- Technical support: xi

### What’s New
- New features for release 11.2.1.6: xiii
- New features for release 11.2.1: xiii

### 1 Tools for Troubleshooting TimesTen
- Using the ttIsql utility: 1-1
- Using the ttStatus utility: 1-2
- Using the ttCapture utility: 1-5
- Using the logs generated by the TimesTen daemon: 1-6
- Using the ttTraceMon utility: 1-6
  - Starting a trace and reading the trace buffer: 1-7
  - SQL tracing: 1-9
  - API tracing: 1-10
  - DEADLOCK tracing: 1-10
  - LOCK tracing: 1-12
  - ERR tracing: 1-13
  - AGING tracing: 1-14
  - AUTOREFRESH tracing: 1-16
- Using the ttXactAdmin utility: 1-19
- Using ODBC tracing: 1-20
- Using SNMP traps to detect events: 1-20
- Monitoring the TimesTen system tables: 1-20
- Using the query optimizer: 1-21

### 2 Troubleshooting TimesTen Applications and Data Stores
- Unable to start or stop TimesTen daemon: 2-1
- No response from TimesTen daemon or subdaemon: 2-2
  - Check the TimesTen user error log: 2-2
Extract a stack trace from the core file ................................................................. 2-2

Unable to create shared segment ................................................................. 2-3

Application unable to connect to data store in direct mode ................ 2-3
  Upgrading your data store ........................................................................ 2-4
  Privileges to connect to data store ......................................................... 2-4
  Check file system permissions to access data store............................. 2-4
  Check that the TimesTen daemon is running ......................................... 2-4
  Check DSN definition ............................................................................. 2-4
    Check DSN attributes ......................................................................... 2-4
    Check path name to data store and transaction log directories .......... 2-4
  Manage semaphores and shared memory segments ........................... 2-5
  Check available swap space (virtual memory) ....................................... 2-5
  Increase the number of available file descriptors ............................... 2-5

Troubleshooting Client/Server problems ................................................. 2-6
  Cannot connect to the TimesTen Server .............................................. 2-6
  TimesTen Server failed ......................................................................... 2-7
  Cannot find Server DSN ....................................................................... 2-7
  TimesTen Server failed to load DRIVER .................................................. 2-7
  Application times out when accessing TimesTen Server ....................... 2-8
  TimesTen Client loses connection with TimesTen Server ................. 2-8
  Failed to attach to shared memory segment for IPC ......................... 2-8
  Increasing the maximum server connections on Windows XP .......... 2-8
  Thread stack overflow when using multiple client connections ........ 2-8
  Out of space when DSN specifies new data store ............................... 2-9

Application connects or disconnects are slow ...................................... 2-9
  Check if data store is being recovered ................................................. 2-9
  Check ODBC tracing ............................................................................. 2-9

Application becomes disconnected unexpectedly ............................. 2-9
  Check for ODBC or JDBC errors ........................................................... 2-10
  Check the user error log ..................................................................... 2-10

Application is slow .................................................................................. 2-10
  Consider connection mode ................................................................... 2-11
  Update statistics for your tables ............................................................ 2-11
  Verify lock and isolation levels .............................................................. 2-12
  Check trace settings ........................................................................... 2-12
  Check partition counts for the tables .................................................... 2-12

Application unresponsive, appears hung ............................................. 2-13
  Check logs and gather trace information .............................................. 2-13
  Check for ODBC errors ....................................................................... 2-13
  Check for deadlocks and timeouts .......................................................... 2-14

Application unable to find previously created objects ...................... 2-14
  Specify object owner ........................................................................... 2-15
  Check privilege to access tables ............................................................ 2-15
  Check temporary DSN attribute ............................................................. 2-15
  Check Overwrite DSN attribute ............................................................ 2-15
  Check path name to data store .............................................................. 2-15

Troubleshooting OCI and Pro*C/C++ applications .............................. 2-16
Running out of a resource ................................................................. 2-16
  Operating system tools and shared memory ........................................ 2-16
  Check the amount of memory allocated to the data store .................... 2-16
    Permanent segment filling up ....................................................... 2-17
    Temporary segment filling up ...................................................... 2-17
  Update query optimizer statistics .................................................... 2-18
  Check memory used by queries ....................................................... 2-18
  Check available swap space (virtual memory) .................................... 2-18
  Check transaction log file use of disk space ..................................... 2-18
  Check the semaphore limit .............................................................. 2-20

Duplicate results from a SELECT statement ........................................ 2-20

Cannot attach PL/SQL shared memory ............................................... 2-20

3 Troubleshooting Installation, Upgrades and Downgrades

Installing 32-bit TimesTen on 64-bit Windows .................................... 3-1
Downgrading a data store with Oracle data types to TimesTen 6.0 ............. 3-1

4 Troubleshooting Oracle In-Memory Database Cache

Unable to create a cache group .......................................................... 4-1
Unable to start or stop the cache agent .............................................. 4-2
  Check status of the cache agent ..................................................... 4-3
  Check ORACLE_HOME environment variable ................................... 4-3
  Check NLS environment variables .................................................. 4-3
Recovering cache grid after unexpected system shutdown ...................... 4-3
  A portion of the cache grid nodes are still running ............................ 4-3
  All cache grid nodes exited unexpectedly ....................................... 4-3
Unable to resolve Oracle Service Name ............................................. 4-4
Unable to resolve connect identifier ................................................. 4-4
Incompatible Oracle Server and Client versions ................................... 4-5
Unable to validate Oracle username and password ............................... 4-5
  Check library path environment variable ........................................ 4-6
  Check status of TNS listener and Oracle Server ............................... 4-6
  Check Oracle privileges ............................................................... 4-6
  Check DSN definition ...................................................................... 4-6
  Reboot TimesTen machine ............................................................. 4-7
  Set the cache administration user id and password ............................. 4-7
  Check user and system environment .............................................. 4-7
  Verify the loaded dynamic libraries ............................................... 4-7
OCI initialization failed ...................................................................... 4-8
Unsupported data type mapping ......................................................... 4-9
Null constraint does not match Oracle .............................................. 4-9
DDL operations on cached Oracle tables may cause cache group operations to fail 4-9
Changes not visible after updating object in cache group ....................... 4-10
Loading or refreshing fails .................................................................. 4-10
Monitoring autorefresh cache groups .................................................. 4-10
  Using the ttCacheAutorefreshStatsGet procedure ............................. 4-11
5 Troubleshooting AWT Cache Groups

Unable to start or stop replication agent ......................................................... 5-1
Replication does not work .............................................................................. 5-2
Using SNMP traps for notification of replication events .................................. 5-2
Monitoring AWT performance ....................................................................... 5-2
Possible causes of poor AWT performance .................................................... 5-3
Permanent Oracle errors reported by TimesTen .............................................. 5-3
Transient Oracle errors reported by TimesTen ................................................ 5-4

6 Troubleshooting Replication

Unable to create a replication scheme .............................................................. 6-1
Unable to alter a replication scheme ............................................................... 6-2
Unable to start or stop replication agent ......................................................... 6-2
Using SNMP traps for notification of replication events .................................. 6-3
Replication does not work .............................................................................. 6-3
Check status of TimesTen daemon and replication agents ............................. 6-3
Check that replication agents are communicating ......................................... 6-5
Check replication state .................................................................................. 6-5
Check replication scheme configuration ....................................................... 6-6
Check ttRepAdmin -showconfig ................................................................. 6-6
Check the TTREP.TTSTORES table .............................................................. 6-7
Check host names .................................................................................................................... 6-7
Check owner names................................................................................................................... 6-8
Checking replication owner ..................................................................................................... 6-8
Checking table owner ............................................................................................................. 6-8
Check consistency between replicated tables ........................................................................ 6-10

Replication unresponsive, appears hung ........................................................................... 6-10
Check replication state ........................................................................................................... 6-10
Check return receipt timeout setting ................................................................................... 6-10

Poor replication or XLA performance ............................................................................... 6-11
Check network bandwidth .................................................................................................. 6-11
Check use of return receipt blocking .................................................................................. 6-11
Check replication configuration ............................................................................................ 6-12
Check size of log buffer ........................................................................................................ 6-12
Check durability settings ....................................................................................................... 6-12
Check for reads from transaction log files ........................................................................ 6-12

Problems using ttRepAdmin ................................................................................................. 6-14
Problems using ttRepAdmin -duplicate ............................................................................ 6-15
Returns 'Must specify -scheme' error .................................................................................... 6-15

Problems with conflict checking ........................................................................................ 6-15
Column cannot be used for replication timestamp ................................................................. 6-16
Timestamp does not exist ...................................................................................................... 6-16
Conflict reporting slows down replication ........................................................................... 6-16

Index
Oracle TimesTen In-Memory Database is a memory-optimized relational database. Deployed in the application tier, Oracle TimesTen In-Memory Database operates on databases that fit entirely in physical memory using standard SQL interfaces. High availability for the in-memory database is provided through real-time transactional replication.

**Audience**

This guide describes how to troubleshoot some of the problems users encounter when using the Oracle TimesTen In-Memory Database.

To work with this guide, you should understand how database systems work and have some knowledge of SQL (Structured Query Language).

**Related documents**

TimesTen documentation is available on the product distribution media and on the Oracle Technology Network:

http://www.oracle.com/technology/documentation/timesten_doc.html

**Conventions**

TimesTen supports multiple platforms. Unless otherwise indicated, the information in this guide applies to all supported platforms. The term Windows refers to Windows 2000, Windows XP and Windows Server 2003. The term UNIX refers to Solaris, Linux, HP-UX and AIX.

This document uses the following text conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><strong>italic</strong></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
Documentation Accessibility

Our goal is to make Oracle products, services, and supporting documentation accessible to all users, including users that are disabled. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at http://www.oracle.com/accessibility/.
Accessibility of Code Examples in Documentation
Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

Accessibility of Links to External Web Sites in Documentation
This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

Access to Oracle Support
Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/support/contact.html or visit http://www.oracle.com/accessibility/support.html if you are hearing impaired.

Technical support
For information about obtaining technical support for TimesTen products, go to the following Web address:

http://www.oracle.com/support/contact.html
What’s New

This section summarizes the new features and functionality of Oracle TimesTen In-Memory Database Release 11.2.1 that are documented in this guide, providing links into the guide for more information.

New features for release 11.2.1.6
This guide now has more information about improving performance for the IMDB cache, which are described in the following sections:

- Optimize Performance for IMDB Cache
- Excessive deadlocks, buffer busy and row lock waits during autorefresh cache group refresh
- Abnormally large log and base tables degrade autorefresh performance
- Performance degrades when autorefresh interval is small

New features for release 11.2.1
This guide has information about the following new features:

- Issues with the NLS_LANG environment variable
- Cannot attach PL/SQL memory
- Changes not visible after updating object in cache group
- Monitoring the usage of the cache administration user’s tablespace
- Considerations when the cache administration user’s tablespace is full
- Poor autorefresh performance
- Poor replication or XLA performance

Issues with the NLS_LANG environment variable
On Windows, if the NLS_LANG environment variable is set to an unsupported value, such as NA, you could experience problems connecting. See "Troubleshooting OCI and Pro*C/C++ applications" on page 2-16.

Cannot attach PL/SQL memory
See "Cannot attach PL/SQL shared memory" on page 2-20 on how to recover if you receive error 8517 "Cannot attach PL/SQL shared memory; PLSQL_MEMORY_ADDRESS not valid or already in use."
Changes not visible after updating object in cache group
If you modify an object in a cache group and then the changes do not appear on a subsequent SQL statement, then see "Changes not visible after updating object in cache group" on page 4-10.

Monitoring the usage of the cache administration user's tablespace
To monitor the cache administration user tablespace, you can use either Oracle Enterprise Manager alerts or set the TimesTen tablespace threshold parameter. See "Monitoring the usage of the cache administration user's tablespace" on page 4-21 for details.

Considerations when the cache administration user's tablespace is full
With Oracle tables that are cached in a TimesTen database, you can configure them to use incremental automatic refresh. See "Considerations when the cache administration user's tablespace is full" on page 4-21 on how to specify what is to occur when the cache administration user's tablespace is full.

Poor autorefresh performance
There is a new method for improving autorefresh performance: "Unresponsive or dead TimesTen database degrades autorefresh performance" on page 4-23.

Poor replication or XLA performance
Additional methods for improving replication or XLA performance were added to "Poor replication or XLA performance" on page 6-11.
Tools for Troubleshooting TimesTen

This chapter describes how to use the TimesTen utilities and other tools that are used to diagnose problems with the TimesTen data store. This chapter includes the following topics:

- Using the *ttIsql* utility
- Using the *ttStatus* utility
- Using the *ttCapture* utility
- Using the logs generated by the TimesTen daemon
- Using the *ttTraceMon* utility
- Using the *ttXactAdmin* utility
- Using ODBC tracing
- Using SNMP traps to detect events
- Monitoring the TimesTen system tables
- Using the query optimizer

**Using the *ttIsql* utility**

The *ttIsql* utility allows you to interactively execute SQL statements and report status information on your data store.

All TimesTen SQL operations can be executed from a *ttIsql Command* prompt.

*Example 1–1 Using the *ttIsql* utility*

To start the *ttIsql* utility for the demo data store, enter:

```
% ttIsql demo
```

You should see output similar to the following:

```
Copyright (c) 1996-2007, Oracle. All rights reserved.
Type ? or 'help' for help, type 'exit' to quit ttIsql.

connect 'DSN=demo';
Connection successful: DSN=demo;UID=ttuser;DataStore=c:\temp\demo;
DatabaseCharacterSet=US7ASCII;ConnectionCharacterSet=US7ASCII;
DRIVER=C:\WINDOWS\system32\ttdv70.dll;Authenticate=0;PermSize=20;TypeMode=0;
(Default setting AutoCommit=1)
Command>
```
You can then execute SQL statements or ttIsql commands at the Command> prompt. "Using the ttIsql Utility" in the Oracle TimesTen In-Memory Database Operations Guide describes how to use the most common ttIsql commands. The following ttIsql commands are commonly used when troubleshooting:

- `monitor` formats the contents of the SYS.MONITOR table.
  See "Displaying data store information" in the Oracle TimesTen In-Memory Database Operations Guide.

- `dssize` prints data store size information.
  See "Displaying data store information" in the Oracle TimesTen In-Memory Database Operations Guide.

- `showplan` prints the optimizer execution plans for selects/updates/deletes in this transaction.
  See "Viewing and changing query optimizer plans" in the Oracle TimesTen In-Memory Database Operations Guide.

- `isolation` sets or displays the isolation level.
  See "Working with transactions" in the Oracle TimesTen In-Memory Database Operations Guide.

- `timing` prints query timing.
  See "Timing ODBC function calls" in the Oracle TimesTen In-Memory Database Operations Guide.

- `optprofile` prints the current optimizer flag settings and join order.
  See "Viewing and changing query optimizer plans" in the Oracle TimesTen In-Memory Database Operations Guide.

For the full list of ttIsql features, see the lists of options and commands under the description of the ttIsql utility in the Oracle TimesTen In-Memory Database Reference.

**Using the ttStatus utility**

Use the ttStatus utility to check the status of the TimesTen daemon and the state of all TimesTen connections.

*Example 1–2 ttStatus shows TimesTen daemon is not running*

In this example, the output from ttStatus indicates that no TimesTen daemon is running. If the daemon has stopped unexpectedly, see "No response from TimesTen daemon or subdaemon" on page 2-2 for troubleshooting information.

On Windows:

```
C:\>ttStatus
ttStatus: Could not connect to the TimesTen service.
If the TimesTen service is not running, please start it by running "ttDaemonAdmin -start".
```

On UNIX platforms:

```
$ ttStatus
ttStatus: Could not connect to the TimesTen daemon.
If the TimesTen daemon is not running, please start it by running "ttDaemonAdmin -start".
```
**Example 1–3  ttStatus shows TimesTen daemon is running**

In this example, the output from `ttStatus` indicates that the TimesTen daemon is running. It recognizes one data store named `demo`.

The first line indicates that the TimesTen daemon is running as process 884 on port 17000 for the TimesTen instance `MYINSTANCE`. The second line indicates the TimesTen Server is running as process 2308 on port 17002.

There are currently seven connections to the data store: one user and six subdaemon connections. You may see up to 2047 connections.

The restart policies for the cache agent and the replication agent in the data store are set to `manual`.

---

**Note:** This example was produced on Windows. The results are the same on UNIX platforms except for the formats of the data store path and the shared memory key.

---

Replication policy : Manual
Cache agent policy : Manual

----------------------------------------------------------

End of report

---

**Example 1–4  ttStatus shows replication information**

In this example, the output from `ttStatus` indicates that the TimesTen daemon is running. It recognizes three data stores: `demo`, `subscriber1ds`, and `masterds`. The `subscriber1ds` and `masterds` data stores are replicated data stores. In this example, the output from `ttStatus` indicates that the replication agents for the replicated data stores have been started. Bidirectional replication has been configured between `masterds` and `subscriber1ds`. Each replication agent has five connections to the data store.

C:\>ttStatus

Daemon pid 5088 port 17000 instance MYINSTANCE
TimesTen server pid 4344 started on port 17002

Cache agent policy : Manual

End of report

**Example 1–5  ttStatus shows cache group information**

This example shows the cache agent running on rep1 data store. There is one cache group in the data store. The cache agent has five connections to the data store.

C:\>ttStatus
TimesTen status report as of Mon Mar 19 10:47:46 2007

Daemon pid 1012 port 17000 instance MYINSTANCE
No TimesTen server running
Using the ttCapture utility

The **ttCapture** utility captures information about the configuration and state of your TimesTen system into a file that provides Technical support with a snapshot of your system at the time the **ttCapture** utility is running. The **ttCapture** utility generates a file named `ttcapture.date.time.log`. By default, the file is written to the directory from which you invoke the **ttCapture** utility. Use the **ttCapture -dest** option to direct the output file to be written to another directory.

If you run **ttCapture** again, it writes the information to a new file.
On Windows platforms, running ttCapture also produces an XML file named ttcapture.date.time.nfo that contains output from the msinfo32 utility.

When you experience a problem with a TimesTen data store, run ttCapture with the DSN option for the data store as soon as possible, either when you are encountering the problem or immediately afterward.

Note: Always double-quote directory and file names in case there are spaces in the names.

When you contact Technical support, upload the ttcapture.date.number.log file to the Service Request. Windows users should also upload the ttcapture.date.time.nfo file.

See "ttCapture" in the Oracle TimesTen In-Memory Database Reference for information about additional options.

Using the logs generated by the TimesTen daemon

TimesTen uses a TimesTen daemon to manage access to the data stores. As the daemon operates, it generates error, warning and informational messages. These messages may be useful for TimesTen system administration and for debugging applications.

By default, informational messages are stored in:

- A user error log that contains information you may need to see. Generally, these messages contain information about actions you may need to take.
- A support log containing everything in the user error log plus information for use by Technical support.

See "Modifying informational messages" in the Oracle TimesTen In-Memory Database Operations Guide for information about configuring the logs, including their location and size.

Using the ttTraceMon utility

Use the ttTraceMon utility to log various trace information on a number of TimesTen components. Each TimesTen component can be traced at different levels of detail. You can list all of the traceable TimesTen components and their current tracing level by specifying ttTraceMon with the show subcommand. The full list of options for ttTraceMon is described in the "ttTraceMon" section in the Oracle TimesTen In-Memory Database Reference.

TimesTen tracing severely impacts application performance and consumes a great deal of disk space if trace output is directed to a file. In addition, when using AWT cache groups, you must restart the replication agent when trying to trace the ORACON component with ttTraceMon. Use the ttTraceMon utility only when diagnosing problems. When you are finished, reset tracing to the default values.

Example 1–7 Default trace levels for components

This example shows that the levels for most tracing components are set to level 0 (off) for the demo data store. Both the ERR and DEADLOCK components are set to 1 for tracing by default. See "ERR tracing" on page 1-13.

% ttTraceMon -e show demo
The output for most TimesTen components is of interest only to Technical support. However, the output for the SQL, API, LOCK, ERR, AGING and AUTOREFRESH components may be useful to you when you are troubleshooting application problems.

The rest of this section includes the following topics:

- Starting a trace and reading the trace buffer
- SQL tracing
- API tracing
- DEADLOCK tracing
- LOCK tracing
- ERR tracing
- AGING tracing
- AUTOREFRESH tracing

Starting a trace and reading the trace buffer

Start a new trace by specifying ttTraceMon datastore. For example, to start a trace on the demo data store, enter:

```
% ttTraceMon demo
Trace monitor; empty line to exit
Trace >
```

At the Trace prompt, specify the type of trace and its level. For example, to start tracing the SQL component at level 3, enter:
Using the ttTraceMon utility

Trace > level sql 3

At this point you can run your application and the TimesTen trace information is written to a trace buffer. There are two ways to read the contents of the trace buffer:

- From the Trace prompt, use the `outfile` command to direct the trace buffer data to a file. (You must do this before running your application.) When writing tracing information to a file, new trace information is concatenated to the existing contents of the file.
- From the Trace prompt, use the `dump` command to display the trace buffer data to your screen.

---

**Note:** The contents of the trace buffer accumulate with each new trace. To clear the trace buffer, use the `flush` command from a ttTraceMon prompt. Clear the buffered trace records for a specific component by specifying the component with the `flush` command.

---

Each record from the trace buffer has the following format:

```
timestamp  sequence  component  level  connection  processid  operation
```

The fields in the records are defined as follows:

- **timestamp** is the time at which the operation was executed.
- **sequence** is the incremental number that identifies the trace line.
- **component** is the TimesTen component being traced (such as SQL, API, LOCK, or ERR).
- **level** is the trace level associated with the trace line. The range of trace levels differs by component, but for all components, the lowest trace level generates the least verbose output and highest trace level generates the most verbose output. For example, if you are tracing SQL at level 4, your output includes lines for levels 2 (prepare), 3 (execute), and 4 (open, close, fetch).

---

**Note:** Trace levels for some components are not a continuous range of numbers. If you enter a number that does not correspond to a supported level for a component, tracing occurs at the highest supported level that is less than the number you entered. For example, if tracing levels for a component are 1, 2, 3, 4, and 6 and you enter 5, tracing events for level 1, 2, 3, and 4 are generated.

---

- **connection** is the internal connection ID identifying the connection that generated the trace. This number corresponds to the ConnID shown in ttStatus output. The connection ID is also used as the first element of the transaction ID.
- **processid** is the operating system process ID for the process that generated the trace.
- **operation** is the operation that occurred (such as SQL statement, API operation, or error message).

