Preface

The Solaris Containers: Resource Management and Solaris Zones Developer's Guide describes how to write applications that partition and manage system resources and discusses which APIs to use. This book provides programming examples and a discussion of programming issues to consider when writing an application.

Who Should Use This Book

This book is for application developers and ISVs who write applications that control or monitor the Solaris Operating System resources.

Before You Read This Book

For a detailed overview of resource management, see the *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

How This Book Is Organized

This guide is organized as follows:

Chapter 1, "Resource Management in the Solaris Operating System," introduces the Solaris 10 Resource Manager product.

Chapter 2, "Projects and Tasks," provides information about the projects and tasks facilities.

Chapter 3, "Using the C Interface to Extended Accounting," describes the C interface to the extended accounting facility.

Chapter 4, "Using the Perl Interface to Extended Accounting," describes the Perl interface to the extended accounting facility.

Chapter 5, "Resource Controls," discusses resource controls and their use.

Chapter 6, "Dynamic Resource Pools," covers dynamic resource pools.

Chapter 7, "Design Considerations for Resource Management Applications in Solaris Zones," describes the precautions that need to be taken for applications to work in Solaris zones.

Chapter 8, "Configuration Examples," provides configuration examples for the /etc/project file.

Documentation, Support, and Training

Sun Function	URL	Description
Documentation	http://www.sun.com/documentation/	Download PDF and HTML documents, and order printed documents
Support and Training	http://www.sun.com/supportraining/	Obtain technical support, download patches, and learn about Sun courses

Typographic Conventions

The following table describes the typographic changes that are used in this book.

TABLE P-1 Typographic Conventions

Typeface or Symbol	Meaning	Example
AaBbCc123	The names of commands, files, and directories, and onscreen computer output	Edit your .login file. Use ls -a to list all files. machine_name% you have mail.
AaBbCc123	What you type, contrasted with onscreen computer output	machine_name% su Password:
AaBbCc123	Command-line placeholder: replace with a real name or value	The command to remove a file is rm filename.
AaBbCc123	Book titles, new terms, and terms to be emphasized	Read Chapter 6 in the <i>User's Guide</i> . Perform a <i>patch analysis</i> . Do <i>not</i> save the file. [Note that some emphasized items appear bold online.]

Shell Prompts in Command Examples

The following table shows the default system prompt and superuser prompt for the C shell, Bourne shell, and Korn shell.

TABLE P-2 Shell Prompts

Shell	Prompt
C shell prompt	machine_name%
C shell superuser prompt	machine_name#
Bourne shell and Korn shell prompt	\$
Bourne shell and Korn shell superuser prompt	#

Resource Management in the Solaris Operating System

The purpose of this manual is to help developers who are writing either utility applications for managing computer resources or self-monitoring applications that can check their own usage and adjust accordingly. This chapter provides an introduction to resource management in the Solaris Operating System (OS). The following topics are included:

- "Understanding Resource Management in the Solaris OS" on page 11
- "Writing Resource Management Applications" on page 14

Understanding Resource Management in the Solaris OS

The main concept behind resource management is that workloads on a server need to be balanced for the system to work efficiently. Without good resource management, faulty runaway workloads can bring progress to a halt, causing unnecessary delays to priority jobs. An additional benefit is that efficient resource management enables organizations to economize by consolidating servers. To enable the management of resources, the Solaris OS provides a structure for organizing workloads and resources, and provides controls for defining the quantity of resources that a particular unit of workload can consume. For an in-depth discussion of resource management from the system administrator's viewpoint, see Chapter 1, "Introduction to Solaris 10 Resource Manager," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

Workload Organization

The basic unit of workload is the *process*. Process IDs (PIDs) are numbered sequentially throughout the system. By default, each user is assigned by the system administrator to a *project*, which is a network–wide administrative identifier. Each successful login to a project creates a new *task*, which is a grouping mechanism for processes. A task contains the login process as well as subsequent child processes.

For more information on projects and tasks, see Chapter 2, "Projects and Tasks (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* for the system administrator's perspective or Chapter 2, "Projects and Tasks," for the developer's point of view.

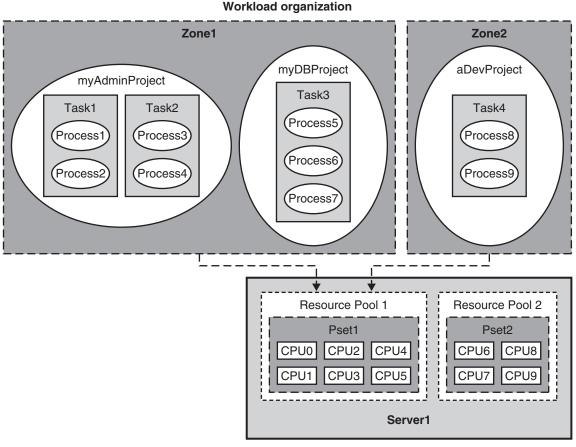

Projects can optionally be grouped into *zones*, which are set up by system administrators for security purposes to isolate groups of users. A zone can be thought of as a box in which one or more applications run isolated from all other applications on the system. Solaris zones are discussed thoroughly in Part II, "Zones," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*. To learn more about special precautions for writing resource management applications that run in zones, see Chapter 7, "Design Considerations for Resource Management Applications in Solaris Zones"

Resource Organization

The system administrator can assign workloads to specific CPUs or defined groups of CPUs in the system. CPUs can be grouped into *processor sets*, otherwise known as *psets*. A pset in turn can be coupled with one or more thread scheduling classes, which define CPU priorities, into a *resource pool*. Resource pools provide a convenient mechanism for a system administrator to make system resources available to users. Chapter 12, "Resource Pools (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* covers resource pools for system administrators. Programming considerations are described in Chapter 6, "Dynamic Resource Pools."

The following diagram illustrates how workload and computer resources are organized in the Solaris OS.

FIGURE 1–1 Workload and Resource Organization in the Solaris Operating System

Resource organization

Resource Controls

Simply assigning a workload unit to a resource unit is insufficient for managing the quantity of resources that users consume. To manage resources, the Solaris OS provides a set of flags, actions, and signals that are referred to collectively as *resource controls* and are stored in the /etc/project file. The Fair Share Scheduler (FSS), for example, can allocate shares of CPU resources among workloads based on the specified importance factor for the workloads. With these resource controls, a system administrator can set privilege levels and limit definitions for a specific project, task, or process. To learn how a system administrator uses resource controls, see Chapter 6, "Resource Controls (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*. For programming considerations, see Chapter 5, "Resource Controls."

Extended Accounting Facility

In addition to the workload and resource organization, the Solaris OS provides the *extended accounting facility* for monitoring and recording system resource usage. The extended accounting facility provides system administrators with a detailed set of resource consumption statistics on processes and tasks.

The facility is described in depth for system administrators in Chapter 4, "Extended Accounting (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*. The Solaris OS provides developers with both a C interface and a PERL interface to the extended accounting facility. Refer to Chapter 3, "Using the C Interface to Extended Accounting," for the C interface or Chapter 4, "Using the Perl Interface to Extended Accounting," for the PERL interface.

Writing Resource Management Applications

This manual focuses on resource management from the developer's point of view and presents information for writing the following kinds of applications:

- Resource administration applications Utilities to perform such tasks as allocating resources, creating partitions, and scheduling jobs.
- Resource monitoring applications Applications that check system statistics through kstats to determine resource usage by systems, workloads, processes, and users.
- Resource accounting utilities Applications that provide accounting information for analysis, billing, and capacity planning.
- Self-adjusting applications Applications that can determine their use of resources and can adjust consumption as necessary.
- Resource advisory applications Provide hints of resource needs.???

Projects and Tasks

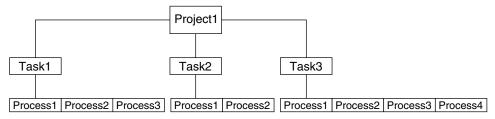

The chapter discusses the workload hierarchy and provides information about projects and tasks. The following topics are covered:

- "Overview of Projects and Tasks" on page 15
- "Project and Task API Functions" on page 17
- "Code Examples for Accessing project Database Entries" on page 18
- "Programming Issues Associated With Projects and Tasks" on page 19

Overview of Projects and Tasks

The Solaris Operating System uses the workload hierarchy to organize the work being performed on the system. A *task* is a collection of processes that represents a workload component. A *project* is a collection of tasks that represents an entire workload. At any given time, a process can be a component of only one task and one project. The relationships in the workload hierarchy are illustrated in the following figure.

FIGURE 2-1 Workload Hierarchy

A user who is a member of more than one project can run processes in multiple projects at the same time. All processes that are started by a process inherit the project of the parent process. When you switch to a new project in a startup script, all child processes run in the new project.

An executing user process has an associated user identity (uid), group identity (gid), and project identity (projid). Process attributes and abilities are inherited from the user, group, and project identities to form the execution context for a task.

For an in-depth discussion of projects and tasks, see Chapter 2, "Projects and Tasks (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*. For the administration commands for managing projects and tasks, see Chapter 3, "Administering Projects and Tasks," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

/etc/project File

The project file is the heart of workload hierarchy. The project database is maintained on a system through the /etc/project file or over the network through a naming service, such as NIS or LDAP.

The /etc/project file contains five standard projects.

system This project is used for all system processes and daemons.

user.root All root processes run in the user.root project.

noproject This special project is for IPQoS.

default A default project is assigned to every user.

group.staff This project is used for all users in the group staff.

To access the project file programmatically, use the following structure:

```
struct project {
         *pj_name;
                          /* name of the project */
 char
                        /* numerical project ID */
 projid_t pj_projid;
          *pj comment; /* project comment */
                       /* vector of pointers to project user names */
          **pj users;
 char
          **pj_groups;
                        /* vector of pointers to project group names */
 char
 char
          *pj attr;
                          /* project attributes */
};
```

The project structure members include the following:

```
*pj_name
Name of the project.
```

```
pj_projid
Project ID.
```

 $*pj_comment$

User-supplied project description.

**pj_users

Pointers to project user members.

**pj_groups

Pointers to project group members.

*pj attr

Project attributes. Use these attributes to set values for resource controls and project pools.

