and creating or modifying an [NDB](#) table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part is not a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in [MyISAM](#).
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 25.7, “NDB Cluster Replication”](#), for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 9.7. GTIDs must be turned OFF when using the [NDB](#) storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

To turn GTIDs off, set the `gtid_mode` and `enforce_gtid_consistency` variables to `OFF`.

Semisynchronous replication is not supported in NDB Cluster.

- **Generated columns.** The [NDB](#) storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that [NDB](#) uses [DataMemory](#) for storage of the generated column as well as [IndexMemory](#) for the index. See [JSON columns and indirect indexing in NDB Cluster](#), for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does not log those made to virtual columns. This should not effect NDB Cluster Replication or replication between [NDB](#) and other MySQL storage engines.

**Note**

See [Section 25.2.7.3, “Limits Relating to Transaction Handling in NDB Cluster”](#), for more information relating to limitations on transaction handling in [NDB](#).

**25.2.7.7 Limitations Relating to Performance in NDB Cluster**

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 10.9.4, “Index Hints”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

**25.2.7.8 Issues Exclusive to NDB Cluster**

The following are limitations specific to the [NDB](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.** NDB Cluster has the following limitations or restrictions with regard to binary logging:
  - NDB Cluster cannot produce a binary log for tables having [BLOB](#) columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is *not* on the [mysqld](#) executing the statement:
    - [CREATE TABLE](#)
    - [ALTER TABLE](#)
    - [DROP TABLE](#)
    - [CREATE DATABASE / CREATE SCHEMA](#)
    - [DROP DATABASE / DROP SCHEMA](#)
    - [CREATE TABLESPACE](#)
    - [ALTER TABLESPACE](#)
    - [DROP TABLESPACE](#)
    - [CREATE LOGFILE GROUP](#)
    - [ALTER LOGFILE GROUP](#)

- [DROP LOGFILE GROUP](#)

- **Schema operations.** Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.
- **Number of fragment replicas.** The number of fragment replicas, as determined by the [NoOfReplicas](#) data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

Setting [NoOfReplicas](#) to a value greater than 2 is supported (to a maximum of 4) but unnecessary to guard against loss of data.

See also [Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 25.2.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 15.1.25, “CREATE TABLESPACE Statement”](#), for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use [DataMemory](#). Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient [DiskPageBufferMemory](#); you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 25.2.7.10 Limitations Relating to Multiple NDB Cluster Nodes

#### Multiple SQL nodes.

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the [NDBCLUSTER](#) storage engine:

- **Stored programs not distributed.** Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the [NDB](#) storage engine, but these do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See [Stored routines and triggers in NDB Cluster](#).
- **No distributed table locks.** A [LOCK TABLES](#) statement or [GET\\_LOCK\(\)](#) call works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

Implementing table locks in `NDBCLUSTER` can be done in an API application, and ensuring that all applications start by setting `LockMode` to `LM_Read` or `LM_Exclusive`. For more information about how to do this, see the description of `NdbOperation::getLockHandle()` in the *NDB Cluster API Guide*.

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

#### Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 25.4.3.10, “NDB Cluster TCP/IP Connections”](#), for more information.

## 25.3 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in [Section 25.4, “Configuration of NDB Cluster”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see [Section 25.3.7, “Upgrading and Downgrading NDB Cluster”](#).

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

**Table 25.4 Network addresses of nodes in example cluster**

Node	IP Address
Management node ( <code>mgmd</code> )	198.51.100.10
SQL node ( <code>mysqld</code> )	198.51.100.20
Data node "A" ( <code>ndbd</code> )	198.51.100.30
Data node "B" ( <code>ndbd</code> )	198.51.100.40

This setup is also shown in the following diagram:

**Figure 25.4 NDB Cluster Multi-Computer Setup**

**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

NDB 9.7 supports IPv6 for connections between all NDB Cluster nodes.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
```

```
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

### Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

### Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL website (see <https://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, Installing MySQL](#). For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see [Section 25.3.1, "Installation of NDB Cluster on Linux"](#). For information about installation of NDB Cluster on Windows operating systems, see [Section 25.3.2, "Installing NDB Cluster on Windows"](#).

For general information about NDB Cluster hardware, software, and networking requirements, see [Section 25.2.3, “NDB Cluster Hardware, Software, and Networking Requirements”](#).

## 25.3.1 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see [Section 25.3.2, “Installing NDB Cluster on Windows”](#).

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmt`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 25.3.3, “Initial Configuration of NDB Cluster”](#).

### 25.3.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the [NDB Cluster downloads page](#). (For the most recent 64-bit NDB 9.7 release, this is `mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see [Section 2.8.5, “Installing MySQL Using a Development Source Tree”](#).

#### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 25.3.3, “Initial Configuration of NDB Cluster”](#)).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
$> groupadd mysql
$> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

**Note**

The actual file and directory names vary according to the NDB Cluster version number.

```
$> cd /var/tmp
$> tar -C /usr/local -xzvf mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64.tar.gz
$> ln -s /usr/local/mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
$> cd mysql
$> mysqld --initialize
```

This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review [Section 2.9.1, “Initializing the Data Directory”](#), for additional information before performing this step. See also [Section 6.4.2, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

4. Set the necessary permissions for the MySQL server and data directories:

```
$> chown -R root .
$> chown -R mysql data
$> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
$> cp support-files/mysql.server /etc/rc.d/init.d/
$> chmod +x /etc/rc.d/init.d/mysql.server
$> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmt` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmt` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
$> cd /var/tmp
$> tar -xzf mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64.tar.gz
$> cd mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64
$> cp bin/ndbd /usr/local/bin/ndbd
```

```
$> cp bin/ndbmysd /usr/local/bin/ndbmysd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
$> cd /usr/local/bin
$> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmysd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this saves time and trouble in the event that you later decide to change from one to the other.

#### Note

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 25.3.3, “Initial Configuration of NDB Cluster”](#).)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
$> cd /var/tmp
$> tar -zxvf mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64.tar.gz
$> cd mysql-cluster-gpl-9.4.0-linux-glibc2.12-x86_64
$> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
$> cd /usr/local/bin
$> chmod +x ndb_mgm*
```

In [Section 25.3.3, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

### 25.3.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle.

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the Yum Repository](#), for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the SLES Repository](#), for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-9.4.0-1.el7.x86_64.rpm
mysql-cluster-license-component-ver-rev.distro.arch.rpm

license:= {commercial | community}

component: {management-server | data-node | server | client | other-see text}

ver: major.minor.release

rev: major[.minor]

distro: {el6 | el7 | sles12}

arch: {i686 | x86_64}
```

*license* indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for *component*, with descriptions, can be found in the following table:

**Table 25.5 Components of the NDB Cluster RPM distribution**

Component	Description
<code>auto-installer</code> (DEPRECATED)	NDB Cluster Auto Installer program; see <a href="#">The NDB Cluster Auto-Installer (NO LONGER SUPPORTED)</a> , for usage
<code>client</code>	MySQL and NDB client programs; includes <code>mysql</code> client, <code>ndb_mgm</code> client, and other client tools
<code>common</code>	Character set and error message information needed by the MySQL server
<code>data-node</code>	<code>ndbd</code> and <code>ndbmt</code> data node binaries
<code>devel</code>	Headers and library files needed for MySQL client development
<code>embedded</code>	Embedded MySQL server
<code>embedded-compat</code>	Backwards-compatible embedded MySQL server
<code>embedded-devel</code>	Header and library files for developing applications for embedded MySQL
<code>java</code>	JAR files needed for support of ClusterJ applications
<code>libs</code>	MySQL client libraries
<code>libs-compat</code>	Backwards-compatible MySQL client libraries
<code>management-server</code>	The NDB Cluster management server ( <code>ndb_mgmd</code> )

Component	Description
<code>memcached</code>	Files needed to support <code>ndbmemcache</code>
<code>minimal-debuginfo</code>	Debug information for package <code>server-minimal</code> ; useful when developing applications that use this package or when debugging this package
<code>ndbclient</code>	NDB client library for running NDB API and MGM API applications ( <code>libndbclient</code> )
<code>ndbclient-devel</code>	Header and other files needed for developing NDB API and MGM API applications
<code>server</code>	The MySQL server ( <code>mysqld</code> ) with NDB storage engine support included, and associated MySQL server programs
<code>server-minimal</code>	Minimal installation of the MySQL server for NDB and related tools
<code>test</code>	<code>mysqltest</code> , other MySQL test programs, and support files

#### Note

The `nodejs` package, which formerly contained files used for setup of `Node.js`, has been removed.

A single bundle (`.tar` file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node*: `management-server`
- *Data node*: `data-node`
- *SQL node*: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in `9.x.x` format, shown as `9.4.0` in the examples. `rev` provides the RPM revision number in `major.minor` format. In the examples shown in this section, we use `1.1` for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `e16` (Oracle Linux 6, Red Hat Enterprise Linux 6), `e17` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`e17`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as 9.4.0) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
$> rpm -Uhv mysql-cluster-community-data-node-9.4.0-1.el17.x86_64.rpm
```

This installs the `ndbd` and `ndbmtbd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
$> rpm -Uhv mysql-cluster-community-server-9.4.0-1.el17.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

### Important

You must use the versions of these RPMs released for NDB Cluster; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
$> rpm -Uhv mysql-cluster-community-client-9.4.0-1.el17.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL website):

```
$> rpm -Uhv mysql-cluster-community-management-server-9.4.0-1.el17.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

See [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see [Section 25.3.3, “Initial Configuration of NDB Cluster”](#), for the relevant information.

*It is very important that all of the Cluster RPMs to be installed have the same version number. The [architecture](#) designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.*

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the [server](#) RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
$> rpm -Uvh MySQL-Cluster-server-gpl-9.4.0-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtdd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the [server](#) RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
$> rpm -Uvh MySQL-Cluster-server-gpl-9.4.0-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with NDB storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the [client](#) RPM, as shown here:

```
$> rpm -Uvh MySQL-Cluster-client-gpl-9.4.0-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the [server](#) RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the [server](#) RPM downloaded from the MySQL website):

```
$> rpm -Uvh MySQL-Cluster-server-gpl-9.4.0-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The [server](#) RPM also installs `ndb_mgm`, the NDB management client.

See [Section 2.5.4, "Installing MySQL on Linux Using RPM Packages from Oracle"](#), for general information about installing MySQL using RPMs supplied by Oracle. See [Section 25.3.3, "Initial Configuration of NDB Cluster"](#), for information about required post-installation configuration.

### 25.3.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See [Installing MySQL NDB Cluster Using the APT Repository](#), for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, *ndbver* is the 3-part NDB engine version number, *debianver* is the major version of Debian (8 or 9), and *arch* is one of *i686* or *x86\_64*. In the examples that follow, we assume you wish to install NDB 9.4.0 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-9.4.0-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```
$> dpkg -i mysql-cluster-gpl-9.4.0-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
$> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where *version* is the 2-part release series version for the included MySQL server. For NDB 9.7, this is always `9.7`. The directory layout is the same as that for the generic Linux binary distribution (see [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

### 25.3.1.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.8, “Installing MySQL from Source”](#). For information about compiling NDB Cluster on Windows platforms, see [Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

MySQL NDB Cluster 9.7 is built from the MySQL Server 9.7 sources, available from the MySQL downloads page at <https://dev.mysql.com/downloads/>. The archived source file should have a name similar to `mysql-9.4.0.tar.gz`. You can also obtain the sources from GitHub at <https://github.com/mysql/mysql-server>.

The `WITH_NDB` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option is required when building NDB Cluster.

#### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [CMake Options for Compiling NDB Cluster](#).

After you have run `make` && `make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.8, "Installing MySQL from Source"](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.8, "Installing MySQL from Source"](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 25.3.3, "Initial Configuration of NDB Cluster"](#), we create configuration files for all of the nodes in our example NDB Cluster.

## 25.3.2 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 9.7 binaries for Windows can be obtained from <https://dev.mysql.com/downloads/cluster/>. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see [Section 25.3.2.1, "Installing NDB Cluster on Windows from a Binary Release"](#).

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 25.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows"](#).

### 25.3.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary "no-install" NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 25.3, "NDB Cluster Installation"](#)), as shown in the following table:

**Table 25.6 Network addresses of nodes in example cluster**

Node	IP Address
Management node ( <code>mgmd</code> )	198.51.100.10
SQL node ( <code>mysqld</code> )	198.51.100.20
Data node "A" ( <code>ndbd</code> )	198.51.100.30
Data node "B" ( <code>ndbd</code> )	198.51.100.40

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmttd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmttd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

**Note**

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from <https://dev.mysql.com/downloads/cluster/>. This archive has a filename of the `mysql-cluster-gpl-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as `9.4.0`), and `arch` is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the NDB Cluster 9.4.0 archive for 64-bit Windows systems is named `mysql-cluster-gpl-9.4.0-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address `198.51.100.20`, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 9.7`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 9.7\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.3, "Configuration: Manually"](#).

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the

command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=198.51.100.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.3.2, “Creating an Option File”](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtbd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtbd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:
  - The IP address or hostname of any SQL nodes
  - The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
  - The number of fragment replicas, using the `NoOfReplicas` configuration parameter (see [Section 25.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions"](#))
  - The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2          # Number of fragment replicas
DataDir=C:/mysql/cluster-data  # Directory for each data node's data files
                          # Forward slashes used in directory path,
                          # rather than backslashes. This is correct;
                          # see Important note in text

DataMemory=80M         # Memory allocated to data storage
IndexMemory=18M        # Memory allocated to index storage
                          # For DataMemory and IndexMemory, we have used the
                          # default values. Since the "world" database takes up
                          # only about 500KB, this should be more than enough for
                          # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10  # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                          # (one [ndbd] section per data node)
HostName=198.51.100.30  # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=198.51.100.40  # Hostname or IP address

[mysqld]
# SQL node options:
HostName=198.51.100.20  # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

### 25.3.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- MySQL NDB Cluster 9.7 is built from the MySQL Server 9.7 sources, available from the MySQL downloads page at <https://dev.mysql.com/downloads/>. The archived source file should have a name similar to `mysql-9.4.0.tar.gz`. You can also obtain the sources from GitHub at <https://github.com/mysql/mysql-server>.
- You must configure the build using the `WITH_NDB` option in addition to any other build options you wish to use with `CMake`. `WITH_NDBCLUSTER` is also supported for backwards compatibility, but is deprecated and subject to future removal.

#### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [CMake Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.8.4, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 25.3.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

### 25.3.2.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-9.5.0-ndb-9.5.0
```

```
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”](#), where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

### Important

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186 (using cleartext)
Node 2: starting (Last completed phase 3) (mysql-9.5.0-ndb-9.5.0)
Node 3: starting (Last completed phase 3) (mysql-9.5.0-ndb-9.5.0)
```

```
Node 2: starting (Last completed phase 4) (mysql-9.5.0-ndb-9.5.0)
Node 3: starting (Last completed phase 4) (mysql-9.5.0-ndb-9.5.0)

Node 2: Started (version 9.5.0)
Node 3: Started (version 9.5.0)

ndb_mgm>
```

**Note**

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 25.6.1, “Commands in the NDB Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2   @198.51.100.30 (Version: 9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=3   @198.51.100.40 (Version: 9.5.0-ndb-9.5.0, Nodegroup: 0)

[ndb_mgmd(MGM)]  1 node(s)
id=1   @198.51.100.10 (Version: 9.5.0-ndb-9.5.0)

[mysqld(API)]   1 node(s)
id=4   @198.51.100.20 (Version: 9.5.0-ndb-9.5.0)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See [Section 25.3.5, “NDB Cluster Example with Tables and Data”](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtl.exe` as Windows services. For information on how to do this, see [Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”](#).

### 25.3.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
as 'C:\mysql\bin\ndbd.exe' "--service=ndb_mgmd"
Service successfully installed.
```

#### Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

#### Note

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

## Installing NDB Cluster on Windows

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmdl
Installing service 'NDB Cluster Management Server'
  as 'C:\mysql\bin\ndb_mgmd.exe' "--service=mgmdl"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmdl
C:\> SC STOP mgmdl
```

To remove the management node service, use `SC DELETE service_name`:

```
C:\> SC DELETE mgmdl
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmdl
Removing service 'mgmdl'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmttd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as 'C:\mysql\bin\ndbd.exe' "--service=ndbd"
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd
C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnodel
Installing service 'dnodel' as 'C:\mysql\bin\ndbd.exe' "--service=dnodel"
Service successfully installed.

C:\> SC START dnodel
C:\> SC STOP dnodel
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```
C:\> SC DELETE dnode1
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). `NET` commands can also be used to start or stop a service. For additional information, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

### 25.3.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

For our four-node, four-host NDB Cluster (see [Cluster nodes and host computers](#)), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connection strings, see [Section 25.4.3.3, “NDB Cluster Connection Strings”](#).

- The management node needs a `config.ini` file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
$> vi /etc/my.cnf
```

#### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important**

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
$> mkdir /var/lib/mysql-cluster
$> cd /var/lib/mysql-cluster
$> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2      # Number of fragment replicas
DataMemory=98M     # How much memory to allocate for data storage

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10 # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster # Directory for management node log files

[ndbd]
# Options for data node "A":
# (one [ndbd] section per data node)
HostName=198.51.100.30 # Hostname or IP address
NodeId=2               # Node ID for this data node
DataDir=/usr/local/mysql/data # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40 # Hostname or IP address
NodeId=3               # Node ID for this data node
DataDir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20 # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

**Note**

The `world` database can be downloaded from <https://dev.mysql.com/doc/index-other.html>.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 25.3.4, “Initial Startup of NDB Cluster”](#).

For more detailed information about the available NDB Cluster configuration parameters and their uses, see [Section 25.4.3, “NDB Cluster Configuration Files”](#), and [Section 25.4, “Configuration of NDB Cluster”](#). For configuration of NDB Cluster as relates to making backups, see [Section 25.6.8.3, “Configuration for NDB Cluster Backups”](#).

The default port for Cluster management nodes is 1186. For data nodes, the cluster can automatically allocate ports from those that are already free.

## 25.3.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
$> ndb_mgmd --initial -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. This option requires that `--initial` or `--reload` also be specified; see [Section 25.5.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), for details.

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
$> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
$> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2   @198.51.100.30 (Version: 9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=3   @198.51.100.40 (Version: 9.5.0-ndb-9.5.0, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1   @198.51.100.10 (Version: 9.5.0-ndb-9.5.0)

[mysqld(API)]   1 node(s)
id=4   @198.51.100.20 (Version: 9.5.0-ndb-9.5.0)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

### Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See [Section 25.3.5, “NDB Cluster Example with Tables and Data”](#), for a brief discussion.

## 25.3.5 NDB Cluster Example with Tables and Data

**Note**

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
$> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file contains this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
```

```

PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)

```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
$> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
$> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```

$> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 9.5.0-ndb-9.5.0

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.9.4, “Securing the Initial MySQL Account”](#).

It is worth taking into account that NDB Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 25.6.19.2, “NDB Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```

mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;

```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

$>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
           FROM City
           ORDER BY Population DESC
           LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  </tbody>
<?
  # then display the results...
  while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
          $row->Name, $row->Population);
?>
</tbody>
```

```

</table>
<?
# ...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
# otherwise, tell us what went wrong
echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

### 25.3.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
$> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtid` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (198.51.100.10 in our example setup):

```
$> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40):

```
$> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (198.51.100.20):

```
$> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see [Section 25.3.2.4, "Installing NDB Cluster Processes as Windows Services"](#)), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:

```
C:\> SC START ndb_mgmd
```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:

```
C:\> SC START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 25.3.2.3, “Initial Startup of NDB Cluster on Windows”](#)).
- On the SQL node host (`198.51.100.20`), execute the following command:

```
C:\> SC START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#).

### 25.3.7 Upgrading and Downgrading NDB Cluster

- [Versions Supported for Upgrade to NDB 9.7](#)
- [Known Issues When Upgrading or Downgrading NDB Cluster](#)

This section provides information about NDB Cluster software and compatibility between different NDB Cluster releases with regard to performing upgrades and downgrades. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See [Section 25.4, “Configuration of NDB Cluster”](#).

For information about upgrades to NDB 9.7 from previous versions, see [Versions Supported for Upgrade to NDB 9.7](#).

For information about known issues and problems encountered when upgrading or downgrading NDB 9.7, see [Known Issues When Upgrading or Downgrading NDB Cluster](#).

#### Versions Supported for Upgrade to NDB 9.7

The following versions of NDB Cluster are supported for upgrades to NDB Cluster 9.7:

- NDB Cluster 8.0: NDB 8.0.19 and later
- NDB Cluster 8.1 (8.1.0)
- NDB Cluster 8.2 (8.2.0)
- NDB Cluster 8.3 (8.3.0)

#### Known Issues When Upgrading or Downgrading NDB Cluster

In this section, provide information about issues known to occur when upgrading or downgrading to or from NDB 9.7.

We recommend that you not attempt any schema changes during any NDB Cluster software upgrade or downgrade. Some of the reasons for this are listed here:

- DDL statements on [NDB](#) tables are not possible during some phases of data node startup.
- DDL statements on [NDB](#) tables may be rejected if any data nodes are stopped during execution; stopping each data node binary (so it can be replaced with a binary from the target version) is required as part of the upgrade or downgrade process.

- DDL statements on [NDB](#) tables are not allowed while there are data nodes in the same cluster running different release versions of the NDB Cluster software.

For additional information regarding the rolling restart procedure used to perform an online upgrade or downgrade of the data nodes, see [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#).

## 25.4 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the [NDB](#) storage engine. This engine is also referred to sometimes as [NDBCLUSTER](#), although [NDB](#) is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the [NDB](#) storage engine disabled. To enable [NDB](#), you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the [NDB](#) storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

For general information about installing NDB Cluster, see [Section 25.3, “NDB Cluster Installation”](#).

### 25.4.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
$> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you do not know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# [api] and [mgm] are aliases for [mysqld] and [ndb_mgmd], respectively.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
```

```

HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]

```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```

$> cd /var/lib/mysql-cluster
$> ndb_mgmd

```

Then start a single data node by running `ndbd`:

```

$> ndbd

```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

#### Note

If you have installed MySQL from a binary tarball, you must to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these can be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```

[mysqld]
ndbcluster