For example, a line from the trace buffer after a SQL trace at level 3 might look like this:

```
10:39:50.231 5281 SQL 2L 1C 3914P Preparing: select cust_num from customer
```
Using the ttTraceMon utility

SQL tracing

Using ttTraceMon with the SQL component provides information about the SQL being prepared or executed by the TimesTen engine. Table 1–1 describes the levels for SQL tracing. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

Table 1–1  SQL tracing levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>SQL commands being prepared.</td>
</tr>
<tr>
<td>3</td>
<td>+ SQL commands being executed</td>
</tr>
<tr>
<td>4</td>
<td>+ The effect of command pooling (prepares not being done because the prepared command already exists in the pool), the need for reprepares (for example, because an index was created), and commands being destroyed. At this level, ttTraceMon also shows when a query command is being opened, fetched, and closed.</td>
</tr>
<tr>
<td>5</td>
<td>+ Some internal data, such as command numbers, which are not generally useful for customer-level debugging.</td>
</tr>
</tbody>
</table>

**Note:** TimesTen recommends tracing SQL at level 3 or 4. SQL tracing does not show any information about the optimizer. Optimizer tracing is managed by a separate component (OPT) at level 4 only, and is not designed for customer use.

**Example 1–8  SQL trace**

In this example, we execute ttTraceMon to do a SQL trace at level 4 on the demo data store. We direct the output from the SQL trace to the SQLtrace.txt file. We then flush the buffer so that the trace does not report past SQL statements.

% ttTraceMon demo
Trace monitor; empty line to exit
Trace > outfile SQLtrace.txt
Trace > level sql 4
Trace > flush

At this point, we execute an application that includes the following SQL statement:

```sql
SELECT * FROM departments WHERE department_id = 10;
```

The trace information is written to the SQLtrace.txt file:

```
12:19:36.582     269 SQL      2L    3C  29570P Preparing: select * from departments where department_id = 10
12:19:36.583     271 SQL      4L    3C  29570P Opening: select * from departments where department_id = 10;
12:19:36.583     272 SQL      4L    3C  29570P Fetching: select * from departments where department_id = 10;
12:19:36.583     273 SQL      4L    3C  29570P Closing: select * from departments where department_id = 10;
5 records dumped
```

When the application has completed, we turn off SQL tracing and exit ttTraceMon.

Trace > level sql 0
API tracing

API traces are generated for database operations such as connecting to a data store, changing a connection attribute, and committing a transaction. Table 1–2 describes the levels for API tracing. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

<table>
<thead>
<tr>
<th>Level</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>All rollback attempts by the subdaemon. This occurs if an application exits abruptly and the subdaemon recovers its connection.</td>
</tr>
<tr>
<td>2</td>
<td>+ Some low-on-space conditions.</td>
</tr>
<tr>
<td>3</td>
<td>+ Create, connect, disconnect, checkpoint, backup, and compact operations for the data store, as well as commit and rollback for each connection, and a few other operations.</td>
</tr>
<tr>
<td>4</td>
<td>+ Most other operations conducted at TimesTen’s internal API level. It does not show numerous operations on the storage manager and indexes that are done internally.</td>
</tr>
</tbody>
</table>

**Example 1–9  API trace**

In this example, we execute ttTraceMon to do a API trace at level 3 on the demo data store. The output from the API trace is written to the APItrace.txt file. Before saving the API trace to the buffer, we use the flush command to empty the buffer.

```bash
% ttTraceMon demo
Trace monitor; empty line to exit
Trace> outfile APItrace.txt
Trace> level api 3
Trace > flush
```

At this point, we execute the application. When the application has completed, we turn off API tracing and exit ttTraceMon:

```bash
Trace > level api 0
Trace > {press ENTER - blank line}
```

The contents of APItrace.txt are similar to the sample output shown below. The output shows connection to the data store, setting the connection character set, setting the isolation level, and committing a transaction.

```
11:54:26.796    1016 API      3L    2C   4848P sb_dbConnect()(X)
11:54:26.796    1017 API      3L    2C   4848P sb_dbConnCharsetSet()(E)
11:54:26.796    1018 API      3L    2C   4848P sb_dbConnSetIsoLevel()(E)
11:54:39.795    1019 API      3L    2C   4848P sb_dbConnSetIsoLevel()(E)
11:54:45.253    1020 API      3L    2C   4848P sb_xactCommitQ()()(E)
```

**DEADLOCK tracing**

Use the DEADLOCK component to trace the occurrences of all deadlocks for all applications.
Table 1–3 describes the DEADLOCK tracing levels. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

<table>
<thead>
<tr>
<th>Level</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Logs deadlock cycles as they are discovered.</td>
</tr>
<tr>
<td>4, 6</td>
<td>+ Provides detail information about how the deadlock is detected.</td>
</tr>
</tbody>
</table>

Example 1–10  DEADLOCK trace

In this example, we execute ttTraceMon to do a DEADLOCK trace at level 1, which is the default, on myDSN data store.

We make two connections to myDSN. For the first connection, autocommit is on. We create table test and insert two rows. Then, we set autocommit off and update the x1=1 row of table test. Because autocommit is off, the row is not inserted into the table until we commit. A lock is held until we commit or roll back the transaction.

Command> create table test (x1 int unique, y1 int);  
Command> insert into test values (1,1);  
1 row inserted.  
Command> insert into test values (2,2);  
1 row inserted.  
Command> autocommit 0;  
Command> update test set y1=y1 where x1=1;  
1 row updated.

For the second connection to myDSN, autocommit is set to off. We update the x1=2 row of table test.

Command> autocommit 0;  
Command> update test set y1=y1 where x1=2;  
1 row updated.

Now, we create a deadlock situation by executing update statements in both connections for rows that are locked by each other. The first connection executes an update against the row where x1=2.

Command> update test set y1=y1 where x1=2;  
6003: Lock request denied because of time-out  
Details: Tran 2.1 (pid 32750) wants Un lock on rowid BMUFVUAAAaAAAAETk,  
table ME.TEST. But tran 3.2 (pid 32731) has it in Xn (request was Xn).  
Holder SQL (update t1 set y1=y1 where x1=2)  
The command failed.

The second connection executes an update against the row where x1=1.

Command> update test set y1=y1 where x1=1;  
6002: Lock request denied because of deadlock  
Details: Tran 3.2 (pid 32731) wants Un lock on rowid BMUFVUAAAaAAAAADzk,  
table ME.TEST. But tran 2.1 (pid 32750) has it in Xn (request was Xn).  
Holder SQL (update t1 set y1=y1 where x1=1)  
The command failed.

We use the flush command to empty the buffer.

% ttTraceMon myDSN  
Trace monitor; empty line to exit  
Trace> flush
The trace buffer contains the following information showing all level 1 deadlock traces, as evidenced by 'IL':

```
Trace> dump
09:50:26.444      13 DEADLOCK 1L 2036C   3484P edge 1: xid 3.2, cid 3,
    <Row BMUFVUAAAAAAdzK,0x8c5
74(574836)> 0 cnt=1 , Tbl 'T1', SQL='update t1 set y1=y1 where x1=1'
09:50:26.455      14 DEADLOCK 1L 2036C   3484P edge 0: xid 2.1, cid 2,
    <Row BMUFVUAAAAAAdaT,0x8c5
74(574836)> 0 cnt=1 , Tbl 'T1', SQL='update t1 set y1=y1 where x1=2'
09:50:26.455      15 DEADLOCK 1L 2036C   3484P Victim: xcb:3.2,
    SQL='update t1 set y1=y1 where x1=1'
```

If you want more information, set DEADLOCK tracing to a higher value. For example, the following sets DEADLOCK tracing to level 4 in `ttTraceMon`:

```
Trace> level deadlock 4
```

### LOCK tracing

Use the LOCK component to trace the locking behavior of your application to detect trouble with deadlocks or lock waits. LOCK tracing generates a great deal of volume, so it is important to choose the appropriate level of tracing. Level 3, for example, begins to generate a large number of traces, as traces are written for fairly common events. In addition, the traces themselves may be somewhat hard to read in places. If you cannot discern enough information for your purposes, contact Technical support for more information.

Table 1–4 describes the LOCK tracing levels. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

#### Table 1–4  LOCK tracing levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Deadlock cycles as they are discovered.</td>
</tr>
<tr>
<td>2</td>
<td>+ Failures to grant locks for any reason.</td>
</tr>
<tr>
<td>3</td>
<td>+ Lock waits (which may or may not be granted).</td>
</tr>
<tr>
<td>4</td>
<td>+ All lock grants/releases, some routine calls, and the mechanism of the deadlock detector.</td>
</tr>
<tr>
<td>6</td>
<td>+ Each step in cycle traversal.</td>
</tr>
</tbody>
</table>

### Example 1–11  LOCK trace

In this example, we execute `ttTraceMon` to do a LOCK trace at level 4 on myDSN data store.

We make two connections to myDSN. For the first connection, we set autocommit on. We create table `test` and insert three rows. We create a materialized view using table `test`.

We turn on tracing at level 4 and use the `flush` command to empty the buffer.

```
% ttTraceMon myDSN
Trace monitor; empty line to exit
Trace> level lock 4
Trace> flush
```
For the second connection to myDSN, we set autocommit off. We insert a row into table test. Because autocommit is off, the row is not inserted into the table until we commit. A lock is held until we commit or roll back the transaction.

If we use the dump command to display the contents of the trace buffer, we see that there are no records in the trace buffer:

```
Trace> dump
0 records dumped
```

From the first connection, we try to drop the materialized view. We cannot drop the view because there is a transaction that has not been committed or rolled back:

```
Command> drop materialized view v;
6003: Lock request denied because of time-out
Details: Tran 3.71 (pid 24524) wants Sn lock on table TTUSER.TTEST. But tran 1.42 (pid 24263) has it in IXn (request was IXn). Holder SQL (insert into test values (100));
The command failed.
```

The trace buffer contains the following information:

```
Trace> dump
20:09:04.789  174759 LOCK     3L    3C  24524P ENQ: xcb:00003 <Tbl 0x9b894,0x0>
0+Sn=>SL activity 0 Sn cnt=0; Holder xcb:00001 IXn
20:09:04.789  174760 LOCK     3L 2047C  24237P Connection 3 scheduled for sleep
20:09:04.789  174761 LOCK     3L    3C  24524P Connection 3 sleeping
20:09:14.871  174762 LOCK     3L    3C  24524P Connection 3 timed out
20:09:14.871  174763 LOCK     3L    3C  24524P Connection 3 woken up
20:09:14.871  174764 LOCK     3L    3C  24524P Connection 3 awake
7 records dumped
```

When finished with the trace, we set LOCK tracing back to its default setting (0) and exit ttTraceMon:

```
Trace > level lock 0
Trace > (press ENTER – blank line)
```

**ERR tracing**

It may be useful to trace the ERR component. For example, an ERR trace at level 4 shows all of the error messages that are pushed in the TimesTen direct driver (not all errors are output to the user because they are handled internally). ERR tracing at level 1 is the default. No output is written for ERR tracing at level 2 and 3.

Table 1-5 describes ERR tracing levels. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

<table>
<thead>
<tr>
<th>Level</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (set by default)</td>
<td>Fatal errors</td>
</tr>
<tr>
<td>4</td>
<td>+ All other error messages, many of which are handled internally by TimesTen.</td>
</tr>
</tbody>
</table>

**Example 1-12 ERR trace**

In this example, we execute ttTraceMon to do a ERR trace at level 4 on myDSN data store.
First we create a table:

```
Command> create table test (id tt_integer);
```

Next we turn on tracing at level 4. Rather than direct the trace output to a file as in the previous examples, we read it directly from the trace buffer. Before saving the ERR trace to the buffer, we use the flush command to empty the buffer.

```
% ttTraceMon myDSN
Trace monitor; empty line to exit
Trace> level err 4
Trace> flush
```

Now we execute a SQL script with three errors in it. The errors are:

- Creating a table with the same name as an existing table
- Using incorrect syntax to insert values into the table
- Inserting CHAR data into a TT_INTEGER column

```
Command> create table test (id tt_integer);
2207: Table TEST already exists
The command failed.
Command> insert into test values 'abcd');
1001: Syntax error in SQL statement before or at: "'abcd'", character position: 25
insert into test values 'abcd');
```

```
Trace > level err 1
Trace > {press ENTER – blank line}
```

AGING tracing

Use the ttTraceMon utility to obtain the following information:

- When aging starts and ends
- How many rows have been deleted by the aging subdaemon

See "Implementing aging in your tables" in the Oracle TimesTen In-Memory Database Operations Guide.
Table 1–6 describes the AGING tracing levels. Each level with a ‘+’ sign includes the trace information described for that level, plus all levels preceding it.

Table 1–6  AGING tracing levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1     | Displays messages about the following events:  
   ■ The aging subdaemon starts least recently used (LRU) or time-based aging.  
   ■ The aging subdaemon repeats LRU aging because the LRU threshold was not met.  
   ■ The aging subdaemon ends LRU or time-based aging. |
| 2     | + Displays messages about the following events for each table:  
   ■ Aging has started.  
   ■ Aging has ended. The message includes the reason for ending and the total number of rows deleted. |
| 3     | + Detailed report on how many rows were deleted during each aging cycle. |
| 4     | + Message every time the aging subdaemon wakes up. |

Example 1–13  AGING trace

In this example, we execute ttTraceMon to do an AGING trace on myDSN data store. The data store contains TTUSER.MYTAB table, which has a time-based aging policy. The table is described as follows:

Command> describe TTUSER.MYTAB;

Table TTUSER.MYTAB:

*ID TT_INTEGER NOT NULL  
TS TIMESTAMP (6) NOT NULL

Aging use TS lifetime 3 minutes cycle 1 minute on

1 table found.  
(primary key columns are indicated with *)

The table contains the following rows before the aging cycle begins:

Command> select * from TTUSER.MYTAB;  
< 1, 2007-03-21 12:54:06.000000 >  
< 3, 2010-03-17 08:00:00.000000 >  
< 4, 2007-03-21 12:59:40.000000 >  
< 5, 2007-03-21 13:00:10.000000 >  
< 6, 2007-03-21 13:01:22.000000 >  
5 rows found.

We execute ttTraceMon to do an AGING trace at level 3. Rather than direct the trace output to a file, we read it directly from the trace buffer. Before saving the AGING trace to the buffer, we use the flush command to empty the buffer.

% ttTraceMon myDSN
Trace monitor; empty line to exit
Trace> level aging 3
Trace> flush

Display the trace information in the buffer by using the dump command.

Trace> dump
13:16:56.802 1247 AGING 1L 2045C 17373P Entering sbAgingTB(): curTime=78
Using the ttTraceMon utility

13:16:56.803 1248 AGING 2L 2045C 17373P Entering sbAgingOneTable():
curTime=78, tblid= 637140
13:16:56.804 1249 AGING 3L 2045C 17373P curTime=78, 4 deleted, 1
remaining, tbl = TTUSER.MYTAB
13:16:56.804 1250 AGING 2L 2045C 17373P Exiting sbAgingOneTable():
curTime=78, reason = 'no more rows', 4 deleted, 1 remaining, tbl = TTUSER.MYTAB
13:16:56.804 1251 AGING 1L 2045C 17373P Exiting sbAgingTB(): curTime=78
5 records dumped

We set AGING tracing back to its default setting (0) and exit ttTraceMon:
Trace > level aging 0
Trace > {press ENTER – blank line}

AUTOREFRESH tracing

Use the ttTraceMon utility to obtain information about the progress of autorefresh
operations for cache groups with the AUTOREFRESH cache group attribute.

See "AUTOREFRESH cache group attribute" in the Oracle In-Memory Database Cache
User’s Guide.

Table 1–7 describes AUTOREFRESH tracing levels. Each level with a ‘+’ sign includes
the trace information described for that level, plus all levels preceding it.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Autorefresh summary for the interval:</td>
</tr>
<tr>
<td></td>
<td>■ The time that autorefresh started</td>
</tr>
<tr>
<td></td>
<td>■ Number of autorefreshed rows for the interval</td>
</tr>
<tr>
<td></td>
<td>■ Number of autorefreshed root table rows for interval</td>
</tr>
<tr>
<td></td>
<td>■ Total number of autorefreshed rows since the cache agent started</td>
</tr>
<tr>
<td></td>
<td>■ Total number of autorefreshed rows in the root table since the cache agent started</td>
</tr>
<tr>
<td></td>
<td>■ The time that autorefresh ended</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Times and information about root table rows are reported for full autorefresh.</td>
</tr>
<tr>
<td>2</td>
<td>+ Autorefresh summary at the cache group level:</td>
</tr>
<tr>
<td></td>
<td>■ The time that autorefresh started for each cache group</td>
</tr>
<tr>
<td></td>
<td>■ Number of autorefreshed rows for each cache group</td>
</tr>
<tr>
<td></td>
<td>■ Number of autorefreshed root table rows for each cache group</td>
</tr>
<tr>
<td></td>
<td>■ Total number of autorefreshed rows for each cache group since the cache agent started</td>
</tr>
<tr>
<td></td>
<td>■ Total number of autorefreshed rows in the root table for each cache group since the cache agent started</td>
</tr>
<tr>
<td></td>
<td>■ The time that autorefresh ended for each cache group</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Times and information about root table rows are reported for full autorefresh.</td>
</tr>
</tbody>
</table>
Example 1–14 AUTOREFRESH trace

In this example, we use the ttTraceMon utility to trace autorefresh operations on the cgDSN data store. When we set the trace level to 1, we see information that is similar to the output of the ttCacheAutorefreshStatsGet built-in procedure.

```plaintext
% tttracemon cgDSN
Trace monitor; empty line to exit
Trace> level autorefresh 1
Trace> dump

08:56:57.445 19398 AUTOREFRESH 1L 5C 32246P Autorefresh number 1415 started for interval 60000
08:56:57.471 19399 AUTOREFRESH 2L 5C 32246P Autorefresh started for cachegroup TESTUSER.READCACHE
```

**Table 1–7 (Cont.) AUTOREFRESH tracing levels**

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>+ Autorefresh summary at the table level:</td>
</tr>
<tr>

7 records dumped
```

Tracing at level 4 produces additional information about autorefresh operation 1415. Information about autorefresh is provided for the testuser.readcache cache group, the testuser.readtab root table and the autorefresh interval.

```plaintext
Trace> level autorefresh 4
Trace> dump

08:56:57.445 19398 AUTOREFRESH 1L 5C 32246P Autorefresh number 1415 started for interval 60000
08:56:57.471 19399 AUTOREFRESH 2L 5C 32246P Autorefresh started for cachegroup TESTUSER.READCACHE
```
Using the `ttTraceMon` utility

We set `AUTOREFRESH` tracing back to its default setting (0) and exit `ttTraceMon`:

```
Trace > level autorefresh 0
Trace > {press ENTER – blank line}
```
Using the ttXactAdmin utility

The ttXactAdmin utility displays ownership, status, log and lock information for each outstanding transaction. You can also use it to show all current connections to a data store. The ttXactAdmin utility is useful for troubleshooting problems with replication, XLA, and asynchronous writethrough cache groups.

Example 1–15  Using ttXactAdmin to diagnose a lock timeout

Use ttXactAdmin to diagnose a lock timeout. Consider two connections that are trying to update the same row. The following transaction by Connection 1 is in progress:

```
UPDATE table1 SET c1 = 2 WHERE c1 = 1;
```

Connection 2 attempts to make the following update:

```
UPDATE table1 SET c1 = 3 WHERE c1 = 1;
```

Connection 2 receives the following error:

```
6003: Lock request denied because of time-out
   Details: Tran 2.3 (pid 2880) wants Un lock on rowid 0x00156bbc, table TTUSER.TABLE1.
   But tran 1.21 (pid 2564) has it in Xn (request was Xn). Holder SQL (update table1 set c1 = 2 where c1 = 1;)
   The command failed.
```

The details of the error indicate that transaction 1.21 has a lock on row 0x00156bbc, the row that transaction 2.3 wants to update. ttXactAdmin displays this information in output that pertains to actions in the entire data store:

```
$ ttXactAdmin myDSN
2007-03-23 11:26:01.643
c:\datastore\myDSN
TimesTen Release 7.0.2.0.0

See "ttXactAdmin" in the Oracle TimesTen In-Memory Database Reference.
Using ODBC tracing

On Windows, use the ODBC trace facility to verify the sequence and content of your commands. The ODBC trace facility works only if you have linked your application with the ODBC Driver Manager. Enable tracing by double-clicking ODBC in the Control Panel. This opens the ODBC Data Source Administrator. Choose the Tracing tab.

On UNIX platforms, ODBC tracing is available only when using a driver manager. To turn on tracing, set the Trace and TraceFile attributes.

Using SNMP traps to detect events

Network management software uses SNMP (Simple Network Management Protocol) to query or control the state of network devices such as routers and switches. These devices can generate alerts called traps to inform the network management systems of problems.

TimesTen sends SNMP traps for particular critical events to help facilitate user recovery mechanisms. These events are also recorded in the support log. Exposing them through SNMP traps allows network management software to take immediate action.

How to configure TimesTen to generate SNMP traps as well as how to receive the traps is described in "Diagnostics through SNMP Traps" in the Oracle TimesTen In-Memory Database Error Messages and SNMP Traps.

To understand how network software might be used to detect SNMP traps, use the snmptrapd program provided in your TimesTen directory: /install_dir/demo/snmp. This demo listens on a designated port for SNMP trap messages and either prints the traps to stdout or logs them to syslogd. See the /install_dir/demo/snmp/README.txt file for details.

Monitoring the TimesTen system tables

Each TimesTen data store contains a group of system tables that store metadata about the current state of the data store. The system tables are described in "System Tables" in the Oracle TimesTen In-Memory Database System Tables and Limits Reference.

Note: You can execute SELECT statements on a system table, but you cannot execute a statement such as INSERT, UPDATE or DELETE on these tables.

Of particular interest when troubleshooting is the SYS.MONITOR table, which contains statistics about certain events that have occurred since the first connection to the data store. For example, the SYS.MONITOR table contains information about the number of connections to the data store; the number of checkpoints taken; the size of the data store; and the amount of memory currently in use. Check the contents of the SYS.MONITOR table by executing SELECT statements on the columns or by using the ttIsqI monitor command. For an example of how to use the ttIsqI monitor command, see "Using the ttIsqI Utility" in the Oracle TimesTen In-Memory Database Operations Guide.

The SYS.MONITOR table is useful for troubleshooting performance problems. See "Reading query plan from the PLAN table" in the Oracle TimesTen In-Memory Database Operations Guide for details. Check the contents of the SYS.MONITOR table by
executing SELECT statements on the columns or by using the ttIsql showplan command, as described in "Viewing and changing query optimizer plans" in the Oracle TimesTen In-Memory Database Operations Guide.