Through project attributes, the resource usage can be controlled. Four prefixes are used to group the types of resource control attributes:

- project.* This prefix denotes attributes that are used to control projects. For example, project.max-device-locked-memory indicates the total amount of locked memory allowed, expressed as a number of bytes. The project.pool attributes binds a project to a resource pool. See Chapter 6, "Dynamic Resource Pools."
- task.* This prefix is used for attributes that are applied to tasks. For example, the task.max-cpu-time attribute sets the maximum CPU time that is available to this task's processes, expressed as a number of seconds.
- process.* This prefix is used for process controls. For example, the process.max-file-size control sets the maximum file offset that is available for writing by this process, expressed as a number of bytes.
- zone.* The zone.* prefix is applied to projects, tasks, and processes in a zone. For example, zone.max-lwps prevents too many LWPs in one zone from affecting other zones.
 A zone's total LWPs can be further subdivided among projects within the zone within the zone by using project.max-lwps entries.

For the complete list of resource controls, see resource controls(5).

Project and Task API Functions

The following functions are provided to assist developers in working with projects. The functions use entries that describe user projects in the project database.

endprojent(3PROJECT)	Close the project database and deallocate resources when processing is complete.
fgetprojent(3PROJECT)	Returns a pointer to a structure containing an entry in the project database. Rather than using nsswitch.conf, fgetprojent() reads a line from a stream.
getdefaultproj(3PROJECT)	Check the validity of the project keyword, look up the project, and return a pointer to the project structure if found.
<pre>getprojbyid(3PROJECT)</pre>	Search the project database for an entry with the number

that specifies the project ID.

getprojbyname(3PROJECT)	Search the project database for an entry with the string that specifies project name.
getprojent(3PROJECT)	Returns a pointer to a structure containing an entry in the project database.
inproj(3PROJECT)	Check whether the specified user is permitted to use the specified project.
setproject(3PROJECT)	Add a user process to a project.
setprojent(3PROJECT)	Rewind the project database to allow repeated searches.

Code Examples for Accessing project Database Entries

EXAMPLE 2-1 Printing the First Three Fields of Each Entry in the project Database The key points for this example include the following:

- setprojent() rewinds the project database to start at the beginning.
- getprojent() is called with a conservative maximum buffer size that is defined in project.h.
- endprojent() closes the project database and frees resources.

EXAMPLE 2-2 Getting a project Database Entry That Matches the Caller's Project ID

The following example calls getprojbyid() to get a project database entry that matches the caller's project ID. The example then prints the project name and the project ID.

EXAMPLE 2-2 Getting a project Database Entry That Matches the Caller's Project ID (Continued)

Programming Issues Associated With Projects and Tasks

Consider the following issues when writing your application:

- No function exists to explicitly create a new project.
- A user cannot log in if no default project for the user exists in the project database.
- A new task in the user's default project is created when the user logs in.
- Process association with a new project applies the new project's resource controls and pools membership to the process.
- setproject() requires privilege. The newtask command does not require privilege if you
 own the process. Either can be used to create a task, but only newtask can change the project
 of a running process.
- No parent/child relationship exists between tasks.
- Finalized tasks can be created by using newtask -F or by using setproject() to associate
 the caller with a new project. Finalized tasks are useful when trying to accurately estimate
 aggregate resource accounting.
- The reentrant functions, getprojent(), getprojbyname(), getprojbyid(), getdefaultproj(), and inproj(), use buffers supplied by the caller to store returned results. These functions are safe for use in both single-threaded applications and multithreaded applications.
- Reentrant functions require these additional arguments: proj, buffer, and bufsize. The proj argument must be a pointer to a project structure allocated by the caller. On successful completion, these functions return the project entry in this structure. Storage referenced by the project structure is allocated from the memory specified by the buffer argument. bufsize specifies the size in number of bytes.

• If an incorrect buffer size is used, getprojent() returns NULL and sets errno to ERANGE.

Using the C Interface to Extended Accounting

This chapter describes the C interface to extended accounting and covers the following topics:

- "Overview of the C Interface to Extended Accounting" on page 21
- "Extended Accounting API Functions" on page 21
- "C Code Examples for Accessing exacct Files" on page 23

Overview of the C Interface to Extended Accounting

Projects and tasks are used to label and separate workloads. The extended accounting subsystem is used to monitor resource consumption by workloads that are running on the system. Extended accounting produces accounting records for the workload tasks and processes.

For an overview of extended accounting and example procedures for administering extended accounting, see Chapter 4, "Extended Accounting (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* and Chapter 5, "Administering Extended Accounting (Tasks)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

Extended Accounting API Functions

The extended accounting API contains functions that perform the following:

- exacct system calls
- Operations on the exacct file
- Operations on exacct objects
- Miscellaneous Operations

exacct System Calls

The following table lists the system calls that interact with the extended accounting subsystem.

TABLE 3-1 Extended Accounting System Calls

Function	Description
putacct(2)	Provides privileged processes with the ability to tag accounting records with additional data that is specific to the process
getacct(2)	Enables privileged processes to request extended accounting buffers from the kernel for currently executing tasks and processes
wracct(2)	Requests the kernel to write resource usage data for a specified task or process

Operations on the exacct File

These functions provide access to the exacct files:

TABLE 3-2 exacct File Functions

Function	Description
ea_open(3EXACCT)	Opens an exacct file.
ea_close(3EXACCT)	Closes an exacct file.
ea_get_object(3EXACCT)	First time use on a group of objects reads data into an ea_object_t structure. Subsequent use on the group cycles through the objects in the group.
ea_write_object(3EXACCT)	Appends the specified object to the open exacct file.
<pre>ea_next_object(3EXACCT)</pre>	Reads the basic fields (eo_catalog and eo_type) into an ea_object_t structure and rewinds to the head of the record.
ea_previous_object(3EXACCT)	Skips back one object in the exacct file and reads the basic fields (eo_catalog and eo_type) into an ea_object_t.
ea_get_hostname(3EXACCT)	Gets the name of the host on which the exacct file was created.
ea_get_creator(3EXACCT)	Determines the creator of the exacct file.

Operations on exacct Objects

These functions are used to access exacct objects:

TABLE 3-3 exacct Object Functions

Function	Description	
ea_set_item(3EXACCT)	Assigns an exacct object and sets the value(s).	
ea_set_group(3EXACCT)	Sets the values of a group of exacct objects.	
ea_match_object_catalog(3EXACCT)Checks an exacct object's mask to see if that object has a specific catalog tag.		
ea_attach_to_object(3EXACCT)	Attaches an exacct object to a specified exacct object.	
ea_attach_to_group(3EXACCT)	Attaches a chain of exacct objects as member items of a specified group.	
ea_free_item(3EXACCT)	Frees the value fields in the specified exacct object.	
ea_free_object(3EXACCT)	Frees the specified exacct object and any attached hierarchies of objects.	

Miscellaneous Operations

These functions are associated with miscellaneous operations:

```
ea_error(3EXACCT)
ea match object catalog(3EXACCT)
```

C Code Examples for Accessing exacct Files

This section provides code examples for accessing exacct files.

EXAMPLE 3-1 Displaying exacct Data for a Designated pid

This example displays a specific pid's exacct data snapshot from the kernel.

EXAMPLE 3-1 Displaying exacct Data for a Designated pid (Continued)

EXAMPLE 3-2 Identifying Individual Tasks During a Kernel Build

This example evaluates kernel builds and displays a string that describes the portion of the source tree being built by this task make. Display the portion of the source being built to aid in the per-source-directory analysis.

The key points for this example include the following:

- To aggregate the time for a make, which could include many processes, each make is initiated as a task. Child make processes are created as different tasks. To aggregate across the makefile tree, the parent-child task relationship must be identified.
- Add a tag with this information to the task's exacct file. Add a current working directory string that describes the portion of the source tree being built by this task make.

```
ea set item(&cwd, EXT STRING | EXC LOCAL | MY CWD,
                                  cwdbuf, strlen(cwdbuf));
/* Omit return value checking and error processing */
/* to keep code sample short */
                     /* Save "parent" task-id */
ptid = gettaskid();
tid = settaskid(getprojid(), TASK_NORMAL);
                                             /* Create new task */
/* Set data for item objects ptskid and cwd */
ea_set_item(&ptskid, EXT_UINT32 | EXC_LOCAL | MY_PTID, &ptid, 0);
ea_set_item(&cwd, EXT_STRING | EXC_LOCAL | MY_CWD, cwdbuf, strlen(cwdbuf));
/* Set grp object and attach ptskid and cwd to grp */
ea set group(&grp, EXT GROUP | EXC LOCAL | EXD GROUP HEADER);
ea_attach_to_group(&grp, &ptskid);
ea attach to group(&grp, &cwd);
/* Pack the object and put it back into the accounting stream */
ea buflen = ea pack object(&grp, ea buf, sizeof(ea buf));
putacct(P_TASKID, tid, ea_buf, ea_buflen, EP_EXACCT_OBJECT);
/* Memory management: free memory allocate in ea set item */
ea free item(&cwd, EUP ALLOC);
  . . .
```

EXAMPLE 3-3 Reading and Displaying the Contents of a System exacct File

This example shows how to read and display a system exacct file for a process or a task.

The key points for this example include the following:

- Call ea_get_object() to get the next object in the file. Call ea_get_object() in a loop until EOF enables a complete traversal of the exacct file.
- catalog_name() uses the catalog_item structure to convert a Solaris catalog's type ID to a
 meaningful string that describes the content of the object's data. The type ID is obtained by
 masking the lowest 24 bits, or 3 bytes.

```
switch(o->eo_catalog & EXT_TYPE_MASK) {
  case EXT_UINT8:
      printf(" 8: %u", o->eo_item.ei_uint8);
      break;
  case EXT_UINT16:
    ...
}
```

- The upper 4 bits of TYPE_MASK are used to find out the data type to print the object's actual data.
- disp_group() takes a pointer to a group object and the number of objects in the group. For
 each object in the group, disp_group() calls disp_obj() and recursively calls
 disp_group() if the object is a group object.

```
/* Omit return value checking and error processing */
/* to keep code sample short */
main(int argc, char *argv)
 ea file t ef;
 ea object t scratch;
  char *fname;
  fname = argv[1];
 ea open(&ef, fname, NULL, EO NO VALID HDR, O RDONLY, 0);
  bzero(&scratch, sizeof (ea_object_t));
 while (ea get object(&ef, &scratch) != -1) {
         disp_obj(&scratch);
         if (scratch.eo type == EO GROUP)
             disp group(&ef, scratch.eo group.eg nobjs);
         bzero(&scratch, sizeof (ea object t));
 ea close(&ef);
struct catalog_item {
                      /* convert Solaris catalog's type ID */
                        /* to a meaningful string */
     int
            type;
     char *name:
 } catalog[] = {

        if (scratch.eo type == EO GROUP)
               disp_group(ef, scratch.eo_group.eg_nobjs);
}
```

• • • CHAPTER 4

Using the Perl Interface to Extended Accounting

The Perl interface provides a Perl binding to the extended accounting tasks and projects. The interface allows the accounting files produced by the exacct framework to be read by Perl scripts. The interface also allows the writing of exacct files by Perl scripts.