```

You can now start the MySQL server as usual:

```

$> mysqld_safe --user=mysql &

```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```

$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 9.7.0

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...

```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
$> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
$> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 9.4.0-ndb-9.4.0, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 9.4.0-ndb-9.4.0)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 9.4.0-ndb-9.4.0)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

## 25.4.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, or `shm`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

**Considerations when restarting nodes.** For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#). In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

### Note

[4294967039](#) often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

## 25.4.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 25.4.3.6, "Defining NDB Cluster Data Nodes"](#).

These parameters also apply to `ndbmt`, the multithreaded version of `ndbd`. A separate listing of parameters specific to `ndbmt` follows.

- [ApiFailureHandlingTimeout](#): Maximum time for API node failure handling before escalating. 0 means no time limit; minimum usable value is 10.
- [Arbitration](#): How arbitration should be performed to avoid split-brain issues in event of node failure.
- [ArbitrationTimeout](#): Maximum time (milliseconds) database partition waits for arbitration signal.
- [BackupDataBufferSize](#): Default size of databuffer for backup (in bytes).
- [BackupDataDir](#): Path to where to store backups. Note that string `'/BACKUP'` is always appended to this setting, so that *\*effective\** default is `FileSystemPath/BACKUP`.
- [BackupDiskWriteSpeedPct](#): Sets percentage of data node's allocated maximum write speed (`MaxDiskWriteSpeed`) to reserve for LCPs when starting backup.

- [BackupLogBufferSize](#): Default size of log buffer for backup (in bytes).
- [BackupMaxWriteSize](#): Maximum size of file system writes made by backup (in bytes).
- [BackupMemory](#): Total memory allocated for backups per node (in bytes).
- [BackupReportFrequency](#): Frequency of backup status reports during backup in seconds.
- [BackupWriteSize](#): Default size of file system writes made by backup (in bytes).
- [BatchSizePerLocalScan](#): Used to calculate number of lock records for scan with hold lock.
- [BuildIndexThreads](#): Number of threads to use for building ordered indexes during system or node restart. Also applies when running `ndb_restore --rebuild-indexes`. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- [CompressedBackup](#): Use zlib to compress backups as they are written.
- [CompressedLCP](#): Write compressed LCPs using zlib.
- [ConnectCheckIntervalDelay](#): Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- [CrashOnCorruptedTuple](#): When enabled, forces node to shut down whenever it detects corrupted tuple.
- [DataDir](#): Data directory for this node.
- [DataMemory](#): Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.
- [DefaultHashMapSize](#): Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- [DictTrace](#): Enable DBDICT debugging; for NDB development.
- [DiskDataUsingSameDisk](#): Set to false if Disk Data tablespaces are located on separate physical disks.
- [DiskIOThreadPool](#): Number of unbound threads for file access, applies to disk data only.
- [Diskless](#): Run without using disk.
- [DiskPageBufferEntries](#): Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.
- [DiskPageBufferMemory](#): Number of bytes on each data node allocated for disk page buffer cache.
- [DiskSyncSize](#): Amount of data written to file before synch is forced.
- [EnablePartialLcp](#): Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
- [EnableRedoControl](#): Enable adaptive checkpointing speed for controlling redo log usage.
- [EncryptedFileSystem](#): Encrypt local checkpoint and tablespace files..
- [EventLogBufferSize](#): Size of circular buffer for NDB log events within data nodes.
- [ExecuteOnComputer](#): String referencing earlier defined COMPUTER.

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **FileSystemPath**: Path to directory where data node stores its data (directory must exist).
- **FileSystemPathDataFiles**: Path to directory where data node stores its Disk Data files. Default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, value of DataDir is used.
- **FileSystemPathDD**: Path to directory where data node stores its Disk Data and undo files. Default value is FileSystemPath, if set; otherwise, value of DataDir is used.
- **FileSystemPathUndoFiles**: Path to directory where data node stores its undo files for Disk Data. Default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, value of DataDir is used.
- **FragmentLogFileSize**: Size of each redo log file.
- **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.
- **HeartbeatOrder**: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- **HostName**: Host name or IP address for this data node.
- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.
- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates.
- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.
- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.
- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.
- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for large index. Set to 0 to disable scaling.
- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for given index. 0 means no delay.
- **InitFragmentLogFiles**: Initialize fragment log files, using sparse or full format.
- **InitialLogFileGroup**: Describes log file group that is created during initial start. See documentation for format.
- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file).
- **InitialTablespace**: Describes tablespace that is created during initial start. See documentation for format.

- [InsertRecoveryWork](#): Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.
- [KeepAliveSendInterval](#): Time between keep-alive signals on links between data nodes, in milliseconds. Set to 0 to disable.
- [LateAlloc](#): Allocate memory after connection to management server has been established.
- [LcpScanProgressTimeout](#): Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- [LocationDomainId](#): Assign this data node to specific availability domain or zone. 0 (default) leaves this unset.
- [LockExecuteThreadToCPU](#): Comma-delimited list of CPU IDs.
- [LockMaintThreadsToCPU](#): CPU ID indicating which CPU runs maintenance threads.
- [LockPagesInMainMemory](#): 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.
- [LogLevelCheckpoint](#): Log level of local and global checkpoint information printed to stdout.
- [LogLevelCongestion](#): Level of congestion information printed to stdout.
- [LogLevelConnection](#): Level of node connect/disconnect information printed to stdout.
- [LogLevelError](#): Transporter, heartbeat errors printed to stdout.
- [LogLevelInfo](#): Heartbeat and log information printed to stdout.
- [LogLevelNodeRestart](#): Level of node restart and node failure information printed to stdout.
- [LogLevelShutdown](#): Level of node shutdown information printed to stdout.
- [LogLevelStartup](#): Level of node startup information printed to stdout.
- [LogLevelStatistic](#): Level of transaction, operation, and transporter information printed to stdout.
- [LongMessageBuffer](#): Number of bytes allocated on each data node for internal long messages.
- [MaxAllocate](#): No longer used; has no effect.
- [MaxBufferedEpochs](#): Allowed numbered of epochs that subscribing node can lag behind (unprocessed epochs). Exceeding causes lagging subscribers to be disconnected.
- [MaxBufferedEpochBytes](#): Total number of bytes allocated for buffering epochs.
- [MaxDiskDataLatency](#): Maximum allowed mean latency of disk access (ms) before starting to abort transactions.
- [MaxDiskWriteSpeed](#): Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- [MaxDiskWriteSpeedOtherNodeRestart](#): Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- [MaxDiskWriteSpeedOwnRestart](#): Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.

- **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- **MaxDMLOperationsPerTransaction**: Limit size of transaction; aborts transaction if it requires more than this many DML operations.
- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- **MaxNoOfAttributes**: Suggests total number of attributes stored in database (sum over all tables).
- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node.
- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator.
- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on data node.
- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations.
- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.
- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node.
- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node.
- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node.
- **MaxNoOfOpenFiles**: Maximum number of files open per data node.(One thread is created per file).
- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.
- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers.
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).
- **MaxNoOfTables**: Suggests total number of NDB tables stored in database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.

- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: Percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which data node belongs; used only during initial start of cluster.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group.
- **NodeId**: Number uniquely identifying data node among all nodes in cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- **NoOfReplicas**: Number of copies of all data in database.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O\_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O\_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- **RedoBuffer**: Number of bytes on each data node allocated for writing redo logs.
- **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- **RedoOverCommitLimit**: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.
- **RequireEncryptedBackup**: Whether backups must be encrypted (1 = encryption required, otherwise 0).
- **RequireCertificate**: Node is required to find key and certificate in TLS search path.
- **RequireTls**: Require TLS-authenticated secure connections.
- **ReservedConcurrentIndexOperations**: Number of simultaneous index operations having dedicated resources on one data node.
- **ReservedConcurrentOperations**: Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.
- **ReservedConcurrentScans**: Number of simultaneous scans having dedicated resources on one data node.

- [ReservedConcurrentTransactions](#): Number of simultaneous transactions having dedicated resources on one data node.
- [ReservedFiredTriggers](#): Number of triggers having dedicated resources on one data node.
- [ReservedLocalScans](#): Number of simultaneous fragment scans having dedicated resources on one data node.
- [ReservedTransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.
- [RestartOnErrorInsert](#): Control type of restart caused by inserting error (when StopOnError is enabled).
- [RestartSubscriberConnectTimeout](#): Amount of time for data node to wait for subscribing API nodes to connect. Set to 0 to disable timeout, which is always resolved to nearest full second.
- [SchedulerExecutionTimer](#): Number of microseconds to execute in scheduler before sending.
- [SchedulerResponsiveness](#): Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- [SchedulerSpinTimer](#): Number of microseconds to execute in scheduler before sleeping.
- [ServerPort](#): Port used to set up transporter for incoming connections from API nodes.
- [SharedGlobalMemory](#): Total number of bytes on each data node allocated for any use.
- [SpinMethod](#): Determines spin method used by data node; see documentation for details.
- [StartFailRetryDelay](#): Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- [StartFailureTimeout](#): Milliseconds to wait before terminating. (0=Wait forever).
- [StartNoNodeGroupTimeout](#): Time to wait for nodes without nodegroup before trying to start (0=forever).
- [StartPartialTimeout](#): Milliseconds to wait before trying to start without all nodes. (0=Wait forever).
- [StartPartitionedTimeout](#): Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- [StartupStatusReportFrequency](#): Frequency of status reports during startup.
- [StopOnError](#): When set to 0, data node automatically restarts and recovers following node failures.
- [StringMemory](#): Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
- [TcpBind\\_INADDR\\_ANY](#): Bind IP\_ADDR\_ANY so that connections can be made from anywhere (for autogenerated connections).
- [TimeBetweenEpochs](#): Time between epochs (synchronization used for replication).
- [TimeBetweenEpochsTimeout](#): Timeout for time between epochs. Exceeding causes node shutdown.
- [TimeBetweenGlobalCheckpoints](#): Time between group commits of transactions to disk.
- [TimeBetweenGlobalCheckpointsTimeout](#): Minimum timeout for group commit of transactions to disk.

- [TimeBetweenInactiveTransactionAbortCheck](#): Time between checks for inactive transactions.
- [TimeBetweenLocalCheckpoints](#): Time between taking snapshots of database (expressed in base-2 logarithm of bytes).
- [TimeBetweenWatchDogCheck](#): Time between execution checks inside data node.
- [TimeBetweenWatchDogCheckInitial](#): Time between execution checks inside data node (early start phases when memory is allocated).
- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers..
- [TransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.
- [TransactionDeadlockDetectionTimeout](#): Time transaction can spend executing within data node. This is time that transaction coordinator waits for each data node participating in transaction to execute request. If data node takes more than this amount of time, transaction is aborted.
- [TransactionInactiveTimeout](#): Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.
- [TransactionMemory](#): Memory allocated for transactions on each data node.
- [TwoPassInitialNodeRestartCopy](#): Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- [UndoDataBuffer](#): Unused; has no effect.
- [UndoIndexBuffer](#): Unused; has no effect.
- [UseShm](#): Use shared memory connections between this data node and API node also running on this host.
- [WatchDogImmediateKill](#): When true, threads are immediately killed whenever watchdog issues occur; used for testing and debugging.

The following parameters are specific to `ndbmtd`:

- [AutomaticThreadConfig](#): Use automatic thread configuration; overrides any settings for `ThreadConfig` and `MaxNoOfExecutionThreads`, and disables `ClassicFragmentation`.
- [ClassicFragmentation](#): When true, use traditional table fragmentation; set false to enable flexible distribution of fragments among LDMs. Disabled by `AutomaticThreadConfig`.
- [EnableMultithreadedBackup](#): Enable multi-threaded backup.
- [MaxNoOfExecutionThreads](#): For `ndbmtd` only, specify maximum number of execution threads.
- [MaxSendDelay](#): Maximum number of microseconds to delay sending by `ndbmtd`.
- [NoOfFragmentLogParts](#): Number of redo log file groups belonging to this data node.
- [NumCPUs](#): Specify number of CPUs to use with `AutomaticThreadConfig`.
- [PartitionsPerNode](#): Determines the number of table partitions created on each data node; not used if `ClassicFragmentation` is enabled.

- **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmysd). Default is empty string; see documentation for syntax and other information.

### 25.4.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 25.4.3.5, “Defining an NDB Cluster Management Server”](#).

- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
- **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- **DataDir**: Data directory for this node.
- **ExecuteOnComputer**: String referencing earlier defined COMPUTER.
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **HeartbeatIntervalMgmdMgmd**: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.
- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.
- **HostName**: Host name or IP address for this management node.
- **Id**: Number identifying management node. Now deprecated; use NodeId instead.
- **LocationDomainId**: Assign this management node to specific availability domain or zone. 0 (default) leaves this unset.
- **LogDestination**: Where to send log messages: console, system log, or specified log file.
- **NodeId**: Number uniquely identifying management node among all nodes in cluster.
- **PortNumber**: Port number to send commands to and fetch configuration from management server.
- **PortNumberStats**: Port number used to get statistical information from management server.
- **RequireTls**: Client connection must authenticate with TLS before being used otherwise.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **wan**: Use WAN TCP setting as default.

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 25.4.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple

management nodes, see [Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 25.4.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `ApiVerbose`: Enable NDB API debugging; for NDB development.
- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting.
- `ArbitrationRank`: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- `AutoReconnect`: Specifies whether an API node should reconnect fully when disconnected from cluster.
- `BatchByteSize`: Default batch size in bytes.
- `BatchSize`: Default batch size in number of records.
- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, `StartConnectBackoffMaxTime` is used instead.
- `ConnectionMap`: Specifies which data nodes to connect.
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- `DefaultOperationRedoProblemAction`: How operations are handled in event that `RedoOverCommitCounter` is exceeded.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by `TotalSendBufferMemory` or `SendBufferMemory`. Default (0) allows up to 16MB.
- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.
- `HostName`: Host name or IP address for this SQL or API node.
- `Id`: Number identifying MySQL server or API node (Id). Now deprecated; use `NodeId` instead.
- `LocationDomainId`: Assign this API node to specific availability domain or zone. 0 (default) leaves this unset.
- `MaxScanBatchSize`: Maximum collective batch size for one scan.
- `NodeId`: Number uniquely identifying SQL node or API node among all nodes in cluster.
- `StartConnectBackoffMaxTime`: Same as `ConnectBackoffMaxTime` except that this parameter is used in its place if no data nodes are connected to this API node.
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.

- `wan`: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

#### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 25.4.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, and `[shm]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see [Section 25.4.3.10, “NDB Cluster TCP/IP Connections”](#), or [Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”](#), as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- `HostName`: Host name or IP address of this computer.
- `Id`: Unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- `AllowUnresolvedHostNames`: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only.
- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.
- `Group`: Used for group proximity; smaller value is interpreted as being closer.
- `HostName1`: Name or IP address of first of two computers joined by TCP connection.
- `HostName2`: Name or IP address of second of two computers joined by TCP connection.
- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeIdServer`: Set server side of TCP connection.
- `OverloadLimit`: When more than this many unsend bytes are in send buffer, connection is considered overloaded.
- `PreferIPVersion`: Indicate DNS resolver preference for IP version 4 or 6.
- `PreSendChecksum`: If this parameter and `Checksum` are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
- `Proxy`: ....

- [ReceiveBufferMemory](#): Bytes of buffer for signals received by this node.
- [RequireLinkTls](#): Read-only; is set to true if either endpoint of this connection requires TLS.
- [SendBufferMemory](#): Bytes of TCP buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- [TcpSpinTime](#): Time to spin before going to sleep when receiving.
- [TCP\\_MAXSEG\\_SIZE](#): Value used for TCP\_MAXSEG.
- [TCP\\_RCV\\_BUF\\_SIZE](#): Value used for SO\_RCVBUF.
- [TCP\\_SND\\_BUF\\_SIZE](#): Value used for SO\_SNDBUF.
- [TcpBind\\_INADDR\\_ANY](#): Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the `config.ini` file's `[shm]` section:

- [Checksum](#): If checksum is enabled, all signals between nodes are checked for errors.
- [Group](#): Used for group proximity; smaller value is interpreted as being closer.
- [HostName1](#): Name or IP address of first of two computers joined by SHM connection.
- [HostName2](#): Name or IP address of second of two computers joined by SHM connection.
- [NodeId1](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeId2](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeIdServer](#): Set server side of SHM connection.
- [OverloadLimit](#): When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- [PreSendChecksum](#): If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- [SendBufferMemory](#): Bytes in shared memory buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files.
- [ShmKey](#): Shared memory key; when set to 1, this is calculated by NDB.
- [ShmSpinTime](#): When receiving, number of microseconds to spin before sleeping.
- [ShmSize](#): Size of shared memory segment.
- [Signum](#): Signal number to be used for signalling.

#### 25.4.2.5 NDB Cluster `mysqld` Option and Variable Reference

The following list includes command-line options, system variables, and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a reference to *all* command-line options, system variables, and status variables used with or relating to `mysqld`, see [Section 7.1.4, “Server Option, System Variable, and Status Variable Reference”](#).

- [Com\\_show\\_ndb\\_status](#): Count of SHOW NDB STATUS statements.

- `Handler_discover`: Number of times that tables have been discovered.
- `ndb-applier-allow-skip-epoch`: Lets replication applier skip epochs.
- `ndb-batch-size`: Size (in bytes) to use for NDB transaction batches.
- `ndb-blob-read-batch-bytes`: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- `ndb-blob-write-batch-bytes`: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- `ndb-cluster-connection-pool`: Number of connections to cluster used by MySQL.
- `ndb-cluster-connection-pool-nodeids`: Comma-separated list of node IDs for connections to cluster used by MySQL; number of nodes in list must match value set for `--ndb-cluster-connection-pool`.
- `ndb-connectstring`: Address of NDB management server distributing configuration information for this cluster.
- `ndb-default-column-format`: Use this value (FIXED or DYNAMIC) by default for `COLUMN_FORMAT` and `ROW_FORMAT` options when creating or adding table columns.
- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `ndb-log-apply-status`: Cause MySQL server acting as replica to log `mysql.ndb_apply_status` updates received from its immediate source in its own binary log, using its own server ID. Effective only if server is started with `--ndbcluster` option.
- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.
- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.
- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- `ndb-log-fail-terminate`: Terminate `mysqld` process if complete logging of all found row events is not possible.
- `ndb-log-orig`: Log originating server id and epoch in `mysql.ndb_binlog_index` table.
- `ndb-log-row-slice-count`: Number of slices to be calculated by this server when subscribing to NDB table change event streams used for writing binary logs.
- `ndb-log-row-slice-id`: ID of virtual slice (of NDB table change event streams) subscribed to by this server.
- `ndb-log-transaction-dependency`: Make binary log thread calculate transaction dependencies for every transaction it writes to binary log.
- `ndb-log-transaction-id`: Write NDB transaction IDs in binary log. Requires `--log-bin-v1-events=OFF`.

- `ndb-log-update-minimal`: Log updates in minimal format.
- `ndb-log-updated-only`: Log updates only (ON) or complete rows (OFF).
- `ndb-log-update-as-write`: Toggles logging of updates on source between updates (OFF) and writes (ON).
- `ndb-mgm-tls`: Whether TLS connection requirements are strict or relaxed.
- `ndb-mgmd-host`: Set host (and port, if desired) for connecting to management server.
- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.
- `ndb-optimized-node-selection`: Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.
- `ndb-tls-search-path`: Directories to search for NDB TLS CAs and private keys.
- `ndb-transid-mysql-connection-map`: Enable or disable `ndb_transid_mysql_connection_map` plugin; that is, enable or disable `INFORMATION_SCHEMA` table having that name.
- `ndb-wait-connected`: Time (in seconds) for MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.
- `ndb-wait-setup`: Time (in seconds) for MySQL server to wait for NDB engine setup to complete.
- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.
- `Ndb_api_adaptive_send_deferred_count`: Number of adaptive send calls not actually sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_deferred_count_session`: Number of adaptive send calls not actually sent in this client session.
- `Ndb_api_adaptive_send_deferred_count_replica`: Number of adaptive send calls not actually sent by this replica.
- `Ndb_api_adaptive_send_deferred_count_slave`: Number of adaptive send calls not actually sent by this replica.
- `Ndb_api_adaptive_send_forced_count`: Number of adaptive sends with forced-send set sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_forced_count_session`: Number of adaptive sends with forced-send set in this client session.
- `Ndb_api_adaptive_send_forced_count_replica`: Number of adaptive sends with forced-send set sent by this replica.
- `Ndb_api_adaptive_send_forced_count_slave`: Number of adaptive sends with forced-send set sent by this replica.
- `Ndb_api_adaptive_send_unforced_count`: Number of adaptive sends without forced-send sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_unforced_count_session`: Number of adaptive sends without forced-send in this client session.

- `Ndb_api_adaptive_send_unforced_count_replica`: Number of adaptive sends without forced-send sent by this replica.
- `Ndb_api_adaptive_send_unforced_count_slave`: Number of adaptive sends without forced-send sent by this replica.
- `Ndb_api_bytes_received_count`: Quantity of data (in bytes) received from data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_received_count_session`: Quantity of data (in bytes) received from data nodes in this client session.
- `Ndb_api_bytes_received_count_replica`: Quantity of data (in bytes) received from data nodes by this replica.
- `Ndb_api_bytes_received_count_slave`: Quantity of data (in bytes) received from data nodes by this replica.
- `Ndb_api_bytes_sent_count`: Quantity of data (in bytes) sent to data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_sent_count_session`: Quantity of data (in bytes) sent to data nodes in this client session.
- `Ndb_api_bytes_sent_count_replica`: Quantity of data (in bytes) sent to data nodes by this replica.
- `Ndb_api_bytes_sent_count_slave`: Quantity of data (in bytes) sent to data nodes by this replica.
- `Ndb_api_event_bytes_count`: Number of bytes of events received by this MySQL Server (SQL node).
- `Ndb_api_event_bytes_count_injector`: Number of bytes of event data received by NDB binary log injector thread.
- `Ndb_api_event_data_count`: Number of row change events received by this MySQL Server (SQL node).
- `Ndb_api_event_data_count_injector`: Number of row change events received by NDB binary log injector thread.
- `Ndb_api_event_nondata_count`: Number of events received, other than row change events, by this MySQL Server (SQL node).
- `Ndb_api_event_nondata_count_injector`: Number of events received, other than row change events, by NDB binary log injector thread.
- `Ndb_api_pk_op_count`: Number of operations based on or using primary keys by this MySQL Server (SQL node).
- `Ndb_api_pk_op_count_session`: Number of operations based on or using primary keys in this client session.
- `Ndb_api_pk_op_count_replica`: Number of operations based on or using primary keys by this replica.
- `Ndb_api_pk_op_count_slave`: Number of operations based on or using primary keys by this replica.
- `Ndb_api_pruned_scan_count`: Number of scans that have been pruned to one partition by this MySQL Server (SQL node).

- `Ndb_api_pruned_scan_count_session`: Number of scans that have been pruned to one partition in this client session.
- `Ndb_api_pruned_scan_count_replica`: Number of scans that have been pruned to one partition by this replica.
- `Ndb_api_pruned_scan_count_slave`: Number of scans that have been pruned to one partition by this replica.
- `Ndb_api_range_scan_count`: Number of range scans that have been started by this MySQL Server (SQL node).
- `Ndb_api_range_scan_count_session`: Number of range scans that have been started in this client session.
- `Ndb_api_range_scan_count_replica`: Number of range scans that have been started by this replica.
- `Ndb_api_range_scan_count_slave`: Number of range scans that have been started by this replica.
- `Ndb_api_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).
- `Ndb_api_read_row_count_session`: Total number of rows that have been read in this client session.
- `Ndb_api_read_row_count_replica`: Total number of rows that have been read by this replica.
- `Ndb_api_read_row_count_slave`: Total number of rows that have been read by this replica.
- `Ndb_api_scan_batch_count`: Number of batches of rows received by this MySQL Server (SQL node).
- `Ndb_api_scan_batch_count_session`: Number of batches of rows received in this client session.
- `Ndb_api_scan_batch_count_replica`: Number of batches of rows received by this replica.
- `Ndb_api_scan_batch_count_slave`: Number of batches of rows received by this replica.
- `Ndb_api_table_scan_count`: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- `Ndb_api_table_scan_count_session`: Number of table scans that have been started, including scans of internal tables, in this client session.
- `Ndb_api_table_scan_count_replica`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_table_scan_count_slave`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_trans_abort_count`: Number of transactions aborted by this MySQL Server (SQL node).
- `Ndb_api_trans_abort_count_session`: Number of transactions aborted in this client session.
- `Ndb_api_trans_abort_count_replica`: Number of transactions aborted by this replica.
- `Ndb_api_trans_abort_count_slave`: Number of transactions aborted by this replica.

- [Ndb\\_api\\_trans\\_close\\_count](#): Number of transactions closed by this MySQL Server (SQL node); may be greater than sum of TransCommitCount and TransAbortCount.
- [Ndb\\_api\\_trans\\_close\\_count\\_session](#): Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) in this client session.
- [Ndb\\_api\\_trans\\_close\\_count\\_replica](#): Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.
- [Ndb\\_api\\_trans\\_close\\_count\\_slave](#): Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.
- [Ndb\\_api\\_trans\\_commit\\_count](#): Number of transactions committed by this MySQL Server (SQL node).
- [Ndb\\_api\\_trans\\_commit\\_count\\_session](#): Number of transactions committed in this client session.
- [Ndb\\_api\\_trans\\_commit\\_count\\_replica](#): Number of transactions committed by this replica.
- [Ndb\\_api\\_trans\\_commit\\_count\\_slave](#): Number of transactions committed by this replica.
- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count](#): Total number of rows that have been read by this MySQL Server (SQL node).
- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count\\_session](#): Total number of rows that have been read in this client session.
- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count\\_replica](#): Total number of rows that have been read by this replica.
- [Ndb\\_api\\_trans\\_local\\_read\\_row\\_count\\_slave](#): Total number of rows that have been read by this replica.
- [Ndb\\_api\\_trans\\_start\\_count](#): Number of transactions started by this MySQL Server (SQL node).
- [Ndb\\_api\\_trans\\_start\\_count\\_session](#): Number of transactions started in this client session.
- [Ndb\\_api\\_trans\\_start\\_count\\_replica](#): Number of transactions started by this replica.
- [Ndb\\_api\\_trans\\_start\\_count\\_slave](#): Number of transactions started by this replica.
- [Ndb\\_api\\_uk\\_op\\_count](#): Number of operations based on or using unique keys by this MySQL Server (SQL node).
- [Ndb\\_api\\_uk\\_op\\_count\\_session](#): Number of operations based on or using unique keys in this client session.
- [Ndb\\_api\\_uk\\_op\\_count\\_replica](#): Number of operations based on or using unique keys by this replica.
- [Ndb\\_api\\_uk\\_op\\_count\\_slave](#): Number of operations based on or using unique keys by this replica.
- [Ndb\\_api\\_wait\\_exec\\_complete\\_count](#): Number of times thread has been blocked while waiting for operation execution to complete by this MySQL Server (SQL node).
- [Ndb\\_api\\_wait\\_exec\\_complete\\_count\\_session](#): Number of times thread has been blocked while waiting for operation execution to complete in this client session.
- [Ndb\\_api\\_wait\\_exec\\_complete\\_count\\_replica](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica.

- `Ndb_api_wait_exec_complete_count_slave`: Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- `Ndb_api_wait_meta_request_count`: Number of times thread has been blocked waiting for metadata-based signal by this MySQL Server (SQL node).
- `Ndb_api_wait_meta_request_count_session`: Number of times thread has been blocked waiting for metadata-based signal in this client session.
- `Ndb_api_wait_meta_request_count_replica`: Number of times thread has been blocked waiting for metadata-based signal by this replica.
- `Ndb_api_wait_meta_request_count_slave`: Number of times thread has been blocked waiting for metadata-based signal by this replica.
- `Ndb_api_wait_nanos_count`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this MySQL Server (SQL node).
- `Ndb_api_wait_nanos_count_session`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes in this client session.
- `Ndb_api_wait_nanos_count_replica`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- `Ndb_api_wait_nanos_count_slave`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- `Ndb_api_wait_scan_result_count`: Number of times thread has been blocked while waiting for scan-based signal by this MySQL Server (SQL node).
- `Ndb_api_wait_scan_result_count_session`: Number of times thread has been blocked while waiting for scan-based signal in this client session.
- `Ndb_api_wait_scan_result_count_replica`: Number of times thread has been blocked while waiting for scan-based signal by this replica.
- `Ndb_api_wait_scan_result_count_slave`: Number of times thread has been blocked while waiting for scan-based signal by this replica.
- `ndb_autoincrement_prefetch_sz`: NDB auto-increment prefetch size.
- `ndb_clear_apply_status`: Causes RESET SLAVE/RESET REPLICA to clear all rows from `ndb_apply_status` table; ON by default.
- `Ndb_cluster_node_id`: Node ID of this server when acting as NDB Cluster SQL node.
- `Ndb_config_from_host`: NDB Cluster management server host name or IP address.
- `Ndb_config_from_port`: Port for connecting to NDB Cluster management server.
- `Ndb_config_generation`: Generation number of the current configuration of the cluster.
- `Ndb_conflict_fn_epoch`: Number of rows that have been found in conflict by `NDB$EPOCH()` NDB replication conflict detection function.
- `Ndb_conflict_fn_epoch2`: Number of rows that have been found in conflict by NDB replication `NDB$EPOCH2()` conflict detection function.
- `Ndb_conflict_fn_epoch2_trans`: Number of rows that have been found in conflict by NDB replication `NDB$EPOCH2_TRANS()` conflict detection function.

- `Ndb_conflict_fn_epoch_trans`: Number of rows that have been found in conflict by NDB `$EPOCH_TRANS()` conflict detection function.
- `Ndb_conflict_fn_max`: Number of times that NDB replication conflict resolution based on "greater timestamp wins" has been applied to update and delete operations.
- `Ndb_conflict_fn_max_del_win`: Number of times that NDB replication conflict resolution based on outcome of `NDB$MAX_DELETE_WIN()` has been applied to update and delete operations.
- `Ndb_conflict_fn_max_ins`: Number of times that NDB replication conflict resolution based on "greater timestamp wins" has been applied to insert operations.
- `Ndb_conflict_fn_max_del_win_ins`: Number of times that NDB replication conflict resolution based on outcome of `NDB$MAX_DEL_WIN_INS()` has been applied to insert operations.
- `Ndb_conflict_fn_old`: Number of times that NDB replication "same timestamp wins" conflict resolution has been applied.
- `Ndb_conflict_last_conflict_epoch`: Most recent NDB epoch on this replica in which some conflict was detected.
- `Ndb_conflict_last_stable_epoch`: Most recent epoch containing no conflicts.
- `Ndb_conflict_reflected_op_discard_count`: Number of reflected operations that were not applied due error during execution.
- `Ndb_conflict_reflected_op_prepare_count`: Number of reflected operations received that have been prepared for execution.
- `Ndb_conflict_refresh_op_count`: Number of refresh operations that have been prepared.
- `ndb_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- `Ndb_conflict_trans_conflict_commit_count`: Number of epoch transactions committed after requiring transactional conflict handling.
- `Ndb_conflict_trans_detect_iter_count`: Number of internal iterations required to commit epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.
- `Ndb_conflict_trans_reject_count`: Number of transactions rejected after being found in conflict by transactional conflict function.
- `Ndb_conflict_trans_row_conflict_count`: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions.
- `Ndb_conflict_trans_row_reject_count`: Total number of rows realigned after being found in conflict by transactional conflict function. Includes `Ndb_conflict_trans_row_conflict_count` and any rows included in or dependent on conflicting transactions.
- `ndb_data_node_neighbour`: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.
- `ndb_default_column_format`: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.
- `ndb_deferred_constraints`: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- `ndb_dbg_check_shares`: Check for any lingering shares (debug builds only).
- `ndb-schema-dist-timeout`: How long to wait before detecting timeout during schema distribution.
- `ndb_distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `Ndb_epoch_delete_delete_count`: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).
- `ndb_eventbuffer_free_percent`: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by `ndb_eventbuffer_max_alloc`.
- `ndb_eventbuffer_max_alloc`: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit).
- `ndb_extra_logging`: Controls logging of NDB Cluster schema, connection, and data distribution events in MySQL error log.
- `Ndb_fetch_table_stats`: Number of times table statistics were fetched from tables rather than cache.
- `ndb_force_send`: Forces sending of buffers to NDB immediately, without waiting for other threads.
- `ndb_fully_replicated`: Whether new NDB tables are fully replicated.
- `ndb_index_stat_enable`: Use NDB index statistics in query optimization.
- `ndb_index_stat_option`: Comma-separated list of tunable options for NDB index statistics; list should contain no spaces.
- `ndb_join_pushdown`: Enables pushing down of joins to data nodes.
- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB.
- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client.
- `ndb_log_apply_status`: Whether or not MySQL server acting as replica logs `mysql.ndb_apply_status` updates received from its immediate source in its own binary log, using its own server ID.
- `ndb_log_bin`: Write updates to NDB tables in binary log. Effective only if binary logging is enabled with `--log-bin`.
- `ndb_log_binlog_index`: Insert mapping between epochs and binary log positions into `ndb_binlog_index` table. Defaults to ON. Effective only if binary logging is enabled.
- `ndb_log_cache_size`: Set size of transaction cache used for recording NDB binary log.
- `ndb_log_empty_epochs`: When enabled, epochs in which there were no changes are written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.
- `ndb_log_empty_update`: When enabled, updates which produce no changes are written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.
- `ndb_log_exclusive_reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- `ndb_log_orig`: Whether id and epoch of originating server are recorded in `mysql.ndb_binlog_index` table. Set using `--ndb-log-orig` option when starting `mysqld`.
- `ndb_log_transaction_id`: Whether NDB transaction IDs are written into binary log (Read-only).
- `ndb_log_transaction_compression`: Whether to compress NDB binary log; can also be enabled on startup by enabling `--binlog-transaction-compression` option.
- `ndb_log_transaction_compression_level_zstd`: The ZSTD compression level to use when writing compressed transactions to the NDB binary log.
- `ndb_metadata_check`: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.
- `ndb_metadata_check_interval`: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.
- `Ndb_metadata_detected_count`: Number of times NDB metadata change monitor thread has detected changes.
- `Ndb_metadata_excluded_count`: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.
- `ndb_metadata_sync`: Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes `ndb_metadata_check` and `ndb_metadata_check_interval` values to be ignored. Resets to false when synchronization is complete.
- `Ndb_metadata_synced_count`: Number of NDB metadata objects which have been synchronized.
- `Ndb_number_of_data_nodes`: Number of data nodes in this NDB cluster; set only if server participates in cluster.
- `ndb-optimization-delay`: Number of milliseconds to wait between processing sets of rows by `OPTIMIZE TABLE` on NDB tables.
- `ndb_optimized_node_selection`: Determines how SQL node chooses cluster data node to use as transaction coordinator.
- `Ndb_pruned_scan_count`: Number of scans executed by NDB since cluster was last started where partition pruning could be used.
- `Ndb_pushed_queries_defined`: Number of joins that API nodes have attempted to push down to data nodes.
- `Ndb_pushed_queries_dropped`: Number of joins that API nodes have tried to push down, but failed.
- `Ndb_pushed_queries_executed`: Number of joins successfully pushed down and executed on data nodes.
- `Ndb_pushed_reads`: Number of reads executed on data nodes by pushed-down joins.
- `ndb_read_backup`: Enable read from any replica for all NDB tables; use `NDB_TABLE=READ_BACKUP={0|1}` with `CREATE TABLE` or `ALTER TABLE` to enable or disable for individual NDB tables.
- `ndb_recv_thread_activation_threshold`: Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads).
- `ndb_recv_thread_cpu_mask`: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- `Ndb_replica_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- `ndb_replica_batch_size`: Batch size in bytes for replica applier.
- `ndb_report_thresh_binlog_epoch_slip`: NDB 7.5 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates `BUFFERED_EPOCHS_OVER_THRESHOLD` event buffer status message; prior to NDB 7.5: Threshold for number of epochs to lag behind before reporting binary log status.
- `ndb_report_thresh_binlog_mem_usage`: Threshold for percentage of free memory remaining before reporting binary log status.
- `ndb_row_checksum`: When enabled, set row checksums; enabled by default.
- `Ndb_scan_count`: Total number of scans executed by NDB since cluster was last started.
- `ndb_schema_dist_lock_wait_timeout`: Time during schema distribution to wait for lock before returning error.
- `ndb_schema_dist_timeout`: Time to wait before detecting timeout during schema distribution.
- `ndb_schema_dist_upgrade_allowed`: Allow schema distribution table upgrade when connecting to NDB.
- `Ndb_schema_participant_count`: Number of MySQL servers participating in NDB schema change distribution.
- `ndb_show_foreign_key_mock_tables`: Show mock tables used to support `foreign_key_checks=0`.
- `ndb_slave_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of `PRIMARY`, `SECONDARY`, `PASS`, or `NONE` (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- `Ndb_slave_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- `Ndb_system_name`: Configured cluster system name; empty if server not connected to NDB.
- `ndb_table_no_logging`: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). Setting in effect when table is created with or altered to use `NDBCLUSTER` persists for table's lifetime.
- `ndb_table_temporary`: NDB tables are not persistent on disk: no schema files are created and tables are not logged.
- `Ndb_trans_hint_count_session`: Number of transactions using hints that have been started in this session.
- `ndb_use_copying_alter_table`: Use copying `ALTER TABLE` operations in NDB Cluster.
- `ndb_use_exact_count`: Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query.
- `ndb_use_transactions`: Set to `OFF`, to disable transaction support by NDB. Not recommended except in certain special cases; see documentation for details.
- `ndb_version`: Shows build and NDB engine version as an integer.

- `ndb_version_string`: Shows build information including NDB engine version in `ndb-x.y.z` format.
- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.
- `ndbinfo`: Enable `ndbinfo` plugin, if supported.
- `ndbinfo_database`: Name used for NDB information database; read only.
- `ndbinfo_max_bytes`: Used for debugging only.
- `ndbinfo_max_rows`: Used for debugging only.
- `ndbinfo_offline`: Put `ndbinfo` database into offline mode, in which no rows are returned from tables or views.
- `ndbinfo_show_hidden`: Whether to show `ndbinfo` internal base tables in `mysql` client; default is OFF.
- `ndbinfo_table_prefix`: Prefix to use for naming `ndbinfo` internal base tables; read only.
- `ndbinfo_version`: `ndbinfo` engine version; read only.
- `replica_allow_batching`: Turns update batching on and off for replica.
- `server_id_bits`: Number of least significant bits in `server_id` actually used for identifying server, permitting NDB API applications to store application data in most significant bits. `server_id` must be less than 2 to power of this value.
- `skip-ndbcluster`: Disable NDB Cluster storage engine.
- `slave_allow_batching`: Turns update batching on and off for replica.
- `transaction_allow_batching`: Allows batching of statements within one transaction. Disable AUTOCOMMIT to use.

### 25.4.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

**Caching of configuration data.** NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the `--initial` option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the `--reload` option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using `--config-cache=FALSE`.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

#### Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 25.5.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in NDB Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let NDB Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

### 25.4.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you should update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

#### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 9.7)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
```

```
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
# IMPORTANT: When starting the management server with this option in the
# configuration file, the use of --initial or --reload on the command line when
# invoking ndb_mgmd is also required.
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 25.4.3.3, “NDB Cluster Connection Strings”](#).)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (works on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional [NDB](#) variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

If used, the `[ndbd default]` section must precede any `[ndbd]` sections in the configuration file. This is also true for `default` sections of any other type.

#### Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysql_d_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysql_d_5.mysql.com
```

#### Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See [Section 25.4.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

#### Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

---

## Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 25.4.3.4, “Defining Computers in an NDB Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 25.4.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 25.4.3.10, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 9.7, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 9.7.

You can define `default` values for each section. If used, a `default` section should come before any other sections of that type. For example, an `[ndbd default]` section should appear in the configuration file before any `[ndbd]` sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

### 25.4.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting config.ini file.** The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 9.7:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one is allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using two fragment replicas is recommended to guarantee availability of data;
# using only one fragment replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to shut down.
# It is also possible (but not required) to use more than two fragment replicas,
# although two fragment replicas are sufficient to provide high availability.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3456M

# The value provided for DataMemory assumes 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
```

## NDB Cluster Configuration Files

```
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtid; in particular, you should not set
# RealTimeScheduler for ndbmtid data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 144 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid
```

```
[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

**Required my.cnf options for SQL nodes.** MySQL servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`.

### 25.4.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short):  "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
```

```
[bind-address=host-definition, ]
host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[, ...]
```

```
host-definition:
  host_name[ :port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.

This should be considered deprecated, and not used in new installations.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

#### 25.4.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

Version (or later)	NDB 9.7.0
Type or units	string

Default	[...]
Range	...
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- [HostName](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This is the computer's hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.7 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then

Symbol	Restart Type	Description
		restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` is assumed for both.

- `Id`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 255
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- [NodeId](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 255
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

[NodeId](#) is the preferred parameter name to use when identifying management nodes. Although the older [Id](#) continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- [ExecuteOnComputer](#)

Version (or later)	NDB 9.7.0
Type or units	name
Default	[...]
Range	...
Deprecated	Yes (in NDB 7.5)
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the

	cluster. (NDB 9.7.0)
--	----------------------

This refers to the `id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `PortNumber`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	1186
Range	0 - 64K
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

This is the port number on which the management server listens for configuration requests and management commands.

- 

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes.

- `HostName`

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Specifying this parameter defines the hostname of the computer on which the management node is to reside. Use `HostName` to specify a host name other than `localhost`.

- [LocationDomainId](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 16
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Assigns a management node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing [NDB](#) which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use [NDB](#) transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [LogDestination](#)

Version (or later)	NDB 9.7.0
Type or units	{CONSOLE  SYSLOG FILE}
Default	FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies where to send cluster logging information. There are three options in this regard—[CONSOLE](#), [SYSLOG](#), and [FILE](#)—with [FILE](#) being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

**Note**

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Version (or later)	NDB 9.7.0
Type or units	0-2
Default	1
Range	0 - 2
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node is never used as an arbitrator.

- **1:** The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.
- **2:** Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- `ArbitrationDelay`

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

Version (or later)	NDB 9.7.0
Type or units	path
Default	.
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination`, as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- [PortNumberStats](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	0 - 64K
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]  
policy:
```

{FIFO | RR}

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first out) or [RR](#) (round robin). The policy value is followed optionally by the priority (an integer).

- [ExtraSendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	0 - 32G
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [RequireTls](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If this parameter is set to [true](#), a client, once connected to this management node, must be authenticated using TLS before the connection can be used for anything else.

- [TotalSendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [HeartbeatIntervalMgmdMgmd](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	1500
Range	100 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.8 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then

Symbol	Restart Type	Description
		restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is `ExecuteOnComputer`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName` and `NodeId` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmt` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmt` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmt\)](#). See also [Section 25.5.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `NodeId`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 144
Restart Type	<b>Initial System Restart:</b> Requires a complete

	shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)
--	--

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. Each node in the cluster must have a unique identifier.

[NodeId](#) is the only supported parameter name to use when identifying data nodes.

- [ExecuteOnComputer](#)

Version (or later)	NDB 9.7.0
Type or units	name
Default	[...]
Range	...
Deprecated	Yes (in NDB 7.5)
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

This refers to the [Id](#) set for one of the computers defined in a [\[computer\]](#) section.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the [HostName](#) parameter instead.

- 

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and [HostName](#) is not sufficient for distinguishing among processes.

- [HostName](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	localhost
Range	...

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

Specifying this parameter defines the hostname of the computer on which the data node is to reside. Use `HostName` to specify a host name other than `localhost`.

- [ServerPort](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 64K
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- [TcpBind\\_INADDR\\_ANY](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [NodeGroup](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	0 - 65536

Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)
--------------	--

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[nbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 25.6.7.3, "Adding NDB Cluster Data Nodes Online: Detailed Example"](#).

- `LocationDomainId`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 16
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Assigns a data node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `NoOfReplicas`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	2
Range	1 - 4
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

This global parameter can be set only in the `[ndbd default]` section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments. Setting this parameter's value to 3 or 4 is also supported.

**Warning**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and

2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

Version (or later)	NDB 9.7.0
Type or units	path
Default	.
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial.</code> (NDB 9.7.0)

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

Version (or later)	NDB 9.7.0
Type or units	path
Default	<code>DataDir</code>
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial.</code> (NDB 9.7.0)

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- [BackupDataDir](#)

Version (or later)	NDB 9.7.0
Type or units	path
Default	FileSystemPath
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

This parameter specifies the directory in which backups are placed.

### Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

## Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` is used, as it usually needs to be updated to reflect actual usage by the cluster.

### Note

`IndexMemory` is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- [DataMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	98M
Range	1M - 16T
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 30000 bytes.

Resources assigned to `DataMemory` are used for storing all data and indexes. (Any memory configured as `IndexMemory` is automatically added to that used by `DataMemory` to form a common resource pool.)

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	1M - 1T

Deprecated	Yes (in NDB 7.6)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The [IndexMemory](#) parameter is deprecated (and subject to future removal); any memory assigned to [IndexMemory](#) is allocated instead to the same pool as [DataMemory](#), which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 9.7, the use of [IndexMemory](#) in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

```
size = ( ( fragments * 32K ) + ( rows * 18 ) )
      * fragment_replicas
```

[fragments](#) is the number of fragments, [fragment\\_replicas](#) is the number of fragment replicas (normally 2), and [rows](#) is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the [mysql.ndb\\_index\\_stat\\_sample](#) table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
              / sample_size
```

In the preceding formula, [key\\_size](#) is the size of the ordered index key in bytes, [key\\_attributes](#) is the number of attributes in the ordered index key, and [rows](#) is the number of rows in the base table.

Assume that table [t1](#) has 1 million rows and an ordered index named [ix1](#) on two four-byte integers. Assume in addition that [IndexStatSaveSize](#) and [IndexStatSaveScale](#) are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ( (1 * ~16.811) +1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus 2 \* 18 \* 29182 = ~1050550 bytes.

The minimum and default value for this parameter is 0 (zero).

- [StringMemory](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	% or bytes
Default	25
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including `DataMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	5
Range	0 - 100
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	4096
Range	32 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
TotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then  $10 * 11 = 110$  transaction records are required for this transaction, per MySQL server, or  $110 * 10 = 1100$  transaction records total. Each data node can be expected to handle  $TotalNoOfConcurrentTransactions / \text{number of data nodes}$ . For an NDB Cluster having 4 data nodes, this would mean setting [MaxNoOfConcurrentTransactions](#) on each data node to  $1100 / 4 = 275$ . In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's [MaxNoOfConcurrentTransactions](#) is sufficient to cover a number of transactions equal to  $TotalNoOfConcurrentTransactions / \text{number of node groups}$ . If this cluster has a single node group, then [MaxNoOfConcurrentTransactions](#) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for [MaxNoOfConcurrentTransactions](#) should always be no more than the value of [MaxNoOfConcurrentOperations](#).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	32K
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a

	rolling restart of the cluster. (NDB 9.7.0)
--	---

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ . To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	UNDEFINED

Range	32 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [MaxDMLOperationsPerTransaction](#)

Version (or later)	NDB 9.7.0
Type or units	operations (DML)
Default	4294967295
Range	32 - 4294967295
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations.