Using the query optimizer

The query optimizer is an important tool for performance tuning.

For details about using the query optimizer, see:

- "The TimesTen Query Optimizer" in the Oracle TimesTen In-Memory Database Operations Guide
- "Viewing and changing query optimizer plans" in the Oracle TimesTen In-Memory Database Operations Guide

If you find that a given query runs more slowly than expected, confirm that the query optimizer has the latest statistics for the tables in your query, as described in "Update query optimizer statistics" on page 2-18. If, after updating your statistics, your query still runs too slowly, it is possible that the TimesTen optimizer is not choosing the optimal query plan to answer that query. Under these circumstances, you can adjust how the optimizer generates a plan by using the ttOpt* procedures described in "Modifying plan generation" in the Oracle TimesTen In-Memory Database Operations Guide.
Using the query optimizer
Troubleshooting TimesTen Applications and Data Stores

This chapter helps you diagnose and remedy some of the problems encountered while using a TimesTen data store.

If you are still having problems with your data store after following the troubleshooting recommendations in this chapter, please contact Technical support.

This chapter includes the following topics:

- Unable to start or stop TimesTen daemon
- No response from TimesTen daemon or subdaemon
- Unable to create shared segment
- Application unable to connect to data store in direct mode
- Troubleshooting Client/Server problems
- Application connects or disconnects are slow
- Application becomes disconnected unexpectedly
- Application is slow
- Application unresponsive, appears hung
- Application unable to find previously created objects
- Troubleshooting OCI and Pro*C/C++ applications
- Running out of a resource
- Duplicate results from a SELECT statement
- Cannot attach PL/SQL shared memory

Unable to start or stop TimesTen daemon

This section describes what to check if you are unable to start or stop the TimesTen main daemon.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Incorrect privilege</td>
<td>You need the ADMIN privilege to start or stop the TimesTen daemon. Ensure that you are using the ttDaemonAdmin utility to start the daemon. The output from ttDaemonAdmin shows whether you have the correct privilege.</td>
</tr>
</tbody>
</table>
No response from TimesTen daemon or subdaemon

This section describes what to do if one or more of the TimesTen processes appears to be unavailable:

- Check the TimesTen user error log
- Extract a stack trace from the core file

Check the TimesTen user error log

If you receive an error that indicates the TimesTen subdaemon has stopped, inspect the user error log, as described in "Using the logs generated by the TimesTen daemon" on page 1-6.

If the TimesTen daemon crashes, it cannot send anything to the user error log, but the subdaemons send a 'main daemon vanished' message to the log before exiting:

09:24:13 Err : 4375 ------------------: Main daemon has vanished

Restart the daemon. The next connection to each data store causes TimesTen to recover from the checkpoint and transaction log files. See "Working with the Oracle TimesTen Data Manager Daemon" in the Oracle TimesTen In-Memory Database Operations Guide.

Extract a stack trace from the core file

If you experience a crash by one of the TimesTen processes on a UNIX system and have exhausted all of the diagnostic options, check to see if TimesTen has generated a core file. Use the ttVersion utility to find the core file. Look for a line in the output that shows a path for the daemon home directory:

TimesTen Release (ttuser:40732)
2007-04-04T17:53:04Z
Instance admin: ttuser
Instance home directory:
/node1/ttuser/ttcur/TTBuild/linux86_dbg/install
Daemon home directory:
/node1/ttuser/ttcur/TTBuild/linux86_dbg/install/info

After locating the core file, attach to the debugger on the system and extract the stack trace from the core file and send the trace results to Technical support.

On Windows systems you can obtain diagnostic information for a service failure by enabling the 'allow service to interact with desktop' option in the properties dialog for the TimesTen data manager in the Service menu. If a fatal fault occurs in the TimesTen
data manager service, a pop-up asks if you would like to start the debugger. Contact Technical support and provide the stack trace.

Unable to create shared segment

You may receive an error that indicates that a shared segment could not be created:

4671: TT14000: TimesTen daemon internal error: Error 28 creating shared segment, KEY 0x0201f7eb
4671: -- OS reports too many shared segments in use
4671: -- Confirm using 'ipcs' and take appropriate action
4671: 18538 ------------------: subdaemon process exited

Using the Linux ipcs command may display information like this:

```
------ Shared Memory Segments ------
key     shmid      owner     perms      bytes    nattch     status
0x00000000 1098350592 user1     777        10624      2          dest
0x00000000 1084817409 user1     777         2439680    2          dest
0x911fc211 1098383362 user2     666        67108864   1
0x2814afba 170721285 root      666         1048576    1
```

A status of dest means the memory segment is marked to be destroyed. nattch shows the number of processes still attached to the memory segment. The ipcrm command cannot free the shared memory until the processes detach from the segment or exit. If an application connects to TimesTen and then becomes inactive, nothing can free the shared memory until the user exits or stops the application.

Application unable to connect to data store in direct mode

This section describes what to check if your application is unable to connect to a data store in direct mode.

<table>

</tr>
</tbody>
</table>
Upgrading your data store

A data store is only guaranteed to be accessible by the same minor release of TimesTen that was used to create the data store. When you upgrade the TimesTen software and you would like to use the new release to access a data store that was previously created, create a data store with the new release. Then use the ttMigrate utility to copy the tables, indexes, and table data from the old data store to the new one.

See "Data Store Upgrades" in the Oracle TimesTen In-Memory Database Installation Guide for details.

Privileges to connect to data store

The user must have the CREATE SESSION privilege to connect to the data store. If you do not have access, the administrator must use the GRANT statement to grant you the CREATE SESSION privilege. See "Granting privileges to connect to the database" in the Oracle TimesTen In-Memory Database Operations Guide.

Check file system permissions to access data store

A "permission denied" error is generated if you attempt to connect to a data store and you do not have the proper permissions to access the checkpoint or transaction log files or the directory where those files reside. Check the file system permissions on the files located in the directory specified in the DataStore attribute in your DSN.

Check that the TimesTen daemon is running

If the TimesTen daemon or Data Manager service is not running, an attempt to connect to a data store generates TimesTen error 799 (Unable to connect to daemon; check daemon status).

Use the ttStatus utility as described in "Check the TimesTen user error log" on page 2-2 to check the status of the TimesTen daemon.

Check DSN definition

In your DSN description:

- Check DSN attributes
- Check path name to data store and transaction log directories

Check DSN attributes

Certain connection options or DSN attribute settings combinations are not compatible. In cases where incompatible settings are used, an error is returned to the application when it attempts to connect to a data store.

Check path name to data store and transaction log directories

Confirm that you have specified the correct path names in the DataStore and LogDir attributes in your DSN. Also confirm that the path names are absolute path names, rather than relative. Otherwise, the path name will be relative to the directory where the application was started.

On Windows, be careful to distinguish between User and System DSNs in the ODBC Data Source Administrator. Do not create user DSNs because they are visible only to the user who defines them. System DSNs are visible to all users. In particular, if you run a TimesTen application as a Windows service, it runs as the user “SYSTEM” by
default and does not see any User DSNs. Make sure that you are not using a mapped drive in the data store path name.

Manage semaphores and shared memory segments

An error is generated if you attempt to connect to or create a shared data store whose size is larger than the maximum size of shared memory segments configured on your system. Also, an error is generated if the system cannot allocate any more shared memory segments.

On UNIX systems, use commands similar to the following:

- `ipcs -ma` to check if you have other shared memory segments using up memory, such as Oracle instances or other instances of TimesTen.
- `ipcrm` to remove a message queue, semaphore set or shared memory segment identifier. Use `ipcrm` to clean up semaphores or shared memory segments after a faulty TimesTen shutdown, instance crash, daemon crash or other application issues that use shared memory segments and semaphores. Use `-m` to remove a shared memory segment. Use `-s` to remove a semaphore.
- `ps -eafl` to see how much memory is being used by running processes.
- `ulimit -a` to see if there are any limits on the maximum amount of memory one process can address, maximum file size, and the maximum number of open files.

If a shared memory segment is available but is too small to hold your data store, use the `ttSize` utility to estimate the amount of memory required for your tables and then check the values of the PermSize and TempSize attributes to verify the amount of memory established for your data store. “Monitoring PermSize and TempSize attributes” in the Oracle TimesTen In-Memory Database Operations Guide describes guidelines for setting the size of your permanent and temporary data partitions. If the amount of memory established for your data store is too large, reset PermSize and TempSize to smaller values. See "Check the amount of memory allocated to the data store" on page 2-16 for more information. Another option is to increase the maximum size of the shared memory segment, as described below.

If a data store becomes invalidated because of a system or application failure, a subsequent connection recovers the data store. If recovery fails because you have run out of data store space, then reconnect to the data store with a larger PermSize and TempSize value than the ones that are currently in effect. If recovery fails because you do not have enough shared memory, then you should increase the maximum size of the shared memory segments for the system.

For more information on how to configure shared memory for TimesTen, see "Installation prerequisites" in the Oracle TimesTen In-Memory Database Installation Guide.

Check available swap space (virtual memory)

There must be enough swap space to back up shared memory.

On UNIX systems, use the swap command to check and add virtual memory to your system.

On Windows systems, check and reset the size of your virtual memory from the Advanced tab in your Computer Management Properties dialog window.
Increase the number of available file descriptors

Each process connected to a TimesTen data store keeps at least one operating system file descriptor open. Additional file descriptors may be opened for each connection if checkpoints are issued, and transactions are committed or rolled back. If you receive an error that all file descriptors are in use when attempting to connect to a data store, then increase the allowable number of file descriptors. See your operating system documentation for limits on file descriptors and information about changing the number of file descriptors.

Troubleshooting Client/Server problems

This section includes the following topics:

- Cannot connect to the TimesTen Server
- TimesTen Server failed
- Cannot find Server DSN
- TimesTen Server failed to load DRIVER
- Application times out when accessing TimesTen Server
- TimesTen Client loses connection with TimesTen Server
- Failed to attach to shared memory segment for IPC
- Increasing the maximum server connections on Windows XP
- Thread stack overflow when using multiple client connections
- Out of space when DSN specifies new data store
- Also consider the topics described in "Application unable to connect to data store in direct mode" on page 2-3.

Cannot connect to the TimesTen Server

You have not correctly identified the system where the TimesTen Server is running.

On a Windows client machine, select the TimesTen Server in the TimesTen Data Source Setup dialog that is displayed as part of the ODBC Data Source Administrator. To verify the TimesTen Server:

2. Double click the ODBC icon. This opens the ODBC Data Source -Administrator.
3. Click the System DSN tab. This displays the System Data Sources list.
4. Select the TimesTen Client data source. This opens the TimesTen Client DSN Setup dialog.
5. Click Servers. This opens the TimesTen Logical Server List.
6. Select the TimesTen Server from the list. This opens the TimesTen Logical Server Name Setup dialog.
7. Verify that the values for the Network Address and Port Number are correct. If necessary, change the values.
If the Network Address and Port Number values are correct, the TimesTen Server may not be running. See "Starting and stopping the Oracle TimesTen Data Manager service on Windows" in the Oracle TimesTen In-Memory Database Operations Guide for information about starting the server manually. See "Testing connections" in the Oracle TimesTen In-Memory Database Operations Guide for more information about identifying this problem.

On UNIX, specify the TimesTen Server with the TTC_Server connection attribute in the odbc.ini file on the client machine. If the value specified for TTC_Server is an actual hostname or IP address, the client tries to connect to the TimesTen Server using the default port. In TimesTen, the default port is associated with the TimesTen release number. If the value specified for TTC_Server is a logical ServerName, this logical ServerName must be defined in the ttconnect.ini file. The ttconnect.ini entry for this ServerName needs to correctly define the hostname/IP address and port number on which the TimesTen Server is listening.

If the Network Address and Port Number values are correct, the TimesTen Server may not be running or did not start. See "Starting and stopping the daemon on UNIX" in the Oracle TimesTen In-Memory Database Operations Guide for information about starting the server manually. See "Testing connections" in the Oracle TimesTen In-Memory Database Operations Guide for more information about identifying this problem.

---

**Note:** If you typed the hostname or network address directly into the Server Name field of the TimesTen Client DSN Setup, the Client tries to connect to the TimesTen Server using the default port.

---

If the Network Address and Port Number values are correct, the TimesTen Server may not be running. See "Starting and stopping the Oracle TimesTen Data Manager service on Windows" in the Oracle TimesTen In-Memory Database Operations Guide for information about starting the server manually. See "Testing connections" in the Oracle TimesTen In-Memory Database Operations Guide for more information about identifying this problem.

On UNIX, specify the TimesTen Server with the TTC_Server connection attribute in the odbc.ini file on the client machine. If the value specified for TTC_Server is an actual hostname or IP address, the client tries to connect to the TimesTen Server using the default port. In TimesTen, the default port is associated with the TimesTen release number. If the value specified for TTC_Server is a logical ServerName, this logical ServerName must be defined in the ttconnect.ini file. The ttconnect.ini entry for this ServerName needs to correctly define the hostname/IP address and port number on which the TimesTen Server is listening.

If the Network Address and Port Number values are correct, the TimesTen Server may not be running or did not start. See "Starting and stopping the daemon on UNIX" in the Oracle TimesTen In-Memory Database Operations Guide for information about starting the server manually. See "Testing connections" in the Oracle TimesTen In-Memory Database Operations Guide for more information about identifying this problem.

---

**TimesTen Server failed**

Check the server's log file. Server log messages are stored in the files specified by the -userlog and -supportlog options in the ttendaemon.options file. See "Creating and configuring Client DSNs on UNIX" and "Managing TimesTen daemon options" in the Oracle TimesTen In-Memory Database Operations Guide.

The maximum number of concurrent IPC connections to the Server of a particular TimesTen instance is 24,999. However, TimesTen has a limit of 2043 connections (direct or client/server) to a single DSN.

Client/server users can change the file descriptor limit to support a large number of connections. For an example, see "Installation prerequisites" in the Oracle TimesTen In-Memory Database Installation Guide.

---

**Cannot find Server DSN**

On UNIX, verify that the Server DSN is defined in the sys.odbc.ini file on the machine running the TimesTen Server.

On Windows, verify that the Server DSN is defined as a System DSN in the ODBC Data Source Administrator on the machine running the TimesTen Server. See "Creating and configuring a logical server name on Windows" in the Oracle TimesTen In-Memory Database Operations Guide.

---

**TimesTen Server failed to load DRIVER**

This error only occurs on UNIX platforms. Open the sys.odbc.ini file on the machine running the TimesTen Server and locate the Server DSN you are trying to
connect. Verify that the dynamic library specified in the DRIVER attribute for the Server DSN exists and is executable.

**Application times out when accessing TimesTen Server**

The default TimeOut interval is 60 seconds.

To increase this interval on UNIX, change the value of the TTC_Timeout attribute in the odbc.ini file.

To set the timeout interval on Windows, see the instructions in "Setting the timeout interval and authentication" in the *Oracle TimesTen In-Memory Database Operations Guide*.

**TimesTen Client loses connection with TimesTen Server**

Check to see if the error was due to the Client timing out. Check the TimesTen Server’s log to see why the Server may have severed connection with the Client. Use ping to determine if your network is up or try using telnet to connect to the TimesTen Server port number.

**Failed to attach to shared memory segment for IPC**

While using shared memory segment (SHM) as IPC, the application may see the following error message from the TimesTen Client ODBC Driver if the application reaches the system-defined per-process file-descriptor-limit.

SQLState    = S1000,
Native Error = 0,
Message     = [TimesTen][TimesTen 11.2.1 CLIENT]Failed to attach to shared memory segment for IPC. System error: 24

This may happen during a connect operation to the Client DSN when the shmat system call fails because the application has more open file descriptors than the system-defined per-process file descriptor limit. To correct this problem, you must increase your system-defined per-process file descriptor limit. For more information about file descriptor limits, see "System Limits" in the *Oracle TimesTen In-Memory Database Reference*.

**Increasing the maximum server connections on Windows XP**

On Windows XP, by default, there can be approximately 47 child server processes. You can increase the number of connections by setting the MaxConnsPerServer connection attribute in the ttendaemon.options file or in the DSN. This increases the number of connections to 47 times the MaxConnsPerServer value.

**Thread stack overflow when using multiple client connections**

On Solaris, you may receive messages in the user error log about thread stack overflow. On other platforms, you may receive messages about a segmentation fault that mention a possible thread stack overflow.

If these messages occur, increase the server stack size by one of the following methods:

- Specify the ServerStackSize connection attribute for a specific DSN. This takes precedence over the value in the ttendaemon.options file.
Increasing the server stack size decreases the number of concurrent connections that can be made before running out of swap space.

See "Working with the TimesTen Client and Server" in the Oracle TimesTen In-Memory Database Operations Guide.

Out of space when DSN specifies new data store

You may receive "out of space" messages if you change a DSN to specify a new data store while there are existing connections to the original data store in a system with multiple client connections. This can happen on 32-bit platforms if either data store is close to 2 GB.

Close all connections to the original data store. This causes a new server process to be created for connections to the data store that is now specified in the DSN. Use the \texttt{ttStatus} utility to list the connections for the old data store. Alternatively, you can restart the server by using the \texttt{ttDaemonAdmin} utility with the -restartServer option, which resets all client connections on all DSNs in the instance.

Application connects or disconnects are slow

This section describes what to check if you encounter slow connects and disconnects to a data store.

<table>
<thead>
<tr>
<th>Possible cause</th>

</tr>
<tr>
<td>Other possible causes</td>
<td>&quot;API tracing&quot; on page 1-10</td>
</tr>
</tbody>
</table>

Check if data store is being recovered

A slow connect may indicate that a TimesTen data store is being recovered. This happens only for a first connect.

Check ODBC tracing

On Windows platforms, if ODBC tracing is enabled, it can slow connect and disconnect speeds. Double-click ODBC in the Control Panel to open the ODBC Data Source Administrator. Select the Tracing tab and confirm tracing is disabled. See "Using ODBC tracing" on page 1-20.

Application becomes disconnected unexpectedly

If an application becomes disconnected from a TimesTen data store, one of the following events occurs:

- If there was no outstanding transaction, the connection is cleanly removed by the TimesTen daemon. Other existing connections continue processing as if no problem had occurred.
- If there was an outstanding transaction but the application was not in the middle of executing code in the TimesTen library, the transaction is rolled back and the connection is cleanly removed by the TimesTen daemon. Other existing connections continue processing as if no problem had occurred.
This section describes what to check if your application unexpectedly disconnects from the data store.

</tbody>
</table>

**Check for ODBC or JDBC errors**

Check for the following types of errors:

- ODBC errors returned by the SQLError function
- JDBC errors returned by the SQLException class

The application may have encountered a problem that caused it to exit prematurely, which in turn may have caused other connections to be forced to disconnect. Call SQLError after each ODBC call to identify error or warning conditions when they first happen. Examples of SQLError usage can be found in the demo programs and in "Retrieving errors and warnings" in the Oracle TimesTen In-Memory Database Error Messages and SNMP Traps.

In more extreme cases, it may be helpful to use ttTraceMon to generate a level 4 ERR trace for the application and review all of the errors messages that are pushed in the TimesTen direct driver. See "ERR tracing" on page 1-13 for details.

**Check the user error log**

If a TimesTen application disconnects without returning an ODBC error or any other warning, look through the user error log. See "Using the logs generated by the TimesTen daemon" on page 1-6.

**Application is slow**

For details on how to maximize the performance of your application and TimesTen data store, see:

- "TimesTen Database Performance Tuning” in the Oracle TimesTen In-Memory Database Operations Guide
- "Application Tuning” in the Oracle TimesTen In-Memory Database C Developer’s Guide
- "Application Tuning” in the Oracle TimesTen In-Memory Database Java Developer’s Guide

This section describes some of the issues that impair performance.

<table>

<tr>
<td>Outdated database statistics</td>
<td>&quot;Update statistics for your tables” on page 2-11</td>
</tr>
</tbody>
</table>
Application is slow

Consider connection mode

Client/server connections are slower than direct connections to TimesTen data stores. Driver manager connections can also moderately impact performance. The performance overhead imposed by client/server connections can be significant because of the network latencies involved in all communication with the data store.

If your application must run on a different machine from the one hosting the data store, see "Client/Server tuning" in the *Oracle TimesTen In-Memory Database Operations Guide*.

Update statistics for your tables

The TimesTen query optimizer in general is very good at choosing the most efficient query plan. However, it needs additional information about the tables involved in complex queries in order to choose the best plan. By knowing the number of rows and data distributions of column values for a table, the optimizer has a much better chance of choosing an efficient query plan to access that table.

Before preparing queries that will access a TimesTen table, use the `ttOptUpdateStats` procedure to update the statistics for that table. When updating the statistics for a table, you get the best results if you update statistics on your tables after loading them with data, but before preparing your queries. For example, if you update statistics on a table before populating it with data, then your queries are optimized with the assumption that the tables contain no rows (or very few). If you later populate your tables with millions of rows and then execute the queries, the plans that worked well for the situation where your tables contained few rows may now be very slow.
For more information about updating statistics, see "The TimesTen Query Optimizer" in the Oracle TimesTen In-Memory Database Operations Guide.

Verify lock and isolation levels

The manner in which multiple applications concurrently access the data store can have a major impact on performance.

An application can acquire locks on the entire data store, individual tables, and individual rows. Additionally, applications can set an isolation level that determines whether they hold read and update locks until their transactions commit or roll back.

Check the SYS.MONITOR table or use the ttXactAdmin utility to detect whether an application is spending time waiting for locks. See "Check for deadlocks and timeouts" on page 2-14 and "Using the ttXactAdmin utility" on page 1-19.

If lock contention is high, you may be able to improve the overall performance of your system by implementing the following:

■ Set the LockLevel configuration attribute or use the ttLockLevel procedure to place locks on rows, rather than on the entire data store. (Row locking is the default.)

■ Use the ttOptSetFlag procedure to prevent the query optimizer from placing locks on tables. (Table locks are sometimes the default, particularly for updates that affect many rows.)

■ Use read-committed isolation level (Isolation=1, the default) for those applications do not require serializable access to the transaction data.

If you see a lot of lock contention, but the above settings are all set to minimize contention, then the contention may be related to the application itself. For example, concurrent threads may be repeatedly accessing the same row. The ttXactAdmin utility can sometimes help you detect this sort of contention. Tracing can also be useful in this situation.

For more information about locks and isolation levels, see "Concurrency control through isolation and locking" in the Oracle TimesTen In-Memory Database Operations Guide.

Check trace settings

Use ttTraceMon -e show as described in "Using the ttTraceMon utility" on page 1-6 to confirm tracing is off on all TimesTen components. ERR should be set to 1; all other components should be set to 0. Trace levels are preserved when a data store is reloaded.