This chapter includes the following topics:

- "Extended Accounting Overview" on page 27
- "Perl Code Examples" on page 42
- "Output From dump Method" on page 45

Extended Accounting Overview

The exacct is a new accounting framework for the Solaris operating system provides additional functionality to that provided by the traditional SVR4 accounting mechanism. Traditional SVR4 accounting has these drawbacks:

- The data collected by SVR4 accounting cannot be modified.

 The type or quantity of statistics SVR4 accounting gathers cannot be customized for each application. Changes to the data SVR4 accounting collects would not work with all of the existing applications that use the accounting files.
- The SVR4 accounting mechanism is not open.
 Applications cannot embed their own data in the system accounting data stream.
- The SVR4 accounting mechanism has no aggregation facilities.
 The Solaris Operating system writes an individual record for each process that exists. No facilities are provided for grouping sets of accounting records into higher-level aggregates.

The exacct framework addresses the limitations of SVR4 accounting and provides a configurable, open, and extensible framework for the collection of accounting data.

The data that is collected can be configured using the exacct API.

- Applications can either embed their own data inside the system accounting files, or create and manipulate their own custom accounting files.
- The lack of data aggregation facilities in the traditional accounting mechanism are addressed by *tasks* and *projects*. Tasks identify a set of processes that are to be considered as a unit of work. Projects allow the processes executed by a set of users to be aggregated into a higher-level entity. See theproject(4) man page for more details about tasks and projects.

For a more extensive overview of extended accounting, see Chapter 4, "Extended Accounting (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

Perl Interface to Libexacct

Object Model

The Sun::Solaris::Exacct module is the parent of all the classes provided by libexacct(3LIB) library. libexacct(3LIB) provides operations on types of entities: exacct format files, catalog tags and exacct objects. exacct objects are subdivided into two types.

- ItemsSingle data values
- GroupsLists of items

Benefits of Using the Perl Interface to libexacct

The Perl extensions to extended accounting provide a Perl interface to the underlying libexacct(3LIB) API and offer the following enhancements.

- Full equivalence to C API provide a Perl interface that is functionally equivalent to the underlying C API.
 - The interface provides a mechanism for accessing exacct files that does not require C coding. All the functionality that is available from C is also available by using the Perl interface.
- Ease of use.
 - Data obtained from the underlying C API is presented as Perl data types. Perl data types ease access to the data and remove the need for buffer pack and unpack operations.
- Automated memory management.

The C API requires that the programmer take responsibility for managing memory when accessing exacct files. Memory management takes the form of passing the appropriate flags to functions, such as ea_unpack_object(3EXACCT), and explicitly allocating buffers to pass to the API. The Perl API removes these requirements, as all memory management is performed by the Perl library.

Prevent incorrect use of API.

The ea_object_t structure provides the in-memory representation of exacct records. The ea_object_t structure is a union type that is used for manipulating both Group and Item records. As a result, an incorrectly typed structure can be passed to some of the API functions. The addition of a class hierarchy prevents this type of programming error.

Perl Double-Typed Scalars

The modules described in this document make extensive use of the Perl double-typed scalar facility. The *double-typed scalar* facility allows a scalar value to behave either as an integer or as a string, depending upon the context. This behavior is the same as exhibited by the \$! Perl variable (errno). The double-typed scalar facility avoids the need to map from an integer value into the corresponding string in order to display a value. The following example illustrates the use of double-typed scalars.

```
# Assume $obj is a Sun::Solaris::Item
my $type = $obj->type();

# prints out "2 EO_ITEM"
printf("%d %s\n", $type, $type);

# Behaves as an integer, $i == 2
my $i = 0 + $type;

# Behaves as a string, $s = "abc EO_ITEM xyx"
my $s = "abc $type xyz";
```

Perl Modules

The various project, task and exacct-related functions have been separated into groups, and each group is placed in a separate Perl module. Each function has the Sun Microsystems standard Sun::Solaris::Perl package prefix.

TABLE 4-1 Perl Modules

Module	Description
"Sun::Solaris::Project Module" on page 31	Provides functions to access the project manipulation functions: getprojid(2), setproject(3PROJECT), project_walk(3PROJECT), getprojent(3PROJECT), getprojbyname(3PROJECT), getprojbyname(3PROJECT), getdefaultproj(3PROJECT), inproj(3PROJECT), getprojidbyname(3PROJECT), setprojent(3PROJECT), endprojent(3PROJECT), fgetprojent(3PROJECT), fgetprojent(3PROJECT).
"Sun::Solaris::Task Module" on page 32	Provides functions to access the task manipulation functions settaskid(2) and gettaskid(2).
"Sun::Solaris::Exacct Module" on page 33	Top-level exacct module. Functions in this module access both the exacct-related system calls getacct(2), putacct(2), and wracct(2) as well as the libexacct(3LIB) library function ea_error(3EXACCT). This module contains constants for all the various exacct EO_*, EW_*, EXR_*, P_* and TASK_* macros.
"Sun::Solaris::Exacct::Catalog Module" on page 35	Provides object-oriented methods to access the bitfields within an exacct catalog tag as well as the EXC_*, EXD_* and EXD_* macros.
"Sun::Solaris::Exacct::File Module" on page 36	Provides object-oriented methods to access the libexacct(3LIB) accounting file functions: ea_open(3EXACCT), ea_close(3EXACCT), ea_get_creator(3EXACCT), ea_get_hostname(3EXACCT), ea_next_object(3XACCT), ea_previous_object(3EXACCT), ea_write_object(3EXACCT).

TABLE 4–1 Perl Modules (Continued)	
Module	Description
"Sun::Solaris::Exacct::Object Module" on page 38	Provides object-oriented methods to access the individual exacct accounting file object. An exacct object is represented as an opaque reference that is blessed into the appropriate Sun::Solaris::Exacct::Object subclass. This module is further subdivided into the two types of possible object: Item and Group. Methods are also provided to access the ea_match_object_catalog(3EXACCT), ea_attach_to_object(3EXACCT) functions.
"Sun::Solaris::Exacct::Object::Item Module" on page 39	Provides object-oriented methods to access an individual exacct accounting file Item. Objects of this type inherit from Sun::Solaris::Exacct::Object.
"Sun::Solaris::Exacct::Object::Group Module" on page 40	Provides object-oriented methods to access an individual exacct accounting file Group. Objects of this type inherit from Sun::Solaris::Exacct::Object, and provide access to the ea_attach_to_group(3EXACCT) function. The Items contained within the Group are presented as a perl array.
"Sun::Solaris::Exacct::Object::_Array Module" on page 41	Private array type, used as the type of the array within a Sun::Solaris::Exacct::Object::Group.

Sun::Solaris::Project Module

The Sun::Solaris::Project module provides wrappers for the project-related system calls and the libproject(3LIB) library.

Sun::Solaris::Project Constants

The Sun::Solaris::Project module uses constants from the project-related header files.

MAXPROJID PROJNAME_MAX PROJF_PATH PROJECT_BUFSZ SETPROJ_ERR_TASK SETPROJ ERR POOL

Sun::Solaris::Project Functions, Class Methods, and Object Methods

The perl extensions to the Libexacct(3LIB) API provide the following functions for projects.

setproject(3PROJECT) setprojent(3PROJECT) getdefaultproj(3PROJECT) inproj(3PROJECT) getprojent(3PROJECT) fgetprojent(3PROJECT) getprojbyname(3PROJECT) getprojbyid(3PROJECT) getprojbyname(3PROJECT) endprojent(3PROJECT)

The Sun::Solaris::Project module has no class methods.

The Sun::Solaris::Project module has no object methods.

Sun::Solaris::Project Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants and functions defined in this module.

Tag	Constant or Function
:SYSCALLS	getprojid()
:LIBCALLS	<pre>setproject(), activeprojects(), getprojent(), setprojent(), endprojent(), getprojbyname(), getprojbyid(), getdefaultproj(), fgetprojent(), inproj(), getprojidbyname()</pre>
: CONSTANTS	$\label{eq:maxprojid_task} {\tt MAXPROJID_TASK}, {\tt PROJNAME_MAX}, {\tt PROJF_PATH}, {\tt PROJECT_BUFSZ}, {\tt SETPROJ_ERR}, {\tt SETPROJ_ERR_POOL}$
:ALL	:SYSCALLS, :LIBCALLS, :CONSTANTS

Sun::Solaris::Task Module

The Sun::Solaris::Task module provides wrappers for the settaskid(2) and gettaskid(2) system calls.

Sun::Solaris::Task Constants

The Sun::Solaris::Task module uses the following constants.

TASK_NORMAL TASK FINAL

Sun::Solaris::Task Functions, Class Methods, and Object Methods

The perl extensions to the libexacct(3LIB) API provides the following functions for tasks.

settaskid(2)
gettaskid(2)

The Sun::Solaris::Task module has no class methods.

The Sun::Solaris::Task module has no object methods.

Sun::Solaris::Task Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants and functions defined in this module.

Tag	Constant or Function
:SYSCALLS	<pre>settaskid(), gettaskid()</pre>
: CONSTANTS	TASK_NORMAL and TASK_FINAL
: ALL	:SYSCALLS and :CONSTANTS

Sun::Solaris::Exacct Module

The Sun::Solaris::Exacct module provides wrappers for the ea_error(3EXACCT) function, and for all the exacct system calls.

Sun::Solaris::Exacct Constants

The Sun::Solaris::Exacct module provides constants from the various exacct header files. The P_PID, P_TASKID, P_PROJID and all the EW_*, EP_*, EXR_* macros are extracted during the module build process. The macros are extracted from the exacct header files under /usr/include and provided as Perl constants. Constants passed to the Sun::Solaris::Exacct functions can either be an integer value such as. EW_FINAL or a string representation of the same variable such as. "EW_FINAL".