The value of this parameter cannot exceed that set for [MaxNoOfConcurrentOperations](#).

**Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	8K

Range	0 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [MaxNoOfFiredTriggers](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	4000
Range	0 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [TransactionBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	1M
Range	1K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF\\_FILESIZE](#) (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, [ZDATABUF\\_FILESIZE](#) (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Transaction resource allocation parameters.** The parameters in the following list are used to allocate transaction resources in the transaction coordinator (`DBTC`). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for [MaxDMLOperationsPerTransaction](#), [MaxNoOfConcurrentIndexOperations](#), [MaxNoOfConcurrentOperations](#), [MaxNoOfConcurrentScans](#), [MaxNoOfConcurrentTransactions](#), [MaxNoOfFiredTriggers](#), [MaxNoOfLocalScans](#), or [TransactionBufferMemory](#) (see [Transaction parameters](#) and [Transaction temporary storage](#)).

- [ReservedConcurrentIndexOperations](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of simultaneous index operations having dedicated resources on one data node.

- [ReservedConcurrentOperations](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.

- [ReservedConcurrentScans](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of simultaneous scans having dedicated resources on one data node.

- [ReservedConcurrentTransactions](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of simultaneous transactions having dedicated resources on one data node.

- [ReservedFiredTriggers](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of triggers that have dedicated resources on one ndbd(DB) node.

- [ReservedLocalScans](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Number of simultaneous fragment scans having dedicated resources on one data node.

- [ReservedTransactionBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.

- [TransactionMemory](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	bytes
Default	0
Range	0 - 16384G
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

**Important**

A number of configuration parameters are incompatible with `TransactionMemory`; it is not possible to set any of these parameters concurrently with `TransactionMemory`, and if you attempt to do so, the management server is unable to start (see [Parameters incompatible with TransactionMemory](#)).

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory is handled as follows:

- If `TransactionMemory` is set, this value is used for determining transaction memory.
- Otherwise, transaction memory is calculated as it was previous to NDB 8.0.

**Parameters incompatible with TransactionMemory.** The following parameters cannot be used concurrently with `TransactionMemory` and are therefore deprecated:

- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfLocalScans`

Explicitly setting any of the parameters just listed when `TransactionMemory` has also been set in the cluster configuration file (`config.ini`) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see [Section 25.4.3.13, “Data Node Memory Management”](#).

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000\*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `BatchSizePerLocalScan`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	256

Range	1 - 992
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

Deprecated.

[BatchSizePerLocalScan](#) has a strong connection to the [BatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	64M
Range	512K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- [MaxFKBuildBatchSize](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	64
Range	16 - 512
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- [MaxNoOfConcurrentScans](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	256
Range	2 - 500
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

- [MaxNoOfLocalScans](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	4 * MaxNoOfConcurrentScans * [# of data nodes] + 2
Range	32 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

$$4 * \text{MaxNoOfConcurrentScans} * [\# \text{ data nodes}] + 2$$

This parameter is deprecated and subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file (`config.ini`), the management server refuses to start.

- [MaxParallelCopyInstances](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 64
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, [MaxParallelCopyInstances](#) provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- [MaxParallelScansPerFragment](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	256
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

It is possible to configure the maximum number of parallel scans ([TUP](#) scans and [TUX](#) scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

- [MaxReorgBuildBatchSize](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	integer
Default	64
Range	16 - 512
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- [MaxUIBuildBatchSize](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	64
Range	16 - 512
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

## Memory Allocation

### [MaxAllocate](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	32M
Range	1M - 1G
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 9.7. It is deprecated and subject to removal in a future release.

## Multiple Transporters

NDB allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the [NodeGroupTransporters](#) parameter introduced in that release.

[NodeGroupTransporters](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 32
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting [NodeGroupTransporters](#) to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes [NDB](#) to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

## Hash Map Size

[DefaultHashMapSize](#)

Version (or later)	NDB 9.7.0
Type or units	LDM threads
Default	240
Range	0 - 3840
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with [DefaultHashMapSize](#) equal to 3840 is not currently supported.

**Logging and checkpointing.** The following [\[ndbd\]](#) parameters control log and checkpoint behavior.

- [FragmentLogFileSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	16M

Range	4M - 1G
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitialNoOfOpenFiles](#)

Version (or later)	NDB 9.7.0
Type or units	files
Default	27
Range	20 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [InitFragmentLogFiles](#)

Version (or later)	NDB 9.7.0
Type or units	[see values]
Default	SPARSE
Range	SPARSE, FULL
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- `SPARSE`. Fragment log files are created sparsely. This is the default value.
- `FULL`. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the redo log.

- `EnablePartialLcp`

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPS can be modified by the setting for the `RecoveryWork` configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- `LcpScanProgressTimeout`

Version (or later)	NDB 9.7.0
Type or units	second
Default	180
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the [LcpScanProgressTimeout](#) data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- [MaxNoOfOpenFiles](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	20 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [MaxNoOfSavedMessages](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	25
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	seconds
Default	0
Range	0 - 600
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[nbdb default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [NoOfFragmentLogFiles](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	16
Range	3 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively)

do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

**Important**

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `RecoveryWork`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	60
Range	25 - 100
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Percentage of storage overhead for LCP files. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for `RecoveryWork` means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting `RecoveryWork` to 60 means that the total size of an LCP is roughly  $1 + 0.6 = 1.6$  times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints.

(This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at  $1 + (1 / \text{RecoveryWork})$  times the rate of data changes during checkpoints—thus, when `RecoveryWork = 60`, it is necessary to write at approximately  $1 + (1 / 0.6) = 2.67$  times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork = 40` means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
$> gcc lcp_simulator.cc
$> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- [InsertRecoveryWork](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	40
Range	0 - 70
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- [EnableRedoControl](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

the cluster. (NDB 9.7.0)
--------------------------

Enable adaptive checkpointing speed for controlling redo log usage.

When enabled (the default), `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

When `NDB` is deployed on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs), the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained I/O subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors. Set `EnableRedoControl` to `false` to disable it in such situations. Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

#### Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	1000
Range	32 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * greatest\_number\_of\_attributes = 600$ .

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	128
Range	8 - 20320
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

**Note**

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfOrderedIndexes](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	128
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. [MaxNoOfOrderedIndexes](#) sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

**Note**

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfUniqueHashIndexes](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	64
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the [USING HASH](#) option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

**Note**

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfTriggers](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	768
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfSubscriptions](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Each [NDB](#) table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for [MaxNoOfSubscriptions](#) is 0, which is treated as equal to [MaxNoOfTables](#). Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

This parameter is of interest only when using NDB Cluster Replication. The default value is 0. It is treated as  $2 * \text{MaxNoOfTables} + 2 * [\text{number of API nodes}]$ . There is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to  $3 * \text{MaxNoOfTables}$ .

For more information, see [Section 25.7, “NDB Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	256
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [CompressedLCP](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- [CrashOnCorruptedTuple](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- [Diskless](#)

Version (or later)	NDB 9.7.0
Type or units	true false (1 0)
Default	false
Range	true, false
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless

tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

**Important**

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, NDB Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `EncryptedFileSystem`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 1
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

Encrypt LCP and tablespace files, including undo logs and redo logs. Disabled by default (0); set to 1 to enable.

**Important**

When file system encryption is enabled, you must supply a password to each data node when starting it, using one of the options `--filesystem-password` or `--filesystem-password-from-stdin`. Otherwise, the data node cannot start.

For more information, see [Section 25.6.19.4, “File System Encryption for NDB Cluster”](#).

- `LateAlloc`

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	1
Range	0 - 1
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 2
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. ([LockPagesInMainMemory](#) uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

#### Note

In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 9.7 treats `true` or `false` for the value of this parameter as an error.

#### Important

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory

could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show\\_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `ODirect`

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `ODirectSyncFlag`

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

- `RequireCertificate`

Version (or later)	NDB 9.7.0
Type or units	boolean

Default	false
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If this parameter is set to `true`, the data node looks for a key and a valid and current certificate in the TLS search path, and cannot start if it does not find them.

- [RequireTls](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If this parameter is set to `true`, connections to this data node must be authenticated using TLS.

- [RestartOnErrorInsert](#)

Version (or later)	NDB 9.7.0
Type or units	error code
Default	2
Range	0 - 4
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- [StopOnError](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	1
Range	0, 1

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and [StopOnError](#) is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when [StopOnError](#) equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- [UseShm](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of [\[ndbd\]](#) parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- [TimeBetweenWatchDogCheckInitial](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- [StartPartialTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	30000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If [StartPartitionedTimeout](#) is set to 0, the cluster waits indefinitely ( $2^{32}-1$  ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

- [StartFailureTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [StartNoNodeGroupTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	15000
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 25.6.7, "Adding NDB Cluster Data Nodes Online"](#), for more information.

- [HeartbeatIntervalDbDb](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	5000
Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- [HeartbeatIntervalDbApi](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	1500

Range	100 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	0
Range	0 - 65535
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers [host1](#) and [host2](#), and that these data nodes make up 2 node groups, as shown in the following table:

**Table 25.9 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.**

Node Group	Nodes Running on <code>host1</code>	Nodes Running on <code>host2</code>
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

**Table 25.10 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.**

Node	HeartbeatOrder Value
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- [TimeBetweenLocalCheckpoints](#)

Version (or later)	NDB 9.7.0
Type or units	number of 4-byte words, as base-2 logarithm
Default	20
Range	0 - 31
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	2000
Range	20 - 32000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

We recommend when you are using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that [MaxDiskDataLatency](#) is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenGlobalCheckpointsTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	120000
Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- [TimeBetweenEpochs](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	100
Range	0 - 32000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 256000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

Version (or later)	NDB 9.7.0
Type or units	epochs
Default	100
Range	0 - 100000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or

threads. (In rare circumstances, the problem may be due to a bug in the [NDB client](#).) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	26214400
Range	26214400 (0x01900000) - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	1000
Range	1000 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	4294967039 (0xFFFFFFFF)

Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	1200
Range	50 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes

Default	4M
Range	32K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

**Note**

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	20M
Range	1M - 1024G
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	50M
Range	1M - 1024G

Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)
--------------	--

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	200M
Range	1M - 1024G
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	10M
Range	1M - 1024G
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the

	cluster. (NDB 9.7.0)
--	----------------------

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters [MaxDiskWriteSpeed](#), [MaxDiskWriteSpeedOwnRestart](#), and [MaxDiskWriteSpeedOtherNodeRestart](#). See the descriptions of these parameters for more information.

- [ApiFailureHandlingTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	seconds
Default	600
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	

Specifies the maximum time (in seconds) that the data node waits for API node failure handling to complete before escalating it to data node failure handling.

- [ArbitrationTimeout](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	7500
Range	10 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

Version (or later)	NDB 9.7.0
Type or units	enumeration
Default	Default
Range	Default, Disabled, WaitExternal

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.
- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.
- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- `RestartSubscriberConnectTimeout`

Version (or later)	NDB 9.7.0
Type or units	ms
Default	12000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

- [KeepAliveSendInterval](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	60000
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

You can enable and control the interval between keep-alive signals sent between data nodes by setting this parameter. The default for [KeepAliveSendInterval](#) is 60000 milliseconds (one minute); setting it to 0 disables keep-alive signals. Values between 1 and 10 inclusive are treated as 10.

This parameter may prove useful in environments which monitor and disconnect idle TCP connections, possibly causing unnecessary data node failures when the cluster is idle.

The heartbeat interval between management nodes and data nodes is always 100 milliseconds, and is not configurable.

**Buffering and logging.** Several [\[ndbd\]](#) configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the [NDB](#) storage engine’s file system abstraction layer.

- [UndoIndexBuffer](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	2M
Range	1M - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter formerly set the size of the undo index buffer, but has no effect in current versions of NDB Cluster.

Use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

- [UndoDataBuffer](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	16M
Range	1M - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 8.0)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter formerly set the size of the undo data buffer, but has no effect in current versions of NDB Cluster.

Use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

- [RedoBuffer](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	32M
Range	1M - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 ([REDO log buffers overloaded](#)). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

[ndbmt\\_d](#) allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an [ndbmt\\_d](#) data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of  $4 * \text{RedoBuffer}$  bytes.

- [EventLogBufferSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	8192
Range	0 - 64K
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that no event reports in that category are made.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	1
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

Version (or later)	NDB 9.7.0
Type or units	log level
Default	0
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

Version (or later)	NDB 9.7.0
Type or units	level
Default	0
Range	0 - 15

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 15
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of `DataMemory`, as set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes.

nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 25.6.3.2, “NDB Cluster Log Events”](#).

- `StartupStatusReportFrequency`

Version (or later)	NDB 9.7.0
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see [Section 25.6.4, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

## Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- `DictTrace`

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	undefined
Range	0 - 100
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

It is possible to cause logging of traces for events generated by creating and dropping tables using [DictTrace](#). This parameter is useful only in debugging NDB kernel code. [DictTrace](#) takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional [DBDICT](#) debugging output.

- [WatchDogImmediateKill](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the [WatchDogImmediateKill](#) data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

**Backup parameters.** The [\[ndbd\]](#) parameters discussed in this section define memory buffers set aside for execution of online backups.

- [BackupDataBufferSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	16M
Range	512K - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 7.6)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as [BackupWriteSize](#), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- [BackupDiskWriteSpeedPct](#)

Version (or later)	NDB 9.7.0
Type or units	percent
Default	50
Range	0 - 90
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

[BackupDiskWriteSpeedPct](#) applies only when a backup is single-threaded; since NDB 9.7 supports multi-threaded backups, it is usually not necessary to adjust this parameter, which has no effect in the multi-threaded case. The discussion that follows is specific to single-threaded backups.

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by [MinDiskWriteSpeed](#) and [MaxDiskWriteSpeed](#). Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the [BackupDiskWriteSpeedPct](#) configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- [BackupLogBufferSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	16M
Range	2M - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must

be large enough to handle the load caused by write activities while the backup is being made. See [Section 25.6.8.3, “Configuration for NDB Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	32M
Range	0 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 7.4)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- [BackupReportFrequency](#)

Version (or later)	NDB 9.7.0
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	256K
Range	32K - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 7.6)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	1M
Range	256K - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 7.6)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

- [CompressedBackup](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- `RequireEncryptedBackup`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 1
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see [Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

**NDB Cluster Realtime Performance Parameters**

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.

- [BuildIndexThreads](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	128
Range	0 - 128
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmt.d`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- [LockExecuteThreadToCPU](#)

Version (or later)	NDB 9.7.0
Type or units	set of CPU IDs
Default	0
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt.d`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- [LockMaintThreadsToCPU](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	CPU ID
Default	0
Range	0 - 64K
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- [Numa](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	1
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmt.d`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmt.d`; this is because `ndbmt.d` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

- [RealtimeScheduler](#)

Version (or later)	NDB 9.7.0
Type or units	boolean

Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- [SchedulerExecutionTimer](#)

Version (or later)	NDB 9.7.0
Type or units	µs
Default	50
Range	0 - 11000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- [SchedulerResponsiveness](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	5
Range	0 - 10
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set the balance in the [NDB](#) scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- [SchedulerSpinTimer](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	µs
Default	0
Range	0 - 500
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

**Note**

If `SpinMethod` is set, any setting for this parameter is ignored.

- `SpinMethod`

Version (or later)	NDB 9.7.0
Type or units	enumeration
Default	StaticSpinning
Range	CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. `StaticSpinning` (default): Sets `EnableAdaptiveSpinning` to `false` and `SchedulerSpinTimer` to 0. (`SetAllowedSpinOverhead` is not relevant in this case.)
2. `CostBasedSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 100, and `SetAllowedSpinOverhead` to 200.
3. `LatencyOptimisedSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 200, and `SetAllowedSpinOverhead` to 1000.
4. `DatabaseMachineSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 500, and `SetAllowedSpinOverhead` to 10000. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by `SpinMethod` are described in the following list:

- `SchedulerSpinTimer`: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by `SpinMethod` overrides any value set in the `config.ini` file.

- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the `ndb_mgm` management client.
- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by `SpinMethod` should be satisfactory, but if it is necessary to change it directly, you can use `DUMP 104002 overhead` to do so, where `overhead` is a value ranging from 0 to 10000, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to 0 in all situations, and values for `SpinMethod` other than `StaticSpinning` are ignored.

- **TwoPassInitialNodeRestartCopy**

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (ndbmt).** `ndbmt` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method makes it possible to set up more complex rules for `ndbmt` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

**Note**

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more information, see [Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#), as well as [Restoring from a backup taken in parallel](#).

- **AutomaticThreadConfig**

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false

Range	true, false
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

When set to 1, enables automatic thread configuration employing the number of CPUs available to a data node taking into account any limits set by [taskset](#), [numactl](#), virtual machines, Docker, and other such means of controlling which CPUs are available to a given application (on Windows platforms, automatic thread configuration uses all CPUs which are online); alternatively, you can set [NumCPUs](#) to the desired number of CPUs (up to 1024, the maximum number of CPUs that can be handled by automatic thread configuration). Any settings for [ThreadConfig](#) and [MaxNoOfExecutionThreads](#) are ignored. In addition, enabling this parameter automatically disables [ClassicFragmentation](#).

- [ClassicFragmentation](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When enabled (set to [true](#)), NDB distributes fragments among LDMs such that the default number of partitions per node is equal to the minimum number of local data manager (LDM) threads per data node.

For new clusters, setting [ClassicFragmentation](#) to [false](#) when first setting up the cluster is preferable; doing so causes the number of partitions per node to be equal to the value of [PartitionsPerNode](#), ensuring that all partitions are spread out evenly between all LDMs.

This parameter and [AutomaticThreadConfig](#) are mutually exclusive; enabling [AutomaticThreadConfig](#) automatically disables [ClassicFragmentation](#).

- [EnableMultithreadedBackup](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	1
Range	0 - 1

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

Enables multi-threaded backup. If each data node has at least 2 LDMS, all LDM threads participate in the backup, which is created using one subdirectory per LDM thread, and each subdirectory containing `.ctl`, `.Data`, and `.log` backup files.

This parameter is normally enabled (set to 1) for `ndbmt.d`. To force a single-threaded backup that can be restored easily using older versions of `ndb_restore`, disable multi-threaded backup by setting this parameter to 0. This must be done for each data node in the cluster.

See [Section 25.6.8.5, "Taking an NDB Backup with Parallel Data Nodes"](#), and [Restoring from a backup taken in parallel](#), for more information.

- [MaxNoOfExecutionThreads](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	2
Range	2 - 72
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

This parameter directly controls the number of execution threads used by `ndbmt.d`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmt.d` and does not apply to `ndbd`.

Enabling `AutomaticThreadConfig` causes any setting for this parameter to be ignored.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/common/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

**Table 25.11** `MaxNoOfExecutionThreads` values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

<code>MaxNoOfExecutionThreads</code> Value	LDM Threads	TC Threads	Send Threads	Receive Threads
0 .. 3	1	0	0	1
4 .. 6	2	0	0	1
7 .. 8	4	0	0	1
9	4	2	0	1
10	4	2	1	1

NDB Cluster Configuration Files

MaxNoOfExecutionThreads Value	DM Threads	TC Threads	Send Threads	Receive Threads
11	4	3	1	1
12	6	2	1	1
13	6	3	1	1
14	6	3	1	2
15	6	3	2	2
16	8	3	1	2
17	8	4	1	2

69	32	18	8	9
70	32	19	8	9
71	32	20	8	9
72	32	20	8	10

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmt.d`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an `NDB` table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmt.d`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes.

See [Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the [DiskPageBufferMemory](#) configuration parameter, for more information.

The thread types are described later in this section (see [ThreadConfig](#)).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For [MaxNoOfExecutionThreads](#), a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

[MaxNoOfExecutionThreads](#) is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use [ThreadConfig](#) instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a [MaxNoOfExecutionThreads](#) value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or [ThreadConfig](#), but it is possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
  - The total number of table fragments is an integer multiple of the number of LDM threads.
- [MaxSendDelay](#)

Version (or later)	NDB 9.7.0
Type or units	microseconds
Default	0
Range	0 - 11000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

This parameter can be used to cause data nodes to wait momentarily before sending data to API nodes; in some circumstances, described in the following paragraphs, this can result in more efficient sending of larger volumes of data and higher overall throughput.

[MaxSendDelay](#) can be useful when there are a great many API nodes at saturation point or close to it, which can result in waves of increasing and decreasing performance. This occurs when the data nodes are able to send results back to the API nodes relatively quickly, with many small packets to process, which can take longer to process per byte compared to large packets, thus slowing down the API nodes; later, the data nodes start sending larger packets again.

To handle this type of scenario, you can set [MaxSendDelay](#) to a nonzero value, which helps to ensure that responses are not sent back to the API nodes so quickly. When this is done, responses are sent immediately when there is no other competing traffic, but when there is, setting [MaxSendDelay](#) causes the data nodes to wait long enough to ensure that they send larger packets. In effect, this introduces an artificial bottleneck into the send process, which can actually improve throughput significantly.

- [NoOfFragmentLogParts](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	4
Range	4, 6, 8, 10, 12, 16, 20, 24, 32
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial.</code> (NDB 9.7.0)

Set the number of log file groups for redo logs belonging to this [ndbmysd](#). The value of this parameter should be set equal to the number of LDM threads used by [ndbmysd](#) as determined by the setting for [MaxNoOfExecutionThreads](#). A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of [MaxNoOfExecutionThreads](#) for more information.

- [NumCPUs](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 1024
Restart Type	<b>Initial System Restart:</b> Requires a complete

	shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)
--	--

Cause automatic thread configuration to use only this many CPUs. Has no effect if [AutomaticThreadConfig](#) is not enabled.

- [PartitionsPerNode](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	2
Range	1 - 32
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Sets the number of partitions used on each node when creating a new [NDB](#) table. This makes it possible to avoid splitting up tables into an excessive number of partitions when the number of local data managers (LDMs) grows high.

While it is possible to set this parameter to different values on different data nodes and there are no known issues with doing so, this is also not likely to be of any advantage; for this reason, it is recommended simply to set it once, for all data nodes, in the [\[ndbd default\]](#) section of the global [config.ini](#) file.

If [ClassicFragmentation](#) is enabled, any setting for this parameter is ignored. (Remember that enabling [AutomaticThreadConfig](#) disables [ClassicFragmentation](#).)

- [ThreadConfig](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	"
Range	...
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the

cluster. (NDB 9.7.0)
----------------------

This parameter is used with `ndbmt` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type := ldm | query | recover | main | recv | send | rep | io | tc | watchdog | idxbld
param := count=number
| cpubind=cpu_list
| cpuset=cpu_list
| spintime=number
| realtime={0|1}
| nosend={0|1}
| thread_prio={0..10}
| cpubind_exclusive=cpu_list
| cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`. `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

`spintime` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

`realtime` cannot be set for offline index build threads.

- By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

- `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread\_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD:* We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

**Table 25.12 Mapping of thread\_prio to nice values on Linux and FreeBSD**

<code>thread_prio</code> value	<code>nice</code> value
0	19
1	16
2	12
3	8
4	4
5	0
6	-4
7	-8
8	-12
9	-16
10	-20

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

- *Solaris:* Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

**Table 25.13 Mapping of thread\_prio to FX priority on Solaris**

<code>thread_prio</code> value	Solaris FX priority
0	15
1	20
2	25
3	30
4	35
5	40
6	45
7	50

<code>thread_prio</code> value	Solaris <b>FX</b> priority
8	55
9	59
10	60

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows:** We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

**Table 25.14 Mapping of `thread_prio` to Windows thread priority**

<code>thread_prio</code> value	Windows thread priority
0 - 1	<code>THREAD_PRIORITY_LOWEST</code>
2 - 3	<code>THREAD_PRIORITY_BELOW_NORMAL</code>
4 - 5	<code>THREAD_PRIORITY_NORMAL</code>
6 - 7	<code>THREAD_PRIORITY_ABOVE_NORMAL</code>
8 - 10	<code>THREAD_PRIORITY_HIGHEST</code>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- **ldm:** Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes.

When `ClassicFragmentation` is set to 0, the number of partitions is independent of the number of LDM threads, and depends on the value of `PartitionsPerNode` instead.) Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. `ldm` can be set to any value in the range 0 to 332 inclusive. When setting it to 0, `main`, `rep`, and `tc` must also be 0, and `recv` must also be set to 1; doing this causes `ndbmt` to emulate `ndbd`.

Each LDM thread is normally grouped with 1 query thread to form an LDM group. A set of 4 to 8 LDM groups is grouped into a round robin groups. Each LDM thread can be assisted in execution by any query or threads in the same round robin group. NDB attempts to form round robin groups such that all threads in each round robin group are locked to CPUs that are attached to the same L3 cache, within the limits of the range stated for a round robin group's size.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations; this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using `MaxNoOfExecutionThreads`.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

If `ldm` is not included in the `ThreadConfig` value string, one `ldm` thread is created.

- **query:** A query thread is tied to an LDM and together with it forms an LDM group; acts only on `READ COMMITTED` queries. The number of query threads must be set to 0, 1, 2, or 3 times the number of

LDM threads. Query threads are not used, unless this is overridden by setting `query` to a nonzero value, or by enabling the `AutomaticThreadConfig` parameter.

A query thread also acts as a recovery thread (see next item), although the reverse is not true.

Changing the number of query threads requires a node restart.

- `recover`: A recovery thread restores data from a fragment as part of an LCP.

Changing the number of recovery threads requires a node restart.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 128.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0-64

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. It is also possible to specify zero or two main threads.

Range: 0-2.

Setting `main` to 0 and `rep` to 1 causes the `main` blocks to be placed into the `rep` thread; the combined thread is shown in the `ndbinfo.threads` table as `main_rep`. This is effectively the same as setting `rep` equal to 1 and `main` equal to 0.

It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

If `main` is omitted from the `ThreadConfig` value string, one `main` thread is created.

- `recv`: Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range: 1 - 64.

If `recv` is omitted from the `ThreadConfig` value string, one `recv` thread is created.

- `send`: Send thread (`CMVMI` kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

Using an excessive number of send threads can have an adverse effect on scalability.

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less

than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range:

- 0 - 64
- `rep`: Replication thread (`SUMA` kernel block). This thread can also be combined with the main thread (see range information).

Range: 0-1.

Setting `rep` to 0 and `main` to 1 causes the `rep` blocks to be placed into the `main` thread; the combined thread is shown in the `ndbinfo.threads` table as `main_rep`. This is effectively the same as setting `main` equal to 1 and `rep` equal to 0.

It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

If `rep` is omitted from the `ThreadConfig` value string, one `rep` thread is created.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

- `watchdog`: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

- `idxbld`: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.

- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:
  - a. Each LDM thread handles a maximum of 8 fragments, and
  - b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

NDB can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `query`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `recover`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the

group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}

ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	64MB
Range	4MB - 16TB
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to

increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- [DiskPageBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	64M
Range	4M - 16T
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This determines the amount of space, in bytes, used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file.

If the value for [DiskPageBufferMemory](#) is set too low in conjunction with using more than the default number of LDM threads in [ThreadConfig](#) (for example `{ldm=6...}`), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase [DiskPageBufferMemory](#), or add smaller tablespace files. You may also need to adjust [DiskPageBufferEntries](#).

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 25.6.15.31, "The ndbinfo diskpagebuffer Table"](#), for more information.

- [SharedGlobalMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	128M
Range	0 - 64T
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. [SharedGlobalMemory](#) can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is [128M](#).

- [DiskIOThreadPool](#)

Version (or later)	NDB 9.7.0
Type or units	threads
Default	2
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter determines the number of unbound threads used for Disk Data file access. Before [DiskIOThreadPool](#) was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With [DiskIOThreadPool](#), you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can (and should) set [DiskIOThreadPool](#) higher to enable separate threads to handle the files on each disk.

You should also disable [DiskDataUsingSameDisk](#) when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for [DiskIOThreadPool](#).

Decreasing [TimeBetweenGlobalCheckpoints](#) is also recommended when using solid-state disk drives, in particular those using NVMe. See also [Disk Data latency parameters](#).

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.
- [FileSystemPathDD](#)

Version (or later)	NDB 9.7.0
Type or units	filename

Default	FileSystemPath
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

Version (or later)	NDB 9.7.0
Type or units	filename
Default	FileSystemPathDD
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- [FileSystemPathUndoFiles](#)

Version (or later)	NDB 9.7.0
Type or units	filename
Default	FileSystemPathDD
Range	...
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for [FileSystemPathDD](#). This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If [FileSystemPathUndoFiles](#) is not specified, then [FileSystemPathDD](#) is used (or [FileSystemPath](#), if [FileSystemPathDD](#) has also not been set).

If a [FileSystemPathUndoFiles](#) directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 25.6.11.1, “NDB Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- [InitialLogFileGroup](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[see documentation]
Range	...
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the

	cluster. (NDB 9.7.0)
--	----------------------

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;) [undo_buffer_size=size;) file-specification-list

file-specification-list:
    file-specification[; file-specification[; ...]]

file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[nbdb default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- [InitialTablespace](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[see documentation]
Range	...
Restart Type	<b>System Restart:</b> Requires a

	complete shutdown and restart of the cluster. (NDB 9.7.0)
--	---

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.
  - `MaxDiskDataLatency`

Version (or later)	NDB 9.7.0
Type or units	ms
Default	0
Range	0 - 8000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a>

	of the cluster. (NDB 9.7.0)
--	--------------------------------

This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, NDB begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use 0 to disable the latency check.

- [DiskDataUsingSameDisk](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set this parameter to `false` if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When [DiskDataUsingSameDisk](#) is `true`, NDB decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of [TimeBetweenGlobalCheckpoints](#) tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for [DiskPageBufferMemory](#) as explained previously, it is also very important that the [DiskIOThreadPool](#) configuration parameter be set correctly; having [DiskIOThreadPool](#) set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the [TimeBetweenEpochsTimeout](#) data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The [TotalSendBufferMemory](#) and [OverLoadLimit](#) data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as [SendBufferMemory](#)), see [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [ExtraSendBufferMemory](#)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [TotalSendBufferMemory](#)

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

See also [Section 25.6.7, “Adding NDB Cluster Data Nodes Online”](#).

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by [DefaultOperationRedoProblemAction](#). The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- [RedoOverCommitCounter](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	3
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When [RedoOverCommitLimit](#) is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for [DefaultOperationRedoProblemAction](#) (by either queuing the operations to be re-tried, or aborting them).

- [RedoOverCommitLimit](#)

Version (or later)	NDB 9.7.0
Type or units	seconds
Default	20
Range	1 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a

	<a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--	---

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than [RedoOverCommitLimit](#), is kept and compared with [RedoOverCommitCounter](#), and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its [DefaultOperationRedoProblemAction](#) setting (it either queues the operations to be re-tried, or aborts them).

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the [MaxStartFailRetries](#) and [StartFailRetryDelay](#) data node configuration parameters.

[MaxStartFailRetries](#) limits the total number of retries made before giving up on starting the data node, [StartFailRetryDelay](#) sets the number of seconds between retry attempts. These parameters are listed here:

- [StartFailRetryDelay](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and [MaxStartFailRetries](#) are ignored unless [StopOnError](#) is equal to 0.

- [MaxStartFailRetries](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	3
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and [StartFailRetryDelay](#) are ignored unless [StopOnError](#) is equal to 0.

**NDB index statistics parameters.** The parameters in the following list relate to NDB index statistics generation.

- [IndexStatAutoCreate](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	1
Range	0, 1
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created.

- [IndexStatAutoUpdate](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	1
Range	0, 1
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes, and trigger automatic statistics updates when these are detected. The degree of change needed to trigger the updates are determined by the settings for the [IndexStatTriggerPct](#) and [IndexStatTriggerScale](#) options.

- [IndexStatSaveSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	32768
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a

	<a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)
--	---

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the `mysqld` memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatSaveScale`

Version (or later)	NDB 9.7.0
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code> . (NDB 9.7.0)

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

Version (or later)	NDB 9.7.0
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must

	be restarted with <code>--initial.</code> (NDB 9.7.0)
--	---

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- `IndexStatTriggerScale`

Version (or later)	NDB 9.7.0
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial.</code> (NDB 9.7.0)

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- `IndexStatUpdateDelay`

Version (or later)	NDB 9.7.0
Type or units	seconds
Default	60
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Initial Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial.</code> (NDB 9.7.0)

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.15 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

#### Note

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

- `Id`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 255
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144.

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- `ConnectionMap`

Version (or later)	NDB 9.7.0
Type or units	string
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Specifies which data nodes to connect.

- `NodeId`

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	1 - 255
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144.

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- [ExecuteOnComputer](#)

Version (or later)	NDB 9.7.0
Type or units	name
Default	[...]
Range	...
Deprecated	Yes (in NDB 7.5)
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- 

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes.

- [HostName](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. Use `HostName` to specify a host name other than `localhost`.

If no `HostName` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- `LocationDomainId`

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 16
Restart Type	<b>System Restart:</b> Requires a complete shutdown and restart of the cluster. (NDB 9.7.0)

Assigns an SQL or other API node to a specific `availability domain` (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `ArbitrationRank`

Version (or later)	NDB 9.7.0
Type or units	0-2
Default	0
Range	0 - 2

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the [Arbitration](#) parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- [ArbitrationDelay](#)

Version (or later)	NDB 9.7.0
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	16K
Range	1K - 1M
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms

of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- [BatchSize](#)

Version (or later)	NDB 9.7.0
Type or units	records
Default	256
Range	1 - 992
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- [ExtraSendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [HeartbeatThreadPriority](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of

	the cluster. (NDB 9.7.0)
--	--------------------------

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
```

```
policy:  
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	256K
Range	32K - 16M
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see [Ndb\\_cluster\\_connection::set\\_auto\\_reconnect\(\)](#), and [Ndb\\_cluster\\_connection::get\\_auto\\_reconnect\(\)](#).

- [DefaultOperationRedoProblemAction](#)

Version (or later)	NDB 9.7.0
Type or units	enumeration
Default	QUEUE
Range	ABORT, QUEUE
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter (along with [RedoOverCommitLimit](#) and [RedoOverCommitCounter](#)) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of [DefaultOperationRedoProblemAction](#), listed here:

- **ABORT:** Any pending operations from aborted transactions are also aborted.
- **QUEUE:** Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when [P\\_TAIL\\_PROBLEM](#) errors occur.

- [DefaultHashMapSize](#)

Version (or later)	NDB 9.7.0
--------------------	-----------

Type or units	buckets
Default	3840
Range	0 - 3840
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The size of the table hash maps used by NDB is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

**Table 25.16 DefaultHashMapSize parameter values**

Value	Description / Effect
0	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
240	Old default hash map size
3840	Hash map size used by default in NDB 9.7

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible.