On Windows platforms, confirm that ODBC tracing is disabled. Double-click ODBC in the Control Panel to open the ODBC Data Source Administrator. Select the Tracing tab and confirm tracing is disabled. See "Using ODBC tracing" on page 1-20.

Check partition counts for the tables

When a table is created, it has one partition. When you use ALTER TABLE ... ADD COLUMN to add new columns, a new partition is added to the table. Adding multiple columns with a single ALTER TABLE ... ADD COLUMN statement only adds one partition.

There is a limit of 255 partitions per table. Exceeding this number generates an 8204 error. An extra read for each new partition slightly degrades performance for each of
the new partitions. A high partition count should be avoided. On replicated tables that have multiple partitions, additional space is used for each update on the subscriber side, proportional to the number of partitions. This can result in the subscribers using slightly more perm space than the master.

The partition value for each table is tracked in the SYS16 column of the system table, SYS.TABLES. Obtain the partition counts for tables by using the following query:

```
SELECT tblname, sys16 FROM SYS.TABLES;
```

If you discover that a table has too many partitions, do one of the following:

- Re-create the table
- Save and restore the table. Use `ttMigrate -c` to create a migration file. Then restore the table without additional partitions by using `ttMigrate -r -noRepUpgrade`.

ALTER TABLE ... DROP COLUMN does not remove partitions from a table. On replicated systems, all master and subscriber data stores must be migrated using the `-noRepUpgrade` option. Replication does not occur for tables that have different partition structures.

### Application unresponsive, appears hung

This section describes what to check if your application is unresponsive and appears to be hung.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>All causes</td>
<td>&quot;Check logs and gather trace information&quot; on page 2-13</td>
</tr>
<tr>
<td>Internal application error</td>
<td>&quot;Check for ODBC errors&quot; on page 2-13</td>
</tr>
<tr>
<td>Inconsistent connection attributes set in DSN</td>
<td>&quot;Consider connection mode&quot; on page 2-11</td>
</tr>
<tr>
<td>Excessive lock contention</td>
<td>&quot;Check for deadlocks and timeouts&quot; on page 2-14</td>
</tr>
</tbody>
</table>

#### Check logs and gather trace information

If your application hangs, check the transaction log by using the `ttXactAdmin` utility. See "Using the `ttXactAdmin` utility" on page 1-19.

Also check the user error log for errors, as described in "Using the logs generated by the TimesTen daemon" on page 1-6.

You can also generate a trace log to detect the activities on various TimesTen components as described in "Using the `ttTraceMon` utility" on page 1-6.

#### Check for ODBC errors

Check the ODBC errors returned by the `SQLError` function in all applications to determine whether one of them has encountered a problem that caused it to hang. Call `SQLError` after each ODBC call to identify error or warning conditions when they first happen. Examples of `SQLError` usage can be found in the demo programs and in "Retrieving errors and warnings" in the *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps*. 

Troubleshooting TimesTen Applications and Data Stores 2-13
If the problem is repeatable, use \texttt{ttTraceMon} to generate a SQL trace to determine where the application is hanging. See "SQL tracing" on page 1-9 for details. In more extreme cases, it may be helpful to generate a level 4 ERR trace for the application and review all of the errors messages that are pushed in the TimesTen direct driver. See "ERR tracing" on page 1-13 for details.

**Check for deadlocks and timeouts**

If there is no connect problem, a deadlock or timeout may be the problem. The SYS.MONITOR table records information about deadlocks and timeouts. See "Monitoring the TimesTen system tables" on page 1-20 for information on how view the contents of this table. You can also use the \texttt{ttXactAdmin} utility to detect the types of locks currently held by uncommitted transactions and the resources on which they are being held.

If a deadlock occurs, the TimesTen subdaemon negotiates the problem by having an application involved in the deadlock generate TimesTen error 6002 (Lock request denied because of deadlock). The error message contains the SQL that the lock holder is running, which can help you diagnose the cause of the deadlock. If your application encounters this error, it should roll back the transaction and then reissue the statements for that transaction. Deadlocks can be caused if your application issues statements in a particular order that results in a circular wait, and can sometimes be prevented by changing the order in which the statements are issued.

An application encounters TimesTen error 6003 (Lock request denied because of timeout) if it is unable to acquire a lock within the time period defined by the lock timeout interval set by the LockWait attribute in the DSN or by the \texttt{ttLockWait} procedure in your application. Upon encountering a timeout error, your application can reissue the statement. Keeping transactions short reduces the possibility of lock timeout errors.

System tables are a common source of lock contention. Reduce contention on the system tables by executing prepared statements, rather than executing the same statements directly each time.

In multithreaded applications, a thread that issues requests on different connection handles to the same data store may encounter lock conflict with itself. TimesTen resolves these conflicts with lock timeouts.

**Application unable to find previously created objects**

This section describes what to check if your application is unable to locate previously created tables, indexes, sequences or views in the data store.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>No owner or incorrect owner specified</td>
<td>&quot;Specify object owner&quot; on page 2-15</td>
</tr>
<tr>

</tr>
<tr>
<td>Path name specified in DSN is relative.</td>
<td>&quot;Check path name to data store&quot; on page 2-15</td>
</tr>
</tbody>
</table>
Specify object owner

Tables, indexes and sequences can be created either with a single name, such as `PARTS`, or with a qualified name incorporating an owner and table name, such as `STAN.PARTS`. When accessing a table or index, if no owner is specified, TimesTen first assumes that the owner is the login ID of the user (the value of the UID attribute). If TimesTen cannot find the table or index under the user’s login ID, it then assumes that the owner is user SYS.

If applications need to connect to a data store as different users and share objects, explicitly specify the owners of the objects when they are created and referenced.

Check privilege to access tables

All privileges for the user can be viewed in the SYS.USER_SYS_PRIVS table, which contains all of the system-level privileges for a given user, and the SYS.USER_TAB_PRIVS table, which contains all of the object-level privileges for a given user. Check these tables to verify if you have ‘SELECT’ privilege for the tables. If you do not have ‘SELECT’ privilege for the tables, the privilege may be granted with the GRANT statement. The method for granting privileges is described in the "Managing Access Control" chapter in the Oracle TimesTen In-Memory Database Operations Guide.

Check temporary DSN attribute

Temporary data stores (DSN attribute: Temporary=1) persist until all connections to the data store have been removed. When attempting to access a table in a temporary data store and the table does not exist, it is possible that the data store in which the table resided in has been dropped.

Check Overwrite DSN attribute

If the Overwrite and AutoCreate DSN attributes are enabled and the data store already exists, TimesTen drops that data store and creates a new one. Any tables that were created in the old data store are dropped.

Check path name to data store

To ensure that you are always accessing the same data store when connecting to a particular DSN, use an absolute data store path name instead of a relative one. For example, if the demo data store is in the datastore directory, specify:

```text
DataStore=/datastore/demo
```

rather than:

```text
DataStore=demo
```

In the latter case, the data store path name is relative to the directory where the application was started. If you are unable to find a table and you are using a relative data store path name, it is possible that the data store in which the table resides in does exist but the data store (checkpoint and log) files are in a different directory than the one that you are accessing.

See “Specifying Data Source Names to identify TimesTen data stores” in the Oracle TimesTen In-Memory Database Operations Guide.
Troubleshooting OCI and Pro*C/C++ applications

On Windows, the NLS_LANG setting is taken from the registry if it is not in the environment. If NLS_LANG is set to an unsupported value, such as NA, an OCI connection failed error or an ORA-12705 error is thrown. If your OCI or Pro*C/C++ program has trouble connecting to TimesTen, verify that the setting of HKEY_LOCAL_MACHINE\Software\ORACLE\NLS_LANG is valid and indicates a character set supported by TimesTen. This is likely only an issue on machines that previously had Oracle9i or earlier Oracle versions installed.

Refer to the "Globalization support" section in the OCI chapter of the Oracle TimesTen In-Memory Database C Developer’s Guide for more information on NLS_LANG.

Running out of a resource

This section describes what to check if TimesTen runs out of resources such as memory space, disk space, file descriptors, and semaphores.

</tbody>
</table>

Operating system tools and shared memory

Operating system tools such as top, vmstat, and sar provide statistics about processes and memory usage. The output from these tools can be misleading as an indicator of TimesTen memory consumption because they report shared memory usage for each process but do not report total shared memory usage. Adding together various memory statistics for TimesTen processes overestimates the amount of memory used by TimesTen because shared memory is by definition shared.

Check the amount of memory allocated to the data store

TimesTen uses both permanent and temporary data partitions. The amount of memory allocated for these partitions is set by the PermSize and TempSize attributes in the DSN definition for the data store.
When the TimesTen data store fills up, it is important to determine whether it is the permanent or the temporary segment that is filling up. Use the `ttIsql dssize` command to list allocated, in-use, and high water mark sizes for the permanent and temporary data partitions. The `dssize` command selects the following values from SYS.MONITOR:

- `PERM_ALLOCATED_SIZE`
- `PERM_IN_USE_SIZE`
- `PERM_IN_USE_HIGH_WATER`
- `TEMP_ALLOCATED_SIZE`
- `TEMP_IN_USE_SIZE`
- `TEMP_IN_USE_HIGH_WATER`

The permanent segment consists of table and index data, while the temporary segment consists of internal structures, such as locks, sorting areas, and compiled commands.

Keeping transactions short and making sure there is enough temporary space in the data store prevents locks from occupying all of the remaining temporary space. You can also use table locks if transactions are acquiring tens of thousands of row locks.

For tips on how to estimate the size of your data store, see "Size your data store correctly" in the *Oracle TimesTen In-Memory Database Operations Guide*.

**Permanent segment filling up**

Consider whether you can drop any indexes. You may want to look at query plans to see which indexes are actually used. See "Viewing and changing query optimizer plans" in the *Oracle TimesTen In-Memory Database Operations Guide*. You can also use the `ttRedundantIndexCheck` procedure to discover redundant indexes. The procedure returns suggestions about which indexes to drop.

Use the `ttSize` utility to estimate the amount of memory used by each table in the data store. If the amount of data you need to store is too big, you may need to reset the PermSize attribute for the data store to increase the size of the permanent segment. Alternatively, you may need to partition your data into several different data stores if, for example, you cannot shrink the temporary segment or create a bigger data store because of limits on the memory segment size.

Sometimes when the permanent segment fills up, copying the data out of the data store, deleting all the data, and copying it back in frees up space. This can be done more efficiently by using the `ttMigrate` utility with the `-noRepUpgrade` option to migrate the data out, destroy and re-create the data store, and migrate the data back in. This operation is described in "Reducing data store size" in the *Oracle TimesTen In-Memory Database Installation Guide*.

Finally, you may have to configure the operating system to allow a larger amount of shared memory to be allocated to a process. You may also have to allocate more swap space for virtual memory. See "Check available swap space (virtual memory)" on page 2-18.

**Temporary segment filling up**

Some commands may be allocating too much space because of out-of-date statistics. See "Update query optimizer statistics" on page 2-18.

If updating the statistics does not reduce temporary segment memory usage, disconnect all connections and then reconnect them. Verify that all connections have
been disconnected by using the ttStatus utility. That frees up all temporary space, but you must reprepare commands.

Diagnose memory usage by queries. See "Check memory used by queries" on page 2-18.

If the problem is chronic, monitor the data store to try to identify the source of the problem. Use the ttWarnOnLowMemory procedure to enable warnings in the user log that indicate that the data store is filling up.

Update query optimizer statistics

If the data store seems to have enough free space but runs out of data store space when executing a query, make sure you have updated the optimizer statistics with the ttOptUpdateStats or ttOptEstimateStats procedure. To execute some queries, TimesTen needs to allocate temporary space. The amount of temporary space required is estimated from statistics about the tables used by the query. Without correct statistics, the temporary space required may be underestimated.

See "Using the query optimizer" on page 1-21.

Check memory used by queries

You can check the memory that a query uses by observing the high water mark for temporary memory usage. The high water mark represents the largest amount of in-use temporary space used since the high water mark was initialized or reset.

Complete the following tasks:

1. Use the ttIsql dssize command to check TEMP_IN_USE_SIZE and TEMP_IN_USE_HIGH_WATER. (Alternatively, you can query the SYS.MONITOR table for these values.)
2. Call the ttMonitorHighWaterReset procedure to reset the TEMP_IN_USE_HIGH_WATER to the current value for TEMP_IN_USE_SIZE.
3. Execute a query.
4. Use dssize to check TEMP_IN_USE_HIGH_WATER for peak memory usage for the query.

Check available swap space (virtual memory)

If you receive an error indicating that you have run out of swap space, you may need to increase the amount of available swap space (also referred to as "virtual memory").

On UNIX systems, use the swap command to check and reset the amount of virtual memory currently established for your system.

On Windows systems, check and reset the size of your virtual memory by choosing Control Panel > System > Advanced.

Check transaction log file use of disk space

TimesTen saves a copy of the data store in one of two checkpoint files, which are stored in the directory specified by the DataStore attribute. Each checkpoint file can grow on disk to be equivalent to the size of the data store in shared memory. For each permanent data store, you must have enough disk space for the two checkpoint files and for transaction log files.
Transaction log files accumulate in the directory specified by the LogDir attribute and are only deleted when checkpoints are performed. If the LogDir attribute is not specified in the DSN, transaction log files accumulate in the directory specified by the DataStore attribute. The maximum size of your transaction log files is set by the LogFileSize attribute.

When a disk fills up with TimesTen data, it is most often due to a build-up of transaction log files. Transaction log files are used for numerous purposes in TimesTen, including checkpointing, backups, and replication. It is important to determine which operation is putting a "hold" on the transaction log files, so that appropriate action can be taken to allow the transaction log files to be purged. This can be done by using the \texttt{ttLogHolds} built-in procedure. There are six types of log holds. They are discussed in detail below.

- **Checkpoint** - If a TimesTen application crashes and the data store needs to be recovered, the checkpoint files and transaction log files are used to recover the data. The "most recent" transaction log files are used -- those written since the checkpoint was done. Transaction log files accumulate during the interval between checkpoints. Your application should periodically call the \texttt{ttCkpt} or \texttt{ttCkptBlocking} procedure to checkpoint the data and free up the space on the disk. If checkpoints are done very infrequently, a large number of transaction log files may accumulate, particularly if many changes are made to the data store during that interval. See "Checkpoint Operations" in the *Oracle TimesTen In-Memory Database Operations Guide*.

- **Replication** - TimesTen replication transmits changes to one data store to one or more other data stores. It does this by reading the log and sending any relevant changes. If replication is paused, the transaction log files build up. To prevent log build-up, avoid pausing replication for too long. Delete subscriptions entirely, and reset replication where appropriate. See "Setting the replication state of subscribers" in *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide* for more information on pausing and restarting or resetting replication.

- **Backup** - TimesTen supports an incremental backup facility that uses transaction log files to augment a backup with changes made since the last backup. Transaction log files accumulate during the interval between incremental backups. To avoid a large log build-up, do incremental backups at relatively frequent intervals. If desired, disable incremental backups and do full backups instead. See "Copying, migrating, backing up and restoring a data store" in the *Oracle TimesTen In-Memory Database Operations Guide*.

- **XLA** - TimesTen's persistent XLA facility reports changes to the data store by using transaction log files. Transaction log files are kept until the corresponding transactions have been acknowledged using the \texttt{ttXlaAcknowledge} C function. Call \texttt{ttXlaAcknowledge} frequently enough to prevent transaction log files building up. See "Retrieving update records from the transaction log" in the *Oracle TimesTen In-Memory Database C Developer's Guide*.

- **XA** - TimesTen's XA support uses transaction log files to resolve distributed transactions. If these transactions are not resolved in a timely manner, transaction log files build up. See "Distributed Transaction Processing XA" in the *Oracle TimesTen In-Memory Database C Developer’s Guide*.

- **Long-running transactions** - TimesTen uses the transaction log to rollback transactions. A log hold is placed for the duration of a transaction. Transactions that are active for a long time result in log file building up if the transaction has written at least one log record. (That is, it is not a read-only transaction.) Commit write transactions with reasonable frequency to avoid significant log file build-up.
Duplicate results from a SELECT statement

Using read-committed isolation level can lead to duplicates in a result set. A SELECT statement selects more or fewer rows than the total number of rows in the table if some rows are added or removed and committed in the range in which the SELECT scan is occurring. This may happen when an UPDATE, INSERT or DELETE statement adds or deletes a value from an index and the SELECT scan is using this index. This can also happen when an INSERT or DELETE adds or deletes rows from the table and the SELECT operation is using an all-table scan.

Index values are ordered. An UPDATE of an index value may delete the old value and insert the new value into a different place. In other words it moves a row from one position in the index to another position. If an index scan sees the same row in both positions, it returns the row twice. This does not happen with a serial scan because table pages are unordered and rows do not need to be moved around for an UPDATE. Hence once a scan passes a row, it will not see that same row again.

The only general way to avoid this problem is for the SELECT statement to use serializable isolation. This prevents a concurrent INSERT, DELETE or UPDATE operation. There is no reliable way to avoid this problem with INSERT or DELETE by forcing the use of an index because these operations affect all indexes. With UPDATE, this problem can be avoided by forcing the SELECT statement to use an index that is not being updated.

For more information about serializable isolation, see "Concurrency control through isolation and locking" in the Oracle TimesTen In-Memory Database Operations Guide.

Cannot attach PL/SQL shared memory

You can receive error 8517 "Cannot attach PL/SQL shared memory; PLSQL_MEMORY_ADDRESS not valid or already in use" for any of the following reasons:
Cannot attach PL/SQL shared memory

- User allocated memory already uses that address.
- Some shared memory already uses that address.
- A shared library already uses that address.

To recover, specify a virtual address that is free in all processes that can connect to the database. If you have a program on a 32-bit operating system that allocates large amounts of memory before connecting to TimesTen, it may clash with the PL/SQL shared memory segment. In this case, either allocate memory after connecting to TimesTen or use a 64-bit operating system.
Cannot attach PL/SQL shared memory
Troubleshooting Installation, Upgrades and Downgrades

This chapter includes the following topics:

- Installing 32-bit TimesTen on 64-bit Windows
- Downgrading a data store with Oracle data types to TimesTen 6.0

Installing 32-bit TimesTen on 64-bit Windows

The default ODBC Data Source Administrator on 64-bit Windows does not show TimesTen 32-bit drivers and DSNs. If Windows is installed in the default location (C:\WINDOWS), use C:\WINOIDS\SysWOW64\odbcad32.exe for the ODBC Data Source Administrator when you are installing 32-bit TimesTen on a 64-bit Windows machine.

Downgrading a data store with Oracle data types to TimesTen 6.0

In rare situations, after upgrading a data store from TimesTen 6.0, you may find that you need to downgrade a TimesTen 7.0 or later data store back to TimesTen 6.0 after the data types are already converted to Oracle types. However, the ttMigrate utility for TimesTen 6.0 does not understand Oracle data types, and this can lead to problems when downgrading data stores from TimesTen 7.0 or later. To avoid any pitfalls in the downgrade process, you should convert the Oracle data types back to TimesTen types using TimesTen 7.0 or later first, and only then downgrade the data store to TimesTen 6.0, using the following steps:

1. Create a migration file using TimesTen 7.0 or later ttMigrate.
   ttMigrate -c datastore datastore.migrate
2. Destroy the data store using TimesTen 7.0 or later ttDestroy.
   ttDestroy datastore
3. Convert the data types to TimesTen types using TimesTen 7.0 or later ttMigrate.
   ttMigrate -r -noRepUpgrade -convertTypesToTT datastore datastore.migrate
4. Create a new migration file using TimesTen 7.0 or later ttMigrate.
   ttMigrate -c datastore datastore.migrate
5. Destroy the data store using TimesTen 7.0 or later ttDestroy.
   ttDestroy datastore
6. In another terminal, with the environment set correctly for TimesTen 6.0, restore the data store as a TimesTen 6.0 data store using TimesTen 6.0 `ttMigrate`.

```
ttMigrate -r datastore datastore.migrate
```

**Note:** Before restoring the data store with TimesTen 6.0 `ttMigrate`, you must modify the DSN attributes appropriately for using with TimesTen 6.0.
This chapter describes how to troubleshoot some of the problems you may encounter when using Oracle In-Memory Database Cache (IMDB Cache). It includes the following topics:

- Unable to create a cache group
- Unable to start or stop the cache agent
- Recovering cache grid after unexpected system shutdown
- Unable to resolve Oracle Service Name
- Unable to resolve connect identifier
- Incompatible Oracle Server and Client versions
- Unable to validate Oracle username and password
- OCI initialization failed
- Unsupported data type mapping
- Null constraint does not match Oracle
- DDL operations on cached Oracle tables may cause cache group operations to fail
- Changes not visible after updating object in cache group
- Loading or refreshing fails
- Monitoring autorefresh cache groups
- Optimize Performance for IMDB Cache
- Autorefresh not refreshing cache at the specified interval
- Incremental autorefresh not progressing
- Incremental autorefresh becomes full autorefresh
- Poor autorefresh performance

If you are having problems with an AWT cache group, see also Chapter 5, "Troubleshooting AWT Cache Groups".

Unable to create a cache group

This section describes some of the problems you might encounter when executing the CREATE CACHE GROUP statement.
Unable to start or stop the cache agent

This section describes some of the problems you might encounter when starting or stopping the cache agent.

### Possible cause | What to do
--- | ---
User does not have the correct Oracle privileges to create the cache group type. | See "Check Oracle privileges" on page 4-6.
User has insufficient access to data store. | You must have CACHE_MANAGER privilege to create a cache group.
The internal/external user does not match the Oracle user. | The TimesTen user name must be the same as the Oracle user name.
Cannot connect to Oracle | See:
- "Unable to resolve Oracle Service Name" on page 4-4
- "Unable to resolve connect identifier" on page 4-4
- "Unable to validate Oracle username and password" on page 4-5
- "Incompatible Oracle Server and Client versions" on page 4-5
- Check whether Oracle needs to be restarted.
- Check the network status.
Cache administration user ID or password not set (when trying to create AWT or autorefresh cache groups) | See "Set the cache administration user id and password" on page 4-7.
Unsupported data type mapping | See "Unsupported data type mapping" on page 4-9.
Different nullability setting in Oracle | See "Null constraint does not match Oracle" on page 4-9.
Failure to specify primary key in root table | The root table of a cache group must have a primary key. See "Defining cache groups" in the Oracle In-Memory Database Cache User’s Guide.

### Unable to start or stop the cache agent

This section describes some of the problems you might encounter when starting or stopping the cache agent.