Sun::Solaris::Exacct Functions, Class Methods, and Object Methods

The perl extensions to the libexacct(3LIB) API provide the following functions for the Sun::Solaris::Exacct module.

```
getacct(2)
putacct(2)
wracct(2)
ea_error(3EXACCT)
ea_error_str
ea_register_catalog
ea_new_file
ea_new_item
ea_new_group
ea_dump_object
```

Note – ea_error_str() is provided as a convenience, so that repeated blocks of code like the following can be avoided:

```
if (ea_error() == EXR_SYSCALL_FAIL) {
         print("error: $!\n");
} else {
         print("error: ", ea_error(), "\n");
}
```

The Sun::Solaris::Exacct module has no class methods.

The Sun::Solaris::Exacct module has no object methods.

Sun::Solaris::Exacct Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants and functions defined in this module.

Tag	Constant or Function
:SYSCALLS	<pre>getacct(), putacct(), wracct()</pre>
:LIBCALLS	ea_error(),ea_error_str()
: CONSTANTS	P_PID, P_TASKID, P_PROJID
	, EW_*, EP_*, EXR_*
:SHORTAND	<pre>ea_register_catalog(), ea_new_catalog(), ea_new_file(), ea_new_item(), ea_new_group(), ea_dump_object()</pre>

Tag	Constant or Function
: ALL	:SYSCALLS, :LIBCALLS, :CONSTANTS and :SHORTHAND
:EXACCT_CONSTANTS	:CONSTANTS, plus the :CONSTANTS tags for Sun::Solaris::Catalog, Sun::Solaris::File, Sun::Solaris::Object
:EXACCT_ALL	:ALL, plus the :ALL tags for Sun::Solaris::Catalog, Sun::Solaris::File, Sun::Solaris::Object

Sun::Solaris::Exacct::Catalog Module

The Sun::Solaris::Exacct::Catalog module provides a wrapper around the 32-bit integer used as a catalog tag. The catalog tag is represented as a Perl object blessed into the Sun::Solaris::Exacct::Catalog class. Methods can be used to manipulate fields in a catalog tag.

Sun::Solaris::Exacct::Catalog Constants

All the EXT_*, EXC_* and EXD_* macros are extracted during the module build process from the /usr/include/sys/exact_catalog.h file and are provided as constants. Constants passed to the Sun::Solaris::Exacct::Catalog methods can either be an integer value, such as EXT_UINT8, or the string representation of the same variable, such as "EXT_UINT8".

Sun::Solaris::Exacct::Catalog Functions, Class Methods, and Object Methods

The Perl extensions to the libexacct(3LIB) API provide the following class methods forSun::Solaris::Exacct::Catalog.Exacct(3PERL) andExacct::Catalog(3PERL)

register new

The Perl extensions to the libexacct(3LIB) API provide the following object methods for Sun::Solaris::Exacct::Catalog.

value
type
catalog
id
type_str
catalog_str
id str

Sun::Solaris::Exacct::Catalog Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants and functions defined in this module.

Tag	Constant or Function
: CONSTANTS	EXT_*, EXC_* and EXD_*.
:ALL	: CONSTANTS

Additionally, any constants defined with the register() function can optionally be exported into the caller's package.

Sun::Solaris::Exacct::File Module

The Sun::Solaris::Exacct::File module provides wrappers for the exacct functions that manipulate accounting files. The interface is object-oriented, and allows the creation and reading of exacct files. The C library calls that are wrapped by this module are:

```
ea_open(3EXACCT)
ea_close(3EXACCT)
ea_next_object(3EXACCT)
ea_previous_object(3EXACCT)
ea_write_object(3EXACCT)
ea_get_object(3EXACCT)
ea_get_creator(3EXACCT)
ea_get_hostname(3EXACCT)
```

The file read and write methods operate on Sun::Solaris::Exacct::Object objects. These methods perform all the necessary memory management, packing, unpacking and structure conversions that are required.

Sun::Solaris::Exacct::File Constants

Sun::Solaris::Exacct::File provides the EO_HEAD, EO_TAIL, EO_NO_VALID_HDR, EO_POSN_MSK and EO_VALIDATE_MSK constants. Other constants that are needed by the new() method are in the standard Perl Fcntl module. Table 4–2 describes the action of new() for various values of \$oflags and \$aflags.

Sun::Solaris::Exacct::File Functions, Class Methods, and Object Methods

The Sun::Solaris::Exacct::File module has no functions.

The Perl extensions to the libexacct(3LIB) API provide the following class method forSun::Solaris::Exacct::File.

new

The following table describes the new() action for combinations of the \$oflags and \$aflags parameters.

TABLE 4-2 \$oflags and \$aflags Parameters

\$oflags	\$aflags	Action
O_RDONLY	Absent or EO_HEAD	Open for reading at the start of the file.
O_RDONLY	EO_TAIL	Open for reading at the end of the file.
O_WRONLY	Ignored	File must exist, open for writing at the end of the file.
O_WRONLY O_CREAT	Ignored	Create file if the file does not exist. Otherwise, truncate, and open for writing.
O_RDWR	Ignored	File must exist, open for reading or writing, at the end of the file.
O_RDWR O_CREAT	Ignored	Create file if the file does not exist. Otherwise, truncate, and open for reading or writing.

Note – The only valid values for \$oflags are the combinations of O_RDONLY, O_WRONLY, O_RDWR or O_CREAT. \$aflags describes the required positioning in the file for O_RDONLY. Either EO_HEAD or EO_TAIL are allowed. If absent, EO_HEAD is assumed.

The perl extensions to the libexacct(3LIB) API provide the following object methods forSun::Solaris::Exacct::File.

creator hostname next previous get write Note - Close a Sun::Solaris::Exacct::File. There is no explicit close() method for a Sun::Solaris::Exacct::File. The file is closed when the filehandle object is undefined or reassigned.

Sun::Solaris::Exacct::File Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants that are defined in this module.

Tag	Constant or Function
: CONSTANTS	EO_HEAD, EO_TAIL, EO_NO_VALID_HDR, EO_POSN_MSK, EO_VALIDATE_MSK.
:ALL	:CONSTANTS and Fcntl(:DEFAULT).

Sun::Solaris::Exacct::Object Module

The Sun::Solaris::Exacct::Object module serves as a parent of the two possible types of exacct objects: Items and Groups. An exacct Item is a single data value, an embedded exacct object, or a block of raw data. An example of a single data value is the number of seconds of user CPU time consumed by a process. An exacct Group is an ordered collection of exacct Items such as all of the resource usage values for a particular process or task. If Groups need to be nested within each other, the inner Groups can be stored as embedded exacct objects inside the enclosing Group.

The Sun::Solaris::Exacct::Object module contains methods that are common to both exacct Items and Groups. Note that the attributes of Sun::Solaris::Exacct::Object and all classes derived from it are read-only after initial creation via new(). The attributes made read-only prevents the inadvertent modification of the attributes which could give rise to inconsistent catalog tags and data values. The only exception to the read-only attributes is the array used to store the Items inside a Group object. This array can be modified using the normal perl array operators.

Sun::Solaris::Exacct::Object Constants

Sun::Solaris::Exacct::Object provides the EO_ERROR, EO_NONE, EO_ITEM and EO_GROUP constants.

Sun::Solaris::Exacct::Object Functions, Class Methods, and Object Methods

The Sun::Solaris::Exacct::Object module has no functions.

The Perl extensions to the libexacct(3LIB) API provide the following class method forSun::Solaris::Exacct::Object.

dump

The Perl extensions to the libexacct(3LIB) API provide the following object methods forSun::Solaris::Exacct::Object.

type
catalog
match_catalog
value

Sun::Solaris::Exacct::Object Exports

By default, nothing is exported from this module. The following tags can be used to selectively import constants and functions defined in this module.

Tag	Constant or Function
: CONSTANTS	EO_ERROR, EO_NONE, EO_ITEM and EO_GROUP
:ALL	:CONSTANTS

Sun::Solaris::Exacct::Object::Item Module

The Sun::Solaris::Exacct::Object::Item module is used for exacct data Items. An exacct data Item is represented as an opaque reference, blessed into the

Sun::Solaris::Exacct::Object::Item class, which is a subclass of the

Sun::Solaris::Exacct::Object class. The underlying exacct data types are mapped onto Perl types as follows.

TABLE 4-3 exacct Data Types Mapped to Perl Data Types

exacct type	Perl internal type
EXT_UINT8	IV (integer)
EXT_UINT16	IV (integer)
EXT_UINT32	IV (integer)
EXT_UINT64	IV (integer)
EXT_DOUBLE	NV (double)

TABLE 4-3 exacct Data Type	es Mapped to Perl Data Types (Continued)
exacct type	Perl internal type
EXT_STRING	PV (string)
EXT_EXACCT_OBJECT	Sun::Solaris::Exacct::Object subclass
EXT_RAW	PV (string)

Sun::Solaris::Exacct::Object::Item Constants

Sun::Solaris::Exacct::Object::Item has no constants.

Sun::Solaris::Exacct::Object::Item Functions, Class Methods, and Object Methods

Sun::Solaris::Exacct::Object::Item has no functions.

Sun::Solaris::Exacct::Object::Item inherits all class methods from the Sun::Solaris::Exacct::Object base class, plus the new() class method.

new

Sun::Solaris::Exacct::Object::Item inherits all object methods from the

Sun::Solaris::Exacct::Object base class.

Sun::Solaris::Exacct::Object::Item Exports

Sun::Solaris::Exacct::Object::Item has no exports.

Sun::Solaris::Exacct::Object::Group Module

The Sun::Solaris::Exacct::Object::Group module is used for exacct Group objects. An exacct Group object is represented as an opaque reference, blessed into the

Sun::Solaris::Exacct::Object::Group class, which is a subclass of the

Sun::Solaris::Exacct::Object class. The Items within a Group are stored inside a Perl array, and a reference to the array can be accessed via the inherited value() method. This means that the individual Items within a Group can be manipulated with the normal Perl array syntax and operators. All data elements of the array must be derived from the

Sun::Solaris::Exacct::Object class. Group objects can also be nested inside each other merely by adding an existing Group as a data Item.

Sun::Solaris::Exacct::Object::Group Constants

Sun::Solaris::Exacct::Object::Group has no constants.

Sun::Solaris::Exacct::Object::Group Functions, Class Methods, and Object Methods

Sun::Solaris::Exacct::Object::Group has no functions.

Sun::Solaris::Exacct::Object::Group inherits all class methods from the Sun::Solaris::Exacct::Object base class, plus the new() class method.

new

Sun::Solaris::Exacct::Object::Group inherits all object methods from the Sun::Solaris::Exacct::Object base class, plus the new() class method.

as_hash as hashlist

Sun::Solaris::Exacct::Object::Group Exports

Sun::Solaris::Exacct::Object::Group has no exports.