- [Wan](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Use WAN TCP setting as default.

- [ConnectBackoffMaxTime](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [ConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

- [StartConnectBackoffMaxTime](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [StartConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** You can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also [DUMP 1229](#).

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 198.51.100.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see [NDB Cluster Status Variables](#).

#### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.17 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.8 Defining the System

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNNode`

are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- [ConfigGenerationNumber](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Configuration generation number. This parameter is currently unused.

- [Name](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- [PrimaryMGMNode](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Node ID of the primary management node. This parameter is currently unused.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.18 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see [Section 7.1, “The MySQL Server”](#).

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 25.4, “Configuration of NDB Cluster”](#).

#### MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see [Section 7.1.7, “Server Command Options”](#).

For information about command-line options used with other NDB Cluster processes, see [Section 25.5, “NDB Cluster Programs”](#).

- `--ndbcluster`

Command-Line Format	<code>--ndbcluster[=value]</code>
Disabled by	<code>skip-ndbcluster</code>
Type	Enumeration
Default Value	ON
Valid Values	OFF FORCE

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table={ON|OFF}`

Command-Line Format	<code>--ndb-allow-copying-alter-table[={OFF ON}]</code>
System Variable	<code>ndb_allow_copying_alter_table</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-applier-allow-skip-epoch`

Command-Line Format	<code>--ndb-applier-allow-skip-epoch</code>
System Variable	<code>ndb_applier_allow_skip_epoch</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Use together with `--replica-skip-errors` to cause NDB to ignore skipped epoch transactions. Has no effect when used alone.

- `--ndb-batch-size=#`

Command-Line Format	<code>--ndb-batch-size</code>
System Variable	<code>ndb_batch_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>32768</code>
Minimum Value	<code>0</code>
Maximum Value	<code>2147483648</code>
Unit	bytes

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

Command-Line Format	<code>--ndb-cluster-connection-pool</code>
System Variable	<code>ndb_cluster_connection_pool</code>
System Variable	<code>ndb_cluster_connection_pool</code>
Scope	Global

Scope	Global
Dynamic	No
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	63

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

#### Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

Command-Line Format	<code>--ndb-cluster-connection-pool-nodeids</code>
System Variable	<code>ndb_cluster_connection_pool_nodeids</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=bytes`

Command-Line Format	<code>--ndb-blob-read-batch-bytes</code>
System Variable	<code>ndb_blob_read_batch_bytes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	65536
Minimum Value	0
Maximum Value	4294967295

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

#### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

Command-Line Format	<code>--ndb-blob-write-batch-bytes</code>
System Variable	<code>ndb_blob_write_batch_bytes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	65536
Minimum Value	0
Maximum Value	4294967295

Unit	bytes
------	-------

This option can be used to set the size (in bytes) for batching of **BLOB** data writes in NDB Cluster applications. When this batch size is exceeded by the amount of **BLOB** data to be written within the current transaction, any pending **BLOB** write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling **BLOB** write batching.

**Note**

In NDB API applications, you can control **BLOB** write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=connection_string`

Command-Line Format	<code>--ndb-connectstring</code>
Type	String

When using the **NDBCLUSTER** storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), for syntax.

- `--ndb-default-column-format={FIXED|DYNAMIC}`

Command-Line Format	<code>--ndb-default-column-format={FIXED DYNAMIC}</code>
System Variable	<code>ndb_default_column_format</code>
Scope	Global
Dynamic	Yes
<b>SET_VAR</b> Hint Applies	No
Type	Enumeration
Default Value	<code>FIXED</code>
Valid Values	<code>FIXED</code> <code>DYNAMIC</code>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 15.1.24, “CREATE TABLE Statement”](#)). The default is `FIXED`.

- `--ndb-deferred-constraints={0|1}`

Command-Line Format	<code>--ndb-deferred-constraints</code>
System Variable	<code>ndb_deferred_constraints</code>
Scope	Global, Session
Dynamic	Yes
<b>SET_VAR</b> Hint Applies	No
Type	Integer

## NDB Cluster Configuration Files

Default Value	0
Minimum Value	0
Maximum Value	1

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-schema-dist-timeout=#`

Command-Line Format	<code>--ndb-schema-dist-timeout=#</code>
System Variable	<code>ndb_schema_dist_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	120
Minimum Value	5
Maximum Value	1200
Unit	seconds

Specifies the maximum time in seconds that this `mysqld` waits for a schema operation to complete before marking it as having timed out.

- `--ndb-distribution=[KEYHASH|LINHASH]`

Command-Line Format	<code>--ndb-distribution={KEYHASH LINHASH}</code>
System Variable	<code>ndb_distribution</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	KEYHASH
Valid Values	LINHASH KEYHASH

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-log-apply-status`

Command-Line Format	<code>--ndb-log-apply-status[={OFF ON}]</code>
System Variable	<code>ndb_log_apply_status</code>
Scope	Global

Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

Command-Line Format	<code>--ndb-log-empty-epochs[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_epochs</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

Command-Line Format	<code>--ndb-log-empty-update[={OFF ON}]</code>
System Variable	<code>ndb_log_empty_update</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Type	Boolean
Default Value	OFF

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads={0|1}`

Command-Line Format	<code>--ndb-log-exclusive-reads[={OFF ON}]</code>
System Variable	<code>ndb_log_exclusive_reads</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	0

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see [Read conflict detection and resolution](#).

- `--ndb-log-fail-terminate`

Command-Line Format	<code>--ndb-log-fail-terminate</code>
System Variable	<code>ndb_log_fail_terminate</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	FALSE

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

- `--ndb-log-orig`

Command-Line Format	<code>--ndb-log-orig[={OFF ON}]</code>
System Variable	<code>ndb_log_orig</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see [Section 25.7.4, “NDB Cluster Replication Schema and Tables”](#).

- `--ndb-log-row-slice-count`

Command-Line Format	<code>--ndb-log-row-slice-count=#</code>
System Variable	<code>ndb_log_row_slice_count</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	256

Sets the number of slices (*count*) used by this server when subscribing to NDB table change event streams used for writing binary logs. If this *count* is greater than 1, the stream of change events for a given table is divided into  $1 / \textit{count}$  logical slices. Each `mysqld` performing binary logging can subscribe to one slice (as determined by `--ndb-log-row-slice-id`), receiving  $100 / \textit{count}$  percent of the changes for each affected table.

This option cannot be set at runtime; the corresponding `ndb_log_row_slice_count` system variable is read-only.

- `--ndb-log-row-slice-id`

Command-Line Format	<code>--ndb-log-row-slice-id=#</code>
System Variable	<code>ndb_log_row_slice_id</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	255

Specifies the ID of the virtual slice of the NDB table change event streams this server subscribes to. The *effective* maximum ID value is `--ndb-log-row-slice-count - 1`. Suppose there are four MySQL servers, all with binary logging enabled and attached to the same NDB Cluster, which we label A, B, C, and D. We can cause each `mysqld` to log one of four equally-sized slices of the table change event stream, by specifying `--ndb-log-row-slice-count=4` when starting each `mysqld`. For

each `mysqld`, we can specify which of the four slices to log using the `--ndb-log-row-slice-id` option, starting with 0 for server A. Using the two options together in this way results in the following four invocations of `mysqld`:

```
A$> mysqld --ndb-log-row-slice-count=4 --ndb-log-row-slice-id=0
B$> mysqld --ndb-log-row-slice-count=4 --ndb-log-row-slice-id=1
C$> mysqld --ndb-log-row-slice-count=4 --ndb-log-row-slice-id=2
D$> mysqld --ndb-log-row-slice-count=4 --ndb-log-row-slice-id=3
```

In addition to providing scaleout capability for binary logging, it is also possible to establish redundant sets of MySQL servers. Using the same four servers A, B, C, and D from the previous example, we can instead create two groups of two servers each, each group splitting the changes to be logged into two parts, by starting the servers as shown here:

```
A$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=0
B$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=1
C$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=0
D$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=1
```

Here, servers A and B split the binary log, and servers C and D do so as well. It is also possible to leverage redundancy for scaleout while maintaining the redundancy. Consider a setup with two MySQL servers started as shown here:

```
A$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=0
B$> mysqld --ndb-log-row-slice-count=2 --ndb-log-row-slice-id=1
```

A second set of servers does not have to be the same size as the first. You can start a second set which consists of three servers D, E, and F, like this:

```
D$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=0
E$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=1
F$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=2
```

Now that the second set is writing a complete copy of the binary log between its three members, you can restart servers A and B, and start another server C (assumed not to be running already), as shown here:

```
A$> mysqladmin shutdown
A$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=0
B$> mysqladmin shutdown
B$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=1
C$> mysqld --ndb-log-row-slice-count=3 --ndb-log-row-slice-id=2
```

This option cannot be set at runtime; the corresponding `ndb_log_row_slice_id` system variable is read-only.

It is also possible to control binary logging in this fashion, but on a per-table basis, using the `mysql.ndb_replication` table. See [ndb\\_replication Table](#), for more information.

- `--ndb-log-transaction-dependency`

Command-Line Format	<code>--ndb-log-transaction-dependency={true false}</code>
System Variable	<code>ndb_log_transaction_dependency</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>false</code>

Causes the NDB binary logging thread to calculate transaction dependencies for each transaction which it writes to the binary log. The default value is `FALSE`.

This option cannot be set at runtime; the corresponding `ndb_log_transaction_dependency` system variable is read-only.

- `--ndb-log-transaction-id`

Command-Line Format	<code>--ndb-log-transaction-id[={OFF ON}]</code>
System Variable	<code>ndb_log_transaction_id</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

`--ndb-log-transaction-id` is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`). For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `--ndb-log-update-as-write`

Command-Line Format	<code>--ndb-log-update-as-write[={OFF ON}]</code>
System Variable	<code>ndb_log_update_as_write</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

Whether updates on the source are written to the binary log as updates (**OFF**) or writes (**ON**). When this option is enabled, and both `--ndb-log-updated-only` and `--ndb-log-update-minimal` are disabled, operations of different types are logged as described in the following list:

- **INSERT**: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- **UPDATE**: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- **DELETE**: Logged as a `DELETE_ROW` event with all columns logged in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see [ndb\\_replication Table](#), for more information.

- `--ndb-log-updated-only`

Command-Line Format	<code>--ndb-log-updated-only[={OFF ON}]</code>
System Variable	<code>ndb_log_updated_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Whether `mysqld` writes updates only (**ON**) or complete rows (**OFF**) to the binary log. When this option is enabled, and both `--ndb-log-update-as-write` and `--ndb-log-update-minimal` are disabled, operations of different types are logged as described in the following list:

- **INSERT**: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- **UPDATE**: Logged as an `UPDATE_ROW` event with primary key columns and updated columns present in both the before and after images.
- **DELETE**: Logged as a `DELETE_ROW` event with primary key columns included in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see [ndb\\_replication Table](#), for more information about how these options interact with one another.

- `--ndb-log-update-minimal`

Command-Line Format	<code>--ndb-log-update-minimal[={OFF ON}]</code>
System Variable	<code>ndb_log_update_minimal</code>
Scope	Global
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than `NDB`. When this option is enabled, and both `--ndb-log-updated-only` and `--ndb-log-update-as-write` are disabled, operations of different types are logged as described in the following list:

- `INSERT`: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- `UPDATE`: Logged as an `UPDATE_ROW` event with primary key columns in the before image; all columns *except* primary key columns are logged in the after image.
- `DELETE`: Logged as a `DELETE_ROW` event with all columns in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see [ndb\\_replication Table](#), for more information.

- `--ndb-mgm-tls=[relaxed|strict]`

Command-Line Format	<code>--ndb-mgm-tls=[strict relaxed]</code>
System Variable	<code>ndb_mgm_tls</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required for TLS connections to NDB Cluster; the value is one of `relaxed` or `strict`. `relaxed` means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect. The default is `relaxed`.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	<code>--ndb-mgmd-host=host_name[:port_num]</code>
Type	String
Default Value	<code>localhost:1186</code>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Command-Line Format	<code>--ndb-nodeid=#</code>
Status Variable	<code>Ndb_cluster_node_id</code>
Scope	Global
Dynamic	No
Type	Integer
Default Value	N/A
Minimum Value	1
Maximum Value	255
Maximum Value	63

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, it is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `--ndbinfo={ON|OFF|FORCE}`

Command-Line Format	<code>--ndbinfo[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON OFF FORCE

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.

- `--ndb-optimization-delay=milliseconds`

Command-Line Format	<code>--ndb-optimization-delay=#</code>
System Variable	<code>ndb_optimization_delay</code>
Scope	Global
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	100000
Unit	milliseconds

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
System Variable	<code>ndb_optimized_node_selection</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	3

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `ndb-tls-search-path=path`

Command-Line Format	<code>--ndb-tls-search-path=path</code>
System Variable	<code>ndb_tls_search_path</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Path name
Default Value (Unix)	<code>\$HOME/tls</code>
Default Value (Windows)	<code>%HOMEDIR%/tls</code>

List of directories to search for CAs and private keys for NDB TLS connections. The list is comma-delimited on Unix platforms and semicolon-delimited on Windows.

- `--ndb-transid-mysql-connection-map=state`

Command-Line Format	<code>--ndb-transid-mysql-connection-map[=state]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON

	OFF
	FORCE

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

Command-Line Format	<code>--ndb-wait-connected=#</code>
System Variable	<code>ndb_wait_connected</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	120
Default Value	30
Minimum Value	0
Maximum Value	31536000
Unit	seconds

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- `--ndb-wait-setup=seconds`

Command-Line Format	<code>--ndb-wait-setup=#</code>
System Variable	<code>ndb_wait_setup</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	120
Default Value	30
Default Value	15
Default Value	15
Minimum Value	0
Maximum Value	31536000

Unit	seconds
------	---------

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 30.

- `--skip-ndbcluster`

Command-Line Format	<code>--skip-ndbcluster</code>
---------------------	--------------------------------

Disable the NDBCLUSTER storage engine. This is the default for binaries that were built with NDBCLUSTER storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 25.4.1, “Quick Test Setup of NDB Cluster”](#), for an example.

## NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see [Section 7.1.8, “Server System Variables”](#). For general information on using system variables, see [Section 7.1.9, “Using System Variables”](#).

- `ndb_autoincrement_prefetch_sz`

Command-Line Format	<code>--ndb-autoincrement-prefetch-sz=#</code>
System Variable	<code>ndb_autoincrement_prefetch_sz</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	512
Minimum Value	1
Maximum Value	65536

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of AUTO\_INCREMENT IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

### Important

This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_clear_apply_status`

Command-Line Format	<code>--ndb-clear-apply-status[={OFF ON}]</code>
System Variable	<code>ndb_clear_apply_status</code>
Scope	Global <span style="float: right;">4469</span>

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

By the default, executing `RESET REPLICAS` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- [ndb\\_conflict\\_role](#)

Command-Line Format	<code>--ndb-conflict-role=value</code>
System Variable	<code>ndb_conflict_role</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	NONE
Valid Values	NONE  PRIMARY  SECONDARY  PASS

Determines the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The replica SQL thread must be stopped before you can change `ndb_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_conflict_role = 'NONE'` first.

This variable replaces the deprecated `ndb_slave_conflict_role`.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- [ndb\\_data\\_node\\_neighbour](#)

Command-Line Format	<code>--ndb-data-node-neighbour=#</code>
System Variable	<code>ndb_data_node_neighbour</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value	255
---------------	-----

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See [Section 15.1.24.12, “Setting NDB Comment Options”](#), for further information.

**Note**

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- `ndb_dbg_check_shares`

Command-Line Format	<code>--ndb-dbg-check-shares=#</code>
System Variable	<code>ndb_dbg_check_shares</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When set to 1, check that no shares are lingering. Available in debug builds only.

- `ndb_default_column_format`

Command-Line Format	<code>--ndb-default-column-format={FIXED DYNAMIC}</code>
System Variable	<code>ndb_default_column_format</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>FIXED</code>
Valid Values	<code>FIXED</code> <code>DYNAMIC</code>

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 15.1.24, “CREATE TABLE Statement”](#)). The default is `FIXED`.

- [ndb\\_deferred\\_constraints](#)

Command-Line Format	<code>--ndb-deferred-constraints=#</code>
System Variable	<code>ndb_deferred_constraints</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- [ndb\\_distribution](#)

Command-Line Format	<code>--ndb-distribution={KEYHASH LINHASH}</code>
System Variable	<code>ndb_distribution</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	KEYHASH
Valid Values	LINHASH KEYHASH

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- [ndb\\_eventbuffer\\_free\\_percent](#)

Command-Line Format	<code>--ndb-eventbuffer-free-percent=#</code>
System Variable	<code>ndb_eventbuffer_free_percent</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	1

Maximum Value	99
---------------	----

Sets the percentage of the maximum memory allocated to the event buffer (`ndb_eventbuffer_max_alloc`) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- [ndb\\_eventbuffer\\_max\\_alloc](#)

Command-Line Format	<code>--ndb-eventbuffer-max-alloc=#</code>
System Variable	<a href="#">ndb_eventbuffer_max_alloc</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	9223372036854775807

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- [ndb\\_extra\\_logging](#)

Command-Line Format	<code>ndb_extra_logging=#</code>
System Variable	<a href="#">ndb_extra_logging</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	1

This variable enables recording in the MySQL error log of information specific to the [NDB](#) storage engine.

When this variable is set to 0, the only information specific to [NDB](#) that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, [NDB](#) table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other [NDB](#) errors and information. If the value is set to 10 or more, information about [NDB](#) internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- [ndb\\_force\\_send](#)

Command-Line Format	<code>--ndb-force-send[={OFF ON}]</code>
System Variable	<a href="#">ndb_force_send</a>
Scope	Global, Session
Dynamic	Yes

SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- `ndb_fully_replicated`

Command-Line Format	<code>--ndb-fully-replicated[={OFF ON}]</code>
System Variable	<code>ndb_fully_replicated</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 15.1.24.12, "Setting NDB Comment Options"](#), for syntax and other information.

- `ndb_index_stat_enable`

Command-Line Format	<code>--ndb-index-stat-enable[={OFF ON}]</code>
System Variable	<code>ndb_index_stat_enable</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Use NDB index statistics in query optimization. The default is ON.

The index statistics tables are always created when the server starts, regardless of this option's value.

- `ndb_index_stat_option`

Command-Line Format	<code>--ndb-index-stat-option=value</code>
System Variable	<code>ndb_index_stat_option</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>loop_checkon=1000ms,loop_idle=1000ms,loop_busy=update_batch=1,read_batch=4,idle_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,err</code>

```
error_delay=1m,evict_batch=8,evict_delay=1m,
cache_lowpct=90
```

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

**Table 25.19 ndb\_index\_stat\_option options and values**

Name	Description	Default/Units	Minimum/Maximum
<code>loop_enable</code>		1000 ms	0/4G
<code>loop_idle</code>	Time to sleep when idle	1000 ms	0/4G
<code>loop_busy</code>	Time to sleep when more work is waiting	100 ms	0/4G
<code>update_batch</code>		1	0/4G
<code>read_batch</code>		4	1/4G
<code>idle_batch</code>		32	1/4G
<code>check_batch</code>		8	1/4G
<code>check_delay</code>	How often to check for new statistics	10 m	1/4G
<code>delete_batch</code>		8	0/4G
<code>clean_delay</code>		1 m	0/4G
<code>error_batch</code>		4	1/4G
<code>error_delay</code>		1 m	1/4G
<code>evict_batch</code>		8	1/4G
<code>evict_delay</code>	Clean LRU cache, from read time	1 m	0/4G
<code>cache_limit</code>	Maximum amount of memory in bytes used for cached index statistics by this <code>mysqld</code> ; clean up the cache when this is exceeded.	32 M	0/4G
<code>cache_lowpct</code>		90	0/100

Name	Description	Default/Units	Minimum/Maximum
<code>zero_total</code>	Setting this to 1 resets all accumulating counters in <code>ndb_index_stat_status</code> to 0. This option value is also reset to 0 when this is done.	0	0/1

- `ndb_join_pushdown`

System Variable	<code>ndb_join_pushdown</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This variable controls whether joins on `NDB` tables are pushed down to the `NDB` kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with

a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type. This means that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

Expressions comparing columns from the same table can also be pushed down. The columns (or the result of any operations on those columns) must be of exactly the same type, including the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH, LIST, or RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
->      SELECT e.first_name, e.last_name, t.title, d.dept_name
->      FROM employees e
->      JOIN dept_emp de ON e.emp_no=de.emp_no
->      JOIN departments d ON d.dept_no=de.dept_no
->      JOIN titles t ON e.emp_no=t.emp_no\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: d
      type: ALL
possible_keys: PRIMARY
      key: NULL
      key_len: NULL
      ref: NULL
      rows: 9
      Extra: Parent of 4 pushed join@1
***** 2. row *****
      id: 1
```

```

select_type: SIMPLE
table: de
type: ref
possible_keys: PRIMARY,emp_no,dept_no
key: dept_no
key_len: 4
ref: employees.d.dept_no
rows: 5305
Extra: Child of 'd' in pushed join@1
***** 3. row *****
id: 1
select_type: SIMPLE
table: e
type: eq_ref
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: employees.de.emp_no
rows: 1
Extra: Child of 'de' in pushed join@1
***** 4. row *****
id: 1
select_type: SIMPLE
table: t
type: ref
possible_keys: PRIMARY,emp_no
key: emp_no
key_len: 4
ref: employees.de.emp_no
rows: 19
Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)

```

**Note**

If inner joined child tables are joined by `ref`, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.
  2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block.
- `ndb_log_apply_status`

Command-Line Format	<code>--ndb-log-apply-status[={OFF ON}]</code>
System Variable	<code>ndb_log_apply_status</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

Command-Line Format	<code>--ndb-log-bin[={OFF ON}]</code>
System Variable	<code>ndb_log_bin</code>
Scope	Global, Session
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. `ndb_log_bin` defaults to 0 (FALSE).

- `ndb_log_binlog_index`

Command-Line Format	<code>--ndb-log-binlog-index[={OFF ON}]</code>
System Variable	<code>ndb_log_binlog_index</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_cache_size`

Command-Line Format	<code>--ndb-log-cache-size=#</code>
System Variable	<code>ndb_log_cache_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	<code>64M</code>
Minimum Value	<code>4096</code>
Maximum Value	<code>18446744073709551615</code>

Set the size of the transaction cache used session for writing the NDB binary log.

- `ndb_log_empty_epochs`

Command-Line Format	<code>--ndb-log-empty-epochs[={OFF ON}]</code>	4479
---------------------	--	------

System Variable	<a href="#">ndb_log_empty_epochs</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in [ndb\\_binlog\\_index](#).

- [ndb\\_log\\_empty\\_update](#)

Command-Line Format	<code>--ndb-log-empty-update[={OFF ON}]</code>
System Variable	<a href="#">ndb_log_empty_update</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

When this variable is set to [ON](#) (1), update transactions with no changes are written to the binary log, even when [log\\_replica\\_updates](#) is enabled.

- [ndb\\_log\\_exclusive\\_reads](#)

Command-Line Format	<code>--ndb-log-exclusive-reads[={OFF ON}]</code>
System Variable	<a href="#">ndb_log_exclusive_reads</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	0

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of [ndb\\_log\\_exclusive\\_reads](#) to 1. 0, which disables such locking, is the default.

For more information, see [Read conflict detection and resolution](#).

- [ndb\\_log\\_orig](#)

Command-Line Format	<code>--ndb-log-orig[={OFF ON}]</code>
System Variable	<a href="#">ndb_log_orig</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No

Type	Boolean
Default Value	OFF

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

System Variable	<code>ndb_log_transaction_id</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 9.7.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_log_transaction_compression`

Command-Line Format	<code>--ndb-log-transaction-compression</code>
System Variable	<code>ndb_log_transaction_compression</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether a replica `mysqld` writes compressed transactions in the binary log; present only if `mysqld` was compiled with support for `NDB`.

You should note that starting the MySQL server with `--binlog-transaction-compression` forces this variable to be enabled (`ON`), and that this overrides any setting for `--ndb-log-transaction-compression` made on the command line or in a `my.cnf` file, as shown here:

```
$> mysqld_safe --ndbcluster --ndb-connectstring=127.0.0.1 \
--binlog-transaction-compression=ON --ndb-log-transaction-compression=OFF &
[1] 27667
$> 2022-07-07T12:29:20.459937Z mysqld_safe Logging to '/usr/local/mysql/data/myhost.err'.
2022-07-07T12:29:20.509873Z mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/data

$> mysql -e 'SHOW VARIABLES LIKE "%transaction_compression%'"
+-----+-----+
| Variable_name | Value |
+-----+-----+
| binlog_transaction_compression | ON |
| binlog_transaction_compression_level_zstd | 3 |
| ndb_log_transaction_compression | ON |
+-----+-----+
```