### Possible cause | What to do
--- | ---
Cache agent already running | See "Check status of the cache agent" on page 4-3.
Unable to locate Oracle libraries | See "Check status of TNS listener and Oracle Server" on page 4-6.
- Check the permissions on the libraries.
ORACLE_HOME is invalid. | See "Check ORACLE_HOME environment variable" on page 4-3.
Insufficient privileges | You must have CACHE_MANAGER privilege to start or stop the cache agent.
Wrong OracleID | Ensure that the OracleID set in your DSN definition matches the Oracle Service Name for the Oracle instance that contains the tables to cache in TimesTen.
Check status of the cache agent

Check the status of the cache agent by using the `ttStatus` utility as described in "Using the `ttStatus` utility" on page 1-2 to check the status of the cache agent.

If the cache agent is not running, start it as described in "Starting the cache agent" in the Oracle In-Memory Database Cache User’s Guide. If attempts to start the cache agent fail, then investigate the possible causes and reboot the machine before attempting to start the cache agent.

Check ORACLE_HOME environment variable

On UNIX or Linux platforms, check that the ORACLE_HOME environment variable is set correctly for the shell from which you are starting the cache agent and the TimesTen daemon. Use the `ttmodinstall` utility if you need to change the setting for ORACLE_HOME.

See "Environment variables" in Oracle TimesTen In-Memory Database Installation Guide.

Check NLS environment variables

NLS environment variables are set in the environment where the TimesTen application is running, even though TimesTen is not using the NLS environment variables. Unset the NLS environment variables and restart the TimesTen daemon, the cache agent, and the replication agent.

Recovering cache grid after unexpected system shutdown

The server may experience a system failure or an unexpected reboot, such as with a power outage. In this case, the cache grid exits unexpectedly without the normal shutdown procedure.

The following sections describe how to recover when the system unexpectedly shuts down for two scenarios:

- A portion of the cache grid nodes are still running
- All cache grid nodes exited unexpectedly

A portion of the cache grid nodes are still running

When the server shuts down, some of the cache grid nodes exited unexpectedly, but others are still active. In this case, you must detach the dead nodes first by executing `ttGridDetachList` from an attached node, as follows:

1. Connect to a surviving grid node and execute `ttGridDetachList` to force a detach of all dead nodes from the grid.
2. Connect to the datastores on the rebooted server. Start the replication agent by executing `ttRepStart`.
3. Attach the cache grid nodes by executing `ttGridAttach`.
4. Resume normal database operations.

All cache grid nodes exited unexpectedly

If all cache grid nodes exited unexpectedly when the server shut down, perform the following tasks to recover the cache grid:
1. Log on to each grid node by connecting to the datastores on the rebooted server. Start the replication agent by executing `ttRepStart`. The replication agent will flush the existing log, even if the log is current.

2. Call `ttGridAttach` on each node, which will fail with a communication error because it cannot communicate with other members. The failed attach cleans up the node information.

3. The last node on which you execute the `ttGridAttach` should succeed. At this point you have cleaned up all nodes, so execute `ttGridAttach` on all nodes again to attach each node to the grid.

4. Resume normal database operations.

**Unable to resolve Oracle Service Name**

If you receive error ORA-12514 indicating "could not resolve service name":

- Use the Oracle TNSPING utility to verify that the service can be reached.
- Ensure that the `OracleID` set in your DSN definition matches the Oracle Service Name for the Oracle instance that contains the tables to cache in TimesTen.
- Ensure that there is a service name defined. If it is a Windows Oracle client, use Oracle Net Configuration Assistant to configure a service name. In Oracle Net Configuration Assistant, navigate to Oracle Net Configuration -> Local -> Service Naming, select your Oracle server and confirm that there is a service name or a SID that identifies the Oracle server. If you add or modify a service name, you may need to reboot.

Check the cache administration user name and password on Oracle with SQL*Plus to make sure this service name works. For example:

```
%sqlplus cache_admin_user/cach_admin_pwd@OracleHost
```

`cache_admin_user` is the cache administration user name, `cache_admin_pwd` is the cache administration user password, and `OracleHost` is the `OracleID` specified in your DSN definition.

---

**Note:** Your cache administration user may be different from your regular Oracle user. See "Create Oracle users" in the *Oracle In-Memory Database Cache User’s Guide*.

---

- Ensure that there is only one copy of `tnsnames.ora` on your TimesTen machine. Also check the permission on `tnsnames.ora`.
- If you are running TimesTen on a UNIX system, check that the `ORACLE_HOME` environment variable points to the correct Oracle installation directory. For example:

```
ORACLE_HOME=/products/oracle10g
```

- Check the Oracle client and server versions. See "Incompatible Oracle Server and Client versions" on page 4-5.

**Unable to resolve connect identifier**

You may receive ORA-12154 "TNS:could not resolve the connect identifier specified" when you try to connect to a data store.
This can occur when you are trying to use IMDB Cache and Oracle on the same machine and the TNS_ADMIN environment variable does not point to the proper tnsnames.ora file for Oracle. For example, you may have several instances of the Oracle Database running on a laptop.

In a production environment, you typically have TimesTen and Oracle running on different machines. In this case, do not reset the TNS_ADMIN environment variable to point to a tnsnames.ora file on the machine where TimesTen is running. The Oracle client uses the TNS_ADMIN setting to resolve the connection, but the TimesTen main daemon, the cache agent, the Web server, and the replication agent are unaware of the TNS_ADMIN setting. IMDB Cache cannot operate properly when the Oracle client and TimesTen use different tnsnames.ora files.

On Windows, set the TNS_ADMIN environment variable as follows:

1. Right-click My Computer and choose Properties.
2. On the Advanced tab, choose Environment Variables.
3. Add or edit TNS_ADMIN as a system environment variable so that it points to the directory that contains the tnsnames.ora file that you wish to use. You can include other tnsnames.ora files with the INAME command inside the tnsnames.ora file.

**Incompatible Oracle Server and Client versions**

If you receive connection timeout errors such as ORA-12170 or ORA-12535, or if you receive ORA-03134 (server version not supported), verify that you are using an Oracle client and Oracle server whose versions are compatible.

Metalink Documentation Note 207303.1, “Client/Server/Interoperability Support Between Different Oracle Versions”, lists the client/server combinations supported by Oracle.

See “Oracle In-Memory Database Cache” in the Oracle TimesTen In-Memory Database Installation Guide for information about Oracle clients and servers supported for use with TimesTen. Also check Oracle and TimesTen release notes for known problems with client/server versions.

**Unable to validate Oracle username and password**

This section describes some of the problems you might encounter when using the Oracle username and password.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>The library environment variable is not set correctly</td>
<td>“Check library path environment variable” on page 4-6.</td>
</tr>
<tr>
<td>Oracle processes not running</td>
<td>“Check status of TNS listener and Oracle Server” on page 4-6.</td>
</tr>
<tr>
<td>User does not have the correct Oracle privileges</td>
<td>“Check Oracle privileges” on page 4-6.</td>
</tr>
<tr>
<td>Incorrectly configured DSN</td>
<td>“Check DSN definition” on page 4-6.</td>
</tr>
<tr>
<td>Problems with cache administration user ID or password</td>
<td>“Set the cache administration user id and password” on page 4-7.</td>
</tr>
<tr>
<td>Inconsistent user and system environments</td>
<td>“Check user and system environment” on page 4-7.</td>
</tr>
</tbody>
</table>
Unable to validate Oracle username and password

<table>
<thead>

<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic libraries not loading</td>
<td>&quot;Verify the loaded dynamic libraries&quot; on page 4-7.</td>
</tr>
</tbody>
</table>

### Check library path environment variable

Check the library path environment variable on your platform.

<table>
<thead>
<tr>
<th>On this platform...</th>
<th>Check this variable...</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX except HP-UX</td>
<td>LD_LIBRARY_PATH</td>
</tr>
<tr>
<td></td>
<td>On 64-bit platforms, LD_LIBRARY_PATH64 takes precedence over LD_LIBRARY_PATH. Make sure that the library path is specified in LD_LIBRARY_PATH64.</td>
</tr>
<tr>
<td>HP-UX</td>
<td>SHLIB_PATH</td>
</tr>
<tr>
<td>Windows</td>
<td>PATH</td>
</tr>
</tbody>
</table>

The library path environment variable must include the following information:

<table>
<thead>
<tr>
<th>TimesTen and platform bit combination</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>64-bit TimesTen or 32-bit TimesTen on 32-bit platform</td>
<td>SORACLE_HOME/LIB and $ORACLE_HOME/NETWORK/LIB</td>
</tr>
<tr>
<td>32-bit TimesTen on 64-bit platform</td>
<td>SORACLE_HOME/LIB32 and $ORACLE_HOME/NETWORK/LIB32</td>
</tr>
</tbody>
</table>

### Check status of TNS listener and Oracle Server

Try to connect to the Oracle database by using SQL*Plus or use Oracle Enterprise Manager to verify the status.

### Check Oracle privileges

From an Oracle SQL*Plus command prompt, list the current Oracle privileges granted to you by entering:

```
SELECT * FROM SESSION_ROLES;
SELECT * FROM SESSION_PRIVS;
```

Compare the privileges listed against the required privileges for the various IMDB Cache operations that are specified in "Grant privileges to Oracle users" in the Oracle In-Memory Database Cache User’s Guide. Contact your Oracle Administrator if you require additional privileges.

### Check DSN definition

- Confirm you have correctly set the DSN attributes as described in "DSN for a TimesTen database that caches data from an Oracle database" in the Oracle In-Memory Database Cache User’s Guide.
- Confirm that the DSN definition for IMDB Cache is a system DSN.
- Confirm that the DSN for IMDB Cache is defined only once.
Unable to validate Oracle username and password

- Confirm Oracle user name and password. Use SQLPlus and connect to Oracle using the same OracleID and OraclePWD used in your DSN definition to confirm they are correct.

**Reboot TimesTen machine**

If the Oracle client was installed and the machine has not been restarted, then the TimesTen daemon is still running under the "old" environment before the Oracle client install. Reboot your machine so the TimesTen can start under the "new" environment.

**Set the cache administration user id and password**

From a ttIsq1 session, connect to the data store and enter the following:

Command> call ttCacheUidPwdSet('scott','tiger');

If it returns an error, then check the Oracle ID, the cache administration user ID and cache administration password. Also check whether the Oracle instance is running.

**Check user and system environment**

Test to see if the problem is due to differences in user and system environment. This procedure requires two session windows (Command Prompt windows in Windows or shell windows in UNIX).

1. Stop the TimesTen daemon.
2. In one session window, start the TimesTen daemon as a regular user.
   - On Windows:
     \% install_dir\srv\ttsrv1121.exe -d -verbose
   - On UNIX:
     \% install_dir\srv\timestend -d verbose
   Some messages will flash by, and then it goes into a wait state.
3. In another session window, try to restart the cache agent.
4. If Step 3 succeeds, then use Ctrl-C on Windows or the kill command on UNIX to stop the TimesTen daemon you started for the other session in Step 2.
5. Compare the user environment and system environment. For example, do both user and system see the same copy of oci.dll? Are there any differences in the path name to the oci.dll library between the user and system environments?
6. If you detect differences, make the necessary modifications.
7. Reboot the system and restart the TimesTen daemon.

**Verify the loaded dynamic libraries**

If you are running on a Windows system with Visual C++ installed, verify the loaded dynamic libraries. This works only if you can start the cache agent without autorefresh:

1. Make sure TimesTen is started.
2. Start the cache agent without autorefresh.
   Command> call ttCacheStart;
Command> create cache group cg1 from t1(c1 int not null primary key);

3. Open the Windows Task Manager, find process ttora1121.exe and highlight it. Right-click on it and select Debug. This brings you into Visual C++ and you should see the loaded DLL in the debug window, as described in "Unable to resolve Oracle Service Name" on page 4-4.

4. Load the cache group to force an cache connection from the cache agent:
Command> load cache group cg1 commit every 100 rows;

5. Compare the loaded DLL in your debug window with the partial list shown in Example 4–1.

Example 4–1 List of loaded dlls
This partial list was created with the Oracle client.
Loaded 'E:\TimesTen\tt1121_32\bin\timestenorad1121.exe', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\ntdll.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\kernel32.dll', no matching symbolic information found.
Loaded 'E:\TimesTen\tt1121_32\bin\ttcommon1121.dll', no matching symbolic information found.
Loaded 'E:\TimesTen\tt1121_32\bin\ttcommon1121.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\wsock32.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\ws2_32.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\msvcrt.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\ws2help.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\advapi32.dll', no matching symbolic information found.
Loaded 'C:\WINDOWS\SYSTEM32\rpcrt4.dll', no matching symbolic information found.
...

OCI initialization failed

Error 5105, "OCI initialization failed," may occur when an operation requires contact with the Oracle database. For example, the error might occur in the following situations:

- Starting the cache agent
- Setting the cache administration user ID or password
- Entering a SQL statement in TimesTen when autocommit=0 and PassThrough=3

Error 5105 contains additional information about its cause:

- OCI is unable to find an Oracle library. See "Check library path environment variable" on page 4-6 and check the permissions on the library specified in the error message.
- ORACLE_HOME is invalid. See "Check ORACLE_HOME environment variable" on page 4-3.
- NLS environment variables are set in the environment where the TimesTen application is running, even though TimesTen is not using the NLS environment variables. Unset the NLS environment variables and restart the TimesTen daemon, the cache agent, and the replication agent.
Unsupported data type mapping

When you try to create a cache group, you may receive the following error:

5115: Unsupported type mapping for column name

For example, table `tab` on Oracle can be described as follows:

```
COL1     NUMBER(38) NOT NULL
COL2     NUMBER(38)
```

Try to create the cache group as follows:

```
CREATE CACHE GROUP cg FROM tab(col1 CHAR(10) NOT NULL PRIMARY KEY);
```

Error 5119 is displayed and the cache group is not created because the statement attempts to map a column of NUMBER data type to a column of CHAR data type.

See "Data type mappings allowed for key columns" in the Oracle In-Memory Database Cache User’s Guide.

Null constraint does not match Oracle

When you try to create a cache group, you may receive the following warning:

Warning 5119: Column name has different nullability setting in Oracle

For example, table `tab` on Oracle can be described as follows:

```
COL1     NUMBER(38) NOT NULL
COL2     NUMBER(38)
```

Try to create the cache group as follows:

```
CREATE CACHE GROUP cg
    FROM tab(col1 INTEGER NOT NULL PRIMARY KEY, col2 INTEGER NOT NULL);
```

Warning 5119 is displayed because `col2` on Oracle does not have a NULL constraint, but `col2` in the cache group is defined as NOT NULL.

DDL operations on cached Oracle tables may cause cache group operations to fail

DDL operations that are performed on an Oracle table that is being cached in TimesTen may cause a failure on the cache group. For example, the user drops a column on the Oracle table that is being cached in TimesTen. When the cache group is propagated or flushed, TimesTen will update the column that no longer exists in the Oracle table. When the cache group loads or refreshes, then TimesTen attempts to retrieve data from the column that has been dropped.

The following cache group operations may fail:

- Autorefresh does not occur.
- AWT cache group operations are not propagated or refreshed to/from Oracle.
- Cache group load or propagate fails.

If you suspect the cache group operations are not working properly because of a DDL operation on the Oracle base table, then use DDL tracking to diagnose the issue. DDL tracking saves the change history for all the cached Oracle tables. The SQL statement
Changes not visible after updating object in cache group

If you modify an object in a cache group and then the changes do not appear on a subsequent SQL statement, then one of the following may have occurred:

- The object was dropped from the Oracle database or was somehow damaged.
- The Oracle database was restored or recovered to a time before the object was created.
- The Oracle database was down.
- The user modified the OracleNetServiceName DSN or connection attribute after creating the cache group, which points to an Oracle database other than the one that the cache group was created upon.

For example, if the user creates an AWT cache group. Then, the user added rows to a table. When the user performs a SELECT * FROM the table, the rows did not appear. The ttmesg.log error file does not display an error that Oracle is not available. Instead, it displays the following messages:

12:09:02.10 Err : REP: 29934: CACHE1:meta.c(904): TT5221: TT5221: Oracle syntax error in OCIStmtExecute(): ORA-00942: table or view does not exist rc = -1 -- file "bdbStmt.c", lineno 1535, procedure "getOraOutTypesNLengths()"
12:09:02.27 Warn: REP: 29934: CACHE1:transmitter.c(6505): TT16060: Failed to read data from the network. select() timed out

To recover, perform the following:

1. Stop all updates to the cache group.
2. If you are using an AWT cache group, then flush the cache group.
3. Recreate the cache group with the drop and create.

Loading or refreshing fails

If the LOAD CACHE GROUP or REFRESH CACHE GROUP statement fails when you specify COMMIT EVERY n ROWS and n is greater than 0, the contents of the target cache group could be in an inconsistent state. Some cache instances may be partially loaded.

Unload the cache group and then load it again. In some situations, it may be easier to drop and re-create the cache group.

Monitoring autorefresh cache groups

This section includes the following topics:

- Using the ttCacheAutorefreshStatsGet procedure
Monitoring autorefresh cache groups

- Displaying information from the change log tables
- Understanding messages about autorefresh in the support log
- Diagnosing autorefresh failure
- Diagnosing autorefresh performance problems
- Using SNMP traps for alerts about autorefresh problems

Using the ttCacheAutorefreshStatsGet procedure

The \texttt{ttCacheAutorefreshStatsGet} procedure returns information about the last ten autorefresh operations on a specified cache group.

The \texttt{ttCacheAutorefreshStatsGet} procedure returns information only when the cache agent is running and the autorefresh state is ON or PAUSED. All of the return fields are set to 0 when the cache agent is restarted or the autorefresh state is changed to OFF.

\textbf{Example 4–2 Calling \texttt{ttCacheAutorefreshStatsGet}}

This example uses testcache, which is a READONLY cache group with one table and an incremental autorefresh interval of 10 seconds.

\begin{verbatim}
Command> call ttcacheautorefreshstatsget('user1', 'testcache');
\end{verbatim}

\begin{verbatim}
< 1164260, 2007-07-23 15:43:52.000000, 850280, 44, 0, 75464, 528255, 75464, 310, 110, 6800, 1890912, 12439795, 1890912, 160020, InProgress >

</table>
### Table 4–1 (Cont.)  ttCacheAutorefreshStatsGet results from last autorefresh operation

<table>
<thead>
<tr>
<th>Result</th>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>autorefNumber</td>
<td>Autorefresh number</td>
</tr>
<tr>
<td>0</td>
<td>autorefDuration</td>
<td>The number of milliseconds spent in this autorefresh operation. It is zero because the operations is in progress.</td>
</tr>
</tbody>
</table>
| 75464  | autorefNumRows           | The number of rows autorefreshed in this autorefresh operation. This would include all rows in the root table and child tables if the cache group had child tables.  
*Note:* This information is not provided for full autorefresh. |
| 528255 | numOracleBytes           | The number of bytes transferred from Oracle in this autorefresh operation.  
*Note:* This information is not provided for full autorefresh. |
| 75464  | autorefNumRootTblRows    | The number of root table rows autorefreshed in this autorefresh operation.  |
| 310    | autorefQueryExecDuration | The duration in milliseconds for the autorefresh query to execute on Oracle.  
*Note:* This information is not provided for full autorefresh. |
| 110    | autorefQueryFetchDuration| The duration in milliseconds for the autorefresh query to fetch rows from Oracle.  
*Note:* This information is not provided for full autorefresh. |
| 6800   | autorefTtApplyDuration   | The duration in milliseconds for TimesTen to apply the updated rows to the cache group.  
*Note:* This information is not provided for full autorefresh. |
| 1890912| totalNumRows             | The total number of rows autorefreshed since the cache agent started.  
*Note:* This information is not provided for full autorefresh. |
| 12439795| totalNumOracleBytes     | The total number of bytes transferred from Oracle since the cache agent started.  
*Note:* This information is not provided for full autorefresh.  
*Note:* This information is not provided for full autorefresh.  
*Note:* This information is not provided for full autorefresh. |
| 1890912| totalNumRootTblRows      | The total number of root table rows autorefreshed since the cache agent started. |
| 160020 | totalDuration            | The total autorefresh duration in milliseconds since the cache agent started. |
| InProgress | autorefreshStatus   | Status. The status can also be **Complete** or **Failed**. |
Note that the total number of autorefreshed rows (1890912) is the same as the total number of autorefreshed root table rows in this example because there are no child tables.

The number of autorefreshed rows in TimesTen does not necessarily reflect the number of rows updated on Oracle. The Oracle updates may be applied in TimesTen more than once, or multiple Oracle updates on the same row may be applied as one update in TimesTen.

Displaying information from the change log tables

TimesTen provides a SQL script that gathers information from the change log tables that exist on the Oracle database for autorefresh cache groups. See “Oracle objects used to manage a caching environment” in the Oracle In-Memory Database Cache User’s Guide for more information about change log tables.

The script displays the following information for each cached table:

****************************
* Host name: my-pc
* TimesTen datastore name: c:\data\tt1121
* Cache table name: USER1.TESTCACHE
* Change log table name: tt_03_55555_L
* number of rows in change log table: 100000
* Maximum logseq on the change log table: 38
* TimesTen has autorefreshed updates up to logseq: 38
* Number of updates waiting to be autorefreshed: 0
* Number of updates that has not been marked with a valid logseq: 0
****************************

The log sequence number (logseq) acts as a marker for the autorefresh operation.

Run the script as the cache administration user on the Oracle database using SQL*Plus. If you run the script as a different user, it reports that the change log tables do not exist.

The script is in the following location:
install_dir/oraclescripts/cacheInfo.sql

Understanding messages about autorefresh in the support log

The support log contains messages that show the progress of autorefresh. For example, testcache is a READONLY cache group with an autorefresh interval of 10 seconds (10,000 milliseconds).

The support log shows when autorefresh starts:

15:43:33.96 Info: ORA: 5264: ora-5264-5676-refresh03918: Starting autorefresh number 43 for interval 10000ms

The message includes the following information:

- Timestamp (15:43:33.96)
- Cache agent process ID (5264)
- Thread ID (5676)

The thread ID is important because autorefresh numbers are unique only for a specific interval. Always check both the thread ID and the autorefresh number when you are tracking a specific autorefresh operation.
The support log also contains a longer message that reports information similar to the `ttCacheAutorefreshStatsGet` procedure. 108544 rows were updated in this autorefresh interval, and 1815448 rows have been updated since the cache agent was started. Note that the total number of rows and the total number of root table rows are the same in this message because there is only one table in the cache group. `Number` refers to the autorefresh number. All times are expressed in milliseconds.

```
```

Additional messages show that the autorefresh operation completes successfully:

```
```

Inspect the timestamps to determine whether autorefresh is progressing as expected.

See "Managing TimesTen daemon options" in the Oracle TimesTen In-Memory Database Operations Guide for information about setting the support log location.