Sun::Solaris::Exacct::Object:: Array Module

The Sun::Solaris::Exacct::Object::_Array class is used internally for enforcing type checking of the data Items that are placed in an exacct Group.

Sun::Solaris::Exacct::Object:: Array should not be created directly by the user.

Sun::Solaris::Exacct::Object:: Array Constants

Sun::Solaris::Exacct::Object:: Array has no constants.

Sun::Solaris::Exacct::Object::_Array Functions, Class Methods, and Object Methods

Sun::Solaris::Exacct::Object::_Array has no functions.

Sun::Solaris::Exacct::Object::_Array has internal-use class methods.

 ${\tt Sun::Solaris::Exacct::Object::_Array}\ uses\ perl\ {\tt TIEARRAY}\ methods.$

Sun::Solaris::Exacct::Object:: Array Exports

Sun::Solaris::Exacct::Object:: Array has no exports.

Perl Code Examples

This section shows perl code examples for accessing exacct files.

EXAMPLE 4–1 Using the Pseudocode Prototype

In typical use the Perl exacct library reads existing exacct files. Use pseudocode to show the relationships of the various Perl exacct classes. Illustrate in pseudocode the process of opening and scanning an exacct file, and processing objects of interest. In the following pseudocode, the 'convenience' functions are used in the interest of clarity.

```
-- Open the exacct file ($f is a Sun::Solaris::Exacct::File)
my \$f = ea new file(...)
-- While not EOF ($o is a Sun::Solaris::Exacct::Object)
while (my \$o = \$f->get())
        -- Check to see if object is of interest
        if ($o->type() == &EO ITEM)
        -- Retrieve the catalog ($c is a Sun::Solaris::Exacct::Catalog)
        $c = $o->catalog()
        -- Retrieve the value
        $v = $o->value();
        -- $v is a reference to a Sun::Solaris::Exacct::Group for a Group
        if (ref($v))
        -- $v is perl scalar for Items
        else
EXAMPLE 4–2 Recursively dumping an exacct Object
sub dump object
    my (\$obj, \$indent) = @_;
    my $istr = ' ' x $indent;
    # Retrieve the catalog tag. Because we are doing this in an array
    # context, the catalog tag will be returned as a (type, catalog, id)
    # triplet, where each member of the triplet will behave as an integer
    # or a string, depending on context. If instead this next line provided
    # a scalar context, e.g.
         my $cat = $obj->catalog()->value();
    # then $cat would be set to the integer value of the catalog tag.
    my @cat = $obj->catalog()->value();
    # If the object is a plain item
```

EXAMPLE 4-2 Recursively dumping an exacct Object (Continued)

if (\$obj->type() == &EO ITEM) {

```
# Note: The '%s' formats provide s string context, so the
          # components of the catalog tag will be displayed as the
          # symbolic values. If we changed the '%s' formats to '%d',
          # the numeric value of the components would be displayed.
          printf("%sITEM\n%s Catalog = %s|%s|%s\n".
              $istr, $istr, @cat);
          $indent++;
          # Retrieve the value of the item. If the item contains in
          # turn a nested exacct object (i.e. a item or group), then
          # the value method will return a reference to the appropriate
          # sort of perl object (Exacct::Object::Item or
          # Exacct::Object::Group). We could of course figure out that
          # the item contained a nested item or group by examining
          # the catalog tag in @cat and looking for a type of
          # EXT EXACCT OBJECT or EXT GROUP.
          my $val = $obj->value();
          if (ref($val)) {
             # If it is a nested object, recurse to dump it.
             dump object($val, $indent);
          } else {
             # Otherwise it is just a 'plain' value, so display it.
printf("%s Value = %s\n", $istr, $val);
          }
        # Otherwise we know we are dealing with a group. Groups represent
        # contents as a perl list or array (depending on context), so we
        # can process the contents of the group with a 'foreach' loop, which
        # provides a list context. In a list context the value method
        # returns the content of the group as a perl list, which is the
        # quickest mechanism, but doesn't allow the group to be modified.
        # If we wanted to modify the contents of the group we could do so
        # like this:
             my $grp = $obj->value(); # Returns an array reference
             prec{sgrp->[0]}{grp->[0]} = prec{snewitem}{grp->[0]}
        # but accessing the group elements this way is much slower.
        } else {
                printf("%sGROUP\n%s Catalog = %s|%s|%s\n",
                    $istr, $istr, @cat);
                $indent++:
                # 'foreach' provides a list context.
                foreach my $val ($obj->value()) {
                        dump object($val, $indent);
                printf("%sENDGROUP\n", $istr);
        }
}
```

EXAMPLE 4-3 Creating a New Group Record and Writing to a File

1,

],

```
# Prototype list of catalog tags and values.
my @items = (
                                                    => "me"
   [ &EXT STRING | &EXC DEFAULT | &EXD CREATOR
   [ &EXT UINT32 | &EXC DEFAULT | &EXD PROC PID
                                                 => $$
                                                  => $<
   [ &EXT_UINT32 | &EXC_DEFAULT | &EXD_PROC_UID
   [ &EXT_UINT32 | &EXC_DEFAULT | &EXD_PROC_GID
                                                 => $(
   [ &EXT_STRING | &EXC_DEFAULT | &EXD_PROC_COMMAND => "/bin/stuff" ],
);
# Create a new group catalog object.
my $cat = new catalog(&EXT GROUP | &EXC DEFAULT | &EXD NONE);
# Create a new Group object and retrieve its data array.
my $group = new group($cat);
my $ary = $group->value();
# Push the new Items onto the Group array.
foreach my $v (@items) {
        push(@\$ary, new item(new catalog(\$v->[0]), \$v->[1]));
}
# Nest the group within itself (performs a deep copy).
push(@$ary, $group);
# Dump out the group.
dump object($group);
EXAMPLE 4–4 Dumping an exacct File
#!/usr/bin/perl
use strict;
use warnings;
use blib;
use Sun::Solaris::Exacct qw(:EXACCT_ALL);
die("Usage is dumpexacct
# Open the exact file and display the header information.
my $ef = ea new file($ARGV[0], &O RDONLY) || die(error str());
printf("Creator: %s\n", $ef->creator());
printf("Hostname: %s\n\n", $ef->hostname());
# Dump the file contents
while (my \$obj = \$ef->get()) {
        ea dump object($obj);
}
# Report any errors
if (ea error() != EXR OK && ea error() != EXR EOF) {
       printf("\nERROR: %s\n", ea error str());
       exit(1);
}
exit(0);
```

Output From dump Method

This example shows the formatted output of the Sun::Solaris::Exacct::Object->dump() method.

```

Resource Controls

This chapter describes resource controls and their properties.

- "Overview of Resource Controls" on page 47
- "Resource Controls Flags and Actions" on page 48
- "Resource Controls API Functions" on page 57
- "Resource Control Code Examples" on page 58
- "Programming Issues Associated With Resource Controls" on page 62

Overview of Resource Controls

Use the extended accounting facility to determine the resource consumption of workloads on your system. After the resource consumption has been determined, use the resource control facility to place bounds on resource usage. Bounds that are placed on resources prevent workloads from over-consuming resources.

For an overview of resource controls and example commands for administering resource controls, see Chapter 6, "Resource Controls (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* and Chapter 7, "Administering Resource Controls (Tasks)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

The resource control facility adds the following benefits.

Dynamically set

Resource controls can be adjusted while the system is running.

■ Containment level granularity

Resource controls are arranged in a containment level of project, task, or process. The containment level simplifies the configuration and aligns the collected values closer to the particular project, task, or process.

Threshold preservation

If an attempt is made to set the maximum value less than the actual resource consumption, no change in to the maximum value is made.

Resource Controls Flags and Actions

This section describes flags, actions, and signals associated with resource controls.

rlimit, Resource Limit

rlimit is process-based. rlimit establishes a restricting boundary on the consumption of a variety of system resources by a process. Each process that the process creates inherits from the original process. A resource limit is defined by a pair of values. The values specify the current (soft) limit and the maximum (hard) limit.

A process might irreversibly lower its hard limit to any value that is greater than or equal to the soft limit. Only a process with superuser ID can raise the hard limit. See setrlimit() and getrlimit().

The rlimit structure contains two members that define the soft limit and hard limit.