```
| ndb_log_transaction_compression_level_zstd | 3 |
+-----+-----+-----+
```

To disable binary log transaction compression for NDB tables only, set the `ndb_log_transaction_compression` system variable to `OFF` in a `mysql` or other client session after starting `mysqld`.

Setting the `binlog_transaction_compression` variable after startup has no effect on the value of `ndb_log_transaction_compression`.

For more information on binary log transaction compression, such as which events are or are not compressed and as well as behavior changes to be aware of when this feature is used, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

- `ndb_log_transaction_compression_level_zstd`

Command-Line Format	<code>--ndb-log-transaction-compression-level-zstd=#</code>
System Variable	<code>ndb_log_transaction_compression_level_zstd</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	1
Maximum Value	22

The `ZSTD` compression level used for writing compressed transactions to the replica's binary log if enabled by `ndb_log_transaction_compression`. Not supported if `mysqld` was not compiled with support for the NDB storage engine.

See [Section 7.4.4.5, “Binary Log Transaction Compression”](#), for more information.

- `ndb_metadata_check`

Command-Line Format	<code>--ndb-metadata-check[={OFF ON}]</code>
System Variable	<code>ndb_metadata_check</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

NDB uses a background thread to check for metadata changes each `ndb_metadata_check_interval` seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting `ndb_metadata_check` to `OFF`. The thread is enabled by default.

- [ndb\\_metadata\\_check\\_interval](#)

Command-Line Format	<code>--ndb-metadata-check-interval=#</code>
System Variable	<a href="#">ndb_metadata_check_interval</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	31536000
Unit	seconds

NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of [ndb\\_metadata\\_check\\_interval](#). To enable or disable the thread, use [ndb\\_metadata\\_check](#).

- [ndb\\_metadata\\_sync](#)

System Variable	<a href="#">ndb_metadata_sync</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	<code>false</code>

Setting this variable causes the change monitor thread to override any values set for [ndb\\_metadata\\_check](#) or [ndb\\_metadata\\_check\\_interval](#), and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. [ndb\\_metadata\\_sync](#) is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for [ndb\\_metadata\\_check](#) and [ndb\\_metadata\\_check\\_interval](#).

Setting this variable to `true` causes the list of excluded objects to be cleared; setting it to `false` clears the list of objects to be retried.

- [ndb\\_optimized\\_node\\_selection](#)

Command-Line Format	<code>--ndb-optimized-node-selection=#</code>
System Variable	<a href="#">ndb_optimized_node_selection</a>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	3

Minimum Value	0
Maximum Value	3

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- 1: Proximity to the SQL node is used to determine the transaction coordinator.
- 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
- 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

Command-Line Format	<code>--ndb-read-backup[={OFF ON}]</code>
System Variable	<code>ndb_read_backup</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

Enable read from any fragment replica for any NDB table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

If the SQL node and the data node use the same host name or IP address, this fact is detected automatically, so that the preference is to send reads to the same host. If these nodes are on the same host but use different IP addresses, you can tell the SQL node to use the correct data node by setting the value of [ndb\\_data\\_node\\_neighbour](#) on the SQL node to the node ID of the data node.

To enable or disable read from any fragment replica for an individual table, you can set the [NDB\\_TABLE](#) option [READ\\_BACKUP](#) for the table accordingly, in a [CREATE TABLE](#) or [ALTER TABLE](#) statement; see [Section 15.1.24.12, “Setting NDB Comment Options”](#), for more information.

- [ndb\\_recv\\_thread\\_activation\\_threshold](#)

Command-Line Format	<code>--ndb-recv-thread-activation-threshold=#</code>
System Variable	<a href="#">ndb_recv_thread_activation_threshold</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0 ( <a href="#">MIN_ACTIVATION_THRESHOLD</a> )
Maximum Value	16 ( <a href="#">MAX_ACTIVATION_THRESHOLD</a> )

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- [ndb\\_recv\\_thread\\_cpu\\_mask](#)

Command-Line Format	<code>--ndb-recv-thread-cpu-mask=mask</code>
System Variable	<a href="#">ndb_recv_thread_cpu_mask</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Bitmap
Default Value	[empty]

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting [ndb\\_recv\\_thread\\_cpu\\_mask](#) to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- [ndb\\_report\\_thresh\\_binlog\\_epoch\\_slip](#)

Command-Line Format	<code>--ndb-report-thresh-binlog-epoch-slip=#</code>
System Variable	<a href="#">ndb_report_thresh_binlog_epoch_slip</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	256

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see [Section 25.6.2.3, “Event Buffer Reporting in the Cluster Log”](#)). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

- [ndb\\_report\\_thresh\\_binlog\\_mem\\_usage](#)

Command-Line Format	<code>--ndb-report-thresh-binlog-mem-usage=#</code>
System Variable	<a href="#">ndb_report_thresh_binlog_mem_usage</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	10

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- [ndb\\_row\\_checksum](#)

System Variable	<a href="#">ndb_row_checksum</a>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Default Value	1
Minimum Value	0
Maximum Value	1

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- `ndb_schema_dist_lock_wait_timeout`

Command-Line Format	<code>--ndb-schema-dist-lock-wait-timeout=value</code>
System Variable	<code>ndb_schema_dist_lock_wait_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	1200
Unit	seconds

Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- `ndb_schema_dist_timeout`

Command-Line Format	<code>--ndb-schema-dist-timeout=value</code>
System Variable	<code>ndb_schema_dist_timeout</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	120
Minimum Value	5
Maximum Value	1200
Unit	seconds

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- `ndb_schema_dist_upgrade_allowed`

Command-Line Format	<code>--ndb-schema-dist-upgrade-allowed=value</code>
System Variable	<code>ndb_schema_dist_upgrade_allowed</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>true</code>

Allow upgrading of the schema distribution table when connecting to [NDB](#). When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

**Note**

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- [ndb\\_show\\_foreign\\_key\\_mock\\_tables](#)

Command-Line Format	<code>--ndb-show-foreign-key-mock-tables[={OFF ON}]</code>
System Variable	<code>ndb_show_foreign_key_mock_tables</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Show the mock tables used by [NDB](#) to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- [ndb\\_slave\\_conflict\\_role](#)

Command-Line Format	<code>--ndb-slave-conflict-role=value</code>
Deprecated	Yes
System Variable	<code>ndb_slave_conflict_role</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NONE</code>
Valid Values	<code>NONE</code> <code>PRIMARY</code>

	SECONDARY
	PASS

Deprecated synonym for `ndb_conflict_role`.

- `ndb_table_no_logging`

System Variable	<code>ndb_table_no_logging</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When this variable is set to `ON` or `1`, it causes all tables created or altered using `ENGINE NDB` to be nonlogging; that is, no data changes for this table are written to the redo log or checkpointed to disk, just as if the table had been created or altered using the `NOLOGGING` option for `CREATE TABLE` or `ALTER TABLE`.

For more information about nonlogging `NDB` tables, see [NDB\\_TABLE Options](#).

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

System Variable	<code>ndb_table_temporary</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

**Note**

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

System Variable	<code>ndb_use_copying_alter_table</code>
Scope	Global, Session
Dynamic	No

SET_VAR Hint Applies	No
----------------------	----

Forces NDB to use copying of tables in the event of problems with online ALTER TABLE operations. The default value is OFF.

- [ndb\\_use\\_exact\\_count](#)

System Variable	<a href="#">ndb_use_exact_count</a>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Forces NDB to use a count of records during SELECT COUNT(\*) query planning to speed up this type of query. The default value is OFF, which allows for faster queries overall.

- [ndb\\_use\\_transactions](#)

Command-Line Format	<code>--ndb-use-transactions[={OFF ON}]</code>
System Variable	<a href="#">ndb_use_transactions</a>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

You can disable NDB transaction support by setting this variable's value to OFF. This is generally not recommended, although it may be useful to disable transaction support within a given client session when that session is used to import one or more dump files with large transactions; this allows a multi-row insert to be executed in parts, rather than as a single transaction. In such cases, once the import has been completed, you should either reset the variable value for this session to ON, or simply terminate the session.

- [ndb\\_version](#)

System Variable	<a href="#">ndb_version</a>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	

NDB engine version, as a composite integer.

- [ndb\\_version\\_string](#)

System Variable	<a href="#">ndb_version_string</a>
-----------------	------------------------------------

Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	

NDB engine version in `ndb-x.y.z` format.

- `replica_allow_batching`

Command-Line Format	<code>--replica-allow-batching[={OFF ON}]</code>
System Variable	<code>replica_allow_batching</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Whether or not batched updates are enabled on NDB Cluster replicas.

Allowing batched updates on the replica greatly improves performance, particularly when replicating `TEXT`, `BLOB`, and `JSON` columns. For this reason, `replica_allow_batching` is enabled by default.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 9.7, it is present but does nothing. For more information, see [Section 25.7.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

- `ndb_replica_batch_size`

Command-Line Format	<code>--ndb-replica-batch-size=#</code>
System Variable	<code>ndb_replica_batch_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2097152
Minimum Value	0
Maximum Value	2147483648
Unit	bytes

Determines the batch size in bytes used by the replication applier thread. Set this variable rather than the `--ndb-batch-size` option to apply this setting to the replica, exclusive of any other sessions.

If this variable is unset (default 2 MB), its effective value is the greater of the value of `--ndb-batch-size` and 2 MB.

- `ndb_replica_blob_write_batch_bytes`

Command-Line Format	<code>--ndb-replica-blob-write-batch-bytes=#</code>
System Variable	<code>ndb_replica_blob_write_batch_bytes</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2097152
Minimum Value	0
Maximum Value	2147483648
Unit	bytes

Control the batch write size used for blob data by the replication applier thread.

Use this variable rather than the `--ndb-blob-write-batch-bytes` option to control the blob batch write size on the replica, exclusive of any other sessions. The reason for this is that, when `ndb_replica_blob_write_batch_bytes` is not set, the effective blob batch size (that is, the maximum number of pending bytes to write for blob columns) is determined by the greater of the value of `--ndb-blob-write-batch-bytes` and 2 MB (the default for `ndb_replica_blob_write_batch_bytes`).

Setting `ndb_replica_blob_write_batch_bytes` to 0 means that NDB imposes no limit on the size of blob batch writes on the replica.

- `server_id_bits`

Command-Line Format	<code>--server-id-bits=#</code>
System Variable	<code>server_id_bits</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	7
Maximum Value	32

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to mask out any

irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 9.7 Server.

- `slave_allow_batching`

Command-Line Format	<code>--slave-allow-batching[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>slave_allow_batching</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Deprecated synonym for `replica_allow_batching`.

- `transaction_allow_batching`

System Variable	<code>transaction_allow_batching</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to 0 or OFF; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

**Important**

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

System Variable	<code>ndbinfo_database</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>ndbinfo</code>

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time.

- `ndbinfo_max_bytes`

Command-Line Format	<code>--ndbinfo-max-bytes=#</code>
System Variable	<code>ndbinfo_max_bytes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	65535

Used in testing and debugging only.

- `ndbinfo_max_rows`

Command-Line Format	<code>--ndbinfo-max-rows=#</code>
System Variable	<code>ndbinfo_max_rows</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	1
Maximum Value	256

Used in testing and debugging only.

- `ndbinfo_offline`

System Variable	<code>ndbinfo_offline</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in `NDB`. No rows are returned from such tables (or views).

- [ndbinfo\\_show\\_hidden](#)

Command-Line Format	<code>--ndbinfo-show-hidden[={OFF ON}]</code>
System Variable	<code>ndbinfo_show_hidden</code>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>
Valid Values	<code>ON</code> <code>OFF</code>

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

**Note**

When `ndbinfo_show_hidden` is enabled, the internal tables are shown in the `ndbinfo` database only; they are not visible in `TABLES` or other `INFORMATION_SCHEMA` tables, regardless of the variable's setting.

- [ndbinfo\\_table\\_prefix](#)

System Variable	<code>ndbinfo_table_prefix</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<code>ndb\$</code>

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- [ndbinfo\\_version](#)

System Variable	<code>ndbinfo_version</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	

Shows the version of the `ndbinfo` engine in use; read-only.

## NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see [Section 7.1.10, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_adaptive_send_deferred_count`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_session`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_replica`

Number of adaptive send calls that were not actually sent by this replica.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_slave`

Deprecated synonym for `Ndb_api_adaptive_send_deferred_count_replica`.

- `Ndb_api_adaptive_send_forced_count`

Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_session`

Number of adaptive send calls using forced-send sent in this client session.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_replica`

Number of adaptive send calls using forced-send sent by this replica.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_slave`  
 Deprecated synonym for `Ndb_api_adaptive_send_forced_count_replica`.
- `Ndb_api_adaptive_send_unforced_count`  
 Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_adaptive_send_unforced_count_session`  
 Number of adaptive send calls without forced-send sent in this client session.  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_adaptive_send_unforced_count_replica`  
 Number of adaptive send calls without forced-send sent by this replica.  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_adaptive_send_unforced_count_slave`  
 Deprecated synonym for `Ndb_api_adaptive_send_unforced_count_replica`.
- `Ndb_api_bytes_sent_count_session`  
 Amount of data (in bytes) sent to the data nodes in this client session.  
 Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_bytes_sent_count_replica`  
 Amount of data (in bytes) sent to the data nodes by this replica.  
 Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_bytes_sent_count_slave`  
 Deprecated synonym for `Ndb_api_bytes_sent_count_replica`.
- `Ndb_api_bytes_sent_count`  
 Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).  
 Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.  
 For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).
- `Ndb_api_bytes_received_count_session`

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_replica`

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_slave`

Deprecated synonym for `Ndb_api_bytes_received_count_replica`.

- `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count_injector`

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count`

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_session`

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_replica`

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_slave`

Deprecated synonym for `Ndb_api_pk_op_count_replica`.

- `Ndb_api_pk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_session`

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_replica`

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_slave`

Deprecated synonym for `Ndb_api_pruned_scan_count_replica`.

- `Ndb_api_pruned_scan_count`

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_session`

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_replica`

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_slave`

Deprecated synonym for `Ndb_api_range_scan_count_replica`.

- `Ndb_api_range_scan_count`

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_replica`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_slave`

Deprecated synonym for `Ndb_api_read_row_count_replica`.

- `Ndb_api_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_session`

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

---

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_replica`

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_slave`

Deprecated synonym for `Ndb_api_scan_batch_count_replica`.

- `Ndb_api_scan_batch_count`

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_session`

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_replica`

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_slave`

Deprecated synonym for `Ndb_api_table_scan_count_replica`.

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_replica`

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_slave`

Deprecated synonym for `Ndb_api_trans_abort_count_replica`.

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_replica`

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_replica` and `Ndb_api_trans_abort_count_replica`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

---

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_slave`

Deprecated synonym for `Ndb_api_trans_close_count_replica`.

- `Ndb_api_trans_close_count`

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_session`

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_replica`

The number of transactions committed by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_slave`

Deprecated synonym for `Ndb_api_trans_commit_count_replica`.

- `Ndb_api_trans_commit_count`

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_replica`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_slave`

Deprecated synonym for `Ndb_api_trans_local_read_row_count_replica`.

- `Ndb_api_trans_local_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_session`

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_replica`

The number of transactions started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_slave`

Deprecated synonym for `Ndb_api_trans_start_count_replica`.

- `Ndb_api_trans_start_count`

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_session`

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_replica`

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_slave`

Deprecated synonym for `Ndb_api_uk_op_count_replica`.

- `Ndb_api_uk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_session`

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_replica`

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_slave`

Deprecated synonym for `Ndb_api_wait_exec_complete_count_replica`.

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_replica`

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

Deprecated synonym for `Ndb_api_wait_meta_request_count_replica`.

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_replica`

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

Deprecated synonym for `Ndb_api_wait_nanos_count_replica`.

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_replica`

The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_slave`

Deprecated synonym for `Ndb_api_wait_scan_result_count_replica`.

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 25.6.14, “NDB API Statistics Counters and Variables”](#).

- `Ndb_cluster_node_id`

If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_generation`

Shows the generation number of the cluster's current configuration. This can be used as an indicator to determine whether the configuration of the cluster has changed since this SQL node last connected to the cluster.

- `Ndb_conflict_fn_epoch`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqlid` since the last time it was restarted.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqlid` since the last time it was restarted.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2`

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the source designated as the primary since the last time it was restarted.

For more information, see `NDB$EPOCH2()`.

- `Ndb_conflict_fn_epoch2_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [NDB\\$EPOCH2\\_TRANS\(\)](#).

- `Ndb_conflict_fn_max`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max_del_win`

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max_del_win_ins`

Shows the number of times that insertion of a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DEL_WIN_INS()`, since the last time that this `mysqld` was started.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max_ins`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not inserted on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_old`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_last_conflict_epoch`

The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_replica_max_replicated_epoch`; if `Ndb_replica_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_discard_count`

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_prepare_count`

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_refresh_op_count`

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_last_stable_epoch`

Number of rows found to be in conflict by a transactional conflict function

See [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_trans_row_conflict_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_detect_iter_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_conflict_commit_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_epoch_delete_delete_count`

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

Provides the number of round trips to the NDB kernel made by operations.

- `Ndb_fetch_table_stats`

This count is incremented whenever a MySQL Server acting as an NDB Cluster API node fetches table statistics for a given table, rather than using cached statistics.

- `Ndb_last_commit_epoch_server`

The epoch most recently committed by NDB.

- `Ndb_last_commit_epoch_session`

The epoch most recently committed by this NDB client.

- `Ndb_metadata_detected_count`

The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

- `Ndb_metadata_excluded_count`

The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.

Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table`, `SELECT * FROM table`, or any other statement that would trigger table discovery.

- `Ndb_metadata_synced_count`

The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

- `Ndb_number_of_data_nodes`

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

**Note**

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- `Ndb_pushed_queries_dropped`

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- `Ndb_pushed_queries_executed`

The number of joins successfully pushed down to `NDB` and executed there.

- `Ndb_pushed_reads`

The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

**Note**

Executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving replica only a single data node.

- `Ndb_replica_max_replicated_epoch`

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_replica_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- `Ndb_schema_participant_count`

Indicates the number of MySQL servers that are participating in NDB schema change distribution.

- `Ndb_slave_max_replicated_epoch`

Deprecated synonym for `Ndb_replica_max_replicated_epoch`.

- `Ndb_system_name`

If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- `Ndb_trans_hint_count_session`

The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints.

### 25.4.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

#### Note

For an exception to this rule, see [Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

#### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `AllowUnresolvedHostNames`

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the global configuration file (usually named `config.ini`), in which case failure to resolve a host name is treated as a warning and `ndb_mgmd` startup continues uninterrupted.

- [Checksum](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is disabled by default. When it is enabled (set to `Y` or `1`), checksums for all messages are calculated before they are placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [Group](#)

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- [HostName1](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]

Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `NodeId1`

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `NodeId2`

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `NodeIdServer`

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]

Range	1 - 63
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set the server side of a TCP connection.

- [OverloadLimit](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When more than this many unsend bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsend data that must be present in the send buffer before the connection is considered overloaded. See [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- [PreferIPVersion](#)

Version (or later)	NDB 9.7.0
Type or units	enumeration
Default	4
Range	4, 6
Restart Type	<b>Initial System Restart:</b> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <a href="#">backup</a> , and then restarting the cluster. (NDB 9.7.0)

Determines the preference of DNS resolution for IP version 4 or version 6. Because the configuration retrieval mechanism employed by NDB Cluster requires that all connections use the same preference, this parameter should be set in the `[tcp default]` of the `config.ini` global configuration file.

- [PreSendChecksum](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [Proxy](#)

Version (or later)	NDB 9.7.0
Type or units	string
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Set a proxy for the TCP connection.

- [ReceiveBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	2M
Range	16K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- [RequireLinkTls](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If the node at either endpoint of this TCP connection requires TLS authentication, the value of this parameter is `true`, otherwise `false`. The value is set by `NDB`, and cannot be changed by the user.

- [SendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	2M
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false (debug builds: true)
Range	true, false

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [TcpBind\\_INADDR\\_ANY](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [TcpSpinTime](#)

Version (or later)	NDB 9.7.0
Type or units	$\mu$ sec
Default	0
Range	0 - 2000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

- [TCP\\_MAXSEG\\_SIZE](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- [TCP\\_RCV\\_BUF\\_SIZE](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0

Range	0 - 2G
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP\\_SND\\_BUF\\_SIZE](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.20 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN.

In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.\* address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

#### Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 25.4.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to `1`, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```

### Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (`config.ini`) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in  $\mu$ s to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.
- `Checksum`: Indicates that a checksum is included in each signal sent through the transporter.
- `PreSendChecksum`: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. `10.0.0.0`: The management server
2. `10.0.0.1`: A data node and an SQL node
3. `10.0.0.2`: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the `config.ini` file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M
```

```
[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the `[shm default]` section; these can be overridden on a per-connection basis in one or more `[shm]` sections. Each such section must be associated with a given SHM connection using `NodeId1` and `NodeId2`; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using `HostName1` and `HostName2`, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the `[tcp default]` section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (`ShmSpinTime` parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in `NDB`.

- [Checksum](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	true
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [Group](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	35
Range	0 - 200
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- [HostName1](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

Version (or later)	NDB 9.7.0
Type or units	name or IP address
Default	[...]
Range	...
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeId2](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeIdServer](#)

Version (or later)	NDB 9.7.0
Type or units	numeric
Default	[none]
Range	1 - 63
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- [OverloadLimit](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	0

Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See [Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), and [Section 25.6.15.66, “The ndbinfo transporters Table”](#), for more information.

- [PreSendChecksum](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [SendBufferMemory](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	2M
Range	256K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- [SendSignalId](#)

Version (or later)	NDB 9.7.0
Type or units	boolean
Default	false
Range	true, false

Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)
--------------	--

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [ShmKey](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If [UseShm](#) is enabled, the shared memory key is calculated automatically by [NDB](#).

- [ShmSize](#)

Version (or later)	NDB 9.7.0
Type or units	bytes
Default	4M
Range	64K - 4294967039 (0xFFFFFFFF)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 4MB.

- [ShmSpinTime](#)

Version (or later)	NDB 9.7.0
Type or units	integer
Default	0

Range	0 - 2000
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

When receiving, the time to wait before sleeping, in microseconds.

- [SigNum](#)

Version (or later)	NDB 9.7.0
Type or units	unsigned
Default	[...]
Range	0 - 4294967039 (0xFFFFFFFF)
Deprecated	Yes (in NDB 7.6)
Restart Type	<b>Node Restart:</b> Requires a <a href="#">rolling restart</a> of the cluster. (NDB 9.7.0)

This parameter was formerly used to override operating system signal numbers; in NDB 9.7, it is no longer used, and any setting for it is ignored.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.21 NDB Cluster restart types**

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see <a href="#">Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”</a> )
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the <code>--initial</code> option

### 25.4.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that **NDB** can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory

- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The [NDB](#) memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory ([DataMemory](#))
- Redo log buffers ([RedoBuffer](#))
- Job buffers
- Send buffers ([SendBufferMemory](#), [TotalSendBufferMemory](#), [ExtraSendBufferMemory](#))
- Disk Data record page cache ([DiskPageBufferMemory](#), [DiskPageBufferEntries](#))
- Transaction memory ([TransactionMemory](#))
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the [SharedGlobalMemory](#) configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the [DataMemory](#) configuration parameter, whose maximum is 16384 GB. [DataMemory](#) is where

records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the `RedoBuffer` configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by `NDB`, based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the `TotalSendBufferMemory` configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for `SendBufferMemory` for a data node connection is 2 MByte, this works out to 26 MB total.
2. To obtain the total reserved size for the send buffer, the value of the `ExtraSendBufferMemory` configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if `TotalSendBufferMemory` has been set, the send buffer size is `TotalSendBufferMemory + ExtraSendBufferMemory`; otherwise, the size of the send buffer is equal to  $([number\ of\ node\ connections] * SendBufferMemory) + ExtraSendBufferMemory$ .

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the `DiskPageBufferMemory` configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the `DiskPageBufferEntries` configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by `NDB`, or is set explicitly using the `TransactionMemory` configuration parameter; transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

Resources are allocated from a common transaction memory resource and can also use resources from global shared memory. the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:

- `MaxNoOfConcurrentOperations`
- `MaxNoOfConcurrentTransactions`
- `MaxNoOfFiredTriggers`

- `MaxNoOfLocalOperations`
- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfConcurrentScans`
- `MaxNoOfLocalScans`
- `BatchSizePerLocalScan`
- `TransactionBufferMemory`

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start.

The `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` parameters are all deprecated; you should expect them to be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- `ReservedConcurrentIndexOperations`
- `ReservedFiredTriggers`
- `ReservedConcurrentOperations`
- `ReservedLocalScans`
- `ReservedConcurrentTransactions`
- `ReservedConcurrentScans`
- `ReservedTransactionBufferMemory`

For any of the parameters just listed that is not set explicitly in `config.ini`, the reserved setting is calculated as 25% of the corresponding maximum setting. For example, if unset, `ReservedConcurrentIndexOperations` is calculated as 25% of `MaxNoOfConcurrentIndexOperations`, and `ReservedLocalScans` is calculated as 25% of `MaxNoOfLocalScans`.

### Note

If `ReservedTransactionBufferMemory` is not set, it is calculated as 25% of `TransactionBufferMemory`.

The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set `TransactionMemory` alone, and to allow the number of records in pools to be governed by its value.

`MaxNoOfConcurrentScans` limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

`MaxNoOfConcurrentOperations` limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that `MaxNoOfConcurrentOperations` be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the `[ndbd default]` section of the `config.ini` global configuration file). While its value can be increased using a rolling restart (see [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#)), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the `MaxDMLOperationsPerTransaction` parameter. If this is not set, the size of one transaction is limited by `MaxNoOfConcurrentOperations` since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

- `MaxNoOfSubscriptions`
- `MaxNoOfSubscribers`
- `MaxNoOfConcurrentSubOperations`
- `MaxNoOfAttributes`
- `MaxNoOfTables`
- `MaxNoOfOrderedIndexes`
- `MaxNoOfUniqueHashIndexes`
- `MaxNoOfTriggers`

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its fragment replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

### 25.4.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 25.22 Transporter types with maximum send buffer sizes**

Transporter	Maximum Send Buffer Size (bytes)
TCP	<code>SendBufferMemory</code> (default = 2M)
SHM	20K

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

## 25.4.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms, or transporters.

NDB Cluster supports three of these (see [Section 25.2.1, “NDB Cluster Core Concepts”](#)). A fourth transporter, Scalable Coherent Interface (SCI), was also supported in very old versions of `NDB`. This required specialized hardware, software, and MySQL binaries that are no longer available.

## 25.5 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmt_d`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

For information about using `mysqld` as an NDB Cluster process, see [Section 25.6.10, “MySQL Server Usage for NDB Cluster”](#).

Other [NDB](#) utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include [ndb\\_restore](#), [ndb\\_show\\_tables](#), and [ndb\\_config](#). These programs are also covered in this section.

## 25.5.1 ndbd — The NDB Cluster Data Node Daemon

The [ndbd](#) binary provides the single-threaded version of the process that is used to handle all the data in tables employing the [NDBCLUSTER](#) storage engine. This data node process enables a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks. When started, [ndbd](#) logs a warning similar to that shown here:

```
2024-05-28 13:32:16 [ndbd] WARNING -- Running ndbd with a single thread of
signal execution. For multi-threaded signal execution run the ndbmtb binary.
```

[ndbmtb](#) is the multi-threaded version of this binary.

In an NDB Cluster, a set of data node processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with [ndbd](#) are shown in the following table. Additional descriptions follow the table.

### Note

All of these options also apply to the multithreaded version of this program ([ndbmtb](#)) and you may substitute “[ndbmtb](#)” for “[ndbd](#)” wherever the latter occurs in this section.

- [--bind-address](#)

Command-Line Format	<a href="#">--bind-address=name</a>
Type	String
Default Value	

Causes [ndbd](#) to bind to a specific network interface (host name or IP address). This option has no default value.

- [--character-sets-dir](#)

Command-Line Format	<a href="#">--character-sets-dir=path</a>
---------------------	---

Directory containing character sets.

- [--connect-delay=#](#)

Command-Line Format	<a href="#">--connect-delay=#</a>
Deprecated	Yes
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	3600

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- `--connect-retries=#`

Command-Line Format	<code>--connect-retries=#</code>
Type	Numeric
Default Value	12
Minimum Value	-1
Maximum Value	65535

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

It is also possible to set this option to -1, in which case, the data node process continues indefinitely to try to connect.

- `--connect-retry-delay=#`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	4294967295

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

The short form `-r` for this option is also deprecated, and thus subject to removal. Use the long form instead.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--daemon, -d`

Command-Line Format	<code>--daemon</code>
---------------------	-----------------------

Instructs `ndbd` or `ndbmt` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--filesystem-password`

Command-Line Format	<code>--filesystem-password=password</code>
---------------------	---

Pass the filesystem encryption and decryption password to the data node process using `stdin`, `tty`, or the `my.cnf` file.

Requires `EncryptedFileSystem = 1`.

For more information, see [Section 25.6.19.4, “File System Encryption for NDB Cluster”](#).

- `--filesystem-password-from-stdin`

Command-Line Format	<code>--filesystem-password-from-stdin={TRUE FALSE}</code>
---------------------	--

Pass the filesystem encryption and decryption password to the data node process from `stdin` (only).

Requires `EncryptedFileSystem = 1`.

For more information, see [Section 25.6.19.4, “File System Encryption for NDB Cluster”](#).

- `--foreground`

Command-Line Format	<code>--foreground</code>
---------------------	---------------------------

Causes `ndbd` or `ndbmtid` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtid` on Windows platforms.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--initial`

Command-Line Format	<code>--initial</code>
---------------------	------------------------

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

The option also causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#)).

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

### Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See

the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

**Important**

This option does *not* affect backup files that have already been created by the affected node.

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with `--initial`, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Command-Line Format	<code>--initial-start</code>
---------------------	------------------------------

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
$> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

**Important**

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndbd</code>

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`.

However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--logbuffer-size=#`

Command-Line Format	<code>--logbuffer-size=#</code>
Type	Integer
Default Value	32768
Minimum Value	2048
Maximum Value	4294967295

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-log-timestamps`

4540	Command-Line Format	<code>--ndb-log-timestamps</code>
	Type	Enumeration

Default Value	UTC
Valid Values	LEGACY UTC SYSTEM

Sets the format used for timestamps in node logs. This is one of the following values:

- **LEGACY**: The system timezone, with resolution in seconds.
- **UTC**: RFC 3339 format, with microsecond resolution.
- **SYSTEM**: RFC 3339 format.

UTC is the default in MySQL 9.7.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable. 4541

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--nodaemon`

Command-Line Format	<code>--nodaemon</code>
---------------------	-------------------------

Prevents `ndbd` or `ndbmt` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--nostart, -n`

Command-Line Format	<code>--nostart</code>
---------------------	------------------------

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 25.6.1, “Commands in the NDB Cluster Management Client”](#)).

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

Command-Line Format	<code>--nowait-nodes=list</code>
Type	String

Default Value	
---------------	--

This option takes a list of data nodes for which the cluster does not wait, prior to starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect, and does not wait for node 3 to start.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--remove [=name]`

Command-Line Format	<code>--remove [=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndbd</code>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose, -v`

Causes extra debug output to be written to the node log.

You can also use `NODELOG DEBUG ON` and `NODELOG DEBUG OFF` to enable and disable this extra logging while the data node is running.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [Data Node Error Messages](#).

### Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that are created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
$> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), for additional information about this issue. For more information about data node configuration parameters, see [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#).

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 9.7 in a production setting. See [Section 25.2.7, “Known Limitations of NDB Cluster”](#).

## 25.5.2 ndbinfo\_select\_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database

Not all `ndbinfo` tables available in the `mysql` client can be read by this program (see later in this section). In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
$> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
$> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type      log_id  log_part      total  used  high
5       0       0       0       33554432 262144 0
6       0       0       0       33554432 262144 0
7       0       0       0       33554432 262144 0
8       0       0       0       33554432 262144 0
== logspaces ==
node_id log_type      log_id  log_part      total  used  high
5       0       0       0       268435456 0      0
5       0       0       1       268435456 0      0
5       0       0       2       268435456 0      0
5       0       0       3       268435456 0      0
6       0       0       0       268435456 0      0
6       0       0       1       268435456 0      0
6       0       0       2       268435456 0      0
6       0       0       3       268435456 0      0
7       0       0       0       268435456 0      0
7       0       0       1       268435456 0      0
7       0       0       2       268435456 0      0
7       0       0       3       268435456 0      0
8       0       0       0       268435456 0      0
8       0       0       1       268435456 0      0
8       0       0       2       268435456 0      0
8       0       0       3       268435456 0      0
$>
```

Options that can be used with `ndbinfo_select_all` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection-string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--delay=seconds`

Command-Line Format	<code>--delay=#</code>
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	MAX_INT

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--loops=number, -l number`

Command-Line Format	<code>--loops=#</code>
Type	Numeric

Default Value	1
Minimum Value	0
Maximum Value	MAX_INT

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection-string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id; ] [host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection-string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

`ndbinfo_select_all` is unable to read the following tables:

- `arbitrator_validity_detail`
- `arbitrator_validity_summary`
- `cluster_locks`
- `cluster_operations`
- `cluster_transactions`
- `disk_write_speed_aggregate_node`
- `locks_per_fragment`
- `memory_per_fragment`
- `memoryusage`
- `operations_per_fragment`
- `server_locks`
- `server_operations`
- `server_transactions`
- `table_info`

### 25.5.3 ndbmttd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmttd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmttd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmttd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmttd` differs from `ndbd`, and you should consult [Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#), for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmttd`. For more information about these options and parameters, see [Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#), and [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#), respectively.

`ndbmttd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmttd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value

before restarting the node if you wish for `ndbmttd` to run in multithreaded fashion.) Similarly, an `ndbmttd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmttd` differs from using `ndbd` in two key respects:

1. Because `ndbmttd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see [Multi-Threading Configuration Parameters \(ndbmttd\)](#).
2. Trace files are generated by critical errors in `ndbmttd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmttd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmttd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmttd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmttd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmttd`. See [Data Node Error Messages](#), for a listing of these.

#### Note

It is possible to use `ndbd` and `ndbmttd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

## 25.5.4 ndb\_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

All options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

- `--bind-address=host`

Command-Line Format	<code>--bind-address=host</code>
Type	String
Default Value	[none]

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `cluster-config-suffix`

Command-Line Format	<code>--cluster-config-suffix=name</code>
Type	String
Default Value	[none]

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

- `--config-cache`

Command-Line Format	<code>--config-cache[=TRUE FALSE]</code>
Type	Boolean
Default Value	TRUE

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 25.4.3, “NDB Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to `0`, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each

time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

*node-id* is the management server's node ID; *seq-number* is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

Command-Line Format	<code>--config-file=file</code>
Disabled by	<code>skip-config-file</code>
Type	File name
Default Value	[none]

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. If `--config-file` is specified without either of `--initial` or `--reload`, `ndb_mgmd` refuses to start.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 25.4.3, “NDB Cluster Configuration Files”](#), for more information.

- `--configdir=dir_name`

Command-Line Format	<code>--configdir=directory</code> <code>--config-dir=directory</code>
Type	File name
Default Value	<code>\$INSTALLDIR/mysql-cluster</code>

Specifies the cluster management server's configuration cache directory. This must be an absolute path. Otherwise, the management server refuses to start.

`--config-dir` is an alias for this option.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
---------------------	----------------------------------

Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--daemon, -d`

Command-Line Format	<code>--daemon</code>
---------------------	-----------------------

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String

Default Value	[none]
---------------	--------

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--initial`

Command-Line Format	<code>--initial</code>
---------------------	------------------------

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 25.4.3, “NDB Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

Command-Line Format	<code>--install[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndb_mgmd</code>

with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

Command-Line Format	<code>--interactive</code>
---------------------	----------------------------

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--log-name=name`

Command-Line Format	<code>--log-name=name</code>
Type	String
Default Value	<code>MgmtSrvr</code>

Provides a name to be used for this node in the cluster log.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--mycnf`

Command-Line Format	<code>--mycnf</code>
---------------------	----------------------

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String

Default Value	[none]
---------------	--------

Set connection string. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`. Ignored if `--config-file` is specified; a warning is issued if both options are used concurrently.

- `--ndb-log-timestamps`

Command-Line Format	<code>--ndb-log-timestamps</code>
Type	Enumeration
Default Value	UTC
Valid Values	LEGACY UTC SYSTEM

Sets the format used for timestamps in node logs. This is one of the following values:

- `LEGACY`: The system timezone, with resolution in seconds.
- `UTC`: [RFC 3339](#) format, with microsecond resolution.
- `SYSTEM`: RFC 3339 format.

UTC is the default in MySQL 9.7.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	relaxed
Valid Values	relaxed strict

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer

Default Value	[none]
---------------	--------

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-nodeid-checks`

Command-Line Format	<code>--no-nodeid-checks</code>
---------------------	---------------------------------

Do not perform any checks of node IDs.

- `--nodaemon`

Command-Line Format	<code>--nodaemon</code>
---------------------	-------------------------

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--nowait-nodes`

Command-Line Format	<code>--nowait-nodes=list</code>
Type	Numeric
Default Value	[none]
Minimum Value	1
Maximum Value	255

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to

a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
$> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
$> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtid` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

#### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--print-full-config, -P`

Command-Line Format	<code>--print-full-config</code>
---------------------	----------------------------------

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

Command-Line Format	<code>--reload</code>
---------------------	-----------------------

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 25.4.3, “NDB Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See [Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for additional information.

- `--remove[=name]`

Command-Line Format	<code>--remove[=name]</code>
Platform Specific	Windows
Type	String
Default Value	<code>ndb_mgmd</code>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--skip-config-file`

Command-Line Format	<code>--skip-config-file</code>
---------------------	---------------------------------

Do not read cluster configuration file; ignore `--initial` and `--reload` options if specified.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), for information about using connection strings. [Section 25.5.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 25.4, “Configuration of NDB Cluster”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 25.6, “Management of NDB Cluster”](#).

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

## 25.5.5 ndb\_mgm — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
$> ndb_mgm [host_name [port_num]]
```

For example:

```
$> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

All options that can be used with `ndb_mgm` are shown in the following table. Additional descriptions follow the table.

- `--backup-password-from-stdin[=TRUE|FALSE]`

Command-Line Format	<code>--backup-password-from-stdin</code>
---------------------	---

This option enables input of the backup password from the system shell (`stdin`) when using `--execute "START BACKUP"` or similar to create a backup. Use of this option requires use of `--execute` as well.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries=#`

Command-Line Format	<code>--connect-retries=#</code>
Type	Numeric
Default Value	3
Minimum Value	0
Maximum Value	4294967295

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--encrypt-backup`

Command-Line Format	<code>--encrypt-backup</code>
---------------------	-------------------------------

When used, this option causes all backups to be encrypted. To make this happen whenever `ndb_mgm` is run, put the option in the `[ndb_mgm]` section of the `my.cnf` file.

- `--execute=command`, `-e command`

Command-Line Format	<code>--execute=command</code>
---------------------	--------------------------------

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
$> ndb_mgm -e "SHOW"
$> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 6.2.2.1, “Using Options on the Command Line”](#).

#### Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connect string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--test-tls`

Command-Line Format	<code>--test-tls</code>
---------------------	-------------------------

Connect using TLS, then exit. Output if successful is similar to what is shown here:

```
>$ ndb_mgm --test-tls
```

```
Connected to Management Server at: sakila:1186
>$
```

See [Section 25.6.19.5, “TLS Link Encryption for NDB Cluster”](#), for more information.

- `--try-reconnect=number`

Command-Line Format	<code>--try-reconnect=#</code>
Deprecated	Yes
Type	Numeric
Type	Integer
Default Value	12
Default Value	3
Minimum Value	0
Maximum Value	4294967295

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

Additional information about using `ndb_mgm` can be found in [Section 25.6.1, “Commands in the NDB Cluster Management Client”](#).

## 25.5.6 ndb\_blob\_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more `BLOB` or `TEXT` columns from that table. If no columns are listed, the tool works on all of the table's `BLOB` and `TEXT` columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

All options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

- `--add-missing`

Command-Line Format	<code>--add-missing</code>
---------------------	----------------------------

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--check-missing`

Command-Line Format	<code>--check-missing</code>
---------------------	------------------------------

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- `--check-orphans`

Command-Line Format	<code>--check-orphans</code>
---------------------	------------------------------

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database=db_name, -d`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	[none]

Specify the database to find the table in.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--delete-orphans`

Command-Line Format	<code>--delete-orphans</code>
---------------------	-------------------------------

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- `--dump-file=file`

Command-Line Format	<code>--dump-file=file</code>
Type	File name
Default Value	[none]

Writes a list of orphaned BLOB column parts to *file*. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code>

	<code>strict</code>
--	---------------------

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	<code>[none]</code>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Provide extra information in the tool's output regarding its progress.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## Example

First we create an NDB table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
  c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c1 TEXT,
  c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
$> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
```

```
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected
```

The tool reports that there are no NDB BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an NDB table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by NDB for this column. See [Section 13.7, “Data Type Storage Requirements”](#), for more information.

## 25.5.7 ndb\_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

All options that can be used with `ndb_config` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `cluster-config-suffix`

Command-Line Format	<code>--cluster-config-suffix=name</code>
Type	String
Default Value	[none]

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage

- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
$> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...
```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-binary-file=path-to-file`

Command-Line Format	<code>--config-binary-file=path/to/file</code>
Type	File name
Default Value	

Gives the path to the management server's cached binary configuration file (`ndb_nodeID_config.bin.seqno`). This may be a relative or absolute path. If the management server and the `ndb_config` binary used reside on different hosts, you must use an absolute path.

This example demonstrates combining `--config-binary-file` with other `ndb_config` options to obtain useful output:

```
$> ndb_config --config-binary-file=./mysql-cluster/ndb_50_config.bin.1 --diff-default --type=ndb
config of [DB] node id 5 that is different from default
CONFIG_PARAMETER,ACTUAL_VALUE,DEFAULT_VALUE
NodeId,5,(mandatory)
BackupDataDir,/local/data/9.7,(null)
DataDir,/local/data/9.7,.
DataMemory,2G,98M
FileSystemPath,/local/data/9.7,(null)
```

```

HostName,127.0.0.1,localhost
Nodegroup,0,(null)
ThreadConfig,,(null)

config of [DB] node id 6 that is different from default
CONFIG_PARAMETER,ACTUAL_VALUE,DEFAULT_VALUE
NodeId,6,(mandatory)
BackupDataDir,/local/data/9.7,(null)
DataDir,/local/data/9.7.
DataMemory,2G,98M
FileSystemPath,/local/data/9.7,(null)
HostName,127.0.0.1,localhost
Nodegroup,0,(null)
ThreadConfig,,(null)

$> ndb_config --config-binary-file=../mysql-cluster/ndb_50_config.bin.1 --diff-default --system
config of [SYSTEM] system
CONFIG_PARAMETER,ACTUAL_VALUE,DEFAULT_VALUE
Name,MC_20220906060042,(mandatory)
ConfigGenerationNumber,1,0
PrimaryMGMNode,50,0
    
```

The relevant portions of the `config.ini` file are shown here:

```

[ndbd default]
DataMemory= 2G
NoOfReplicas= 2

[ndb_mgmd]
NodeId= 50
HostName= 127.0.0.1

[ndbd]
NodeId= 5
HostName= 127.0.0.1
DataDir= /local/data/9.7

[ndbd]
NodeId= 6
HostName= 127.0.0.1
DataDir= /local/data/9.7
    
```

By comparing the output with the configuration file, you can see that all of the settings in the file have been written by the management server to the binary cache, and thus, applied to the cluster.

- `--config-file=path-to-file`

Command-Line Format	<code>--config-file=file_name</code>
Type	File name
Default Value	

Gives the path to the cluster configuration file (`config.ini`). This may be a relative or absolute path. If the management server and the `ndb_config` binary used reside on different hosts, you must use an absolute path.

- `--config_from_node=#`

Command-Line Format	<code>--config-from-node=#</code>
Type	Numeric
Default Value	<code>none</code>

Minimum Value	1
Maximum Value	48

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--connections`

Command-Line Format	<code>--connections</code>
---------------------	----------------------------

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see [Section 25.4.3.10, “NDB Cluster TCP/IP Connections”](#), and [Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”](#), for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--diff-default`

Command-Line Format	<code>--diff-default</code>
---------------------	-----------------------------

Print only configuration parameters that have non-default values.