### Diagnosing autorefresh failure

If `ttCacheAutorefreshStatsGet` shows that the status of an autorefresh operation is **Failed**, check the support log for messages related to the autorefresh operation with number the number shown in the `ttCacheAutorefreshStatsGet` output. Look for errors that occurred after the autorefresh operation started.

**Example 4–3 ttCacheAutorefreshStatsGet output shows autorefresh failure**

This row of output from `ttCacheAutorefreshStatsGet` shows a failed autorefresh operation.

```
< 1164260, 2007-08-01 14:56:36.000000, 959350, 9, 0, 0, 0, 0, 0, 0, 1, 7, 1, 50, Failed >
```

The autorefresh number is 9.

The support log shows the start message for autorefresh number 9:

```
14:56:36.10 Info: ORA:  5988: ora-5988-4724-refresh03926: Starting autorefresh number 9 for interval 15000ms
```

The thread ID for autorefresh number 9 is 4724. Look for error messages with this thread ID.

The following messages appear in the support log:

```
14:56:36.10 Info: ORA:  5988: ora-5988-4724-refresh03953: Autorefresh thread for interval 15000ms is connected to instance inst1 on host host1. Server handle 231976252
```

The autorefresh number 9 is 4724. Look for error messages with this thread ID.
finished for interval 15000ms with error.
failed for cache groups with interval 15000 ms after 10 retries.

The error message for thread ID 4724 shows that the change log table, TT_03_81799_L,
is missing. The introduction to “Autorefresh not refreshing cache at the specified
interval” on page 4-16 has a table entry that describes what to do in this situation.

**Diagnosing autorefresh performance problems**

You can use the `ttTraceMon` utility to diagnose autorefresh performance problems. See “AUTOREFRESH tracing” on page 1-16.

TimesTen tracing severely impacts application performance and consumes a great deal
of disk space if trace output is directed to a file. When you are finished, reset tracing to
the default values.

**Using SNMP traps for alerts about autorefresh problems**

Enable SNMP traps to alert you when autorefresh problems occur. The SNMP traps
related to autorefresh include:

- `ttCacheAutoRefQueFullTrap`
- `ttCacheIncAutoRefFailedTrap`
- `ttCacheValidation_ErrorTrap`
- `ttCacheValidationWarnTrap`
- `ttCacheValidationAbortedTrap`

See “Diagnostics through SNMP Traps” in the *Oracle TimesTen In-Memory Database
Error Messages and SNMP Traps*.

**Optimize Performance for IMDB Cache**

The following recommendations optimize performance for the IMDB Cache:

- Pin the IMDB Cache meta tables and cache group base tables in the SGA by
  executing the "ALTER TABLE `<table_name>` CACHE" statement to indicate to the
  Oracle database that these tables should be stored in the keep portion of the SGA
  buffer cache. Pinning IMDB Cache tables in the SGA increases the probability that
  any given datablock needed for a IMDB Cache refresh operation will be available
  in the SGA when the refresh is performed and will not force a disk read. This
  minimizes physical disk reads executed during TimesTen cache refresh
  operations. For more information about Oracle buffer cache management, see
  "Configuring and Using Memory" in the *Oracle Database Performance Tuning Guide*.

- Pin IMDB Cache triggers into the shared pool using the `dbms_shared_pool.keep`
  procedure. Pinning triggers into the shared pool for applications
  where updates to the cache group base tables are infrequent keeps the trigger from
  having to be reloaded and reparsed. This is not necessary for highly volatile tables
  where the trigger will be executed frequently and will remain in the shared pool
  under any circumstances.

- Enable parallel query. For very large base tables with 10 million rows or more,
  consider using the Oracle database parallel query facility. The primary join query
  between the log table and the base table is the kind of query which the Oracle
database parallel query is designed to handle. When parallel processing is
enabled, the parallel query optimizer generates a query plan that allows the original query to be broken into sections to be worked concurrently by different parallel query slave processes. When using parallel query, users should assign a default degree of parallelism of (2*N) to the cache group base table, where "N" is the number of CPUs on the machine. Then, experiment to understand what level of parallelism works best for their environment. Experiment with different table structures for base tables, as follows:

- Use a standard heap table with default degree of parallelism assigned during table creation or by use of the ALTER TABLE PARALLEL command. Build an N-partition primary key index against the table.
- Use an N-way partitioned table structure with partition range key based either on the table primary key or, in the case of a concatenated primary key, the high-order column of the primary key. The number of partitions should be set to the degree of parallelism. Use a local primary key index with the same number of partitions.
- Use an N-way hashed partition structure using the primary key as the hash key, a local partitioned primary key index, and both index and table partitions equal to the degree of parallelism. The log table should not be partitioned, as the cardinalities of the log table should never be large enough that a partitioned log table would have any performance benefit. Further, given the continuously increasing value of the log table primary key column, range partitions cannot be used.

### Autorefresh not refreshing cache at the specified interval

The following table shows possible causes for autorefresh problems.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache agent not started with a cache administration user</td>
<td>Specify a cache administration user ID and password when starting the cache agent, as described in &quot;Starting the cache agent&quot; in the Oracle In-Memory Database Cache User's Guide.</td>
</tr>
<tr>
<td>Object ID of the base table has changed.</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>Autorefresh trigger not enabled</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>Current log sequence number recorded in the TT_version_USER_COUNT table is less than to the maximum log sequence number in the autorefresh log table.</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>There is no row in the TT_version_USER_COUNT table with usercount &gt; 0 for every active incrementally autorefresh table</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>Change log table is empty.</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>User count is less than 0 or any TT_version_USER_COUNT log sequence anomalies</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
</tbody>
</table>
Autorefresh not refreshing cache at the specified interval

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autorefresh log table, trigger, or sequence associated with a cached table does not exist or is not valid.</td>
<td>Check whether the cache agent was started with the correct cache administration user ID. If the cache administration user ID is correct, follow the procedure described in &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17. Check the user error log for messages about &quot;fatal anomalies&quot;. This indicates corrupt or missing Oracle objects.</td>
</tr>
<tr>
<td>TT_version_USER_COUNT table is missing.</td>
<td>Check whether the cache agent was started with the correct cache administration user ID. If the cache administration user ID is correct, follow the procedure in &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17. Check the user error log for messages about “fatal anomalies”. This indicates corrupt or missing Oracle objects.</td>
</tr>
<tr>
<td>If the current log sequence number in the TT_version_USER_COUNT table changes, is different from the bookmark and the associated cached table is not refreshed by the next committed autorefresh.</td>
<td>Restart the cache agent. If that does not work, follow the procedure in &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>Resource problem</td>
<td>Restart the cache agent.</td>
</tr>
</tbody>
</table>

Reset autorefresh state

Incremental autorefresh does not work if the TRUNCATE statement is used on an Oracle base table. If TRUNCATE is used on an Oracle base table, then you must reset autorefresh by using the ALTER CACHE GROUP statement to set the autorefresh state to OFF followed by another ALTER CACHE GROUP to reset the autorefresh state to ON.

Recover and reset autorefresh Oracle objects

If you know or suspect the Oracle objects used by autorefresh are the cause of the problem, use the following procedure to re-create the Oracle objects.

1. Use ALTER CACHE GROUP to reset the autorefresh state to OFF on all cache groups on all data stores that have the affected cached table:

   ```sql
   ALTER CACHE GROUP cache_group_name SET AUTOREFRESH STATE OFF;
   ```

2. Shut down all cache agents on all affected data stores.

3. Check if the user count is zero for each table in the cache group.

   On the Oracle database, execute the following statement:

   ```sql
   SELECT usercount FROM autorefresh_id.tt_version_user_count
   WHERE tablename = 'owner.tablename';
   ```

   If the count is not zero, set the count to zero:

   ```sql
   UPDATE autorefresh_id.tt_version_user_count SET usercount = 0
   WHERE tablename = 'owner.tablename';
   ```
4. Start one of the cache agents. The cache agent performs a clean up operation. It displays the following message to the support log after it has completed the cleanup:

   Cleanup of the Oracle objects completed

5. After the cache agent has completed the clean up, use ALTER CACHE GROUP to reset the autorefresh state back to ON:

   \texttt{ALTER CACHE GROUP cache\_group\_name SET AUTOREFRESH STATE ON;}

6. Start all other cache agents.

7. Use ALTER CACHE GROUP to reset the autorefresh state back to ON for all of the affected cache groups on all data stores.

### Incremental autorefresh not progressing

If incremental autorefresh is not progressing, verify that:

- Autorefresh state is ON
- Cache agent is running

Inspect the support log for the conditions described in the following table:

Table summary is in the first heading cell.

<table>
<thead>
<tr>
<th>Condition</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle server connection errors or warnings</td>
<td>See &quot;Troubleshooting Client/Server problems&quot; on page 2-6 for information about resolving connection problems.</td>
</tr>
<tr>
<td>Lock timeout errors or warnings on TimesTen</td>
<td>This usually occurs because of an open DDL transaction on the cache group. Commit the DDL transaction so that autorefresh can get the necessary locks.</td>
</tr>
<tr>
<td>Insufficient permanent data partition errors on TimesTen</td>
<td>Increase PermSize.</td>
</tr>
<tr>
<td>Autorefresh Oracle object validations errors or warnings</td>
<td>See &quot;Recover and reset autorefresh Oracle objects&quot; on page 4-17.</td>
</tr>
<tr>
<td>Cache agent exits unexpectedly.</td>
<td>Contact Technical support.</td>
</tr>
<tr>
<td>Core files in main daemon directory</td>
<td>Contact Technical support.</td>
</tr>
<tr>
<td>Warnings about incremental autorefresh becoming full refresh</td>
<td>See &quot;Incremental autorefresh becomes full autorefresh&quot; on page 4-19.</td>
</tr>
<tr>
<td>Warnings that autorefresh has not finished for a long time</td>
<td>The autorefresh transaction can take a long time if many transactions have occurred since the last autorefresh.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: Cache groups with the same autorefresh interval are autorefreshed in one transaction.</td>
</tr>
</tbody>
</table>

### Validate autorefresh Oracle objects

The cache agent automatically verifies that Oracle objects exist and that they are valid so that autorefresh can progress. In normal operation, you should not see object validation errors or warnings in the user error log. If you see object validation errors, contact Technical support. \textit{unless} one of the following conditions has occurred:
Incremental autorefresh becomes full autorefresh

Incremental autorefresh can become full autorefresh if the cache administration user tablespace becomes full.

This section includes the following topics:

- Detecting when incremental autorefresh becomes full
- Understanding the cache administration user tablespace
- Diagnosing a full cache administration user tablespace
- Monitoring the usage of the cache administration user’s tablespace
- Considerations when the cache administration user’s tablespace is full

Detecting when incremental autorefresh becomes full

You can detect when incremental autorefresh becomes full refresh by several methods:

- Check for messages in the support log that indicate full autorefresh operations are occurring. For example:

  2007-08-08 08:06:51.35 Warn: ORA: 22119: ora-22119-0015-refresh05652: A full autorefresh will be performed for Incremental autorefresh table USER1.READTAB because change log table T_03_55555_L on Oracle has been truncated.

- Use the `ttCacheAutorefreshStatsGet` procedure.
  - If autorefresh is `InProgress` for longer than usual, full autorefresh may be occurring.
  - If a much larger number of rows (`autoRefNumRows`) was autorefreshed than usual, full autorefresh may have occurred.

- Check the support log for messages about full autorefresh.

- If SNMP traps are enabled, the `ttCacheRecoveryAutorefreshTrap` SNMP trap indicates a full autorefresh.

Understanding the cache administration user tablespace

TimesTen strongly recommends creating a separate tablespace for the cache administration user. This tablespace is used as the cache administration user’s default tablespace. The tablespace contains autorefresh triggers for each Oracle table, change log tables for each Oracle table, and other objects that TimesTen needs for each cache administration user. If you do not specify a separate tablespace, then these objects are placed in the Oracle system tablespace.
Specify the tablespace when you create the cache administration user on Oracle. You can also specify the tablespace after user creation with the DEFAULT TABLESPACE clause of the Oracle ALTER USER statement.

Change log tables for each of the cached Oracle tables reside in the cache administration user tablespace. For each update on an Oracle table, one row (a change log record) is inserted into the change log table for that Oracle table. The size of a change log record in bytes is as follows:

\[
\text{size of change log record} = \text{size of primary key on Oracle table} + 250
\]

The number of records in a change log table depends on the update rate on the Oracle table and on the autorefresh interval on TimesTen. Every 20 seconds, TimesTen removes change log records that have been applied to all data stores that cache the associated Oracle table.

When change logs are removed, a message similar to the following is displayed in the support log:

```
16:32:26.73 Info: ORA: 5652: ora-5652-4756-ogTblGC01036: Garbage collector deleted 1 rows from TT_03_383270_L where logseq < 1
```

There are options on how to manage what happens when the cache administration user tablespace is filled. See "Considerations when the cache administration user's tablespace is full" on page 4-21 for more information.

### Diagnosing a full cache administration user tablespace

Check for the following conditions if the cache administration user tablespace is full:

- Is the autorefresh state set to PAUSED? Change log records accumulate when the state is PAUSED.

- Has the cache group been created but not loaded? The default autorefresh state for cache group creation is PAUSED.

- Is a cache group being created or is a data store being duplicated? Both of these operations temporarily stop clean-up operations on the change log table.

- Are the cache agents on all TimesTen data stores running? If a cache agent is not running, change log records accumulate.

- Has a data store been abandoned without dropping autorefresh cache groups in the data store? Abandoned data stores result from scenarios such as the following:
  - The data store is destroyed by `ttDestroy -force`.
  - The application connected to the data store with the `Overwrite` connection attribute set to 1, but the cache groups that were in the old data store are not re-created.

  If the data store still exists, connect to the abandoned data store and drop the cache group.

Use the `cacheInfo.sql` script to find out how large the change log tables are for each cached Oracle table. Use the output to verify that the data stores are still in use. See "Displaying information from the change log tables" on page 4-13.

If the data stores are still in use, verify that the cache agents are running.

Compare the autorefresh progress on TimesTen to the maximum log sequence number on the change log table. If TimesTen is behind, then call the `ttCacheAutorefreshStatsGet` procedure to see whether the autorefresh
operations are successful. See "Using the ttCacheAutorefreshStatsGet procedure" on page 4-11.

If the status is InProgress longer than seems reasonable, see "Poor autorefresh performance" on page 4-22.

You may need to decrease the autorefresh interval or increase the size of the cache administration user tablespace.

There are options on how to manage what happens when the cache administration user tablespace is filled. See "Considerations when the cache administration user's tablespace is full" on page 4-21 for more information.

### Monitoring the usage of the cache administration user's tablespace

To monitor the cache administration user tablespace, you can use either Oracle Enterprise Manager alerts or set the TimesTen tablespace threshold parameter.

The cache agent can be configured to periodically monitor the tablespace usage and issue a warning when it exceeds a specified threshold. Set the tablespace threshold percentage with the TblspaceThreshold parameter of the ttCacheConfig built-in procedure. For example, if you set the TblspaceThreshold parameter to 80, then a warning is issued when more than 80% of the tablespace is used.

- If the threshold is set to zero, then no warning is issued. This is the default.
- If the threshold is set between 1 and 99, a warning is issued when the tablespace threshold exceeds that number.
- If the threshold is set to 100, then a warning is issued when the tablespace is full.

For example, to configure for a warning to be issued if the tablespace exceeds 80%, execute the following:

```sql
call ttCacheConfig('TblspaceThreshold', , , '80');
```

For full details of the ttCacheConfig built-in procedure, see the "ttCacheConfig" section in the Oracle TimesTen In-Memory Database Reference.

### Considerations when the cache administration user's tablespace is full

With Oracle tables that are cached in a TimesTen database, you can configure them to use incremental automatic refresh. For these tables, you can specify which one of the following is to occur when the cache administration user's tablespace is full:

- The application performing the DML is to fail. This is the default.

    The tablespace full recovery is set to none. The application receives an "Out of Tablespace" error from Oracle when the tablespace is full. At that point, the application will need to rollback the transaction.

    Setting the tablespace full recovery to none is configured when you set the Param parameter to TblSpaceFullRecovery and the Value parameter to None with the ttCacheConfig built-in procedure. For example, the following configures Param to TblSpaceFullRecovery and Value to None for the employees table that is owned by terry:

    ```sql
    call ttCacheConfig('TblSpaceFullRecovery','terry', 'employees','None');
    ```

- Truncate the change log table to free up space and cause a full autorefresh.

    When the cache administration user's tablespace is full, any application that is executing DML statements on the autorefresh cached Oracle tables continues to
execute. A trigger executes to free up space for new change log records by deleting existing change log records. This can result in a full automatic refresh on cache groups that have the incremental automatic refresh mode configured. However, if the Oracle table is not configured for incremental automatic refresh, then no trigger executes.

To set the operation to allow the application to continue and cause an autorefresh, set the Param parameter to TblSpaceFullRecovery and the Value parameter to Reload with the ttCacheConfig procedure. The user will see stale data until the full autorefresh is complete.

However, even if the user sets the cache configuration parameter TblSpaceFullRecovery with the value of Reload, the tablespace may not be able to be emptied enough to handle the case of a growing index. Deleting rows from the change log table may not free up enough space for the index that is on the change log table. If the index is growing so fast that it uses all the tablespace to the point where purging the change log tables does not help, then the user’s application may receive the following error:

ORA-01654: unable to extend index <index> by 128 in tablespace <tblspace>

For full details of the ttCacheConfig built-in procedure, see the "ttCacheConfig" section in the Oracle TimesTen In-Memory Database Reference.

Poor autorefresh performance

Poor autorefresh performance is usually the result of large autorefresh operations. Use the ttCacheAutorefreshStatsGet procedure to check the autorefresh duration and observe whether the status remains InProgress for a long time.

Factors that can cause large autorefresh operations include:

- Incremental autorefresh becomes full autorefresh
- Unresponsive or dead TimesTen database degrades autorefresh performance
- Excessive deadlocks, buffer busy and row lock waits during autorefresh cache group refresh
- Abnormally large log and base tables degrade autorefresh performance
- Performance degrades when autorefresh interval is small
- Large autorefresh interval
- Large number of cache groups with the same interval
- High rate of changes to the Oracle tables
- The number of generations of child tables in a cache group
- The number of rows in the cached Oracle tables
- The size of the rows in the cached Oracle tables

Enable an AUTOREFRESH trace to diagnose autorefresh performance problems. See "AUTOREFRESH tracing" on page 1-16.
Unresponsive or dead TimesTen database degrades autorefresh performance

**Note:** Automatic recovery for TimesTen cache groups only applies to read-only and user managed cache groups that use the AUTOREFRESH cache group attribute. In this section, all references to autorefresh cache groups are read-only and user managed cache groups that use the AUTOREFRESH cache group attribute.

If any TimesTen databases containing autorefresh cache groups are destroyed or no longer in use, TimesTen continues to track autorefresh changes to the Oracle tables for the TimesTen database for which the cache agent is not running. This causes automatic refresh to cache groups in active TimesTen databases to slow down.

The cache agent is responsible for detecting if a database is unresponsive or no longer in use. You can specify if and how a dead TimesTen database is to be recovered. However, you cannot recover a TimesTen database if all of the Oracle objects have been removed.

The following sections describe how you can avoid a degraded autorefresh performance for inactive TimesTen databases:

- Setting cached TimesTen database timeout
- Configuring recovery method for certain cache groups

**Setting cached TimesTen database timeout**

You can instruct TimesTen to mark the database as dead and no longer accepting updates if the cache agent has not communicated with the Oracle server within a specific timeout period.

Set the timeout for the TimesTen database and the recovery method for each autorefresh cache group with the AgentTimeOut parameter in the ttCacheConfig built-in procedure. The timeout value applies to the all TimesTen databases that use the same cache administration user. You should set the timeout value greater than the time necessary to load the TimesTen database into memory on first connect and start the cache agent. Otherwise, the TimesTen database could be incorrectly marked as dead. For any planned maintenance for the TimesTen instance, you could temporarily set the AgentTimeOut value to zero to disable the timeout. For full details of the ttCacheConfig built-in procedure, see the "ttCacheConfig" section in the Oracle TimesTen In-Memory Database Reference.

For example, the following sets the timeout value for the TimesTen database to 6000 seconds or 100 minutes. If the cache agent does not contact the Oracle server within a 100-minute period, then the TimesTen database is marked as dead.

```
ttIsql> call ttCacheConfig('AgentTimeOut',,,'6000');
```

**Configuring recovery method for certain cache groups**

You can recover a TimesTen database and autorefresh cache groups if they are not synchronizing with the Oracle database. If there is no synchronization, then updates on the Oracle tables are not automatically refreshed to the corresponding TimesTen cache tables.

You can configure the DeadDbRecovery parameter of the ttCacheConfig built-in procedure to specify how to recover the synchronization for the TimesTen database and all autorefresh cache groups. The setting for DeadDbRecovery applies to all TimesTen databases that use the same cache administrator user. Set the
Poor autorefresh performance

DeadDbRecovery parameter to Normal, Manual or None to describe how TimesTen is to recover the database and all autorefresh cache groups. The DeadDbRecovery setting applies to all TimesTen databases that use the same cache administration user. While TimesTen is recovering the database and its autorefresh cache groups, there is an autorefresh status for the TimesTen database and the autorefresh cache groups that describes the recovery status for each of these entities. The TimesTen database can have an automatic refresh status of Alive, Dead or Recovering. The autorefresh cache groups can have an automatic refresh status of OK, Dead or Recovering. The TimesTen database status changes are linked to changes in the status for the autorefresh cache groups, as follows:

- If the recovery method is set to Normal, then when TimesTen starts a full automatic refresh on an autorefresh cache group, the cache group’s status is set to Recovering and the database’s status is also set to Recovering.
- The TimesTen database’s status is only set to Alive when all of the autorefresh cache groups have either been recovered to OK or have been dropped.
- When the database status is set to Dead, then all of its autorefresh cache groups are also set to Dead.

**Note:** You can determine the autorefresh status of the TimesTen database and autorefresh cache groups with the `ttCacheDbCgStatus` built-in procedure, which is described in the "ttCacheDbCgStatus" section in the *Oracle TimesTen In-Memory Database Reference*.

When communication between the cache agent and the Oracle server is re-established, TimesTen determines how to recover the autorefresh cache groups. TimesTen follows the recovery method you configured in the DeadDbRecovery parameter in the `ttCacheConfig` built-in procedure. This parameter can be set to one of the following:

- **Normal:** This is the default. The autorefresh cache groups will each be recovered with a full automatic refresh. After the first full refresh, the cache group is recovered and will incrementally perform autorefresh.
  