```
rlim_t rlim_cur; /* current (soft) limit */
rlim_t rlim_max /* hard limit */
```

rctl, Resource Control

rctl extends the process-based limits of rlimit by controlling resource consumption by processes, tasks, and projects defined in the project database.

Note – The rctl mechanism is preferred to the use of rlimit to set resource limits. The only reason to use the rlimit facility is when portability is required across UNIX platforms.

Applications fall into the following broad categories depending on how an application deals with resource controls. Based on the action that is taken, resource controls can be further classified. Most report an error and terminate operation. Other resource controls allow applications to resume operation and adapt to the reduced resource usage. A progressive chain of actions at increasing values can be specified for each resource control.

The list of attributes for a resource control consists of a privilege level, a threshold value, and an action that is taken when the threshold is exceeded.

Resource Control Values and Privilege Levels

Each threshold value on a resource control must be associated with one of the following privilege levels:

RCPRIV_BASIC

Privilege level can be modified by the owner of the calling process. RCPRIV_BASIC is associated with a resource's soft limit.

RCPRIV PRIVILEGED

Privilege level can be modified only by privileged (superuser) callers. RCPRIV PRIVILEGED is associated with a resource's hard limit.

RCPRIV_SYSTEM

Privilege level remains fixed for the duration of the operating system instance.

Figure 5–2 shows the timeline for setting privilege levels for signals that are defined by the /etc/project file process.max-cpu-time resource control.

Local Actions and Local Flags

The local action and local flags are applied to the current resource control value represented by this resource control block. Local actions and local flags are value-specific. For each threshold value that is placed on a resource control, the following local actions and local flags are available:

RCTL_LOCAL_NOACTION

No local action is taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, set by rctlblk_set_local_action(), is sent to the process that placed this resource control value in the value sequence.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource is denied. Set on all values if RCTL_GLOBAL_DENY_ALWAYS is set for this control. Cleared on all values if RCTL_GLOBAL_DENY_NEVER is set for this control.

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control,

RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value that is never exceeded.

Global Actions and Global Flags

Global flags apply to all current resource control values represented by this resource control block. Global actions and global flags are set by rctladm(1M). Global actions and global flags cannot be set with setrctl(). Global flags apply to all resource controls. For each threshold value that is placed on a resource control, the following global actions and global flags are available:

RCTL_GLOBAL_NOACTION

No global action is taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_SYSLOG

A standard message is logged by the syslog() facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_DENY_ALWAYS

The action that is taken when a control value is exceeded on this control always includes denial of the resource.

RCTL_GLOBAL_DENY_NEVER

The action that is taken when a control value is exceeded on this control always excludes denial of the resource. The resource is always granted, although other actions can also be taken.

RCTL GLOBAL FILE SIZE

The valid signals for local actions include the SIGXFSZ signal.

RCTL GLOBAL CPU TIME

The valid signals for local actions include the SIGXCPU signal.

RCTL GLOBAL SIGNAL NEVER

No local actions are permitted on this control. The resource is always granted.

RCTL GLOBAL INFINITE

This resource control supports the concept of an unlimited value. Generally, an unlimited value applies only to accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_UNOBSERVABLE

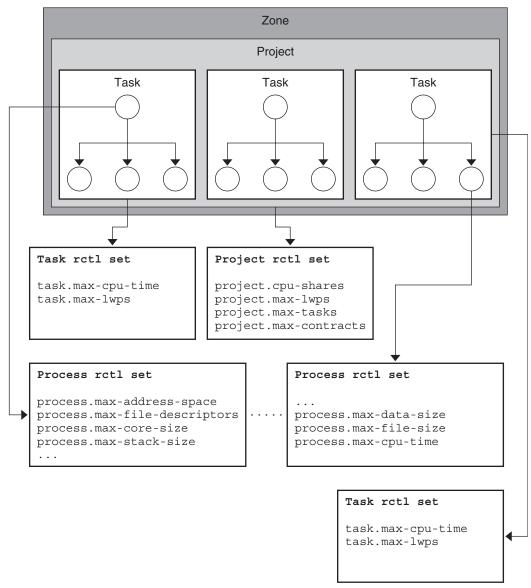

Generally, a task or project related resource control does not support observational control values. An RCPRIV_BASIC privileged control value placed on a task or process generates an action only if the value is exceeded by that process.

In the Solaris 10 5/08 release, the level n/a was added for resource controls on which no global action can be configured.

Resource Control Sets Associated With a Project, Processes and Tasks

The following figure shows the resource control sets associated with tasks, processes and a project.

FIGURE 5-1 Resource Control Sets for Task, Project, and Process

= Circle designates a process within a task

More than one resource control can exist on a resource, each resource control at a containment level in the process model. Resource controls can be active on the same resource for both a process and collective task or collective project. In this case, the action for the process takes

precedence. For example, action is taken on process.max-cpu-time before task.max-cpu-time if both controls are encountered simultaneously.

Resource Controls Associated With a Project

Resource controls associated with a project include the following:

```
project.cpu-cap
```

In Solaris 10 8/07, the absolute limit on the amount of CPU resources that can be consumed by a project. A value of 100 means 100% of one CPU as the project.cpu-cap setting. A value of 125 is 125%, because 100% corresponds to one full CPU on the system when using CPU caps.

```
project.cpu-shares
```

The number of CPU shares that are granted to this project for use with the fair share scheduler, FSS(7).

```
project.max-crypto-memory
```

Total amount of kernel memory that can be used by libpkcs11 for hardware crypto acceleration. Allocations for kernel buffers and session-related structures are charged against this resource control.

```
project.max-locked-memory
```

Total amount of physical locked memory allowed.

Note that this resource control replaced project.max-device-locked-memory, which has been removed.

```
project.max-msg-ids
```

Maximum number of System V message queues allowed for a project.

```
project.max-port-ids
```

Maximum allowable number of event ports.

```
project.max-sem-ids
```

Maximum number of System V semaphores allowed for a project.

```
project.max-shm-ids
```

Maximum number of shared memory IDs allowed for this project.

```
project.max-msg-ids
```

Maximum number of message queue IDs allowed for this project.

```
project.max-shm-memory
```

Total amount of System V shared memory allowed for this project.

```
project.max-lwps
```

Maximum number of LWPs simultaneously available to this project.

```
project.max-tasks
```

Maximum number of tasks allowable in this project.

```
project.max-contracts
```

Maximum number of contracts allowed in this project.

Resource Controls Associated With Tasks

Resource controls associated with tasks include the following:

```
task.max-cpu-time
```

Maximum CPU time (seconds) available to this task's processes.

```
task.max-lwps
```

Maximum number of LWPs simultaneously available to this task's processes.

Resource Controls Associated With Processes

Resource controls associated with processes include the following:

```
process.max-address-space
```

Maximum amount of address space (bytes), as summed over segment sizes, available to this process.

```
process.max-core-size
```

Maximum size (bytes) of a core file that is created by this process.

```
process.max-cpu-time
```

Maximum CPU time (seconds) available to this process.

```
process.max-file-descriptor
```

Maximum file descriptor index that is available to this process.

```
process.max-file-size
```

Maximum file offset (bytes) available for writing by this process.

```
process.max-msg-messages
```

Maximum number of messages on a message queue. This value is copied from the resource control at msgget() time.

```
process.max-msg-qbytes
```

Maximum number (bytes) of messages on a message queue. This value is copied from the resource control at msgget() time. When you set a new project.max-msg-qbytes value, initialization occurs only on the subsequently created values. The new project.max-msg-qbytes value does not effect existing values.

```
process.max-sem-nsems
```

Maximum number of semaphores allowed for a semaphore set.

```
process.max-sem-ops
```

Maximum number of semaphore operations that are allowed for a semop() call. This value is copied from the resource control at msgget() time. A new project.max-sem-ops value only affects the initialization of subsequently created values and has no effect on existing values.

process.max-port-events

Maximum number of events that are allowed per event port.

Zone-Wide Resource Controls

Zone-wide resource controls are available on a system with zones installed. Zone-wide resource controls limit the total resource usage of all process entities within a zone.

zone.cpu-cap	In the Solaris 10 5/08 release, sets an absolute limit on the amount of CPU resources that can be consumed by a zone. A value of 100 means 100 percent of one CPU as the project.cpu-cap setting. A value of 125 is 125 percent, because 100 percent corresponds to one full CPU on the system when using CPU caps.
zone.cpu-shares	Limit on the number of fair share scheduler (FSS) CPU shares for a zone. The scheduling class must be FSS. CPU shares are first allocated to the zone, and then further subdivided among projects within the zone as specified in the project.cpu-shares entries. A zone with a higher number of zone.cpu-shares is allowed to use more CPU than a zone with a low number of shares.
zone.max-locked-memory	Total amount of physical locked memory available to a zone.
zone.max-lwps	Maximum number of LWPs simultaneously available to this zone
zone.max-msg-ids	Maximum number of message queue IDs allowed for this zone
zone.max-sem-ids	Maximum number of semaphore IDs allowed for this zone
zone.max-shm-ids	Maximum number of shared memory IDs allowed for this zone
zone.max-shm-memory	Total amount of shared memory allowed for this zone
zone.max-swap	Total amount of swap that can be consumed by user process address space mappings and tmpfs mounts for this zone.

For information on configuring zone-wide resource controls, see Chapter 17, "Non-Global Zone Configuration (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* and Chapter 18, "Planning and Configuring Non-Global Zones (Tasks)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*. Note that it is possible to use the zonecfg command to apply a zone-wide resource control to the global zone on a system with non-global zones installed.

Signals Used With Resource Controls

For each threshold value that is placed on a resource control, the following restricted set of signals is available:

SIGBART

Terminate the process.

SIGXRES

Signal generated by resource control facility when the resource control limit is exceeded.

SIGHUP

When carrier drops on an open line, the process group that controls the terminal is sent a hangup signal, SIGHUP.

SIGSTOP

Job control signal. Stop the process. Stop signal not from terminal.

SIGTERM

Terminate the process. Termination signal sent by software.

SIGKILL

Terminate the process. Kill the program.

SIGXFSX

Terminate the process. File size limit exceeded. Available only to resource controls with the RCTL_GLOBAL_FILE_SIZE property.

SIGXCPU

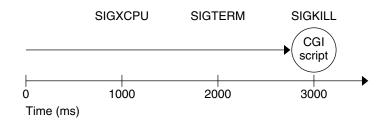

Terminate the process. CPU time limit exceeded. Available only to resource controls with the RCTL_GLOBAL_CPUTIME property. See rctlblk_set_value(3C) for more information.

Other signals might be permitted due to global properties of a specific control.

Note - Calls to setrctl() with illegal signals fail.

FIGURE 5-2 Setting Privilege Levels for Signals

```
/etc/project
```

Resource Controls API Functions

The resource controls API contains functions that:

- "Operate on Action-Value Pairs of a Resource Control" on page 57
- "Operate on Local Modifiable Values" on page 57
- "Retrieve Local Read-Only Values" on page 58
- "Retrieve Global Read-Only Actions" on page 58

Operate on Action-Value Pairs of a Resource Control

The following list contains the functions that set or get the resource control block.

```
setrctl(2)
getrctl(2)
```

Operate on Local Modifiable Values

The following list contains the functions associated with the local, modifiable resource control block.

```
rctlblk_set_privilege(3C)
rctlblk_get_privilege(3C)
rctlblk_set_value(3C)
rctlblk_get_value(3C)
```

```
rctlblk_set_local_action(3C)
rctlblk_get_local_action(3C)
rctlblk_set_local_flags(3C)
rctlblk_get_local_flags(3C)
```

Retrieve Local Read-Only Values

The following list contains the functions associated with the local, read-only resource control block.

```
rctlblk_get_recipient_pid(3C)
rctlblk_get_firing_time(3C)
rctlblk_get_enforced_value(3C)
```

Retrieve Global Read-Only Actions

The following list contains the functions associated with the global, read-only resource control block.