- `--fields=delimiter, -f delimiter`

Command-Line Format	<code>--fields=string</code>
Type	String
Default Value	

Specifies a *delimiter* string used to separate the fields in the result. The default is `,` (the comma character).

**Note**

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--host=hostname`

Command-Line Format	<code>--host=name</code>
Type	String
Default Value	

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read given path from login file.

- `--mycnf`

Command-Line Format	<code>--mycnf</code>
---------------------	----------------------

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string, -c connection_string`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), and defaults to `localhost:1186`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
---------------------	----------------------------------

Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	<code>[none]</code>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--nodeid=node_id`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

Command-Line Format	<code>--nodes</code>
---------------------	----------------------

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#)).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--query=query-options, -q query-options`

Command-Line Format	<code>--query=string</code>
Type	String

Default Value	
---------------	--

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

**Note**

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all, -a`

Command-Line Format	<code>--query-all</code>
Type	String
Default Value	

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

- `--rows=separator, -r separator`

Command-Line Format	<code>--rows=string</code>
Type	String
Default Value	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

**Note**

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--system`

Command-Line Format	<code>--system</code>
---------------------	-----------------------

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `***** SYSTEM *****`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

Command-Line Format	<code>--type=name</code>
Type	Enumeration
Default Value	<code>[none]</code>

Valid Values	<p>ndbd</p> <p>mysqld</p> <p>ndb_mgmd</p>
--------------	---

Filters results so that only configuration values applying to nodes of the specified *node\_type* (ndbd, mysqld, or ndb\_mgmd) are returned.

- `--usage`, `--help`, or `-?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

Command-Line Format	<code>--configinfo --xml</code>
---------------------	---------------------------------

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```
$> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.44-ndb-7.5.36"
  ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
  ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
      default="false"/>
    <param name="HostName" comment="Name of computer for this node"
      type="string" default=""/>
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
      min="1" max="255" deprecated="true"/>
    <param name="NodeId" comment="Number identifying application node (mysqld(API))"
      type="unsigned" mandatory="true" min="1" max="255"/>
    <param name="ExecuteOnComputer" comment="HostName" type="string"
      deprecated="true"/>
    ...
  </section>
  ...
</configvariables>
```

```
</configvariables>
```

### Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
  restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
  type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Parameters that are required are indicated with `mandatory="true"`, as shown here:

```
<param name="NodeId"
  comment="Number identifying application node (mysqld(API))"
  type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

### Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this

reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

## Examples

1. To obtain the node ID and type of each node in the cluster:

```
$> ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
$> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
$> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
$> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

## 25.5.8 ndb\_delete\_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

## Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database, -d`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	TEST_DB

Name of the database containing the table to delete from.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--diskscan`

Command-Line Format	<code>--diskscan</code>
---------------------	-------------------------

Run a disk scan.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code>  <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

- `--tupscan`

Run a tuple scan.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## 25.5.9 ndb\_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 337
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
```

```

uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count    Frag fixed memory    Frag var sized memory    Extent_spa
0              2              2              32768                32768                    0
1              4              4              32768                32768                    0
    
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```

$> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex
    
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see [NDB Schema Object Versions](#).

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
+-----+-----+-----+
| Level   | Code | Message
+-----+-----+-----+
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in comment'
+-----+-----+-----+
1 row in set (0.00 sec)
```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; `NDB` sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish\G
***** 1. row *****
      Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
```

```
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition          Row count          Commit count      Frag fixed memory      Frag varsized memory      Extent_spa
```

For more information about these table properties, see [Section 15.1.24.12, “Setting NDB Comment Options”](#).

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see [Section 25.6.11.1, “NDB Cluster Disk Data Objects”](#), as well as [Section 15.1.20, “CREATE LOGFILE GROUP Statement”](#), and [Section 15.1.25, “CREATE TABLESPACE Statement”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
DROP TABLE IF EXISTS fish;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```

$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 1001
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
Tablespace id: 16
Tablespace: ts_1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(80;utf8mb4_0900_ai_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag varsized memory      Extent_space
0               2               2                 32768                  32768                    1048576
1               4               4                 32768                  32768                    1048576

```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words,  $1048576 - 1044440 = 4136$  bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the Information Schema `FILES` table.

`Tablespace id` and `Tablespace` are also displayed for Disk Data tables.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

All options that can be used with `ndb_desc` are shown in the following table. Additional descriptions follow the table.

- `--auto-inc, -a`

Show the next value for a table's `AUTO_INCREMENT` column, if it has one.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--context, -x`

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database=db_name, -d`

Specify the database in which the table should be found.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connect string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name

Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--retries=#, -r`

Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name, -t`

Specify the table in which to look for an index.

- `--unqualified, -u`

Use unqualified table names.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

Table indexes listed in the output are ordered by ID.

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

## Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database, -d`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	TEST_DB

Name of the database in which the table resides.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id:] [host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>	4599
Type	Path name	
Default Value (Unix)	<code>\$HOME/ndb-tls</code>	

Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>
-------------------------	--------------------------------

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

### Warning

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*

```
$> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

$> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.44-ndb-7.5.36
```

```
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;

| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 25.5.11, “ndb\\_drop\\_table — Drop an NDB Table”](#)) to drop the table.

## 25.5.11 ndb\_drop\_table — Drop an NDB Table

`ndb_drop_table` drops the specified `NDB` table. (If you try to use this on a table created with a storage engine other than `NDB`, the attempt fails with the error `723: No such table exists`.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an `NDB` table.

### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with `ndb_drop_table` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
---------------------	--------------------------------------

Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database, -d`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	TEST_DB

Name of the database in which the table resides.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## 25.5.12 ndb\_error\_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

Options that can be used with `ndb_error_reporter` are shown in the following table. Additional descriptions follow the table.

### Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where `YYYYMMDDhhmmss` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

Command-Line Format	<code>--connection-timeout=#</code>
Type	Integer
Default Value	0

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

Command-Line Format	<code>--dry-scp</code>
---------------------	------------------------

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--fs`

Command-Line Format	<code>--fs</code>
---------------------	-------------------

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodgroup=nodgroup_id`

Command-Line Format	<code>--connection-timeout=#</code>
Type	Integer
Default Value	0

Skip all nodes belong to the node group having the supplied node group ID.

## 25.5.13 ndb\_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

### Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section.

`ndb_import` rejects any empty lines which it reads from the CSV file, except when importing a single column, in which case an empty value can be used as the column value. `ndb_import` handles this in the same manner as a `LOAD DATA` statement does.

`ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused `[api]` slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as `InnoDB`, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing `InnoDB` table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

```
mysql> USE myinnodb;

mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
> FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
> LINES TERMINATED BY '\n'
> FROM myinnodbttable;

mysql> CREATE DATABASE myndb;
```

```
mysql> USE myndb;

mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;

mysql> ALTER TABLE myndb_table ENGINE=NDB;

mysql> EXIT;
Bye
$>
```

Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
$> cd path-to-mysql-bin-dir

$> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by=''' \
--fields-terminated-by="," --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
$>
```

All options that can be used with `ndb_import` are shown in the following table. Additional descriptions follow the table.

- `--abort-on-error`

Command-Line Format	<code>--abort-on-error</code>
---------------------	-------------------------------

Dump core on any fatal error; used for debugging only.

- `--ai-increment=#`

Command-Line Format	<code>--ai-increment=#</code>
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- `--ai-offset=#`

Command-Line Format	<code>--ai-offset=#</code>
Type	Integer
Default Value	1

Minimum Value	1
Maximum Value	4294967295

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- `--ai-prefetch-sz=#`

Command-Line Format	<code>--ai-prefetch-sz=#</code>
Type	Integer
Default Value	1024
Minimum Value	1
Maximum Value	4294967295

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connections=#`

Command-Line Format	<code>--connections=#</code>
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

Number of cluster connections to create.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0

Maximum Value	5
---------------	---

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--continue`

Command-Line Format	<code>--continue</code>
---------------------	-------------------------

When a job fails, continue to the next job.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--csvopt=string`

Command-Line Format	<code>--csvopt=opts</code>
Type	String
Default Value	[none]

Provides a shortcut method for setting typical CSV import options. The argument to this option is a string consisting of one or more of the following parameters:

- `c`: Fields terminated by comma
- `d`: Use defaults, except where overridden by another parameter
- `n`: Lines terminated by `\n`
- `q`: Fields optionally enclosed by double quote characters (")
- `r`: Line terminated by `\r`

The order of parameters used in the argument to this option is handled such that the rightmost parameter always takes precedence over any potentially conflicting parameters which have already been used in the same argument value. This also applies to any duplicate instances of a given parameter.

This option is intended for use in testing under conditions in which it is difficult to transmit escapes or quotation marks.

- `--db-workers=#`

Command-Line Format	<code>--db-workers=#</code>
Type	Integer

Default Value	4
Minimum Value	1
Maximum Value	4294967295

Number of threads, per data node, executing database operations.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--errins-type=name`

Command-Line Format	<code>--errins-type=name</code>
Type	Enumeration
Default Value	[none]
Valid Values	<code>stopjob</code> <code>stopall</code> <code>sigint</code> <code>list</code>

Error insert type; use `list` as the `name` value to obtain all possible values. This option is used for testing purposes only.

- `--errins-delay=#`

Command-Line Format	<code>--errins-delay=#</code>
---------------------	-------------------------------

Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295
Unit	ms

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- `--fields-enclosed-by=char`

Command-Line Format	<code>--fields-enclosed-by=char</code>
Type	String
Default Value	[none]

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- `--fields-escaped-by=name`

Command-Line Format	<code>--fields-escaped-by=char</code>
Type	String
Default Value	\

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

- `--fields-optionally-enclosed-by=char`

Command-Line Format	<code>--fields-optionally-enclosed-by=char</code>
Type	String
Default Value	[none]

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- `--fields-terminated-by=char`

Command-Line Format	<code>--fields-terminated-by=char</code>
Type	String
Default Value	\t

This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--idlesleep=#`

Command-Line Format	<code>--idlesleep=#</code>
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295
Unit	ms

Number of milliseconds to sleep waiting for more work to perform.

- `--idlespin=#`

Command-Line Format	<code>--idlespin=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Number of times to retry before sleeping.

- `--ignore-lines=#`

Command-Line Format	<code>--ignore-lines=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Cause `ndb_import` to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- `--input-type=name`

Command-Line Format	<code>--input-type=name</code>
Type	Enumeration
Default Value	<code>csv</code>
Valid Values	<code>random</code> <code>csv</code>

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only. .

- `--input-workers=#`

Command-Line Format	<code>--input-workers=#</code>
---------------------	--------------------------------

Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	4294967295

Set the number of threads processing input.

- `--keep-state`

Command-Line Format	<code>--keep-state</code>
---------------------	---------------------------

By default, `ndb_import` removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- `--lines-terminated-by=name`

Command-Line Format	<code>--lines-terminated-by=char</code>
Type	String
Default Value	<code>\n</code>

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- `--log-level=#`

Command-Line Format	<code>--log-level=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--max-rows=#`

Command-Line Format	<code>--max-rows=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Import only this number of input data rows; the default is 0, which imports all rows.

- `--missing-ai-column`

Command-Line Format	<code>--missing-ai-column='name'</code>
Type	Boolean
Default Value	FALSE

This option can be employed when importing a single table, or multiple tables. When used, it indicates that the CSV file being imported does not contain any values for an `AUTO_INCREMENT` column, and that `ndb_import` should supply them; if the option is used and the `AUTO_INCREMENT` column contains any values, the import operation cannot proceed.

- `--monitor=#`

Command-Line Format	<code>--monitor=#</code>
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id; ] [host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	relaxed

Valid Values	<code>relaxed</code> <code>strict</code>
--------------	---

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	<code>[none]</code>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-async`

Command-Line Format	<code>--no-async</code>
---------------------	-------------------------

Run database operations as batches, in single transactions.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--no-hint`

Command-Line Format	<code>--no-hint</code>
---------------------	------------------------

Do not use distribution key hinting to select a data node.

- `--opbatch=#`

Command-Line Format	<code>--opbatch=#</code>
Type	Integer
Default Value	256
Minimum Value	1
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- `--opbytes=#`

Command-Line Format	<code>--opbytes=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- `--output-type=name`

Command-Line Format	<code>--output-type=name</code>
Type	Enumeration
Default Value	<code>ndb</code>
Valid Values	<code>null</code>

Set the output type. `ndb` is the default. `null` is used only for testing.

- `--output-workers=#`

Command-Line Format	<code>--output-workers=#</code>
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	4294967295

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

Command-Line Format	<code>--pagesize=#</code>
Type	Integer
Default Value	4096
Minimum Value	1
Maximum Value	4294967295
Unit	bytes

Align I/O buffers to the given size.

- `--pagecnt=#`

Command-Line Format	<code>--pagecnt=#</code>
Type	Integer
Default Value	64
Minimum Value	1
Maximum Value	4294967295

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

Command-Line Format	<code>--polltimeout=#</code>
Type	Integer
Default Value	1000
Minimum Value	1
Maximum Value	4294967295
Unit	ms

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--rejects=#`

Command-Line Format	<code>--rejects=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the `.rej` file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using `--resume` is considered a “new” run for this purpose.

- `--resume`

Command-Line Format	<code>--resume</code>
---------------------	-----------------------

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- `--rowbatch=#`

Command-Line Format	<code>--rowbatch=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	rows

Set a limit on the number of rows per row queue. Use 0 for no limit.

- `--rowbytes=#`

Command-Line Format	<code>--rowbytes=#</code>
Type	Integer
Default Value	262144
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- `--stats`

Command-Line Format	<code>--stats</code>
---------------------	----------------------

Save information about options related to performance and other internal statistics in files named `*.sto` and `*.stt`. These files are always kept on successful completion (even if `--keep-state` is not also specified).

- `--state-dir=name`

Command-Line Format	<code>--state-dir=path</code>
Type	String
Default Value	.

Where to write the state files (`tbl_name.map`, `tbl_name.rej`, `tbl_name.res`, and `tbl_name.stt`) produced by a run of the program; the default is the current directory.

- `--table=name`

Command-Line Format	<code>--table=name</code>
Type	String
Default Value	[input file base name]

By default, `ndb_import` attempts to import data into a table whose name is the base name of the CSV file from which the data is being read. You can override the choice of table name by specifying it with the `--table` option (short form `-t`).

- `--tempdelay=#`

Command-Line Format	<code>--tempdelay=#</code>
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	4294967295
Unit	ms

Number of milliseconds to sleep between temporary errors.

- `--temperrors=#`

Command-Line Format	<code>--temperrors=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- `--verbose, -v`

Command-Line Format	<code>--verbose[=#]</code>
Type	Boolean
Default Value	<code>false</code>

Enable verbose output.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

## 25.5.14 ndb\_index\_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

### Usage

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
$> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
$> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

$>
```

If the output from the program is empty, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

## Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
---------------------	--------------------------------------

Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database=name, -d name`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	[none]
Minimum Value	
Maximum Value	

The name of the database that contains the table being queried.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
---------------------	---

Type	String
Default Value	[none]

Also read groups with concat(group, suffix).

- `--delete`

Command-Line Format	<code>--delete</code>
---------------------	-----------------------

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--dump`

Command-Line Format	<code>--dump</code>
---------------------	---------------------

Dump the contents of the query cache.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--loops=#`

Command-Line Format	<code>--loops=#</code>
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	MAX_INT

Repeat commands this number of times (for use in testing).

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code>  <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	<code>[none]</code>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory

reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--query=#`

Command-Line Format	<code>--query=#</code>
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	<code>MAX_INT</code>

Perform random range queries on first key attribute (must be int unsigned).

- `--sys-drop`

Command-Line Format	<code>--sys-drop</code>
---------------------	-------------------------

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

Command-Line Format	<code>--sys-create</code>
---------------------	---------------------------

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `--sys-create-if-not-exist`

Command-Line Format	<code>--sys-create-if-not-exist</code>
---------------------	--

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

Command-Line Format	<code>--sys-create-if-not-valid</code>
---------------------	--

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

Command-Line Format	<code>--sys-check</code>
---------------------	--------------------------

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

Command-Line Format	<code>--sys-skip-tables</code>
---------------------	--------------------------------

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

Command-Line Format	<code>--sys-skip-events</code>
---------------------	--------------------------------

Do not apply any `--sys-*` options to any events.

- `--update`

Command-Line Format	<code>--update</code>
---------------------	-----------------------

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Turn on verbose output.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

**ndb\_index\_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb\\_index\\_stat statistics options](#)).

- `--sys-drop`
- `--sys-create`

- `--sys-create-if-not-exist`
- `--sys-create-if-not-valid`
- `--sys-check`
- `--sys-skip-tables`
- `--sys-skip-events`

**ndb\_index\_stat statistics options.** The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see [ndb\\_index\\_stat system options](#)).

- `--database`
- `--delete`
- `--update`
- `--dump`
- `--query`

## 25.5.15 ndb\_move\_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

### Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

Options that can be used with `ndb_move_data` are shown in the following table. Additional descriptions follow the table.

- `--abort-on-error`

Command-Line Format	<code>--abort-on-error</code>
---------------------	-------------------------------

Dump core on permanent error (debug option).

- `--character-sets-dir=name`

Command-Line Format	<code>--character-sets-dir=path</code>
Type	String
Default Value	[none]

Directory where character sets are.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
---------------------	--------------------------------------

Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database=dbname, -d`

Command-Line Format	<code>--database=name</code>
Type	String
Default Value	TEST_DB

Name of the database in which the table is found.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
---------------------	-----------------------------------

Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--drop-source`

Command-Line Format	<code>--drop-source</code>
---------------------	----------------------------

Drop source table after all rows have been moved.

- `--error-insert`

Command-Line Format	<code>--error-insert</code>
---------------------	-----------------------------

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

Command-Line Format	<code>--exclude-missing-columns</code>
---------------------	--

Ignore extra columns in source or target table.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--lossy-conversions, -l`

Command-Line Format	<code>--lossy-conversions</code>
---------------------	----------------------------------

Allow attribute data to be truncated when converted to a smaller type.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name

Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--promote-attributes, -A`

Command-Line Format	<code>--promote-attributes</code>
---------------------	-----------------------------------

Allow attribute data to be converted to a larger type.

- `--staging-tries=x[,y[,z]]`

Command-Line Format	<code>--staging-tries=x[,y[,z]]</code>
Type	String
Default Value	<code>0,1000,60000</code>

Specify tries on temporary errors. Format is `x[,y[,z]]` where `x`=max tries (0=no limit), `y`=min delay (ms), `z`=max delay (ms).

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Enable verbose messages.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## 25.5.16 ndb\_perror — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. This is intended as a drop-in replacement for `pererror --ndb`, which is no longer supported.

### Usage

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
$> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
$> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `pererror`, `ndb_perror` accepts multiple error codes:

```
$> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.

`ndb_perror` replaces `pererror --ndb`, which is no longer supported by NDB Cluster. To make substitution easier in scripts and other applications that might depend on `pererror` for obtaining NDB error information, `ndb_perror` supports its own “dummy” `--ndb` option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program `ndb_perror`. Additional descriptions follow the table.

### Additional Options

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display program help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--ndb`

Command-Line Format	<code>--ndb</code>
---------------------	--------------------

For compatibility with applications depending on old versions of `perror` that use that program's `--ndb` option. The option when used with `ndb_perror` does nothing, and is ignored by it.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--silent, -s`

Command-Line Format	<code>--silent</code>
---------------------	-----------------------

Show error message only.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Print program version information and exit.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Verbose output; disable with `--silent`.

## 25.5.17 ndb\_print\_backup\_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

### Usage

```
ndb_print_backup_file [-P password] file_name
```

*file\_name* is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 25.6.8.1, “NDB Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

This program can also be used to read undo log files.

### Options

`ndb_print_backup_file` supports the options described in the following list.

- `--backup-key, -K`

Command-Line Format	<code>--backup-key=key</code>
---------------------	-------------------------------

Specify the key needed to decrypt an encrypted backup.

- `--backup-key-from-stdin`

Command-Line Format	<code>--backup-key-from-stdin</code>
---------------------	--------------------------------------

Allow input of the decryption key from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- `--backup-password`

Command-Line Format	<code>--backup-password=password</code>
Type	String
Default Value	[none]

Specify the password needed to decrypt an encrypted backup.

- `--backup-password-from-stdin`

Command-Line Format	<code>--backup-password-from-stdin</code>
---------------------	---

Allow input of the password from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- `--control-directory-number`

Command-Line Format	<code>--control-directory-number=#</code>
Type	Integer
Default Value	0

Control file directory number. Used together with `--print-restored-rows`.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--fragment-id`

Command-Line Format	<code>--fragment-id=#</code>
Type	Integer

Default Value	0
---------------	---

Fragment ID. Used together with `--print-restored-rows`.

- `--help`

Command-Line Format	<code>--help</code> <code>--usage</code>
---------------------	---

Print program usage information.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--no-print-rows`

Command-Line Format	<code>--no-print-rows</code>
---------------------	------------------------------

Do not include rows in output.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--print-header-words`

Command-Line Format	<code>--print-header-words</code>
---------------------	-----------------------------------

Include header words in output.

- `--print-restored-rows`

Command-Line Format	<code>--print-restored-rows</code>
---------------------	------------------------------------

Include restored rows in output, using the file `LCP/c/TtFf.ct1`, for which the values are set as follows:

- `c` is the control file number set using `--control-directory-number`
- `t` is the table ID set using `--table-id`
- `f` is the fragment ID set using `--fragment-id`
- `--print-rows`

Command-Line Format	<code>--print-rows</code>
---------------------	---------------------------

Print rows. This option is enabled by default; to disable it, use `--no-print-rows`.

- `--print-rows-per-page`

Command-Line Format	<code>--print-rows-per-page</code>
---------------------	------------------------------------

Print rows per page.

- `--rowid-file`

Command-Line Format	<code>--rowid-file=path</code>
Type	File name
Default Value	[none]

File to check for row ID.

- `--show-ignored-rows`

Command-Line Format	<code>--show-ignored-rows</code>
---------------------	----------------------------------

Show ignored rows.

- `--table-id`

Command-Line Format	<code>--table-id=#</code>
Type	Integer
Default Value	[none]

Table ID. Used together with `--print-restored-rows`.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose`

Command-Line Format	<code>--verbose[=#]</code>
Type	Integer
Default Value	0

Verbosity level of output. A greater value indicates increased verbosity.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## 25.5.18 ndb\_print\_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

### Usage

```
ndb_print_file [-v] [-q] file_name+
```

*file\_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Options

`ndb_print_file` supports the following options:

- `--file-key, -K`

Command-Line Format	<code>--file-key=hex_data</code>
---------------------	----------------------------------

Supply file system encryption or decryption key from `stdin`, `tty`, or a `my.cnf` file.

- `--file-key-from-stdin`

Command-Line Format	<code>--file-key-from-stdin</code>
Type	Boolean
Default Value	FALSE
Valid Values	TRUE

Supply file system encryption or decryption key from `stdin`.

- `--help, -h, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Print help message and exit.

- `--quiet, -q`

Command-Line Format	<code>--quiet</code>
---------------------	----------------------

Suppress output (quiet mode).

- `--usage, -?`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Print help message and exit.

- `--verbose, -v`

Command-Line Format	<code>--verbose</code>
---------------------	------------------------

Make output verbose.

- `--version, -v`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Print version information and exit.

For more information, see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#).

## 25.5.19 ndb\_print\_frag\_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

### Usage

```
ndb_print_frag_file file_name
```

*file\_name* is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where *X* is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID *nodeid*, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where *N* is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

### Sample Output

```
$> ndb_print_frag_file /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192

```

## 25.5.20 ndb\_print\_schema\_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

### Usage

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 25.5.21 ndb\_print\_sys\_file — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

### Usage

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_sys_file` must be run on a cluster data node, since it accesses the data node file

system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 25.5.22 ndb\_redo\_log\_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Options that can be used with `ndb_redo_log_reader` are shown in the following table. Additional descriptions follow the table.

### Usage

```
ndb_redo_log_reader file_name [options]
```

`file_name` is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#.FragLog.nodeid` is the data node's node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see [NDB Cluster Data Node File System Directory](#).

The name of the file to be read may be followed by one or more of the options listed here:

- `-dump`

Command-Line Format	<code>-dump</code>
---------------------	--------------------

Print dump info.

- `--file-key, -K`

Command-Line Format	<code>--file-key=key</code>
---------------------	-----------------------------

Supply file decryption key using `stdin`, `tty`, or a `my.cnf` file.

- `--file-key-from-stdin`

Command-Line Format	<code>--file-key-from-stdin</code>
---------------------	------------------------------------

Supply file decryption key using `stdin`.

- `-filedescriptors`

Command-Line Format	<code>-filedescriptors</code>
---------------------	-------------------------------

`-filedescriptors`: Print file descriptors only.

- |                     |                     |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

`--help`: Print usage information.

- `-lap`

Command-Line Format	<code>-lap</code>
---------------------	-------------------

Provide lap info, with max GCI started and completed.

- |                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>-mbyte #</code> |
| Type                | Numeric               |
| Default Value       | 0                     |
| Minimum Value       | 0                     |
| Maximum Value       | 15                    |

`-mbyte #`: Starting megabyte.

`#` is an integer in the range 0 to 15, inclusive.

- |                     |                            |
|---------------------|----------------------------|
| Command-Line Format | <code>-mbyteheaders</code> |
|---------------------|----------------------------|

`-mbyteheaders`: Show only the first page header of every megabyte in the file.

- |                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>-noprint</code> |
|---------------------|-----------------------|

`-noprint`: Do not print the contents of the log file.

- |                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>-nocheck</code> |
|---------------------|-----------------------|

`-nocheck`: Do not check the log file for errors.

- |                     |                      |
|---------------------|----------------------|
| Command-Line Format | <code>-page #</code> |
| Type                | Integer              |
| Default Value       | 0                    |
| Minimum Value       | 0                    |
| Maximum Value       | 31                   |

`-page #`: Start at this page.

`#` is an integer in the range 0 to 31, inclusive.

- |                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>-pageheaders</code> |
|---------------------|---------------------------|

`-pageheaders`: Show page headers only.

- |                     |                           |
|---------------------|---------------------------|
| Command-Line Format | <code>-pageindex #</code> |
| Type                | Integer                   |

Default Value	12
Minimum Value	12
Maximum Value	8191

`-pageindex #`: Start at this page index.

`#` is an integer between 12 and 8191, inclusive.

- `-twiddle`

Command-Line Format	<code>-twiddle</code>
---------------------	-----------------------

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### 25.5.23 ndb\_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 25.6.6, “NDB Cluster Single User Mode”](#), for more information.

Options that can be used with `ndb_restore` are shown in the following table. Additional descriptions follow the table.

- `--allow-pk-changes`

Command-Line Format	<code>--allow-pk-changes[=0 1]</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When this option is set to 1, `ndb_restore` allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using `ndb_restore` is simpler or more efficient than issuing many `ALTER TABLE` statements after restoring table schemas and data.

The following changes in primary key definitions are supported by `--allow-pk-changes`:

- **Extending the primary key:** A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

### Important

When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by `ndb_restore` cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the `--ignore-extended-pk-updates` option; see the description of this option for more information.

- **Contracting the primary key (1):** A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.
- **Contracting the primary key (2):** A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel. (Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

- `--append`

Command-Line Format	<code>--append</code>
---------------------	-----------------------

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- `--backup-path=dir_name`

Command-Line Format	<code>--backup-path=path</code>
Type	Directory name
Default Value	<code>./</code>

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 25.3.7, “Upgrading and Downgrading NDB Cluster”](#), for more information.

**Important**

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 8.4.7 to a cluster running NDB Cluster 8.0.44, you must use the `ndb_restore` that comes with the NDB Cluster 8.0.44 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backup-password=password`

Command-Line Format	<code>--backup-password=password</code>
Type	String
Default Value	<code>[none]</code>

This option specifies a password to be used when decrypting an encrypted backup with the `--decrypt` option. This must be the same password that was used to encrypt the backup.

The password must be 1 to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for `!`, `'`, `"`, `$`, `%`, `\`, and `^`.

It is possible to omit the password, in which case `ndb_restore` waits for it to be supplied from `stdin`, as when using `--backup-password-from-stdin`.

- `--backup-password-from-stdin[=TRUE|FALSE]`

Command-Line Format	<code>--backup-password-from-stdin</code>
---------------------	---

When used in place of `--backup-password`, this option enables input of the backup password from the system shell (`stdin`), similar to how this is done when supplying the password interactively to `mysql` when using the `--password` without supplying the password on the command line.

- `--backupid=#, -b`

Command-Line Format	<code>--backupid=#</code>
Type	Numeric
Default Value	<code>none</code>

This option is required; it is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).)

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups results at best in restoring the cluster to an inconsistent state, and is likely to fail altogether.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect, -c`

Command-Line Format	<code>--connect=connection_string</code>
Type	String
Default Value	<code>localhost:1186</code>

Alias for `--ndb-connectstring`.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	<code>12</code>
Minimum Value	<code>0</code>
Maximum Value	<code>12</code>

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
---------------------	--------------------------------------

Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--decrypt`

Command-Line Format	<code>--decrypt</code>
---------------------	------------------------

Decrypt an encrypted backup using the password supplied by the `--backup-password` option.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--disable-indexes`

Command-Line Format	<code>--disable-indexes</code>
---------------------	--------------------------------

Disable restoration of indexes during restoration of the data from a native `NDB` backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

This option also drops any foreign keys specified in the backup.

MySQL can open an `NDB` table for which one or more indexes cannot be found, provided the query does not use any of the affected indexes; otherwise the query is rejected with `ER_NOT_KEYFILE`. In the latter case, you can temporarily work around the problem by executing an `ALTER TABLE` statement such as this one:

```
ALTER TABLE tbl ALTER INDEX idx INVISIBLE;
```

This causes MySQL to ignore the index `idx` on table `tbl`. See [Primary Keys and Indexes](#), for more information, as well as [Section 10.3.12, “Invisible Indexes”](#).

- `--dont-ignore-systab-0, -f`

Command-Line Format	<code>--dont-ignore-systab-0</code>
---------------------	-------------------------------------

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the `NDB` system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

Command-Line Format	<code>--exclude-databases=list</code>
Type	String
Default Value	

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

Command-Line Format	<code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code>
Type	Boolean
Default Value	TRUE

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- `--exclude-missing-columns`

Command-Line Format	<code>--exclude-missing-columns</code>
---------------------	--

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

Command-Line Format	<code>--exclude-missing-tables</code>
---------------------	---------------------------------------

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- `--exclude-tables=table-list`

Command-Line Format	<code>--exclude-tables=list</code>
Type	String
Default Value	

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

**Table 25.23** Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.

Option	Result
<code>--exclude-databases=db1</code>	All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored
<code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code> )	All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored
<code>--exclude-tables=db1.t1</code>	All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored
<code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code> )	All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are

Option	Result
	restored; all tables in all other databases are restored

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
$> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

Command-Line Format	<code>--fields-enclosed-by=char</code>
Type	String
Default Value	

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

Command-Line Format	<code>--fields-optionally-enclosed-by</code>
Type	String
Default Value	

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

Command-Line Format	<code>--fields-terminated-by=char</code>
---------------------	--

Type	String
Default Value	\t (tab)

The string passed to this option is used to separate column values. The default value is a tab character (\t).

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--hex`

Command-Line Format	<code>--hex</code>
---------------------	--------------------

If this option is used, all binary values are output in hexadecimal format.

- `--ignore-extended-pk-updates`

Command-Line Format	<code>--ignore-extended-pk-updates[=0 1]</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

When using `--allow-pk-changes`, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

### Important

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.

- `--include-databases=db-list`

Command-Line Format	<code>--include-databases=list</code>
Type	String
Default Value	

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-stored-grants`

Command-Line Format	<code>--include-stored-grants</code>
---------------------	--------------------------------------

`ndb_restore` does not by default restore shared users and grants (see [Section 25.6.13, “Privilege Synchronization and NDB\\_STORED\\_USER”](#)) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- `--include-tables=table-list`

Command-Line Format	<code>--include-tables=list</code>
Type	String
Default Value	

Comma-delimited list of tables to restore; each table reference must include the database name.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 25.24** Several invocations of `ndb_restore` using `--include-*` options, and their effects on restoring from an NDB Cluster backup.

Option	Result
<code>--include-databases=db1</code>	Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored
<code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code> )	Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored
<code>--include-tables=db1.t1</code>	Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored

Option	Result
<code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code> )	Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
$> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...]] | tbl_name[,tbl_name][[,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- `--lines-terminated-by=char`

Command-Line Format	<code>--lines-terminated-by=char</code>
Type	String
Default Value	<code>\n</code> (linebreak)

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--lossy-conversions, -L`

Command-Line Format	<code>--lossy-conversions</code>
---------------------	----------------------------------

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for

MySQL replication; see [Replication of Columns Having Different Data Types](#), for information about specific type conversions currently supported by attribute demotion.

This option also makes it possible to restore a `NULL` column as `NOT NULL`. The column must not contain any `NULL` entries; otherwise `ndb_restore` stops with an error.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`

Command-Line Format	<code>--no-binlog</code>
---------------------	--------------------------

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-restore-disk-objects, -d`

Command-Line Format	<code>--no-restore-disk-objects</code>
---------------------	--

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#), for more information about these.

- `--no-upgrade, -u`

Command-Line Format	<code>--no-upgrade</code>
---------------------	---------------------------

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id; ] [host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodegroup-map=map, -z`

Command-Line Format	<code>--ndb-nodegroup-map=map</code>
---------------------	--------------------------------------

Any value set for this option is ignored, and the option itself does nothing.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--nodeid=#, -n`

Command-Line Format	<code>--nodeid=#</code>
Type	Numeric
Default Value	<code>none</code>

Specify the node ID of the data node on which the backup was taken; required.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See [Restoring to a different number of data nodes](#), for additional information and examples.

- `--num-slices=#`

Command-Line Format	<code>--num-slices=#</code>
Type	Integer
Default Value	<code>1</code>
Minimum Value	<code>1</code>
Maximum Value	<code>1024</code>

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of `ndb_restore` to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the `--slice-id` option. The two options must always be used together, and the value set by `--slice-id` must always be less than the number of slices.

`ndb_restore` encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a `BLOB` table, the slice to which a given fragment belongs is determined using the formula shown here:

$$[slice\_ID] = [fragment\_counter] \% [number\_of\_slices]$$

For a `BLOB` table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the `BLOB` table (recall that `NDB` stores `BLOB` values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

$$[slice\_ID] =$$

```
(([main_table_ID] + [fragment_ID]) % [number_of_slices])
```

Thus, restoring by *N* slices means running *N* instances of `ndb_restore`, all with `--num-slices=N` (along with any other necessary options) and one each with `--slice-id=1`, `--slice-id=2`, `--slice-id=3`, and so on through `slice-id=N-1`.