  The autorefresh cache groups within the same automatic refresh interval will be transactionally consistent. Because it is a full refresh, it is not as performant as an incremental refresh.

  The autorefresh sets the status to Recovering. When the full autorefresh is completed successfully, the autorefresh cache group status is set to OK.

- **Manual:** You must manually refresh an autorefresh cache group to recover it, or unload it if the cache group is dynamic.

- **None:** The autorefresh cache group will never be recovered by a TimesTen autorefresh. Drop and recreate the cache group to recover it.

The database status changes as the first autorefresh cache group status changes. If there is at least one cache group that is in the process of recovery, then the database status is set to Recovering. Once all cache groups have been recovered, the status of the TimesTen database is marked as Alive.

The following example sets the DeadDbRecovery parameter to Normal for all autorefresh cache groups. The dead TimesTen database will be recovered when all of its autorefresh cache groups have each been recovered with a full automatic refresh.

```
ttIsql> call ttCacheConfig('DeadDbRecovery',,,'Normal');
```
When TimesTen databases participating in an active standby pair replication scheme contains cache groups, if the autorefresh status of the active master database is Dead and the autorefresh status of the standby master database is Alive, the standby master does not automatically assume the role of the active master. The recovery requires that you manually ensure that the cache and replication agents are executing. The specifics for each situation is as follows:

<table>
<thead>
<tr>
<th>DeadDbRecovery Setting</th>
<th>Active Master</th>
<th>Standby Master</th>
<th>Resulting Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>Alive</td>
<td>Dead</td>
<td>Make sure that the cache and replication agents are executing on the standby master. Once the cache agent can connect to the Oracle Database, then the status of all autorefresh cache groups is set to Recovering. This sets the database to Recovering. Once a single cache group has received enough data to resume autorefresh, the status is set to OK. After all cache group are set to OK, the database is set to Alive. Alternatively, you can fail the standby master and rollout a new standby master.</td>
</tr>
<tr>
<td>Normal</td>
<td>Dead</td>
<td>Alive</td>
<td>Make sure that the cache and replication agents are executing on the active master. Once the cache agent can connect to the Oracle Database, then the status of all autorefresh cache groups is set to Recovering. This sets the database to Recovering. Once a single cache group has received enough data to resume autorefresh, the status is set to OK. After all cache group are set to OK, the database is set to Alive. Alternatively, you can fail the active master, switch the standby master as the new active and then rollout a new standby master.</td>
</tr>
<tr>
<td>Normal</td>
<td>Dead</td>
<td>Dead</td>
<td>Make sure that the cache and replication agents are executing on both masters. Once the cache agent can connect to the Oracle Database, then the status of all autorefresh cache groups is set to Recovering. This sets the database to Recovering. Once a single cache group has received enough data to resume autorefresh, the status is set to OK. After all cache group are set to OK, the database is set to Alive. Alternatively, you can rollout new masters.</td>
</tr>
<tr>
<td>Manual</td>
<td>Alive</td>
<td>Dead</td>
<td>Make sure that the cache and replication agents are executing on the standby master. Use a manual refresh to recover the autorefresh cache groups on the active master. After all cache group are set to OK or have been dropped, the database is set to Alive. Alternatively, you can fail the standby master and rollout a new standby master.</td>
</tr>
<tr>
<td>Manual</td>
<td>Dead</td>
<td>Alive</td>
<td>Make sure that the cache and replication agents are executing on the active master. Use a manual refresh to recover the autorefresh cache groups on the active master. After all cache group are set to OK or have been dropped, the database is set to Alive. Changes are then replicated to the standby master.</td>
</tr>
<tr>
<td>Manual</td>
<td>Dead</td>
<td>Dead</td>
<td>Make sure that the cache and replication agents are executing on the active master. Use a manual refresh to recover the autorefresh cache groups on the active master. After all cache group are set to OK or have been dropped, the database is set to Alive. Changes are then replicated to the standby master.</td>
</tr>
</tbody>

Poor autorefresh performance

During an autorefresh cache group refresh, there can be excessive buffer busy waits, row lock waits, and deadlocks on updates in the Oracle database, which can negatively affect the throughput performance. When there are multiple deadlocks on updates in the Oracle database involving the autorefresh log tables, the following may appear in the support log:

Oracle native error code = 60, msg = ORA-00060: deadlock detected while waiting for resource
An error occurred while preparing or executing the following Oracle sql statement: <some statement involving <cache admin user>.TT_##_#######_L where the # is some number>

You can improve your performance by modifying the INITRANS and FREELISTS settings, which can affect the concurrent inserts into the autorefresh log table as well as internal maintenance of these tables. The application updating the base table that is being autorefreshed encounters a throughput performance hit when these settings are not appropriately configured.

You can automatically or manually manage these settings as follows:

- Use ASSM tablespace, which automatically manages FREELISTS.
- Manually adjust FREELISTS and INITRANS for the autorefresh log table on the Oracle database.

The following details how to manually modify INITRANS and FREELISTS for the autorefresh log table on the Oracle database:

1. Retrieve the name of the autorefresh log table that is on the Oracle database.

   Under the cache administration user login, execute the SQL*Plus script cacheInfo.sql that lists the autorefresh change log table name, along with other items. The following example executes the cacheInfo.sql script that lists the autorefresh change log table name as tt_05_1216726_L, as shown in bold:

   ```sql
   SQL> @cacheInfo.sql
   ****************************Autorefresh Objects Information  ****************************
   Host name: gordon-tt
   Timesten datastore name: /scratch/ds/myDB
   Cache table name: SCOTT.ALOBN
   Change log table name: tt_05_1216726_L
   Number of rows in change log table: 1
   Maximum logseq on the change log table: 2
   Timesten has autorefreshed updates upto logseq: 1
   Number of updates waiting to be autorefreshed: 1
   ```

Table 4–2 (Cont.) Recovery for cache groups involved in active standby replication pair

Poor autorefresh performance

Number of updates that has not been marked with a valid logseq: 0  
*****************************
Host name: conobar-tt
Timesten datastore name: /scratch/ds/myDB
Cache table name: SCOTT.A
Change log table name: tt_05_1279699_L
Number of rows in change log table: 7
Maximum logseq on the change log table: 0
Timesten has autorefreshed updates upto logseq: 0
Number of updates waiting to be autorefreshed: 5
Number of updates that has not been marked with a valid logseq: 5
*****************************

2. Manually alter the table on the Oracle database. The following example uses the table from the previous example. This example alters the INITRANS and FREELISTS settings for the bar.tt_05_1279699_L table.

```sql
ALTER TABLE BAR.TT_05_1279699_L INITRANS 10;
ALTER TABLE BAR.TT_05_1279699_L STORAGE(FREELISTS 5);
or
ALTER TABLE BAR.TT_05_1279699_L MOVE STORAGE(FREELISTS 5);
```

3. Alter the INITRANS and FREELISTS settings for the index for this table, which have the same name as the autorefresh change log table with an additional "L" at the end of it. For example, the index for table bar.tt_05_1279699_L is bar.tt_05_1279699_LL

These settings should be the same as what you set for the autorefresh change log table.

```sql
ALTER INDEX BAR.TT_05_1279699_LL INITRANS 10;
ALTER INDEX BAR.TT_05_1279699_LL STORAGE(FREELISTS 5);
```

**Abnormally large log and base tables degrade autorefresh performance**

The cache thread SQL refresh joins the log table and the base table, which identifies rows needed to be refreshed into TimesTen. The larger the cardinalities of the base table and the log table, the longer the time necessary to perform this join. Performance degradation may occur if either the log table or the base table is abnormally large.

The following describe scenarios where the log table can become abnormally large:

- If the log table is never purged in configurations where cache groups from multiple DSNs all reference the same base table, it increases in size indefinitely. If one or more of the cache agents for these groups are turned off, those DSNs will not properly refresh their cache groups and the log tables will not be purged. If the autorefresh state is turned to paused on one of multiple nodes, the other nodes may slow down.

- The log table can grow abnormally large if some of the cache agents have been shutdown. Resolve this issue by restarting the cache, which will purge all of the backlogged log rows to be purged and all of the cache groups to be synchronized after the completion of the refresh cycle for all cache groups.
The log table can be abnormally large if rows inserted into the log table are never purged and can never be purged by normal processing. This occurs when one or more DSNs are destroyed or rebuilt without first removing the cache groups. The cache group tables on the Oracle database have no information that the cache groups have been destroyed, which corrupts the entire cache group. Rebuild and reinitialize all of the cache groups associated with this base table. Alternatively, never destroy a DSN with cache groups. Instead, always drop the cache groups before destroying a DSN.

**Performance degrades when autorefresh interval is small**

When a relatively short refresh interval, such as a few hundred milliseconds, is combined with a large number of entries in the log table or in the base table, a cache refresh operation does not complete before the next refresh operation is scheduled to begin. In this case, the entries in the log table can be un-marked when the current autorefresh cycle finishes.

Thus, the same rows can be refreshed from the base table to the cache group in the next autorefresh cycle, by which time the rows will be marked. Make sure that the time it for the refresh is greater than the refresh interval. Set the refresh interval to a value where redundant refreshes will not occur.
Troubleshooting AWT Cache Groups

Creating an asynchronous writethrough (AWT) cache group automatically creates a replication scheme that allows the data store to communicate with the Oracle database. You must start the replication agent after you create an AWT cache group and start the cache agent. See "Creating an AWT cache group" in the Oracle In-Memory Database Cache User’s Guide.

Material in Chapter 6, "Troubleshooting Replication" is useful for troubleshooting AWT cache group problems. Useful replication topics are summarized in the current chapter in these sections:

- Unable to start or stop replication agent
- Replication does not work
- Using SNMP traps for notification of replication events

This chapter also contains the following sections:

- Monitoring AWT performance
- Possible causes of poor AWT performance
- Permanent Oracle errors reported by TimesTen
- Transient Oracle errors reported by TimesTen

Unable to start or stop replication agent

This section describes what to check if you are unable to start or stop a replication agent.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not have ADMIN privileges</td>
<td>You must have ADMIN privileges to use the ttAdmin utility or the ttRepStart or ttRepStop procedures to start or stop a replication agent.</td>
</tr>
<tr>
<td>TimesTen daemon not started</td>
<td>Check the state of the TimesTen daemon, as described in &quot;Check the TimesTen user error log&quot; on page 2-2. If necessary, start the TimesTen daemon as described in &quot;Working with the Oracle TimesTen Data Manager Daemon&quot; in the Oracle TimesTen In-Memory Database Operations Guide.</td>
</tr>
</tbody>
</table>
Replication does not work

If you are unable to get replication working, the problem may be one or more of the following:

<table>
<thead>
<tr>
<th>Possible Cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimesTen daemon or replication agents not running</td>
<td>&quot;Check status of TimesTen daemon and replication agents&quot; on page 6-3</td>
</tr>
<tr>
<td>Replication agents not communicating</td>
<td>&quot;Check that replication agents are communicating&quot; on page 6-5</td>
</tr>
<tr>
<td>Replication not in Start state</td>
<td>&quot;Check replication state&quot; on page 6-5</td>
</tr>
</tbody>
</table>

Using SNMP traps for notification of replication events

TimesTen can send SNMP traps for certain replication events to enable network management software to take immediate action. TimesTen can send the following SNMP traps:

- ttRepAgentExitingTrap
- ttRepAgentDiedTrap
- ttRepAgentStartingTrap

These traps are described in "Diagnostics through SNMP Traps" in the Oracle TimesTen In-Memory Database Error Messages and SNMP Traps.

Monitoring AWT performance

You can monitor the performance of asynchronous writethrough (AWT) cache groups to determine how much time is spent performing tasks in the AWT workflow. Use the ttCacheAwtMonitorConfig built-in procedure to enable monitoring.

For example, enable monitoring and set the sampling frequency to 16. A sampling factor of 16 is recommended for accuracy and performance.

Command> CALL ttCacheAwtMonitorConfig('ON',16);
< ON, 16 >
1 row found.

Use the ttRepAdmin utility with the -awtmoninfo and -showstatus commands to display the monitoring results. The AWT monitoring statistics include:

- TimesTen processing time: The total number of milliseconds spent in processing AWT transaction data since monitoring was enabled.
- Oracle bookmark management time: The total number of milliseconds spent in managing AWT metadata on Oracle since monitoring was enabled.
- Oracle execute time: The total number of milliseconds spent in OCI preparation, binding and execution for AWT SQL operations since monitoring was enabled. This statistic includes network latency between TimesTen and Oracle.
- Oracle commit time: The total number of milliseconds spent in committing AWT updates on Oracle since monitoring was enabled. This statistic includes network latency between TimesTen and Oracle.
- Time since monitoring was started
- Total number of TimesTen row operations: The total number of rows updated in AWT cache groups since monitoring was enabled.
- Total number of TimesTen transactions: The total number of transactions in AWT cache groups since monitoring was enabled.
- Total number of flushes to Oracle: The total number of times that TimesTen data has been sent to Oracle.

The output also includes the percentage of time spent on TimesTen processing, Oracle bookmark management, Oracle execution and Oracle commits.

For example:

```
ttRepAdmin -showstatus -awtmoninfo myDSN

[other -showstatus output]
...
```

AWT Monitoring statistics

-------------------------
TimesTen processing time : 0.689000 millisecs (0.164307 %)
Oracle bookmark management time : 3.229000 millisecs (0.770027 %)
Oracle execute time : 342.908000 millisecs (81.774043 %)
Oracle commit time : 72.450000 millisecs (17.277315 %)
Time since monitoring was started: 8528.641000 millisecs

Cache-connect Operational Stats :
- Total Number of TimesTen row operations : 2
- Total Number of TimesTen transactions : 2
- Total Number of flushes to Oracle : 2

### Possible causes of poor AWT performance

This section addresses issues that may degrade AWT performance.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slow network</td>
<td>&quot;Check network bandwidth&quot; on page 6-11</td>
</tr>
<tr>
<td>Log buffer too small</td>
<td>&quot;Check size of log buffer&quot; on page 6-12</td>
</tr>
<tr>
<td>Frequent or inefficient disk writes</td>
<td>&quot;Check durability settings&quot; on page 6-12</td>
</tr>
<tr>
<td>Reading from transaction log files on disk instead of the log buffer</td>
<td>&quot;Check for reads from transaction log files&quot; on page 6-12</td>
</tr>
</tbody>
</table>

### Permanent Oracle errors reported by TimesTen

Insert, update, or delete errors that occur while applying changes to Oracle are saved in an error file located in the data store directory with the following name:

```
DatastoreName.awterr
```

Errors reported to this file are *permanent* errors. TimesTen does not retry the transaction. The errors may be reported in the AWT error file long after the commit to TimesTen occurs.

The format of the messages in the AWT error file is similar to those generated for conflict and transaction errors in replication, as shown in Example 5–1. Oracle error messages are also reported in the support log and the user log.
Example 5–1  Cache violation occurs when update is propagated to Oracle

If a constraint violation occurs when a cache group update is propagated to Oracle, the message in the AWT error file is similar to the following:

Error occurred 14:48:55 on 03-22-2007
Datastore: c:\temp\cgDSN
Oracle Id: system1
Transmitting name: cgDSN
Error message:
  TT5210: Oracle unique constraint violation error in OCIStmtExecute():
  ORA-00001: unique constraint (GUSER.SYS_C00357240) violated rc = -1 -- file
    "bdbTblH.c", lineno 1205, procedure "ttBDbStmtForce()"
  TT5025: Commit failure in Oracle. Transaction must be rolled back in TimesTen.
    -- file "bdbConnect.c", lineno 885, procedure "ttBDbXact()"

Operation that caused the error:
Insert into table TESTUSER.T1 <9,1000>

Failed transaction:
Insert into table TESTUSER.T1 <9, 1000>
End of failed transaction

Example 5–2  An object that TimesTen has placed on Oracle is dropped

If an object that TimesTen has placed on Oracle is dropped, the message in the AWT error file is similar to the following:

May 04 18:12:36 HOST1 TimesTen Replication 7.0[2136]:
[Err ] DEFAULT:meta.c(639):
TT16062: Failed to compile command:
select p.commit_timestamp, p.commit_seqnum, p.protocol from owner1.TT_03_REPPEERS
p where p.replication_name = :rname and p.replication_owner = :rowner and
p.tt_store_id = :oid and psubscriber_id = :sid

May 04 18:12:36 HOST1 TimesTen Replication 7.0[2136]:
[Err ] DEFAULT:meta.c(639):
TT5221: TT5221: Oracle syntax error in OCIStmtExecute():
ORA-00942: table or view does not exist rc = -1 -- file "bdbStmt.c", lineno 1041,
procedure "getOraOutTypesNLengths()"

In this example, the TT_03_REPPEERS table does not exist. To recover from this error,
perform the following tasks:
1. Stop the replication agent.
2. Drop and re-create the cache group.
3. Restart the replication agent.

Transient Oracle errors reported by TimesTen

The support log for data stores with AWT cache groups may contain Oracle errors if
the replication agent encounters a problem on the Oracle database. If the replication
agent encounters one of these errors, AWT rolls back the transaction and retries it. If
the support log becomes full, the oldest messages are deleted and replaced by new
messages.

The Oracle errors in the support log are considered transient because AWT retries the
transaction.
Some transient errors indicate an underlying problem on the Oracle database must be solved before AWT operations can continue. For example:

ORA-01536: space quota exceeded for tablespace
ORA-01034: ORACLE not available

After the underlying problem has been fixed, AWT retries the operation.

For more information about the Oracle errors, see Oracle Database Error Messages for the Oracle release you are using.

The following Oracle errors are transient:

ORA-00018: maximum number of sessions exceeded
ORA-00019: maximum number of session licenses exceeded
ORA-00020: maximum number of processes (%s) exceeded
ORA-00025: failed to allocate %s
ORA-00028: your session has been killed
ORA-00038: Cannot create session: server group belongs to another user
ORA-00051: timeout occurred while waiting for a resource
ORA-00052: maximum number of enqueue resources (%s) exceeded
ORA-00053: maximum number of enqueues exceeded
ORA-00054: resource busy and acquire with NOWAIT specified
ORA-00055: maximum number of DML locks exceeded
ORA-00057: maximum number of temporary table locks exceeded
ORA-00058: DB_BLOCK_SIZE must be %s to mount this database (not %s)
ORA-00059: maximum number of DB_FILES exceeded
ORA-00060: deadlock detected while waiting for resource
ORA-00061: maximum number of LOG_FILES exceeded
ORA-00064: object is too large to allocate on this O/S (%s,%s)
ORA-00099: recovery session still in progress
ORA-00104: deadlock detected; all public servers blocked waiting for resources
ORA-00107: failed to connect to ORACLE listener process
ORA-00115: failed to connect to ORACLE listener process
ORA-00125: connection refused; invalid presentation
ORA-00126: connection refused; invalid duplication
ORA-00284: recovery session still in progress
ORA-00370: potential deadlock during kcbchange operation
ORA-00371: not enough shared pool memory
ORA-00376: file %s cannot be read at this time
ORA-00379: no free buffers available in buffer pool %s for block size %sK
ORA-00384: Insufficient memory to grow cache
ORA-00568: Maximum number of interrupt handlers exceeded
ORA-00600: internal error code, arguments: [%s], [%s], [%s], [%s], [%s], [%s], [%s], [%s]
ORA-00603: ORACLE server session terminated by fatal error
ORA-01000: maximum open cursors exceeded
ORA-01012: not logged on
ORA-01014: ORACLE shutdown in progress
ORA-01019: unable to allocate memory in the user side
ORA-01031: insufficient privileges
ORA-01033: ORACLE initialization or shutdown in progress
ORA-01034: ORACLE not available
ORA-01035: ORACLE only available to users with RESTRICTED SESSION privilege
ORA-01037: maximum cursor memory exceeded
ORA-01046: cannot acquire space to extend context area
ORA-01073: fatal connection error; unrecognized call type
ORA-01089: immediate shutdown in progress - no operations are permitted
ORA-01090: shutdown in progress - connection is not permitted
ORA-01092: ORACLE instance terminated. Disconnection forced
ORA-01094: ALTER DATABASE CLOSE in progress. Connections not permitted
Transient Oracle errors reported by TimesTen

ORA-01109: database not open
ORA-01147: SYSTEM tablespace file %s is offline
ORA-01154: database busy. Open, close, mount, and dismount not allowed now
ORA-01155: the database is being opened, closed, mounted or dismounted
ORA-01219: database not open: queries allowed on fixed tables/views only
ORA-01237: cannot extend datafile %s
ORA-01456: may not perform insert/delete/update operation inside a READ ONLY transaction
ORA-01536: space quota exceeded for tablespace '%s'
ORA-01539: tablespace '%s' is not online
ORA-01542: tablespace '%s' is offline, cannot allocate space in it

ORA-37013: (XSACQUIRE_DEADLOCK) Cannot wait to acquire object %j since doing so would cause a deadlock.
ORA-44317: database open read-only
Troubleshooting Replication

This chapter describes how to troubleshoot some of the problems you may encounter when replicating data stores.