```
rctlblk_get_global_action(3C)
rctlblk get global flags(3C)
```

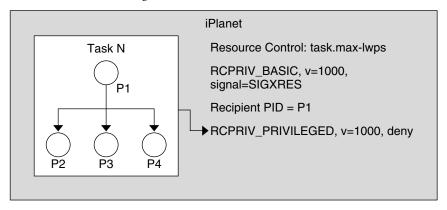

Resource Control Code Examples

Master Observing Process for Resource Controls

The following example is the master observer process. Figure 5–3 shows the resource controls for the master observing process.

Note – The line break is not valid in an /etc/project file. The line break is shown here only to allow the example to display on a printed or displayed page. Each entry in the /etc/project file must be on a separate line.

FIGURE 5-3 Master Observing Process

```
/etc/project
```

```
...
iPlanet:200:iPlanet Application Server:root::\
    task.max=lwps=(PRIVILEGED,1000,deny)
```

The key points for the example include the following:

- Because the task's limit is privileged, the application cannot change the limit, or specify an action, such as a signal. A master process solves this problem by establishing the same resource control as a basic resource control on the task. The master process uses the same value or a little less on the resource, but with a different action, signal = XRES. The master process creates a thread to wait for this signal.
- The rctlblk is opaque. The struct needs to be dynamically allocated.
- Note the blocking of all signals before creating the thread, as required by sigwait(2).
- The thread calls sigwait(2) to block for the signal. If sigwait() returns the SIGXRES signal, the thread notifies the master process' children, which adapts to reduce the number of LWPs being used. Each child should also be modelled similarly, with a thread in each child, waiting for this signal, and adapting its process' LWP usage appropriately.

```
/* Now, create the thread which waits for the signal */
        sigemptyset(&smask);
        sigaddset(&smask, SIGXRES);
        thr sigsetmask(SIG BLOCK, &smask, NULL);
thr create(NULL, 0, sigthread, (void *)SIGXRES, THR DETACHED, NULL));
/* Omit return value checking/error processing to keep code sample short */
void *sigthread(void *a)
        int sig = (int)a;
        int rsig;
        sigset t sset;
        sigemptyset(&sset);
        sigaddset(&sset, sig);
        while (1) {
                 rsig = sigwait(&sset);
          if (rsig == SIGXRES) {
              notify all children();
              /* e.g. sigsend(P_PID, child_pid, SIGXRES); */
        }
}
```

List all the Value-action Pairs for a Specific Resource Control

The following example lists all the value-action pairs for a specific resource control, task.max-lwps. The key point for the example is that getrctl(2) takes two resource control blocks, and returns the resource control block for the RCTL_NEXT flag. To iterate through all resource control blocks, repeatedly swap the resource control block values, as shown here using the rcb tmp rctl block.

```
rctlblk_t *rcb1, *rcb2, *rcb tmp;
/* Omit return value checking/error processing to keep code sample short */
rcb1 = calloc(1, rctlblk_size()); /* rctl blocks are opaque: */
                               /* "rctlblk t rcb" does not work */
rcb2 = calloc(1, rctlblk size());
getrctl("task.max-lwps", NULL, rcb1, RCTL_FIRST);
while (1) {
     print rctl(rcb1);
     rcb tmp = rcb2;
     rcb2 = rcb1;
                            /* swap rcb1 with rcb2 */
     rcb1 = rcb tmp;
     if (getrctl("task.max-lwps", rcb2, rcb1, RCTL NEXT) == -1) {
          if (errno == ENOENT) {
               break;
     } else {
          perror("getrctl");
          exit (1);
```

```
}
}
}
```

Set project.cpu-shares and Add a New Value

The key points of the example include the following:

- This example is similar to the example shown in "Set pool. comment Property and Add New Property" on page 74.
- Use bcopy(), rather than buffer swapping as in "List all the Value-action Pairs for a Specific Resource Control" on page 60.
- To change the resource control value, call setrctl() with the RCTL_REPLACE flag. The
 new resource control block is identical to the old resource control block except for the new
 control value.

```
rctlblk_set_value(blk1, nshares);
if (setrctl("project.cpu-shares", blk2, blk1, RCTL_REPLACE) != 0)
```

The example gets the project's CPU share allocation, project.cpu-shares, and changes its value to *nshares*.

```
/* Omit return value checking/error processing to keep code sample short */
blk1 = malloc(rctlblk size());
getrctl("project.cpu-shares", NULL, blk1, RCTL_FIRST);
my_shares = rctlblk_get_value(blk1);
printout my shares(my shares);
/* if privileged, do the following to */
/* change project.cpu-shares to "nshares" */
blk1 = malloc(rctlblk size());
blk2 = malloc(rctlblk size());
if (getrctl("project.cpu-shares", NULL, blk1, RCTL_FIRST) != 0) {
     perror("getrctl failed");
     exit(1);
bcopy(blk1, blk2, rctlblk_size());
rctlblk set value(blk1, nshares);
if (setrctl("project.cpu-shares", blk2, blk1, RCTL_REPLACE) != 0) {
     perror("setrctl failed");
     exit(1);
}
```

Set LWP Limit on Resource Control Blocks

In the following example, our application has set a privileged limit of 3000 LWPs that may not be exceeded. In addition, our application has set a basic limit of 2000 LWPs. When this limit is exceeded, a SIGXRES is sent to the application. Upon receiving a SIGXRES, our application might send notification to its child processes that might in turn reduce the number of LWPs the processes use or need.

```
/* Omit return value and error checking */
#include <rctl.h>
rctlblk t *rcb1, *rcb2;
         * Resource control blocks are opaque
         * and must be explicitly allocated.
rcb1 = calloc(rctlblk size());
rcb2 = calloc(rctlblk_size());
/* Install an RCPRIV PRIVILEGED, v=3000: do not allow more than 3000 LWPs */
rctlblk set value(rcb1, 3000);
rctlblk set privilege(rcb1, RCPRIV PRIVILEGED);
rctlblk_set_local_action(rcb1, RCTL_LOCAL_DENY);
setrctl("task.max-lwps", NULL, rcb1, RCTL INSERT);
/* Install an RCPRIV BASIC, v=2000 to send SIGXRES when LWPs exceeds 2000 */
rctlblk set value(rcb2, 2000);
rctlblk set privilege(rcb2, RCPRIV BASIC);
rctlblk set local action(rcb2, RCTL LOCAL SIGNAL, SIGXRES);
setrctl("task.max-lwps", NULL, rcb2, RCTL_INSERT);
```

Programming Issues Associated With Resource Controls

Consider the following issues when writing your application:

- The resource control block is opaque. The control block needs to be dynamically allocated.
- If a basic resource control is established on a task or project, the process that establishes this resource control becomes an observer. The action for this resource control block is applied to the observer. However, some resources cannot be observed in this manner.
- If a privileged resource control is set on a task or project, no observer process exists.
 However, any process that violates the limit becomes the subject of the resource control action.
- Only one action is permitted for each type: global and local.
- Only one basic rctl is allowed per process per resource control.

Dynamic Resource Pools

This chapter describes resource pools and their properties.

- "Overview of Resource Pools" on page 63
- "Dynamic Resource Pool Constraints and Objectives" on page 64
- "Resource Pools API Functions" on page 68
- "Resource Pool Code Examples" on page 72
- "Programming Issues Associated With Resource Pools" on page 75

Overview of Resource Pools

Resource pools provide a framework for managing processor sets and thread scheduling classes. Resource pools are used for partitioning machine resources. Resource pools enable you to separate workloads so that workload consumption of certain resources does not overlap. The resource reservation helps to achieve predictable performance on systems with mixed workloads.

For an overview of resource pools and example commands for administering resource pools, see Chapter 12, "Resource Pools (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* and Chapter 13, "Creating and Administering Resource Pools (Tasks)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

A processor set groups the CPUs on a system into a bounded entity, on which a process or processes can run exclusively. Processes cannot extend beyond the processor set, nor can other processes extend into the processor set. A processor set enables tasks of similar characteristics to be grouped together and a hard upper boundary for CPU use to be set.

The resource pool framework allows the definition of a soft processor set with a maximum and minimum CPU count requirement. Additionally, the framework provides a hard-defined scheduling class for that processor set.

A resource pool defines

- Processor set groups
- Scheduling class

Scheduling Class

Scheduling classes provide different CPU access characteristics to threads that are based on algorithmic logic. The scheduling classes include:

- Realtime scheduling class
- Interactive scheduling class
- Fixed priority scheduling class
- Timesharing scheduling class
- Fair share scheduling class

For an overview of fair share scheduler and example commands for administering the fair share scheduler, see Chapter 8, "Fair Share Scheduler (Overview)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones* and Chapter 9, "Administering the Fair Share Scheduler (Tasks)," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

Do not mix scheduling classes in a set of CPUs. If scheduling classes are mixed in a CPU set, system performance might become erratic and unpredictable. Use processor sets to segregate applications by their characteristics. Assign scheduling classes under which the application best performs. For more information about the characteristics of an individual scheduling class, see priorntl(1).

For an overview of resource pools and a discussion of when to use pools, see Chapter 6, "Dynamic Resource Pools."

Dynamic Resource Pool Constraints and Objectives

The libpool library defines properties that are available to the various entities that are managed within the pools facility. Each property falls into the following categories:

Configuration constraints

A constraint defines boundaries of a property. Typical constraints are the maximum and minimum allocations specified in the libpool configuration.

Objective

An objective changes the resource assignments of the current configuration to generate new candidate configurations that observe the established constraints. (See poold(1M).) An objective has the following categories:

Workload dependent

A workload-dependent objective varies according to the conditions imposed by the workload. An example of the workload dependent objective is the utilization objective.

Workload independent

A workload-independent objective does not vary according to the conditions imposed by the workload. An example of the workload independent objective is the cpu locality objective.

An objective can take an optional prefix to indicate the importance of the objective. The objective is multiplied by this prefix, which is an integer from 0 to INT64_MAX,, to determine the significance of the objective.

System Properties

```
system.bind-default (writable boolean)
```

If the specified pool is not found in <filename>/etc/project</filename>, bind to pool with the pool.default property set to TRUE.

```
system.comment (writable string)
```

User description of system. system. comment is not used by the default pools commands, except when a configuration is initiated by the pool of gutility. In this case, the system puts an informative message in the system.comment property for that configuration.

```
system.name (writable string)
```

User name for the configuration.

```
system.version (read-only integer)
```

libpool version required to manipulate this configuration.

Pools Properties

All pool properties are writable.

```
pool.active (writable boolean)
```

If TRUE, mark this pool as active.

```
pool.comment (writable string)
```

User description of pool.

```
pool.default (writable boolean)
```

If TRUE, mark this pool as the default pool. See the system. bind-default property.

```
pool.importance (writable integer)
```

Relative importance of this pool. Used for possible resource dispute resolution.