**Example.** Assume that you want to restore a backup named `BACKUP-1`, found in the default directory `/var/lib/mysql-cluster/BACKUP/BACKUP-3` on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using `ndb_restore` as shown here:

```
$> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
```

2. Restore the cluster data to the data nodes invoking `ndb_restore` as shown here:

```
$> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/B

$> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/B

$> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/B

$> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/B
$> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/B
```

All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the `--backup-path` option).

3. Restore indexes as usual, as shown here:

```
$> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```
$> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a *single* `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism`

causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMS.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

- `--parallelism=#, -p`

Command-Line Format	<code>--parallelism=#</code>
Type	Numeric
Default Value	128
Minimum Value	1
Maximum Value	1024

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces, -P`

Command-Line Format	<code>--preserve-trailing-spaces</code>
---------------------	---

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

Command-Line Format	<code>--print</code>
---------------------	----------------------

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

**Note**

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected

to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- `--print-data`

Command-Line Format	<code>--print-data</code>
---------------------	---------------------------

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

`TEXT` and `BLOB` column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--print-log`

Command-Line Format	<code>--print-log</code>
---------------------	--------------------------

Cause `ndb_restore` to output its log to `stdout`.

- `--print-meta`

Command-Line Format	<code>--print-meta</code>
---------------------	---------------------------

Print all metadata to `stdout`.

- `print-sql-log`

Command-Line Format	<code>--print-sql-log</code>
---------------------	------------------------------

Log SQL statements to `stdout`. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by `NDB` cannot be converted to valid SQL.

This option does not work with tables having `BLOB` columns.

- `--progress-frequency=N`

Command-Line Format	<code>--progress-frequency=#</code>
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	65535

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- `--promote-attributes, -A`

Command-Line Format	<code>--promote-attributes</code>
---------------------	-----------------------------------

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Replication of Columns Having Different Data Types](#), for a table of type conversions currently supported by attribute promotion.

This option also makes it possible to restore a `NOT NULL` column as `NULL`.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$Stnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- `--rebuild-indexes`

Command-Line Format	<code>--rebuild-indexes</code>
---------------------	--------------------------------

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMS.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMS by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data

node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--remap-column=db.tbl.col:fn:args`

Command-Line Format	<code>--remap-column=string</code>
Type	String
Default Value	[none]

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- `db`: Database name, following any renames performed by `--rewrite-database`.
- `tbl`: Table name.
- `col`: Name of the column to be updated. This column must be of type `INT` or `BIGINT`. The column can also be but is not required to be `UNSIGNED`.
- `fn`: Function name; currently, the only supported name is `offset`.
- `args`: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an `INT` column, then the allowed range of the argument passed to the `offset` function is `-2147483648` to `2147483647` (see [Section 13.1.2, "Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT"](#)).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a `BIGINT`, and the option attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since  $4294967291 + 8 = 4294967299 > 4294967295$ .

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see [Section 25.6.8.2, "Using The NDB Cluster Management Client to Create a Backup"](#)) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
$> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
```

```
--remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
$> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
--remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can be obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

- `--restore-data, -r`

Command-Line Format	<code>--restore-data</code>
---------------------	-----------------------------

Output `NDB` table data and logs.

- `--restore-epoch, -e`

Command-Line Format	<code>--restore-epoch</code>
---------------------	------------------------------

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 25.7.9, “NDB Cluster Backups With NDB Cluster Replication”](#).)

- `--restore-meta, -m`

Command-Line Format	<code>--restore-meta</code>
---------------------	-----------------------------

This option causes `ndb_restore` to print `NDB` table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--`

`restore-meta` (`-m`) option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

`ndb_restore` uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option, it is recommended that auto synchronization be disabled by setting `ndb_metadata_check=OFF` until `ndb_restore` has completed restoring the metadata, after which it can be turned on again to synchronize objects newly created in the NDB dictionary.

**Note**

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--rewrite-database=olddb,newdb`

Command-Line Format	<code>--rewrite-database=string</code>
Type	String
Default Value	<code>none</code>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
$> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

**Important**

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

Command-Line Format	<code>--skip-broken-objects</code>
---------------------	------------------------------------

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-fk-checks`

Command-Line Format	<code>--skip-fk-checks</code>
---------------------	-------------------------------

This option modifies the behavior of `ndb_restore --rebuild-indexes` so that, when foreign keys are re-enabled, the existing data in the table is not checked for consistency.

- `--skip-table-check, -s`

Command-Line Format	<code>--skip-table-check</code>
---------------------	---------------------------------

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

- `--skip-unknown-objects`

Command-Line Format	<code>--skip-unknown-objects</code>
---------------------	-------------------------------------

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

Command-Line Format	<code>--slice-id=#</code>
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value	1023
---------------	------

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name, -T dir_name`

Command-Line Format	<code>--tab=path</code>
Type	Directory name

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--timestamp-printouts`

Command-Line Format	<code>--timestamp-printouts{=true false}</code>
Type	Boolean
Default Value	<code>true</code>

Causes info, error, and debug log messages to be prefixed with timestamps.

This option is enabled by default. Disable it with `--timestamp-printouts=false`.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose=#`

Command-Line Format	<code>--verbose=#</code>
Type	Numeric
Default Value	1
Minimum Value	0
Maximum Value	255

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--with-apply-status`

Command-Line Format	<code>--with-apply-status</code>
---------------------	----------------------------------

Restore all rows from the backup's `ndb_apply_status` table (except for the row having `server_id = 0`, which is generated using `--restore-epoch`). This option requires that `--restore-data` also be used.

If the `ndb_apply_status` table from the backup already contains a row with `server_id = 0`, `ndb_restore --with-apply-status` deletes it. For this reason, we recommend that you use `ndb_restore --restore-epoch` after invoking `ndb_restore` with the `--with-apply-status` option. You can also use `--restore-epoch` concurrently with the last of any invocations of `ndb_restore --with-apply-status` used to restore the cluster.

For more information, see [ndb\\_apply\\_status Table](#).

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
  [-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup-path` options.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see [Section 25.4.3.3, “NDB Cluster Connection Strings”](#)). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#)).

`ndb_restore` can decrypt an encrypted backup using `--decrypt` and `--backup-password`. Both options must be specified to perform decryption. See the documentation for the `START BACKUP` management client command for information on creating encrypted backups.

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
$> ndb_mgm -e "SHOW"
```

### Error reporting.

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

### Important

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START REPLICHA`. This is a known issue in NDB Cluster.

## 25.5.24 ndb\_secretsfile\_reader — Obtain Key Information from an Encrypted NDB Data File

`ndb_secretsfile_reader` gets the encryption key from an NDB encryption secrets file, given the password.

### Usage

```
ndb_secretsfile_reader options file
```

The `options` must include one of `--filesystem-password` or `--filesystem-password-from-stdin`, and the encryption password must be supplied, as shown here:

```
> ndb_secretsfile_reader --filesystem-password=54kl14 ndb_5_fs/D1/NDBCNTN/S0.sysfile
ndb_secretsfile_reader: [Warning] Using a password on the command line interface can be insecure.
cac256e18b2ddf6b5ef82d99a72f18e864b78453cc7fa40bfaf0c40b91122d18
```

These and other options that can be used with `ndb_secretsfile_reader` are shown in the following table. Additional descriptions follow the table.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--filesystem-password`

Command-Line Format	<code>--filesystem-password=password</code>
---------------------	---

Pass the filesystem encryption and decryption password to `ndb_secretsfile_reader` using `stdin`, `tty`, or the `my.cnf` file.

- `--filesystem-password-from-stdin`

Command-Line Format	<code>--filesystem-password-from-stdin={TRUE FALSE}</code>
---------------------	--

Pass the filesystem encryption and decryption password to `ndb_secretfile_reader` from `stdin` (only).

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## 25.5.25 ndb\_select\_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

## Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

Options that can be used with `ndb_select_all` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database=dbname, -d dbname`

Name of the database in which the table is found. The default value is `TEST_DB`.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--delimiter=character, -D character`

Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--gci`

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See [Section 25.2, “NDB Cluster Overview”](#), and [Section 25.6.3.2, “NDB Cluster Log Events”](#), for more information about checkpoints.

- `--gci64`

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--header=FALSE`

Excludes column headers from the output.

- `--nodata`

Causes any table data to be omitted.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`.

**Note**

This is the name of an index, not of a column; the index must have been explicitly named when created.

- `parallelism=#, -p #`

Specifies the degree of parallelism.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--tupscan, -t`

Scan the table in the order of the tuples.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

## Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name  |
+----+-----+
| 3  | shark |
| 6  | puffer|
| 2  | tuna  |
| 4  | manta ray |
| 5  | grouper|
| 1  | guppy |
+----+-----+
```

```
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
$> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
```

All string values are enclosed by square brackets ([...]) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
$> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name          breed          DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]     [Mutt]        [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]      [Collie]     [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned
```

## 25.5.26 ndb\_select\_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

### Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Options that can be used with `ndb_select_count` are shown in the following table. Additional descriptions follow the table.

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id; ] [host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code>  <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
---------------------	--

Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>%HOMEDIR%/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

### Sample Output

```
$> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
```

## 25.5.27 ndb\_show\_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

Options that can be used with `ndb_show_tables` are shown in the following table. Additional descriptions follow the table.

### Usage

```
ndb_show_tables [-c connection_string]
```

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5

Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--database, -d`

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String

Default Value	[none]
---------------	--------

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

#### Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 25.5.25, “ndb\\_select\\_all — Print Rows from an NDB Table”](#)).

## 25.5.28 ndb\_sign\_keys — Create, Sign, and Manage TLS Keys and Certificates for NDB Cluster

Management of TLS keys and certificates is implemented in NDB Cluster as the executable utility program `ndb_sign_keys`, which can normally be found in the MySQL `bin` directory. The program performs such functions as creating, signing, and retiring keys and certificates, and normally works as follows:

1. `ndb_sign_keys` connects to `ndb_mgmd` and fetches the cluster' configuration.
2. For each cluster node that is configured to run on the local machine, `ndb_sign_keys` finds the node' private key and sign it, creating an active node certificate.

Some additional tasks that can be performed by `ndb_sign_keys` are listed here:

- Obtaining configuration information from a `config.ini` file rather than a running `ndb_mgmd`
- Creating the cluster' certificate authority (CA) if it does not yet exist

- Creating private keys
- Saving keys and certificates as pending rather than active
- Signing the key for a single node as specified using command-line options described later in this section
- Requesting a CA located on a remote host to sign a local key

Options that can be used with `ndb_sign_keys` are shown in the following table. Additional descriptions follow the table.

- `--bind-host`

Command-Line Format	<code>--bind-host=host</code>
Type	String
Default Value	<code>mgmd, api</code>

Create a certificate bound to a hostname list of node types that should have certificate hostname bindings, from the set `(mgmd,db,api)`.

- `--bound-hostname`

Command-Line Format	<code>--bound-hostname=hostname</code>
Type	String
Default Value	<code>[none]</code>

Create a certificate bound to the hostname passed to this option.

- `--CA-cert`

Command-Line Format	<code>--CA-cert=name</code>
Type	File name
Default Value	<code>NDB-Cluster-cert</code>

Use the name passed to this option for the CA Certificate file.

- `--CA-key`

Command-Line Format	<code>--CA-key=name</code>
Type	File name
Default Value	<code>NDB-Cluster-private-key</code>

Use the name passed to this option for the CA private key file.

- `--CA-ordinal`

Command-Line Format	<code>--CA-ordinal=name</code>
Type	String
Default Value	<code>[none]</code>
Valid Values	<code>First</code> <code>Second</code>

Set the ordinal CA name; defaults to `First` for `--create-CA` and `Second` for `--rotate-CA`. The Common Name in the CA certificate is “MySQL NDB Cluster *ordinal* Certificate”, where *ordinal* is the ordinal name passed to this option.

- `--CA-search-path`

Command-Line Format	<code>--CA-search-path=name</code>
Type	File name
Default Value	<code>[none]</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path is limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `$HOMEPATH\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This default can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--CA-tool`

Command-Line Format	<code>--CA-tool=name</code>
Type	File name
Default Value	<code>[none]</code>

Designate an executable helper tool, including the path.

- `--check`

Command-Line Format	<code>--check</code>
---------------------	----------------------

Check certificate expiry dates.

- `--config-file`

Command-Line Format	<code>--config-file=file</code>
Disabled by	<code>no-config</code>
Type	File name
Default Value	<code>[none]</code>

Supply the path to the cluster configuration file (usually `config.ini`).

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer

Default Value	12
Minimum Value	-1
Maximum Value	12

Set the number of times that `ndb_sign_keys` attempts to connect to the cluster. If you use `-1`, the program keeps trying to connect until it succeeds or is forced to stop.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Set the number of seconds after a failed connection attempt which `ndb_sign_keys` waits before trying again, up to the number of times determined by `--connect-retries`.

- `--create-CA`

Command-Line Format	<code>--create-CA</code>
---------------------	--------------------------

Create the CA key and certificate.

- `--CA-days`

Command-Line Format	<code>--CA-days=#</code>
Type	Integer
Default Value	1461
Minimum Value	-1
Maximum Value	2147483647

Set the lifetime of the certificate to this many days. The default is equivalent to 4 years plus 1 day. `-1` means the certificate never expires.

This option was added in NDB 8.4.1.

- `--create-key`

Command-Line Format	<code>--create-key</code>
---------------------	---------------------------

Create or replace private keys.

- `--curve`

Command-Line Format	<code>--curve=name</code>
Type	String
Default Value	<code>P-256</code> <span style="float: right;">4685</span>

Use the named curve for encrypting node keys.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read this option file after the global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read this option file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Read not only the usual option groups, but also groups with the usual names and a suffix of *string*.

- `--duration`

Command-Line Format	<code>--duration=#</code>
Type	Integer
Default Value	0
Minimum Value	-500000
Maximum Value	0
Unit	seconds

Set the lifetime of certificates or signing requests, in seconds.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Print help text and exit.

- `--keys-to-dir`

Command-Line Format	<code>--keys-to-dir=dirname</code>
Type	Directory name
Default Value	[none]

Specify output directory for private keys (only); for this purpose, it overrides any value set for `--to-dir`.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	<code>[none]</code>

Read this path from the login file.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
Type	String
Default Value	<code>[none]</code>

Set the connection string to use for connecting to `ndb_mgmd`, using the syntax `[nodeid=id; ] [host=]hostname[:port]`. If this option is set, it overrides the value set for `NDB_CONNECTSTRING` (if any), as well as any value set in a `my.cnf` file.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required for the `ndb_mgm` client; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories containing TLS keys and certificates.

For syntax, see the description of the `--CA-search-path` option.

- `--no-config`

Command-Line Format	<code>--no-config</code>
---------------------	--------------------------

Do not obtain the cluster configuration; create a single certificate based on the options supplied (including defaults for those not specified).

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than the login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Do not read login paths from the login path file.

- `--passphrase`

Command-Line Format	<code>--passphrase=phrase</code>
Type	String
Default Value	[none]

Specify a CA key pass phrase.

- `--node-id`

Command-Line Format	<code>--node-id=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	255

Create or sign a key for the node having the specified node ID.

- `--node-type`

Command-Line Format	<code>--node-type=set</code>
Type	Set
Default Value	<code>mgmd,db,api</code>

Create or sign keys for the specified type or types from the set (`mgmd,db,api`).

- `--pending`

Command-Line Format	<code>--pending</code>
---------------------	------------------------

Save keys and certificates as pending, rather than active.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print the program argument list, then exit.

- `--promote`

Command-Line Format	<code>--promote</code>
---------------------	------------------------

Promote pending files to active, then exit.

- `--remote-CA-host`

Command-Line Format	<code>--remote-CA-host=hostname</code>
Type	String
Default Value	[none]

Specify the address or hostname of a remote CA host.

- `--remote-exec-path`

Command-Line Format	<code>--remote-exec-path</code>
Type	Path name
Default Value	[none]

Provide the full path to an executable on the remote CA host specified with `--remote-CA-host`.

- `--remote-openssl`

Command-Line Format	<code>--remote-openssl</code>
---------------------	-------------------------------

Use OpenSSL for signing of keys on the remote CA host specified with `--remote-CA-host`.

- `--replace-by`

Command-Line Format	<code>--replace-by=#</code>
Type	Integer
Default Value	-10
Minimum Value	-128
Maximum Value	127

Suggest a certificate replacement date for periodic checks, as a number of days after the CA expiration date. Use a negative number to indicate days before expiration.

- `--rotate-CA`

Command-Line Format	<code>--rotate-CA</code>
---------------------	--------------------------

Replace an older CA with a newer one. The new CA can be created using OpenSSL, or you can allow `ndb_sign_keys` to create the new one, in which case the new CA is created with an intermediate CA certificate, signed by the old CA.

- `--schedule`

Command-Line Format	<code>--schedule=list</code>
Type	String

Default Value	120,10,130,10,150,0
---------------	---------------------

Assign a schedule of expiration dates to certificates. The schedule is defined as a comma-delimited list of six integers, in the format shown here:

```
api_valid,api_extra,dn_valid,dn_extra,mgm_valid,mgm_extra
```

These values are defined as follows:

- `api_valid`: A fixed number of days of validity for client certificates.
- `api_extra`: A number of extra days for client certificates.
- `dn_valid`: A fixed number of days of validity for client certificates for data node certificates.
- `dn_extra`: A number of extra days for data node certificates.
- `mgm_valid`: A fixed number of days of validity for management server certificates.
- `mgm_extra`: A number of extra days for management server certificates.

In other words, for each node type (API node, data node, management node), certificates are created with a lifetime equal to a whole fixed number of days, plus some random amount of time less than or equal to the number of extra days. The default schedule is shown here:

```
--schedule=120,10,130,10,150,0
```

Following the default schedule, client certificates begin expiring on the 120<sup>th</sup> day, and expire at random intervals over the next 10 days; data node certificates expire at random times between the 130<sup>th</sup> and 140<sup>th</sup> days; and management node certificates expire on the 150<sup>th</sup> day (with no random interval following).

- `--sign`

Command-Line Format	<code>--sign</code>
Disabled by	<code>skip-sign</code>

Create signed certificates; enabled by default. Use `--skip-sign` to create certificate signing requests instead.

- `--skip-sign`

Command-Line Format	<code>--skip-sign</code>
---------------------	--------------------------

Create certificate signing requests instead of signed certificates.

- `--stdio`

Command-Line Format	<code>--stdio</code>
---------------------	----------------------

Read certificate signing requests from `stdin`, and write X.509 to `stdout`.

- `--to-dir`

Command-Line Format	<code>--to-dir=dirname</code>
Type	Directory name

Default Value	[none]
---------------	--------

Specify the output directory for created files. For private key files, this can be overridden using `--keys-to-dir`.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Print help text, then exit (alias for `--help`).

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Print version information, then exit.

## 25.5.29 ndb\_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

### Note

`ndb_size.pl` is no longer supported; you should expect it to be removed from a future version of the NDB Cluster distribution, and modify any dependent applications accordingly.

## Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

Options that can be used with `ndb_size.pl` are shown in the following table. Additional descriptions follow the table.

## Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
  [--user=user] [--password=password] \
  [--help|-h] [--format={html|text}] \
  [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name

of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

  Fixedsize DataMemory (KB) 0         0         0

  Rows/32kb Varsize DM Page  0         0       2040
  Varsize DataMemory (KB)  0         0         0

  Rows/8kb IM Page         248       512       512
  IndexMemory (KB)         0         0         0

Parameter Minimum Requirements
-----
```

\* indicates greater than default

Parameter	Default	4.1	5.0	5.1
DataMemory (KB)	81920	0	0	0
NoOfOrderedIndexes	128	1	1	1
NoOfTables	128	1	1	1
IndexMemory (KB)	18432	0	0	0
NoOfUniqueHashIndexes	64	0	0	0
NoOfAttributes	1000	3	3	3
NoOfTriggers	768	5	5	5

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

## 25.5.30 ndb\_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

### Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host` (`-h`) and `--port` (`-t`). To specify a MySQL user and password, use the `--user` (`-u`) and `--passwd` (`-p`) options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpusstat` and related tables).

For more information about MySQL user accounts and passwords, see [Section 8.2, “Access Control and Account Management”](#).

Output is available as plain text or an ASCII graph; you can specify this using the `--text` (`-x`) and `--graph` (`-g`) options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort, -r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load (-m)` and `--os-load (-o)` options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id (-n)` option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time (-s)`.

**Note**

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

**Additional Options**

- `--color, -c`

Command-Line Format	<code>--color</code>
---------------------	----------------------

Show ASCII graphs in color; use `--skip-colors` to disable.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
---------------------	---

Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--graph, -g`

Command-Line Format	<code>--graph</code>
---------------------	----------------------

Display data using graphs; use `--skip-graphs` to disable. This option or `--text` must be true; both options may be true.

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Show program usage information.

- `--host[=name], -h`

Command-Line Format	<code>--host=string</code>
Type	String
Default Value	<code>localhost</code>

Host name or IP address of MySQL Server to connect to.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--measured-load, -m`

Command-Line Format	<code>--measured-load</code>
---------------------	------------------------------

Show measured load by thread. This option or `--os-load` must be true; both options may be true.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--node-id[=#], -n`

Command-Line Format	<code>--node-id=#</code>
Type	Integer
Default Value	1

Watch the data node having this node ID.

- `--os-load, -o`

Command-Line Format	<code>--os-load</code>
---------------------	------------------------

Show load measured by operating system. This option or `--measured-load` must be true; both options may be true.

- `--password[=password], -p`

Command-Line Format	<code>--password=password</code>
Type	String
Default Value	NULL

Connect to a MySQL Server using this password and the MySQL user specified by `--user`.

This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted NDB backups.

- `--port[=#], -P`

Command-Line Format	<code>--port=#</code>
Type	Integer
Default Value	3306

Port number to use when connecting to MySQL Server.

(Formerly, the short form for this option was `-t`, which was repurposed as the short form of `--text`.)

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--sleep-time[=seconds], -s`

Command-Line Format	<code>--sleep-time=#</code>
Type	Integer
Default Value	1

Time to wait between display refreshes, in seconds.

- `--socket=path/to/file, -S`

Command-Line Format	<code>--socket=path</code>
---------------------	----------------------------

Type	Path name
Default Value	[none]

Use the specified socket file for the connection.

- `--sort, -r`

Command-Line Format	<code>--sort</code>
---------------------	---------------------

Sort threads by usage; use `--skip-sort` to disable.

- `--text, -t`

Command-Line Format	<code>--text</code>
---------------------	---------------------

Display data using text. This option or `--graph` must be true; both options may be true.

(The short form for this option was `-x` in previous versions of NDB Cluster, but this is no longer supported.)

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--user[=name], -u`

Command-Line Format	<code>--user=name</code>
Type	String
Default Value	<code>root</code>

Connect as this MySQL user. Normally requires a password supplied by the `--password` option.

**Sample Output.** The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmt_d` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

Figure 25.5 ndb\_top Running in Terminal

```

jon@valhaj:....7-cluster-7.6/bin
ldm thr_no 2 OS view [user: 24%, system: 13%, idle: 63%] 37%
ldm thr_no 2 OS view [ ] 37%
main thr_no 0 OS view [user: 5%, system: 11%, idle: 84%] 16%
main thr_no 0 OS view [ ] 16%
recv thr_no 3 OS view [user: 3%, system: 10%, idle: 87%] 13%
recv thr_no 3 OS view [ ] 13%
rep thr_no 1 OS view [user: 0%, system: 0%, idle: 100%] 0%
rep thr_no 1 OS view [ ] 0%

```

`ndb_top` also shows spin times for threads, displayed in green.

### 25.5.31 `ndb_waiter` — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.

- **STARTING**: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING\_DOWN**: The node is shutting down.
- **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with `ndb_waiter` are shown in the following table. Additional descriptions follow the table.

## Usage

```
ndb_waiter [-c connection_string]
```

## Additional Options

- `--character-sets-dir`

Command-Line Format	<code>--character-sets-dir=path</code>
---------------------	--

Directory containing character sets.

- `--connect-retries`

Command-Line Format	<code>--connect-retries=#</code>
Type	Integer
Default Value	12
Minimum Value	0
Maximum Value	12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format	<code>--connect-retry-delay=#</code>
Type	Integer
Default Value	5
Minimum Value	0
Maximum Value	5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format	<code>--connect-string=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format	<code>--core-file</code>
---------------------	--------------------------

Write core file on error; used in debugging.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `concat(group, suffix)`.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--help`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Display help text and exit.

- `--ndb-connectstring`

Command-Line Format	<code>--ndb-connectstring=connection_string</code>
---------------------	--

Type	String
Default Value	[none]

Set connection string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgm-tls`

Command-Line Format	<code>--ndb-mgm-tls=level</code>
Type	Enumeration
Default Value	<code>relaxed</code>
Valid Values	<code>relaxed</code> <code>strict</code>

Sets the level of TLS support required to connect to the management server; one of `relaxed` or `strict`. `relaxed` (the default) means that a TLS connection is attempted, but success is not required; `strict` means that TLS is required to connect.

- `--ndb-mgmd-host`

Command-Line Format	<code>--ndb-mgmd-host=connection_string</code>
Type	String
Default Value	[none]

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

Command-Line Format	<code>--ndb-nodeid=#</code>
Type	Integer
Default Value	[none]

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
---------------------	---

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-tls-search-path`

Command-Line Format	<code>--ndb-tls-search-path=list</code>
Type	Path name
Default Value (Unix)	<code>\$HOME/ndb-tls</code>
Default Value (Windows)	<code>\$HOMEDIR/ndb-tls</code>

Specify a list of directories to search for a CA file. On Unix platforms, the directory names are separated by colons (:); on Windows systems, the semicolon character (;) is used as the separator. A directory

reference may be relative or absolute; it may contain one or more environment variables, each denoted by a prefixed dollar sign (\$), and expanded prior to use.

Searching begins with the leftmost named directory and proceeds from left to right until a file is found. An empty string denotes an empty search path, which causes all searches to fail. A string consisting of a single dot (.) indicates that the search path limited to the current working directory.

If no search path is supplied, the compiled-in default value is used. This value depends on the platform used: On Windows, this is `\ndb-tls`; on other platforms (including Linux), it is `$HOME/ndb-tls`. This can be overridden by compiling NDB Cluster using `-DWITH_NDB_TLS_SEARCH_PATH`.

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --nowait-nodes=1,3,7-9
```

**Important**

Do *not* use this option together with the `--wait-nodes` option.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--usage`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Display help text and exit; same as `--help`.

- `--verbose`

Command-Line Format	<code>--verbose=#</code>
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	2

Controls verbosity level of printout. Possible levels and their effects are listed here:

- 0: Do not print (return exit code only; see following for exit codes).
- 1: Print final connection status only.
- 2: Print status each time it is checked.

This is the same behavior as in versions of NDB Cluster previous to 8.4.

Exit codes returned by `ndb_waiter` are listed here, with their meanings:

- 0: Success.
- 1: Wait timed out.
- 2: Parameter error, such as an invalid node ID.
- 3: Failed to connect to the management server.

- `--version`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Display version information and exit.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --wait-nodes=2,4-6,10
```

### Important

Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```
$> ./ndb_waiter -c localhost
```

```
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
```

**Note**

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

## 25.5.32 ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The `ndbxfrm` utility can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

## Usage

```
ndbxfrm --info file[ file ...]
ndbxfrm --compress input_file output_file
ndbxfrm --decrypt-password=password input_file output_file
ndbxfrm [--encrypt-ldf-iter-count=#] --encrypt-password=password input_file output_file
```

`input_file` and `output_file` cannot be the same file.

## Options

- `--compress, -c`

Command-Line Format	<code>--compress</code>
---------------------	-------------------------

Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup file that is not encrypted, it is necessary only to invoke `ndbxfrm` using the names of the compressed file and an output file (with no options required).

- `--decrypt-key=key, -K key`

Command-Line Format	<code>--decrypt-key=key</code>
---------------------	--------------------------------

Decrypts a file encrypted by NDB using the supplied key.

### Note

This option cannot be used together with `--decrypt-password`.

- `--decrypt-key-from-stdin`

Command-Line Format	<code>--decrypt-key-from-stdin</code>
---------------------	---------------------------------------

Decrypts a file encrypted by NDB using the key supplied from `stdin`.

- `--decrypt-password=password`

Command-Line Format	<code>--decrypt-password=password</code>
Type	String
Default Value	[none]

Decrypts a file encrypted by NDB using the password supplied.

### Note

This option cannot be used together with `--decrypt-key`.

- `--decrypt-password-from-stdin[=TRUE|FALSE]`

Command-Line Format	<code>--decrypt-password-from-stdin</code>
---------------------	--

Decrypts a file encrypted by NDB, using a password supplied from standard input. This is similar to entering a password after invoking `mysql --password` with no password following the option.

- `--defaults-extra-file`

Command-Line Format	<code>--defaults-extra-file=path</code>
Type	String
Default Value	[none]

Read given file after global files are read.

- `--defaults-file`

Command-Line Format	<code>--defaults-file=path</code>
Type	String
Default Value	[none]

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format	<code>--defaults-group-suffix=string</code>
Type	String
Default Value	[none]

Also read groups with `CONCAT(group, suffix)`.

- `--detailed-info`

Command-Line Format	<code>--encrypt-block-size=#</code>
Type	Boolean
Default Value	FALSE

Print out file information like `--info`, but include the file's header and trailer.

Example:

```
$> ndbxfrm --detailed-info S0.sysfile
File=/var/lib/cluster-data/ndb_7_fs/D1/NDBCNTNTR/S0.sysfile, compression=no, encryption=yes
header: {
  fixed_header: {
    magic: {
      magic: { 78, 68, 66, 88, 70, 82, 77, 49 },
      endian: 18364758544493064720,
      header_size: 32768,
      fixed_header_size: 160,
      zeros: { 0, 0 }
    },
    flags: 73728,
    flag_extended: 0,
    flag_zeros: 0,
    flag_file_checksum: 0,
```

```

flag_data_checksum: 0,
flag_compress: 0,
flag_compress_method: 0,
flag_compress_padding: 0,
flag_encrypt: 18,
flag_encrypt_cipher: 2,
flag_encrypt_krm: 1,
flag_encrypt_padding: 0,
flag_encrypt_key_selection_mode: 0,
dbg_writer_ndb_version: 524320,
octets_size: 32,
file_block_size: 32768,
trailer_max_size: 80,
file_checksum: { 0, 0, 0, 0 },
data_checksum: { 0, 0, 0, 0 },
zeros01: { 0 },
compress_dbg_writer_header_version: { ... },
compress_dbg_writer_library_version: { ... },
encrypt_dbg_writer_header_version: { ... },
encrypt_dbg_writer_library_version: { ... },

  102, 68, 56, 125, 78, 217, 110, 94, 145, 121, 203, 234, 26, 164, 137, 180,
  100, 224, 7, 88, 173, 123, 209, 110, 185, 227, 85, 174, 109, 123, 96, 156,
}
}
trailer: {
  fixed_trailer: {
    flags: 48,
    flag_extended: 0,
    flag_zeros: 0,
    flag_file_checksum: 0,
    flag_data_checksum: 3,
    data_size: 512,
    file_checksum: { 0, 0, 0, 0 },
    data_checksum: { 226, 223, 102, 207 },
    magic: {
      zeros: { 0, 0 }
      fixed_trailer_size: 56,
      trailer_size: 32256,
      endian: 18364758544493064720,
      magic: { 78, 68, 66, 88, 70, 82, 77, 49 },
    },
  },
}
}

```

- `--encrypt-block-size=#`

Command-Line Format	<code>--encrypt-block-size=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

Size of input data chunks that are encrypted as a unit. Used with XTS; set to 0 (the default) for CBC mode.

- `--encrypt-cipher=#`

Command-Line Format	<code>--encrypt-cipher=#</code>
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	2147483647

Cipher used for encryption. Set to 1 for CBC mode (the default), or 2 for XTS.

- `--encrypt-kdf-iter-count=#, -k #`

Command-Line Format	<code>--encrypt-kdf-iter-count=#</code>
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2147483647

When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the `--encrypt-password` option.

- `--encrypt-key=key`

Command-Line Format	<code>--encrypt-key=key</code>
---------------------	--------------------------------

Encrypts a file using the supplied key.

**Note**

This option cannot be used together with `--encrypt-password`.

- `--encrypt-key-from-stdin`

Command-Line Format	<code>--encrypt-key-from-stdin</code>
---------------------	---------------------------------------

Encrypt a file using the key supplied from `stdin`.

- `--encrypt-password=password`

Command-Line Format	<code>--encrypt-password=password</code>
Type	String

Default Value	[none]
---------------	--------

Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

- Uses any of the printable ASCII characters except !, ', ", \$, %, \, `, and ^
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

**Note**

This option cannot be used together with `--encrypt-key`.

- `--encrypt-password-from-stdin[=TRUE|FALSE]`

Command-Line Format	<code>--encrypt-password-from-stdin</code>
---------------------	--

Encrypts a file using a password supplied from standard input. This is similar to entering a password is entered after invoking `mysql --password` with no password following the option.

- `--help, -?`

Command-Line Format	<code>--help</code>
---------------------	---------------------

Prints usage information for the program.

- `--info, -i`

Command-Line Format	<code>--info</code>
---------------------	---------------------

Prints the following information about one or more input files:

- The name of the file
- Whether the file is compressed (`compression=yes` or `compression=no`)
- Whether the file is encrypted (`encryption=yes` or `encryption=no`)

Example:

```
$> ndbxfrm -i BACKUP-10-0.5.Data BACKUP-10.5.ct1 BACKUP-10.5.log
File=BACKUP-10-0.5.Data, compression=no, encryption=yes
File=BACKUP-10.5.ct1, compression=no, encryption=yes
File=BACKUP-10.5.log, compression=no, encryption=yes
```

You can also see the file's header and trailer using the `--detailed-info` option.

- `--login-path`

Command-Line Format	<code>--login-path=path</code>
Type	String
Default Value	[none]

Read given path from login file.

- `--no-login-paths`

Command-Line Format	<code>--no-login-paths</code>
---------------------	-------------------------------

Skips reading options from the login path file.

- `--no-defaults`

Command-Line Format	<code>--no-defaults</code>
---------------------	----------------------------

Do not read default options from any option file other than login file.

- `--print-defaults`

Command-Line Format	<code>--print-defaults</code>
---------------------	-------------------------------

Print program argument list and exit.

- `--usage, -?`

Command-Line Format	<code>--usage</code>
---------------------	----------------------

Synonym for `--help`.

- `--version, -V`

Command-Line Format	<code>--version</code>
---------------------	------------------------

Prints out version information.