This chapter includes the following topics:

- Unable to create a replication scheme
- Unable to alter a replication scheme
- Unable to start or stop replication agent
- Using SNMP traps for notification of replication events
- Replication does not work
- Replication unresponsive, appears hung
- Poor replication or XLA performance
- Problems using ttRepAdmin
- Problems with conflict checking

Unable to create a replication scheme

This section describes what to check if you are unable to use CREATE REPLICATION to create a replication scheme.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not have ADMIN privilege</td>
<td>You must have ADMIN privilege to use the CREATE REPLICATION or DROP REPLICATION statements.</td>
</tr>
</tbody>
</table>
| Incorrect data store name, host name, or element name. | - Check the CREATE REPLICATION statement for typographical errors.  
  - See "Check host names" on page 6-7.  
  - Use official host names instead of aliases.  
  - The host name should match the value returned by the hostname command on your system and should be used consistently throughout the replication scheme. |
| The local host is not part of the replication scheme.| Create the replication scheme on a host that will be part of the replication scheme.                                                     |
Unable to alter a replication scheme

This section describes what to check if you are unable to use ALTER REPLICATION to alter a replication scheme.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Replication tables defined in the CREATE REPLICATION statement do not exist.</td>
<td>The name, owner, and column definitions of the tables participating in the replication scheme must be identical on both the master and subscriber data stores. Use CREATE TABLE to create tables on the data store, or use the <code>ttRepAdmin -duplicate</code> utility or the <code>ttRepDuplicateEx</code> function to duplicate the entire data store to be replicated.</td>
</tr>
<tr>
<td>Other problems</td>
<td>Review the procedures and requirements described in &quot;Defining Replication Schemes&quot; in the <em>Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide</em>.</td>
</tr>
</tbody>
</table>

Unable to start or stop replication agent

This section describes what to check if you are unable to start or stop a replication agent.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not have ADMIN privilege</td>
<td>You must have ADMIN privilege to use the ALTER REPLICATION statement.</td>
</tr>
<tr>
<td>Replication agent in Start state</td>
<td>Most ALTER REPLICATION operations are supported only when the replication agent is stopped (<code>ttAdmin -repStop</code>). Stop the replication agents on both master and subscriber data stores, alter the replication scheme on both master and subscriber data stores, then restart both replication agents.</td>
</tr>
</tbody>
</table>
| Incorrect data store name, host name, or element name | 1. Check ALTER REPLICATION statement for typographical errors.  
2. See "Check host names" on page 6-7. |
| Replication table defined in the ALTER REPLICATION statement does not exist | Use CREATE TABLE to create a table on the data store. |
| Other problems | Review the procedures and requirements described in "Altering Replication" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide*. |

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>You do not have ADMIN privileges</td>
<td>You must have ADMIN privileges to use the <code>ttAdmin</code> utility or the <code>ttRepStart</code> or <code>ttRepStop</code> procedures to start or stop a replication agent.</td>
</tr>
<tr>
<td>TimesTen daemon not started</td>
<td>Check the state of the TimesTen daemon, as described in &quot;Check the TimesTen user error log&quot; on page 2-2. If necessary, start the TimesTen daemon as described in &quot;Working with the Oracle TimesTen Data Manager Daemon&quot; in the <em>Oracle TimesTen In-Memory Database Operations Guide</em>.</td>
</tr>
</tbody>
</table>
Replication does not work

If you are unable to get replication working between a master and subscriber data store, the problem may be one or more of the following:

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>What to do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data store does not participate in a replication scheme.</td>
<td>If a data store does not participate in a replication scheme, attempts to start a replication agent for that data store will fail. Use CREATE REPLICATION to create a replication scheme for the data store.</td>
</tr>
</tbody>
</table>

**Using SNMP traps for notification of replication events**

TimesTen can send SNMP traps for certain replication events to enable network management software to take immediate action. TimesTen can send the following traps for replication events:

- `ttRepAgentExitingTrap`
- `ttRepAgentDiedTrap`
- `ttRepAgentStartingTrap`
- `ttRepCatchupStartTrap`
- `ttRepCatchupStopTrap`
- `ttRepReturnTransitionTrap`
- `ttRepSubscriberFailedTrap`
- `ttRepUpdateFailedTrap`

These traps are described in “Diagnostics through SNMP Traps” in the *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps*.

**Replication does not work**

If you are unable to get replication working between a master and subscriber data store, the problem may be one or more of the following:

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimesTen daemon and/or replication agents not running</td>
<td>&quot;Check status of TimesTen daemon and replication agents&quot; on page 6-3</td>
</tr>
<tr>
<td>Master and subscriber agents not communicating</td>
<td>&quot;Check that replication agents are communicating&quot; on page 6-5</td>
</tr>
<tr>
<td>Replication not in Start state</td>
<td>&quot;Check replication state&quot; on page 6-5</td>
</tr>
<tr>
<td>Error in replication scheme</td>
<td>&quot;Check replication scheme configuration&quot; on page 6-6</td>
</tr>
<tr>
<td>Inconsistent owner names for replication scheme and tables</td>
<td>&quot;Check owner names&quot; on page 6-8</td>
</tr>
<tr>
<td>Inconsistent replication tables</td>
<td>&quot;Check consistency between replicated tables&quot; on page 6-10</td>
</tr>
</tbody>
</table>

**Check status of TimesTen daemon and replication agents**

Use the `ttStatus` utility to confirm the main TimesTen daemon is running and the replication agents are started for all of your master and subscriber data stores. The output from a simple replication scheme using a single master and subscriber data store should look like that shown in *Example 6–1*.

If the TimesTen daemon is running, but the replication agents are not, the output looks like that shown in *Example 6–2*. In this case, start the replication agents as described in...
"Starting and stopping the replication agents" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide*.

If neither the TimesTen daemon or replication agents are running, the output looks like that shown in Example 6–3. In this case, confirm you have correctly installed TimesTen and the Data Manager service is started, as described in "TimesTen Installation" in the *Oracle TimesTen In-Memory Database Installation Guide*.

**Example 6–1 ttStatus output for one master and one subscriber**

C:\>ttStatus

Example 6–3  TimesTen daemon and replication agent are not running

> ttStatus
ttStatus: Could not connect to TimesTen daemon: Connection refused

Check that replication agents are communicating

Use ttRepAdmin -receiver -list to see that the replication agents are communicating with each other. If the masterds data store is replicating to subscriberds, the output should look similar to the following:

Example 6–4  Check that the replication agents are communicating

> ttRepAdmin -receiver -list masterDSN
Peer name  Host name  Port  State  Proto
----------------  -------------------  ------  ------- -----
SUBSCRIBERDS    MYHOST  Auto  Start  10

Last Msg Sent Last Msg Recv Latency TPS  RecordsPS Logs
-------------  -------------  -------  ------  -------- -------
0:01:12   -  19.41 5  52  2

Check replication state

Use the ttReplicationStatus procedure to check state of the subscriber data store with respect to its master. If the subscriber is in the Stop, Pause, or Failed state, use the ttReplicationStatus procedure to reset the subscriber state to Start, as described in "Setting the replication state of subscribers" in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide.

Example 6–5  Obtain status of the subscriber data store from the master data store

Use ttReplicationStatus to obtain the status of the subscriberds data store from its master data store, masterDSN, enter:

> ttIsql masterDSN
Command> CALL ttReplicationStatus ('subscriberds');
Replication does not work

To reset state to Start call the ttRepSubscriberStateSet procedure:

Command> CALL ttRepSubscriberStateSet('REPSCHEME', 'REPL', 'SUBSCRIBERDS', 'MYHOST', 0)
Command> CALL ttReplicationStatus ('subscriberds');
< SUBSCRIBERDS, MYHOST, 0, start, 1, 152959, REPSCHEME, REPL >
1 row found.

Check replication scheme configuration

This section describes some procedures you can use to confirm the correct configuration of the various components in your replicated system. The basic procedure categories are:

- Check ttRepAdmin -showconfig
- Check the TTREP.TTSTORES table
- Check host names

Check ttRepAdmin -showconfig

Use ttRepAdmin -showconfig to confirm the configuration of your replication scheme.

What to look for:

- Are all of the subscriber agents started and reported to be in the Start state? If not, reset the agents to the Start state. See "Setting the replication state of subscribers" in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide.

- Do the reported Peer names match the names given in the DataStore attributes in the DSN definitions for the replicated data stores? Replication does not work if you specified the names given for the Data Source Name attributes.

- Is there anything under List of subscribers? If not, confirm the data store names you specified in the DSN definition are consistent with those you specified in your replication scheme configuration file.

- Are the Host names correct? If in doubt, see "Check host names" on page 6-7.

- Are the correct table names displayed under Table details? If not, correct the table names in your replication scheme configuration file.

Example 6–6  Confirm the configuration of the replication scheme

> ttRepAdmin -showconfig masterDSN
Self host "MYHOST", port auto, name "MASTERDS", LSN 4/2970276, timeout 120,
threshold 0
List of subscribers

<table>
<thead>
<tr>
<th>Peer name</th>
<th>Host name</th>
<th>Port</th>
<th>State</th>
<th>Proto</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBSCRIBERDS</td>
<td>MYHOST</td>
<td>Auto</td>
<td>Start</td>
<td>10</td>
</tr>
</tbody>
</table>

List of tables and subscriptions

-------------------------
Check the TTREP.TTSTORES table

Check the TTREP.TTSTORES table to confirm that replication associates the replication scheme with the local data store.

Example 6–7  Confirm that the replication scheme is associated with the local data store

Connect to the data store and enter:

```
SELECT * FROM ttrep.ttstores WHERE is_local_store <> 0x0;
Command> select * from ttrep.ttstores where is_local_store <> 0x0;
< -5193710757373683, MYHOST, MASTERDS, 01, 0, 0, 4, 0 >
1 row found.
```

There should be exactly one row returned. If more than one row is returned, contact Technical support. If no rows are returned, then none of the hosts returned by the following statement is perceived to be a local system by TimesTen replication:

```
SELECT DISTINCT host_name FROM ttrep.ttstores;
```

It may also be that none of the data store names specified in your replication scheme match those specified in your DSN descriptions.

Check host names

Some hosts or IP addresses specified in a replication scheme cannot be resolved by the replication agent because:

- Host names or IP addresses specified in the replication scheme are wrong or misspelled.
- Host names or IP addresses cannot be resolved or found by DNS or in the /etc/hosts file
- Entries in the /etc/hosts file are incorrectly ordered in appearance. This error is most common when multiple NICs are used. You must have root privilege to make changes to the /etc/hosts files.

See “Configuring host IP addresses” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide for details on how to configure DNS and /etc/hosts files for host machines used for replication.

To check if a host name in the replication scheme matches the host name of the local machine, write an application to perform these tasks:

1. Use a gethostname OS function call to determine the host name of the running host.
2. Call gethostbyname with the output from Step 1.
3. Call gethostbyname with the host name specified in the replication scheme.
4. Compare output of Step 2 and Step 3. If there is a match, then the running host is involved in replication. Otherwise, it is not involved in replication.
Check owner names

As described in "Table requirements and restrictions" and "Owner of the replication scheme and tables" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide*, the owner names of your replication scheme and your replicated tables must be consistent across all participating data stores.

Checking replication owner

Check the owner name assigned to your replication scheme by calling the `ttIsql repschemes` command or by listing the contents of the TTREP.REPLICATIONS table.

**Example 6–8** shows that the replication scheme name, `REPSCHEME`, has a consistent owner name (`REPL`) in the data stores on both `SYSTEM1` and `SYSTEM2`. **Example 6–9** shows the scheme name with inconsistent owner names. This can occur if you omit the owner name from the replication scheme definition and the system uses the Id of the replication scheme creator.

**Example 6–8  Consistent owner names for replication scheme**

On `SYSTEM1`:

```
> ttIsql masterDSN
Command> select * from ttrep.replications;
< REPSCHEME, REPL, C, 0, 0, -1 >
1 row found.
```

On `SYSTEM2`:

```
> ttIsql -connStr 'dsn=subscriberDSN'
Command> select * from ttrep.replications;
< REPSCHEME, REPL, C, 0, 0, -1 >
1 row found.
```

**Example 6–9  Inconsistent owner names for replication scheme**

On `SYSTEM1`:

```
> ttIsql masterDSN
Command> select * from ttrep.replications;
< REPSCHEME, SYSTEM1, C, 0, 0, -1 >
1 row found.
```

On `SYSTEM2`:

```
> ttIsql -connStr 'dsn=subscriberDSN'
Command> select * from ttrep.replications;
< REPSCHEME, SYSTEM2, C, 0, 0, -1 >
1 row found.
```

Checking table owner

Check the owner names assigned to the tables in each data store by using the `ttIsql tables` command.

**Example 6–10  Consistent table owner names**

This example shows that the `TAB` table has a consistent owner name (`REPL`) in the data stores on both `SYSTEM1` and `SYSTEM2`. 
Example 6–11 Inconsistent table owner names

This example shows the TAB table with inconsistent owner names, which were automatically assigned for each host.

Check consistency between replicated tables

Replicated tables on both master and subscriber data stores must be exactly the same.

Example 6–12 Check consistency between replicated tables

This output from the user error log shows a mismatch on the number of columns for the subscriber table TTUSER.MYDSN.

```
11:37:58.00 Info: REP: 9430: REP1:transmitter.c(4936): TT16136: Sending definition for table TTUSER.MYDSN (1 columns)

Check replication state

Use the ttReplicationStatus procedure to check state of the subscriber data store with respect to its master. If the subscriber is in the Failed state, see “Managing data store failover and recovery” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide for information on how to deal with failed data stores.

Example 6–13 Check replication state

Use ttReplicationStatus to obtain the status of the subscriberds data store from its master data store, masterDSN, enter:

```
> ttIsql masterDSN
```
Check return receipt timeout setting

Use the `ttRepSyncGet` procedure to check the return receipt timeout setting. A value of -1 indicates the application is to wait until it receives an acknowledgement from the subscriber. Network latency or other issues might delay receipt of the subscriber acknowledgment. You either address these issues or use the `ttRepSyncGet` procedure to reset the return receipt timeout period.

See "Checking the status of return service transactions" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide* for more information.

Poor replication or XLA performance

Most of this section addresses issues that may impact replication performance. Some issues, such as log buffer too small and reading from the transaction log files on disk, can impact the performance of both replication and XLA applications.

</tr>
</tbody>
</table>

Check network bandwidth

Replication agents typically communicate over some type of network connection. If replicating over a network slower than 10 MB per second (such as common with a 100 Base-T Ethernet typical in a LAN), you must be careful to match the transaction load to the available bandwidth of the network. see "Network bandwidth requirements" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide* for details.

Check use of return receipt blocking

Unless you need receipt confirmation for all your transactions, disable RETURN RECEIPT BLOCKING. If you require receipt confirmation for some transactions, then set RETURN RECEIPT BY REQUEST and call the `ttRepSyncSet` procedure to enable the return receipt service for specific transactions. See "RETURN RECEIPT BY REQUEST" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide* for details.
Note: The performance degradation caused by return-receipt becomes less of an issue when multiple applications (or threads) are updating the data store. If you must use return-receipt in a transaction, you can improve the performance of your application by using multiple threads to update the data store. Though each thread must block for receipt confirmation, the other threads are free to make updates.

Check replication configuration

In addition to return-receipt setting described above, other factors related to the configuration of your replication scheme could impact replication performance. As described in “Making decisions about performance and recovery trade-offs” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide, you often have to weigh the ability to efficiently failover and recover a data store against replication performance.

For more information about direct replication, see "Direct replication or propagation" in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide.

Check size of log buffer

Setting your log buffer too small may impact replication performance. Instead, Set the LogBufMB DSN attribute to a larger size. For more information on this DSN attribute, see "Setting attributes for logging" in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide.

Check durability settings

You can improve replication performance by setting TRANSMIT NONDURABLE on the replication ELEMENT to eliminate the flush-log-to-disk operation from the replication cycle. See “Setting transmit durability on data store elements” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide for details.

Enabling the DURABLE COMMIT option in your replication scheme also impacts performance. See “DURABLE COMMIT” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide for more information.

Check for reads from transaction log files

In some situations a "log reader," such as a master replication agent 'transmitter' thread or a ttXlaNextUpdate call in an XLA application, may not be able to keep up with the update rate of the applications writing to the data store. Normally, replication and XLA readers get update records from the log buffer in memory. When the readers fall behind the application update rate, transaction log files can accumulate on the disk until the backlog can be cleared. This forces the readers to read transactions from the transaction log files on disk, which is much slower. Should you detect reads from the transaction log files, you may want to respond by decreasing the rate of application updates to that sustainable by the log readers.

Applications can monitor whether log readers are obtaining update records from transaction log files on disk rather than from the log buffer in memory by tracking the SYS.MONITOR table entry LOG_FS_READS. For example, you can check the value of LOG_FS_READS for the data store, MASTERSDN, with the following ttIsql command:
Poor replication or XLA performance

% ttIsq1 -v1 -e "select log_fs_reads from monitor; quit;" -connStr dsn=MASTERDSN

If the LOG_FS_READS counter is increasing, the log readers are falling behind or clearing out a backlog in the transaction log files.

For more complete monitoring of replication progress, create a simple shell script like the following:

```bash
#!/bin/sh
trap exit 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
DSN=$1

while [ 1 ] ; do
    date
ttRepAdmin -receiver -list -connStr dsn=$DSN
echo -n 'Log reads from disk: '
ttIsql -v1 -e "select log_fs_reads from monitor; quit;" -connStr dsn=$DSN
echo
ttRepAdmin -bookmark -connStr dsn=$DSN
sleep 15
done

```

**Example 6–14  Check the status of the transaction log**

For example, you name the above script monitorLog and your replication scheme replicates from the MASTERDSN data store to the SUBSCRIBER1DSN data store. You can then check the status of the transaction log by entering:

```
$ monitorLog masterdsn
```

This generates output similar to the following:

```
Mon Aug 2 10:44:40 2004
Peer name       Host name      Port  State  Proto
----------------- -------------------- ------ ------- -----
SUBSCRIBER1DSN  MYHOST          Auto  Start  12

Last Msg Sent   Last Msg Recv  Latency  TPS   RecordsPS  Logs
----------------- ----------- ------- ------- ------- -------
00:00:05         -1.00       -1       -1       1

Log reads from disk: < 0 >

Replication hold LSN ....... 10/2656136
Last written LSN ............ 10/4015824
Last LSN forced to disk ... 10/3970152
```

The output from the script displays an updated status every 15 seconds until you enter Ctrl-C to exit.

Following the date in the output in **Example 6–14** is the name of the subscriber, its host, and so on. Next is latency and rate information, as well as the number of transaction log files being retained on behalf of this subscriber. The specific meaning of each value is described in “Using ttRepAdmin to display subscriber list” in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide. The main interest here is the 'Last Msg Sent' and 'Logs' values. The 'Last Msg Sent' value indicates the elapsed time since the last message was sent by the master to the subscriber and 'Logs' indicates how many transaction log files behind the replication log reader is from the current log insertion point used by the writers (Last written LSN).
Normally the 'Logs' value should be '1', as shown in Example 6–14. A steadily increasing 'Logs' value indicates latency is increasing and eventually log reads are satisfied from disk.

**Note:** If the LogBufMB is larger than the LogFileSize, an increase in the 'Logs' value does not necessarily mean the log readers are reading from the transaction log files. This is because the log manager does not allow more than one log file's worth of data to be outstanding before writing it to the file system. After the log manager writes the data, the data remains in the log buffer to be read directly by the log readers. So, when the LogBufMB is larger than the LogFileSize, the 'Logs' value alone may not be the best measure of whether log readers are reading from memory or from disk.

The output from:

```
ttRepAdmin -bookmark -connStr dsn=$DSN
```

displays the number of the transaction log files and the location of the bookmarks set by the log manager, as described in "From the command line: ttRepAdmin -bookmark" in the Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide. The difference between the Replication hold LSN and the last written LSN indicates the number of records in the transaction log that have not yet been transmitted to the subscribers. A steady increase in the difference between these values is another indication that replication latency is increasing and log file reads are likely to occur.

**Example 6–15  Log reader must read from transaction log files**

In this example, assume the LogBufMB is 16MB and the LogFileSize is 8MB. The following output indicates the log reader is approximately 1.8 MB behind the capacity of the log buffer and must read from the transaction log files, 14 and 15.

```
Peer name  Host name Port State Proto
------------ ------------------------ ------ ------- ----- 
SUBSCRIBER1DSN MYHOST Auto Start 12

Last Msg Sent Last Msg Recv Latency TPS RecordsPS Logs
------------- ------------- ------- ------- --------- ----
00:00:03 - -1.00 -1 -1 4

Log reads from disk: <20>

Replication hold LSN ...... 14/7007464
Last written LSN ............ 17/465336
Last LSN forced to disk ... 17/456152
```

**Problems using ttRepAdmin**

This section includes the following topics:

- Problems using ttRepAdmin -duplicate
- Returns 'Must specify -scheme' error
Problems using `ttRepAdmin -duplicate`

If you connected to your new subscriber DSN before running `ttRepAdmin -duplicate`, the data store has already been created. In this situation, `-duplicate` returns:

```
Error : Restore not done : The datastore already exists.
Unable to restore datastore locally
```

Confirm the existence of the data store by running `ttStatus` and checking to see if the data store is in the returned list. If the new subscriber data store exists, destroy it and try `ttRepAdmin -duplicate` again:

```
> ttDestroy /tmp/newstore
> ttRepAdmin -dsn newstoreDSN -duplicate -name newstore
   -from masterds -host 'server1'
```

If you have made an error entering the subscriber data store name or host name in the replication scheme, you may see something like the following:

```
Unable to swap datastore locally
No receiver NEWSTORE on SERVER2 found to swap with
```

Returns 'Must specify -scheme' error

If you have more than one scheme specified in your `TTREP.REPLICATIONS` table, some `ttRepAdmin` commands may return the error:

```
Must specify -scheme to identify which replication scheme to use
```

To check the names of the replication schemes used by your data store, use the `ttIsql` utility to connect, and enter:

```
Command> SELECT * from TTREP.REPLICATIONS;
```

**Example 6–16  Two replication schemes assigned to the data store**

This example shows that two replication schemes, `REPSHEME1` and `REPSHEME2`, are assigned to the data store associated with `subDSN`. In this case, it is necessary to use the `ttRepAdmin -scheme` option.

```
> ttIsql -connStr 'dsn=subDSN'

Command> SELECT * from TTREP.REPLICATIONS;

<p>| | | | | |</p>
<table>
<thead>
<tr>

```

Problems with conflict checking

This section includes the following topics:

- Column cannot be used for replication timestamp
- Timestamp does not exist
- Conflict reporting slows down replication

**Column cannot be used for replication timestamp**

When attempting to set CHECK CONFLICTS for an element in a CREATE REPLICATION statement, you may encounter an error similar to the following:

8004: Column REPL.TABS.TS cannot be used for replication timestamp checking if in an index or added by ALTER TABLE; and must be binary(8) with NULL values allowed.

In this situation, check:

- That the timestamp column in the specified table is a nullable column of type BINARY(8). In the above example, the TS column in the REPL.TAB table should have a type of BINARY(8).
- The timestamp column is defined in the original CREATE TABLE statement, rather than added later using ALTER TABLE.

**Timestamp does not exist**

You may receive an error similar to the following:

2208: Column TS does not exist in table.

In this situation, confirm that you have specified the correct name for the timestamp COLUMN in the CHECK CONFLICTS clause and that it exists in the specified table. Also, make sure the timestamp column is not part of a primary key or index.

**Conflict reporting slows down replication**

If you have configured replication to check conflicts, TimesTen sends reports to the local host. You can also configure a report file. See "Diagnostics through SNMP Traps" in the *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps.*

If there is a large number of conflicts in a short period of time, subscriber performance can slow down because of the reporting requirements. You can use store attributes in the CREATE REPLICATION or ALTER REPLICATION statements to suspend and resume conflict reporting at specified rates of conflict:

- CONFLICT REPORTING SUSPEND AT rate
- CONFLICT REPORTING RESUME AT rate

Information about conflicts that occur while reporting is suspended cannot be retrieved.

See "Reporting conflicts" in the *Oracle TimesTen In-Memory Database TimesTen to TimesTen Replication Guide.*