`ndbxfrm` can encrypt backups created by any version of NDB Cluster. The `.Data`, `.ctl`, and `.log` files comprising the backup must be encrypted separately, and these files must be encrypted separately for each data node. Once encrypted, such backups can be decrypted only by `ndbxfrm`, `ndb_restore`, or `ndb_print_backup`.

An encrypted file can be re-encrypted with a new password using the `--encrypt-password` and `--decrypt-password` options together, like this:

```
ndbxfrm --decrypt-password=old --encrypt-password=new input_file output_file
```

In the example just shown, *old* and *new* are the old and new passwords, respectively; both of these must be quoted. The input file is decrypted and then encrypted as the output file. The input file itself is not changed; if you do not want it to be accessible using the old password, you must remove the input file manually.

## 25.6 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in [Section 25.4, “Configuration of NDB Cluster”](#), and [Section 25.5, “NDB Cluster Programs”](#).

The next few sections cover the management of a running NDB Cluster.

For general information about security issues relating to management and deployment of an NDB Cluster, see [Section 25.6.19, “NDB Cluster Security”](#). For information about encrypted file systems and NDB, see

[Section 25.6.19.4, “File System Encryption for NDB Cluster”](#). [Section 25.6.19.5, “TLS Link Encryption for NDB Cluster”](#), provides information about support for encrypted connections between nodes. NDB Cluster also supports encrypted backups which can be read by many NDB command-line programs including `ndb_restore`, `ndbxfrm`, `ndb_print_backup_file`, and `ndb_mgm`. See [Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for more information.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 25.6.15, “ndbinfo: The NDB Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting Ndb objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL Cluster Manager 9.7.0 User Manual](#), for more information.

## 25.6.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 25.6.3, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 25.6.8, “Online Backup of NDB Cluster”](#).

**Using `ndb_mgm` with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these

tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CONNECT connection-string`

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs; the presence of any duplicates causes the command to return an error. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 25.6.7, “Adding NDB Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the NDB Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3 @10.100.2.67 (9.5.0-ndb-9.5.0, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 25.6.7, “Adding NDB Cluster Data Nodes Online”](#).

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID *node\_id* is permitted to access the database.

The `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:

```
ndb_mgm> ENTER SINGLE USER MODE 100
Single user mode entered
Access is granted for API node 100 only.
```

In addition, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=5   @127.0.0.1 (mysql-9.5.0 ndb-9.5.0, single user mode, Nodegroup: 0, *)
id=6   @127.0.0.1 (mysql-9.5.0 ndb-9.5.0, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=50  @127.0.0.1 (mysql-9.5.0 ndb-9.5.0)

[mysqld(API)]   2 node(s)
id=100 @127.0.0.1 (mysql-9.5.0 ndb-9.5.0, allowed single user)
id=101 (not connected, accepting connect from any host)
```

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

#### Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `HELP`

Displays information on all available commands.

- `node_id NODELOG DEBUG {ON|OFF}`

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

- `PROMPT [prompt]`

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:'
'mymgm:' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
$>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `node_id RESTART [-n] [-i] [-a] [-f]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

#### Note

Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `SHOW`

Displays basic information about the cluster and cluster nodes. For all nodes, the output includes the node's ID, type, and `NDB` software version. If the node is connected, its IP address is also shown; otherwise the output shows `not connected, accepting connect from ip_address`, with `any host` used for nodes that are permitted to connect from any address.

In addition, for data nodes, the output includes `starting` if the node has not yet started, and shows the node group of which the node is a member. If the data node is acting as the master node, this is indicated with an asterisk (\*).

Consider a cluster whose configuration file includes the information shown here (possible additional settings are omitted for clarity):

```
[ndbd default]
DataMemory= 128G
NoOfReplicas= 2

[ndb_mgmd]
NodeId=50
HostName=198.51.100.150

[ndbd]
NodeId=5
HostName=198.51.100.10
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=6
HostName=198.51.100.20
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=7
HostName=198.51.100.30
DataDir=/var/lib/mysql-cluster
```

```
[ndbd]
NodeId=8
HostName=198.51.100.40
DataDir=/var/lib/mysql-cluster

[mysqld]
NodeId=100
HostName=198.51.100.100

[api]
NodeId=101
```

After this cluster (including one SQL node) has been started, `SHOW` displays the following output:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)] 4 node(s)
id=5 @198.51.100.10 (mysql-9.5.0 ndb-9.5.0, Nodegroup: 0, *)
id=6 @198.51.100.20 (mysql-9.5.0 ndb-9.5.0, Nodegroup: 0)
id=7 @198.51.100.30 (mysql-9.5.0 ndb-9.5.0, Nodegroup: 1)
id=8 @198.51.100.40 (mysql-9.5.0 ndb-9.5.0, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=50 @198.51.100.150 (mysql-9.5.0 ndb-9.5.0)

[mysqld(API)] 2 node(s)
id=100 @198.51.100.100 (mysql-9.5.0 ndb-9.5.0)
id=101 (not connected, accepting connect from any host)
```

The output from this command also indicates when the cluster is in single user mode (see the description of the `ENTER SINGLE USER MODE` command, as well as [Section 25.6.6, "NDB Cluster Single User Mode"](#)). It also indicates which API or SQL node has exclusive access when this mode is in effect.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `node_id START`

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

### Important

To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

The output from this command also indicates when the cluster is in single user mode.

- `node_id STOP [-a] [-f]`

Stops the data or management node identified by `node_id`.

**Note**

`ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

**Warning**

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- `TLS INFO`

Displays cluster TLS information such as whether the current connection is using TLS, TLS certificates currently known to the management node, and the management node's counts of total connections, connections upgraded to TLS, and authorization failures. Sample output is shown here:

```
ndb_mgm> TLS INFO

Session ID:          1
Peer address:        127.0.0.1
Certificate name:     NDB Management Node Jun 2023
Certificate serial:   B5:23:8F:D1:11:85:E5:93:ED
Certificate expires:  23-Nov-2023

Server statistics since restart
Total accepted connections: 6
Total connections upgraded to TLS: 2
Current connections: 3
Current connections using TLS: 2
Authorization failures: 0
```

```
ndb_mgm>
```

For more information, see [Section 25.6.19.5, “TLS Link Encryption for NDB Cluster”](#).

**Additional commands.** A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see [Section 25.6.8, “Online Backup of NDB Cluster”](#).
- The `CLUSTERLOG` command is used to perform various logging functions. See [Section 25.6.3, “Event Reports Generated in NDB Cluster”](#), for more information and examples. `NODELOG DEBUG` activates or deactivates debug printouts in node logs, as described previously in this section.
- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see [NDB Cluster Management Client DUMP Commands](#).

## 25.6.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on [NDB](#) transporter errors.

### 25.6.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common [NDB](#) cluster log messages. For information about the cluster log, log events, and event types, see [Section 25.6.3, “Event Reports Generated in NDB Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb\\_logevent\\_type Type](#), for related information of interest to Cluster API developers.

**Table 25.25 Common NDB cluster log messages**

Log Message	Description	Event Name	Event Type	Priority	Severity
Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Connected	The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i> ).	Connected	Connection	8	INFO
Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Disconnected	The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i> ).	Disconnected	Connection	8	ALERT

### 25.6.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]

- `Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]`
- `Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]`
- `Initial start with nodes %s [ missing: %s no-wait: %s ]`
- `Start with all nodes %s`
- `Start with nodes %s [ missing: %s no-wait: %s ]`
- `Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]`
- `Unknown startreport: 0x%x [ %s %s %s %s ]`

### 25.6.2.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each `Ndb` object subscribing to table events, which means that there are usually two buffers for each `mysqld` performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- `node_id`: ID of the node where the report originated.
- `object_id`: ID of the `Ndb` object where the report originated.
- `bytes_used`: Number of bytes used by the buffer.
- `percent_used`: Percentage of allocated bytes used.
- `bytes_allocated`: Number of bytes allocated to this buffer.
- `percent_alloc`: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- `bytes_available`: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- `latest_consumed_epoch`: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- `latest_buffered_epoch`: The epoch most recently buffered (completely) in the event buffer.
- `report_reason`: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- `ENOUGH_FREE_EVENTBUFFER`: The event buffer has sufficient space.  
`LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.  
The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.
- `BUFFERED_EPOCHS_OVER_THRESHOLD`: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- `PARTIALLY_DISCARDING`: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.
- `COMPLETELY_DISCARDING`: No epochs are buffered.
- `PARTIALLY_BUFFERING`: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.
- `COMPLETELY_BUFFERING`: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

#### 25.6.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

0x00	<code>TE_NO_ERROR</code>	No error
0x01	<code>TE_ERROR_CLOSING_SOCKET</code>	Error found during closing of socket
0x02	<code>TE_ERROR_IN_SELECT_BEFORE_ACCEPT</code>	Error found before accept. The transporter will retry
0x03	<code>TE_INVALID_MESSAGE_LENGTH</code>	Error found in message (invalid message length)
0x04	<code>TE_INVALID_CHECKSUM</code>	Error found in message (checksum)
0x05	<code>TE_COULD_NOT_CREATE_SOCKET</code>	

## NDB Cluster Log Messages

---

	Error found while creating socket(can't create socket)
0x06	<b>TE_COULD_NOT_BIND_SOCKET</b>
	Error found while binding server socket
0x07	<b>TE_LISTEN_FAILED</b>
	Error found while listening to server socket
0x08	<b>TE_ACCEPT_RETURN_ERROR</b>
	Error found during accept(accept return error)
0x0b	<b>TE_SHM_DISCONNECT</b>
	The remote node has disconnected
0x0c	<b>TE_SHM_IPC_STAT</b>
	Unable to check shm segment

0x14	<b>TE_SIGNAL_LOST_SEND_BUFFER_FULL</b>
	Send buffer was full,and trying to force send fails
0x15	<b>TE_SIGNAL_LOST</b>
	Send failed for unknown reason(signal lost)
0x16	<b>TE_SEND_BUFFER_FULL</b>

```

                                The send buffer was full, but sleeping for a while
                                solved
0x21                                TE_SHM_IPC_PERMANENT
                                Shm ipc Permanent error

```

**Note**

Transporter error codes `0x17` through `0x20` and `0x22` are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

### 25.6.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *node\_id* is the node ID of the management server) in the management server's `DataDir`.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 25.4.3.5, “Defining an NDB Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *node\_id* is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ON`, `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL`, `ALERT`, or `ALL`. (This is also sometimes referred to as the log level.)

The cluster log can be filtered on these properties using the NDB management client `CLUSTERLOG` command. This command affects the cluster log only, and has no effect on the node logs; debug logging in one or more node logs can be turned on and off using the `ndb_mgm NODELOG DEBUG` command.

The format used in a log message generated by NDB Cluster is as shown here:

```
timestamp [node_type] level -- Node node_id: message
```

Each line in the log, or log message, contains the following information:

- A *timestamp* in `YYYY-MM-DD HH:MM:SS` format. The timestamp value currently resolves to whole seconds only; fractional seconds are not supported.
- The *node\_type*, or type of node or application which is performing the logging. In the cluster log, this is always `[MgmtSrvr]`; in the data node log, it is always `[ndbd]`. `[NdbApi]` and other values are possible in logs generated by NDB API applications and tools.
- The *level* of the event, sometimes also referred to as its severity level or log level. See earlier in this section, as well as [Section 25.6.3.1, “NDB Cluster Logging Management Commands”](#), for more information about severity levels.
- The ID of the node reporting the event (*node\_id*).
- A *message* containing a description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status or other information.

A sample from an actual cluster log is shown here:

```

For additional information, see [Section 25.6.3.2, “NDB Cluster Log Events”](#).

### 25.6.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, *node\_id* denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`  
Turns the cluster log on.
- `CLUSTERLOG OFF`  
Turns the cluster log off.
- `CLUSTERLOG INFO`  
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`  
Logs *category* events with priority less than or equal to *threshold* in the cluster log.
- `CLUSTERLOG TOGGLE severity_level`  
Toggles cluster logging of events of the specified *severity\_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

**Note**

Events are reported per data node, and that the threshold can be set to different values on different nodes.

**Table 25.26 Cluster log categories, with default threshold setting**

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	8
ERROR	15
INFO	7
BACKUP	15
CONGESTION	7
SCHEMA	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 25.6.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

**Note**

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

**Table 25.27 Event severity levels**

Severity Level Value	Severity	Description
1	<code>ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database
2	<code>CRITICAL</code>	Critical conditions, such as device errors or insufficient resources
3	<code>ERROR</code>	Conditions that should be corrected, such as configuration errors
4	<code>WARNING</code>	Conditions that are not errors, but that might require special handling
5	<code>INFO</code>	Informational messages
6	<code>DEBUG</code>	Debugging messages used for <code>NDBCLUSTER</code> development

Event severity levels can be turned on or off using `CLUSTERLOG TOGGLE`. If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

**Important**

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 25.6.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

### CONNECTION Events

These events are associated with connections between Cluster nodes.

**Table 25.28 Events associated with connections between cluster nodes**

Event	Priority	Severity Level	Description
Connected	8	INFO	Data nodes connected
Disconnected	8	ALERT	Data nodes disconnected
CommunicationClosed	8	INFO	SQL node or data node connection closed
CommunicationOpened	8	INFO	SQL node or data node connection open
ConnectedApiVersion	8	INFO	Connection using API version

## CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

**Table 25.29 Events associated with checkpoints**

Event	Priority	Severity Level	Description
GlobalCheckpointStarted	9	INFO	Start of GCP: REDO log is written to disk
GlobalCheckpointCompleted	10	INFO	GCP finished
LocalCheckpointStarted	7	INFO	Start of LCP: data written to disk
LocalCheckpointCompleted	7	INFO	LCP completed normally
LCPStoppedInCalcKeepCci	10	ALERT	LCP stopped
LCPFragmentCompleted	11	INFO	LCP on a fragment has been completed
UndoLogBlocked	7	INFO	UNDO logging blocked; buffer near overflow
RedoStatus	7	INFO	Redo status

## STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 25.30 Events relating to the startup of a node or cluster**

Event	Priority	Severity Level	Description
NDBStartStarted	1	INFO	Data node start phases initiated (all nodes starting)
NDBStartCompleted	1	INFO	Start phases completed, all data nodes
STTORYRYRecieved	15	INFO	Blocks received after completion of restart

## Event Reports Generated in NDB Cluster

Event	Priority	Severity Level	Description
StartPhaseCompleted	4	INFO	Data node start phase <i>X</i> completed
CM_REGCONF	3	INFO	Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID
CM_REGREF	8	INFO	Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
FIND_NEIGHBOURS	8	INFO	Shows neighboring data nodes
NDBStopStarted	1	INFO	Data node shutdown initiated
NDBStopCompleted	1	INFO	Data node shutdown complete
NDBStopForced	1	ALERT	Forced shutdown of data node
NDBStopAborted	1	INFO	Unable to shut down data node normally
StartREDOLog	4	INFO	New redo log started; GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
StartLog	10	INFO	New log started; log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
UNDORecordsExecuted	15	INFO	Undo records executed
StartReport	4	INFO	Report started
LogFileInitStatus	7	INFO	Log file initialization status
LogFileInitCompStatus	7	INFO	Log file completion status
StartReadLCP	10	INFO	Start read for local checkpoint
ReadLCPComplete	10	INFO	Read for local checkpoint completed
RunRedo	8	INFO	Running the redo log
RebuildIndex	10	INFO	Rebuilding indexes

### NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

**Table 25.31 Events relating to restarting a node**

Event	Priority	Severity Level	Description
NR_CopyDict	7	INFO	Completed copying of dictionary information
NR_CopyDistr	7	INFO	Completed copying distribution information
NR_CopyFragStarted	7	INFO	Starting to copy fragments
NR_CopyFragDone	10	INFO	Completed copying a fragment
NR_CopyFragCompleted	7	INFO	Completed copying all fragments
NodeFailCompleted	8	ALERT	Node failure phase completed
NODE_FAILREP	8	ALERT	Reports that a node has failed
ArbitState	6	INFO	<p>Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here:</p> <ul style="list-style-type: none"> <li>• Management server restarts arbitration thread [state=<i>X</i>]</li> <li>• Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Receive arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Started arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> &lt;error msg&gt; [state=<i>Y</i>]</li> </ul>
ArbitResult	2	ALERT	Report arbitrator results; there are eight different possible results for arbitration attempts, listed here:

Event	Priority	Severity Level	Description
			<ul style="list-style-type: none"> <li>• Arbitration check failed: less than 1/2 nodes left</li> <li>• Arbitration check succeeded: node group majority</li> <li>• Arbitration check failed: missing node group</li> <li>• Network partitioning: arbitration required</li> <li>• Arbitration succeeded: affirmative response from node <i>x</i></li> <li>• Arbitration failed: negative response from node <i>x</i></li> <li>• Network partitioning: no arbitrator available</li> <li>• Network partitioning: no arbitrator configured</li> </ul>
GCP_TakeoverStarted	7	INFO	GCP takeover started
GCP_TakeoverCompleted	7	INFO	GCP takeover complete
LCP_TakeoverStarted	7	INFO	LCP takeover started
LCP_TakeoverCompleted	7	INFO	LCP takeover complete (state = <i>x</i> )
ConnectCheckStarted	6	INFO	Connection check started
ConnectCheckCompleted	6	INFO	Connection check completed
NodeFailRejected	6	ALERT	Node failure phase failed

## STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

**Table 25.32 Events of a statistical nature**

Event	Priority	Severity Level	Description
TransReportCounters	8	INFO	Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts

Event	Priority	Severity Level	Description
OperationReportCounters	8	INFO	Number of operations
TableCreated	7	INFO	Report number of tables created
JobStatistic	9	INFO	Mean internal job scheduling statistics
ThreadConfigLoop	9	INFO	Number of thread configuration loops
SendBytesStatistic	9	INFO	Mean number of bytes sent to node <i>x</i>
ReceiveBytesStatistic	9	INFO	Mean number of bytes received from node <i>x</i>
MemoryUsage	5	INFO	Data and index memory usage (80%, 90%, and 100%)
MTSignalStatistics	9	INFO	Multithreaded signals

## SCHEMA Events

These events relate to NDB Cluster schema operations.

**Table 25.33 Events relating to NDB Cluster schema operations**

Event	Priority	Severity Level	Description
CreateSchemaObject	8	INFO	Schema object created
AlterSchemaObject	8	INFO	Schema object updated
DropSchemaObject	8	INFO	Schema object dropped

## ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

**Table 25.34 Events relating to cluster errors and warnings**

Event	Priority	Severity Level	Description
TransporterError	2	ERROR	Transporter error
TransporterWarning	8	WARNING	Transporter warning
MissedHeartbeat	8	WARNING	Node <i>x</i> missed heartbeat number <i>y</i>
DeadDueToHeartbeat	8	ALERT	Node <i>x</i> declared “dead” due to missed heartbeat
WarningEvent	2	WARNING	General warning event
SubscriptionStatus	4	WARNING	Change in subscription status

## INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

**Table 25.35 Information events**

Event	Priority	Severity Level	Description
<code>SentHeartbeat</code>	12	INFO	Sent heartbeat
<code>CreateLogBytes</code>	11	INFO	Create log: Log part, log file, size in MB
<code>InfoEvent</code>	2	INFO	General informational event
<code>EventBufferStatus</code>	7	INFO	Event buffer status
<code>EventBufferStatus2</code>	7	INFO	Improved event buffer status information

**Note**

`SentHeartbeat` events are available only if NDB Cluster was compiled with `VM_TRACE` enabled.

## SINGLEUSER Events

These events are associated with entering and exiting single user mode.

**Table 25.36 Events relating to single user mode**

Event	Priority	Severity Level	Description
<code>SingleUser</code>	7	INFO	Entering or exiting single user mode

## BACKUP Events

These events provide information about backups being created or restored.

**Table 25.37 Backup events**

Event	Priority	Severity Level	Description
<code>BackupStarted</code>	7	INFO	Backup started
<code>BackupStatus</code>	7	INFO	Backup status
<code>BackupCompleted</code>	7	INFO	Backup completed
<code>BackupFailedToStart</code>	7	ALERT	Backup failed to start
<code>BackupAborted</code>	7	ALERT	Backup aborted by user
<code>RestoreStarted</code>	7	INFO	Started restoring from backup
<code>RestoreMetaData</code>	7	INFO	Restoring metadata
<code>RestoreData</code>	7	INFO	Restoring data

Event	Priority	Severity Level	Description
<a href="#">RestoreLog</a>	7	INFO	Restoring log files
<a href="#">RestoreCompleted</a>	7	INFO	Completed restoring from backup
<a href="#">SavedEvent</a>	7	INFO	Event saved

### 25.6.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

#### Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

**Note**

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is  $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$ . (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 25.4.3.6, “Defining NDB Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

**Note**

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete

operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

#### Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see [Section 25.6.3.1, “NDB Cluster Logging Management Commands”](#).

## 25.6.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](#), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 25.6.1, “Commands in the NDB Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

### Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start. Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. `NDB` Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as *Started*. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by *DBDIH*).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 25.6.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

### **Configuration change.**

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a "rolling upgrade" (or "rolling downgrade", when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

### System reset (cluster reset).

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmt`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes. This also forces the removal of all Disk Data objects and files associated with those objects.
- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 25.6.8, “Online Backup of NDB Cluster”](#), and [Section 25.5.23, “ndb\\_restore — Restore an NDB Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

### Resource Recovery.

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers.](#))
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmt` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

#### Note

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see [Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”](#)).

The type of restart required is indicated in the documentation for each node configuration parameter. See [Section 25.4.3, “NDB Cluster Configuration Files”](#).

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- You must upgrade all nodes of the same type (management, data, or API node) before upgrading any nodes of a different type. This remains true regardless of the order in which the nodes are upgraded.
- You must upgrade all management nodes before upgrading any data nodes. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade. In addition, it is not possible to perform native backups while an upgrade or downgrade is ongoing.

**Rolling restarts with multiple management servers.** When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 25.6.15.48, “The ndbinfo nodes Table”](#).

## 25.6.6 NDB Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 25.6.15.48, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

**Note**

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes
- Method 2:

Restart storage nodes prior to entering single user mode.

## 25.6.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

### 25.6.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization

of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

**Table 25.38 Data node failure handling during node group creation and table reorganization**

Failure during	Failure in “Old” data node	Failure in “New” data node	System Failure
Node group creation	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of CREATE NODEGROUP has reached the internal commit point:</b> When restarted, the cluster includes the new node group. Otherwise it without.</li> <li>• <b>If the execution of CREATE NODEGROUP has not yet reached the internal commit point:</b> When restarted, the cluster does not include the new node group.</li> </ul>
Table reorganization	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the</b></li> </ul>

Failure during	Failure in “Old” data node	Failure in “New” data node	System Failure
	<ul style="list-style-type: none"> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using the “new” data nodes.</li> <li>• <b>If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes.</li> </ul>

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

### 25.6.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmt` binaries for the data node processes. For a more detailed example, see [Section 25.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

**Important**

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.
5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.
7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

*Exception:* For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 15.1.24.12, “Setting NDB Comment Options”](#), for more information.

**Note**

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory `NDB` tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

### 25.6.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

### Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=2 @198.51.100.2 (9.5.0-ndb-9.5.0, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (9.5.0-ndb-9.5.0)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (9.5.0-ndb-9.5.0)
id=21 @198.51.100.21 (9.5.0-ndb-9.5.0)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address VARCHAR(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
```

```
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

### Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
```

```
$>
```

- Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
$> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO      -- NDB Cluster Management Server. 9.5.0-ndb-9.5.0
2008-12-08 17:29:23 [MgmSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @198.51.100.1  (9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=2      @198.51.100.2  (9.5.0-ndb-9.5.0, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10     @198.51.100.10  (9.5.0-ndb-9.5.0)

[mysqld(API)]   2 node(s)
id=20     @198.51.100.20  (9.5.0-ndb-9.5.0)
id=21     @198.51.100.21  (9.5.0-ndb-9.5.0)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 9.5.0)
Node 1: Started (version 9.5.0)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 9.5.0)
ndb_mgm> Node 2: Started (version 9.5.0)
```

### Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
$> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
$> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
$> ndbd -c 198.51.100.10 --initial
```

#### Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=2 @198.51.100.2 (9.5.0-ndb-9.5.0, Nodegroup: 0)
id=3 @198.51.100.3 (9.5.0-ndb-9.5.0, no nodegroup)
id=4 @198.51.100.4 (9.5.0-ndb-9.5.0, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (9.5.0-ndb-9.5.0)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (9.5.0-ndb-9.5.0)
id=21 @198.51.100.21 (9.5.0-ndb-9.5.0)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186 (using cleartext)
```

```
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (9.5.0-ndb-9.5.0, Nodegroup: 0, *)
id=2 @198.51.100.2 (9.5.0-ndb-9.5.0, Nodegroup: 0)
id=3 @198.51.100.3 (9.5.0-ndb-9.5.0, Nodegroup: 1)
id=4 @198.51.100.4 (9.5.0-ndb-9.5.0, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (9.5.0-ndb-9.5.0)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (9.5.0-ndb-9.5.0)
id=21 @198.51.100.21 (9.5.0-ndb-9.5.0)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag varsized memory
0          26086      26086         1572864             557056
```

1	26329	26329	1605632	557056
---	-------	-------	---------	--------

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

### Important

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 15.1.24.12, “Setting NDB Comment Options”](#), for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag var sized memory
0          12981      52296         1572864             557056
1          13236      52515         1605632             557056
2          13105      13105         819200              294912
3          13093      13093         819200              294912
```

### Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE, ] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is

an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 15.1.11, “ALTER TABLE Statement”](#).

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the Information Schema `TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

#### Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

#### Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior* to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1
```

```
[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
$> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

#### Note

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
$> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 25.6.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup

from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 6.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see [Section 25.5.23, “ndb\\_restore — Restore an NDB Cluster Backup”](#).

It is also possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See [Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#).

### 25.6.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 25.6.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 25.6.8.3, “Configuration for NDB Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup, and has the syntax shown here:

```
START BACKUP [backup_id]
             [encryption_option]
             [wait_option]
             [snapshot_option]

encryption_option:
```

```

ENCRYPT [PASSWORD=password]

password:
{'password_string' | "password_string"}

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND

```

Successive backups are automatically identified sequentially, so the *backup\_id*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *backup\_id* value is used, the backup fails with the error `Backup failed: file already exists`. If used, the *backup\_id* must follow immediately after the `START BACKUP` keywords, before any other options are used.

`START BACKUP` supports the creation of encrypted backups using `ENCRYPT PASSWORD=password`. The *password* must meet all of the following requirements:

- Uses any of the printable ASCII characters except `!`, `'`, `"`, `$`, `%`, `\`, and `^`
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

When `ENCRYPT PASSWORD='password'` is used, the backup data record and log files written by each data node are encrypted with a key derived from the user-provided *password* and a randomly-generated salt using a key derivation function (KDF) that employs the PBKDF2-SHA256 algorithm to generate a symmetric encryption key for that file. This function has the form shown here:

```
key = KDF(random_salt, password)
```

The key so generated is then used to encrypt the backup data using AES 256 CBC inline, and symmetric encryption is employed for encrypting the backup fileset (with the generated key).

#### Note

NDB Cluster *never* saves the user-furnished password or generated encryption key.

The `PASSWORD` option can be omitted from *encryption\_option*. In this case, the management client prompts the user for a password.

It is possible using `PASSWORD` to set an empty password (`' '` or `" "`), but this is not recommended.

An encrypted backup can be decrypted using any of the following commands:

- `ndb_restore --decrypt --backup-password=password`
- `ndbxfrm --decrypt-password=password input_file output_file`
- `ndb_print_backup_file -P password file_name`
- `ndb_restore --decrypt --backup-password-from-stdin`
- `ndbxfrm --decrypt-password-from-stdin input_file output_file`
- `ndb_print_backup_file --backup-password=password file_name`

- `ndb_print_backup_file --backup-password-from-stdin file_name`
- `ndb_mgm --backup-password-from-stdin --execute "START BACKUP ..."`

See the descriptions of these programs for more information, such as additional options that may be required.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

#### Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```

ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>

```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup\_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node\_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup\_id* is the unique identifier for this particular backup, and *node\_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```

Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes

```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
$> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given *backup\_id* are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number *backup\_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

- The management client acknowledges the abort request with `Abort of backup backup_id ordered.`

**Note**

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

- After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

**Note**

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
$> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 25.6.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- [BackupWriteSize](#)

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- [BackupMaxWriteSize](#)

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, [CompressedBackup](#) causes [NDB](#) to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the [BackupDataDir](#) configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

You can enforce encryption of backup files by setting [RequireEncryptedBackup](#) to 1; this prevents the creation of backups without specifying `ENCRYPT PASSWORD=password` as part of a `START BACKUP` command.

#### 25.6.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

#### Important

If you have set [BackupDataBufferSize](#) and [BackupLogBufferSize](#) and their sum is greater than 4MB, then you must also set [BackupMemory](#) as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

[NDB](#) does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an [NDB Cluster](#) from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

#### 25.6.8.5 Taking an NDB Backup with Parallel Data Nodes

It is possible to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmt_d` (`ndbd` is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; `ndbmt_d` by default runs in single-threaded mode. You can cause them to use multiple LDMs by choosing an appropriate setting for one of the multi-threaded data node configuration parameters [MaxNoOfExecutionThreads](#) or [ThreadConfig](#). Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart. In addition, the [EnableMultithreadedBackup](#) parameter must be set to 1 for each data node (this is the default).

Depending on the number of LDMs and other factors, you may also need to increase [NoOfFragmentLogParts](#). If you are using large Disk Data tables, you may also need to increase

`DiskPageBufferMemory`. As with single-threaded backups, you may also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see [Backup parameters](#)).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmtid` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/BACKUP-backup_id/` (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-backup_id-PART-1-OF-N/`, `BACKUP-backup_id-PART-2-OF-N/`, and so on, up to `BACKUP-backup_id-PART-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-backup_id-0.node_id.Data`, `BACKUP-backup_id.node_id.ctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

`ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see [Restoring from a backup taken in parallel](#).

To force creation of a single-threaded backup, set `EnableMultithreadedBackup = 0` for all data nodes (you can do this by setting the parameter in the `[ndbd default]` section of the `config.ini` global configuration file). It is also possible to restore a parallel backup to a cluster running an older version of NDB. See [Restoring an NDB backup to a previous version of NDB Cluster](#), for more information.

## 25.6.9 Importing Data Into MySQL Cluster

It is common when setting up a new instance of NDB Cluster to need to import data from an existing NDB Cluster, instance of MySQL, or other source. This data is most often available in one or more of the following formats:

- An SQL dump file such as produced by `mysqldump`. This can be imported using the `mysql` client, as shown later in this section.
- A CSV file produced by `mysqldump` or other export program. Such files can be imported into NDB using `LOAD DATA INFILE` in the `mysql` client, or with the `ndb_import` utility provided with the NDB Cluster distribution. For more information about the latter, see [Section 25.5.13, “ndb\\_import — Import CSV Data Into NDB”](#).
- A native NDB backup produced using `START BACKUP` in the NDB management client. To import a native backup, you must use the `ndb_restore` program that comes as part of NDB Cluster. See [Section 25.5.23, “ndb\\_restore — Restore an NDB Cluster Backup”](#), for more about using this program.

When importing data from an SQL file, it is often not necessary to enforce transactions or foreign keys, and temporarily disabling these features can speed up the import process greatly. This can be done using the `mysql` client, either from a client session, or by invoking it on the command line. Within a `mysql` client session, you can perform the import using the following SQL statements:

```
SET ndb_use_transactions=0;
SET foreign_key_checks=0;

source path/to/dumpfile;

SET ndb_use_transactions=1;
SET foreign_key_checks=1;
```

When performing the import in this fashion, you *must* enable `ndb_use_transaction` and `foreign_key_checks` again following execution of the `mysql` client's `source` command. Otherwise, it is possible for later statements in same session may also be executed without enforcing transactions or foreign key constraints, and which could lead to data inconsistency.

From the system shell, you can import the SQL file while disabling enforcement of transaction and foreign keys by using the `mysql` client with the `--init-command` option, like this:

```
$> mysql --init-command='SET ndb_use_transactions=0; SET foreign_key_checks=0' < path/to/dumpfile
```

It is also possible to load the data into an `InnoDB` table, and convert it to use the `NDB` storage engine afterwards using `ALTER TABLE ... ENGINE NDB`). You should take into account, especially for many tables, that this may require a number of such operations; in addition, if foreign keys are used, you must mind the order of the `ALTER TABLE` statements carefully, due to the fact that foreign keys do not work between tables using different MySQL storage engines.

You should be aware that the methods described previously in this section are not optimized for very large data sets or large transactions. Should an application really need big transactions or many concurrent transactions as part of normal operation, you may wish to increase the value of the `MaxNoOfConcurrentOperations` data node configuration parameter, which reserves more memory to allow a data node to take over a transaction if its transaction coordinator stops unexpectedly.

You may also wish to do this when performing bulk `DELETE` or `UPDATE` operations on `NDB` Cluster tables. If possible, try to have applications perform these operations in chunks, for example, by adding `LIMIT` to such statements.

If a data import operation does not complete successfully, for whatever reason, you should be prepared to perform any necessary cleanup including possibly one or more `DROP TABLE` statements, `DROP DATABASE` statements, or both. Failing to do so may leave the database in an inconsistent state.

## 25.6.10 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with `NDB` Cluster, `mysqld` needs to be built with support for the `NDB` storage engine, as it is in the precompiled binaries available from <https://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDB=1` or (deprecated) `-DWITH_NDBCLUSTER=1` option to include support for `NDB`.

For more information about compiling `NDB` Cluster from source, see [Section 25.3.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to `NDB` Cluster, see [Section 25.4.3.9, “MySQL Server Options and Variables for NDB Cluster”](#).)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in

the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
$> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 25.4.3.3, “NDB Cluster Connection Strings”](#), for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

### Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

## 25.6.11 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of **NDB** tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see [Section 25.6.11.1, “NDB Cluster Disk Data Objects”](#).

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [Disk Data Configuration Parameters](#), and [Disk Data and GCP Stop errors](#).

You should also set the `DiskDataUsingSameDisk` data node configuration parameter to `false` when using separate disks for Disk Data files.

For more information, see the following:

- [Disk Data file system parameters](#).
- [Disk Data latency parameters](#)
- [Section 25.6.15.32, “The ndbinfo diskstat Table”](#)
- [Section 25.6.15.33, “The ndbinfo diskstats\\_1sec Table”](#)
- [Section 25.6.15.50, “The ndbinfo pgman\\_time\\_track\\_stats Table”](#)

### 25.6.11.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- *Tablespace*: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- *Data file*: Stores column data. A data file is assigned directly to a tablespace.
- *Undo log file*: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- *log file group*: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by **NDB** tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We employ it merely to make the log files easily recognizable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

#### Important

There can exist at most one log file group in the same NDB Cluster at any given time.