```
pool.name (writable string)
```

User name for pool. setproject(3PROJECT) uses pool.name as the value for the project.pool project attribute in the project(4) database.

pool.scheduler (writable string)

Scheduler class to which consumers of this pool are bound. This property is optional and if not specified, the scheduler bindings for consumers of this pool are not affected. For more information about the characteristics of an individual scheduling class, see priocntl(1). Scheduler classes include:

- RT for realtime scheduler
- TS for timesharing scheduler
- IA for interactive scheduler
- FSS for fair share scheduler
- FX for fixed priority scheduler

Processor Set Properties

```
pset.comment (writable string)
```

User description of resource.

```
pset.default (read-only boolean)
```

Identifies the default processor set.

```
pset.escapable (writable boolean)
```

Represents whether PSET_NOESCAPE is set for this pset. See the pset_setattr(2) man page.

```
pset.load (read-only unsigned integer)
```

The load for this processor set. The lowest value is 0. The value increases in a linear fashion with the load on the set, as measured by the number of jobs in the system run queue.

```
pset.max (writable unsigned integer)
```

Maximum number of CPUs that are permitted in this processor set.

```
pset.min (writable unsigned integer)
```

Minimum number of CPUs that are permitted in this processor set.

```
pset.name (writable string)
```

User name for the resource.

```
pset.size (read-only unsigned integer)
```

Current number of CPUs in this processor set.

```
pset.sys id (read-only integer)
```

System-assigned processor set ID.

```
pset.type (read-only string)
```

Names the resource type. Value for all processor sets is pset.

```
pset.units (read-only string)
```

Identifies the meaning of size-related properties. The value for all processor sets is population.

cpu.comment (writable string)
User description of CPU

Using Libpool to Manipulate Pool Configurations

The libpool(3LIB) pool configuration library defines the interface for reading and writing pools configuration files. The library also defines the interface for committing an existing configuration to becoming the running operating system configuration. The <pool.h> header provides type and function declarations for all library services.

The resource pools facility brings together process-bindable resources into a common abstraction that is called a pool. Processor sets and other entities can be configured, grouped, and labelled in a persistent fashion. Workload components can be associated with a subset of a system's total resources. The libpool(3LIB) library provides a C language API for accessing the resource pools facility. The pooladm(1M), poolbind(1M), and poolcfg(1M) make the resource pools facility available through command invocations from a shell.

Manipulate psets

The following list contains the functions associated with creating or destroying psets and manipulating psets.

processor_bind(2)	specified processor.
<pre>pset_assign(2)</pre>	Assign a processor to a processor set.
<pre>pset_bind(2)</pre>	Bind one or more LWPs (lightweight processes) to a processor set.
<pre>pset_create(2)</pre>	Create an empty processor set that contains no processors.
<pre>pset_destroy(2)</pre>	Destroy a processor set and release the associated constituent processors and processes.
<pre>pset_setattr(2), pset_getattr(2)</pre>	Set or get processor set attributes.

Resource Pools API Functions

This section lists all of the resource pool functions. Each function has a link to the man page and a short description of the function's purpose. The functions are divided into two groups, depending on whether the function performs an action or a query:

- "Functions for Operating on Resource Pools and Associated Elements" on page 68
- "Functions for Querying Resource Pools and Associated Elements" on page 70

The imported interfaces for libpool for swap sets is identical to the ones defined in this document.

Functions for Operating on Resource Pools and Associated Elements

The interfaces listed in this section are for performing actions related to pools and the associated elements.

${\sf pool_associate}(3{\sf POOL})$	Associate a resource with a specified pool.
pool_component_to_elem(3POOL)	Convert specified component to the pool element type.
pool_conf_alloc(3POOL)	Create a pool configuration.
<pre>pool_conf_close(3POOL)</pre>	Close the specified pool configuration and release the associated resources.
<pre>pool_conf_commit(3POOL)</pre>	Commit changes made to the specified pool configuration to permanent storage.
<pre>pool_conf_export(3POOL)</pre>	Save the given configuration to the specified location.
<pre>pool_conf_free(3POOL)</pre>	Release a pool configuration.
<pre>pool_conf_open(3POOL)</pre>	Create a pool configuration at the specified location.
<pre>pool_conf_remove(3POOL)</pre>	Removes the permanent storage for the configuration.
pool_conf_rollback(3POOL)	Restore the configuration state to the state that is held in the pool configuration's permanent storage.
<pre>pool_conf_to_elem(3POOL)</pre>	Convert specified pool configuration to the pool element type.
pool_conf_update(3POOL)	Update the library snapshot of kernel state.

pool_create(3POOL)	Create a new pool with the default properties and with default resources for each type.
pool_destroy(3POOL)	Destroy the specified pool. The associated resources are not modified.
pool_dissociate(3POOL)	Remove the association between the given resource and pool.
<pre>pool_put_property(3POOL)</pre>	Set the named property on the element to the specified value.
<pre>pool_resource_create(3POOL)</pre>	Create a new resource with the specified name and type for the provided configuration.
<pre>pool_resource_destroy(3POOL)</pre>	Remove the specified resource from the configuration file.
<pre>pool_resource_to_elem(3POOL)</pre>	Convert specified pool resource to the pool element type.
<pre>pool_resource_transfer(3POOL)</pre>	Transfer basic units from the source resource to the target resource.
<pre>pool_resource_xtransfer(3POOL)</pre>	Transfer the specified components from the source resource to the target resource.
<pre>pool_rm_property(3POOL)</pre>	Remove the named property from the element.
<pre>pool_set_binding(3POOL)</pre>	Bind the specified processes to the resources that are associated with pool on the running system.
<pre>pool_set_status(3POOL)</pre>	Modify the current state of the pools facility.
<pre>pool_to_elem(3POOL)</pre>	Convert specified pool to the pool element type.
pool_value_alloc(3POOL)	Allocate and return an opaque container for a pool property value.
<pre>pool_value_free(3POOL)</pre>	Release an allocated property values.
${\tt pool_value_set_bool(3POOL)}$	Set a property value of type boolean.
${\tt pool_value_set_double(3POOL)}$	Set a property value of type double.
<pre>pool_value_set_int64(3POOL)</pre>	Set a property value of type int64.
<pre>pool_value_set_name(3POOL)</pre>	Set a name=value pair for a pool property.
<pre>pool_value_set_string(3POOL)</pre>	Copy the string that was passed in.
<pre>pool_value_set_uint64(3POOL)</pre>	Set a property value of type uint64.

Functions for Querying Resource Pools and Associated Elements

The interfaces listed in this section are for performing queries related to pools and the associated elements.

```
pool component_info(3POOL)
```

Return a string that describes the given component.

```
pool conf info(3POOL)
```

Return a string describing the entire configuration.

```
pool conf location(3POOL)
```

Return the location string that was provided to pool_conf_open() for the given specified configuration.

```
pool conf status(3POOL)
```

Return the validity status for a pool configuration.

```
pool conf validate(3POOL)
```

Check the validity of the contents of the given configuration.

```
pool dynamic location(3POOL)
```

Return the location that was used by the pools framework to store the dynamic configuration.

```
pool error(3POOL)
```

Return the error value of the last failure that was recorded by calling a resource pool configuration library function.

```
pool_get_binding(3POOL)
```

Return the name of the pool on the running system that contains the set of resources to which the specified process is bound.

```
pool_get_owning_resource(3POOL)
```

Return the resource that currently contains the specified component.

```
pool_get_pool(3POOL)
```

Return the pool with the specified name from the provided configuration.

```
pool_get_property(3POOL)
```

Retrieve the value of the named property from the element.

```
pool get resource(3POOL)
```

Return the resource with the given name and type from the provided configuration.

```
pool get resource binding(3POOL)
```

Return the name of the pool on the running system that contains the set of resources to which the given process is bound.

```
pool get status(3POOL)
  Retrieve the current state of the pools facility.
pool_info(3POOL)
   Return a description of the specified pool.
pool query components(3POOL)
  Retrieve all resource components that match the specified list of properties.
pool query pool resources(3POOL)
  Return a null-terminated array of resources currently associated with the pool.
pool query pools(3POOL)
  Return the list of pools that match the specified list of properties.
pool query resource components(3POOL)
  Return a null-terminated array of the components that make up the specified resource.
pool query resources(3POOL)
  Return the list of resources that match the specified list of properties.
pool_resource_info(3POOL)
  Return a description of the specified resource.
pool resource type list(3POOL)
  Enumerate the resource types that are supported by the pools framework on this platform.
pool static location(3POOL)
  Return the location that was used by the pools framework to store the default configuration
  for pools framework instantiation.
pool strerror(3POOL)
  Return a description of each valid pool error code.
pool value get bool(3POOL)
  Get a property value of type boolean.
pool value get double(3POOL)
  Get a property value of type double.
pool value get int64(3POOL)
  Get a property value of type int64.
pool value get name(3POOL)
  Return the name that was assigned to the specified pool property.
pool value get string(3POOL)
  Get a property value of type string.
pool value get type(3POOL)
```

Return the type of the data that is contained by the specified pool value.

```
pool_value_get_uint64(3POOL)
Get a property value of type uint64.

pool_version(3POOL)
Get the version number of the pool library.

pool_walk_components(3POOL)
Invoke callback on all components that are contained in the resource.

pool_walk_pools(3POOL)
Invoke callback on all pools that are defined in the configuration.

pool_walk_properties(3POOL)
Invoke callback on all properties defined for the given element.

pool_walk_resources(3POOL)
Invoke callback on all resources that are associated with the pool.
```

Resource Pool Code Examples

This section contains code examples of the resource pools interface.

Ascertain the Number of CPUs in the Resource Pool

sysconf(3C) provides information about the number of CPUs on an entire system. The following example provides the granularity of ascertaining the number of CPUs that are defined in a particular application's pools pset.

The key points for this example include the following:

- pvals[] should be a NULL terminated array.
- pool_query_pool_resources() returns a list of all resources that match the pvals array type pset from the application's pool my_pool. Because a pool can have only one instance of the pset resource, each instance is always returned in nelem. reslist[] contains only one element, the pset resource.

```
pool_value_t *pvals[2] = {NULL}; /* pvals[] should be NULL terminated */
/* NOTE: Return value checking/error processing omitted */
/* in all examples for brevity */

conf_loc = pool_dynamic_location();
conf = pool_conf_alloc();
pool_conf_open(conf, conf_loc, PO_RDONLY);
my_pool_name = pool_get_binding(getpid());
my_pool = pool_get_pool(conf, my_pool_name);
pvals[0] = pool_value_alloc();
```

```
pvals2[2] = { NULL, NULL };
pool_value_set_name(pvals[0], "type");
pool_value_set_string(pvals[0], "pset");

reslist = pool_query_pool_resources(conf, my_pool, &nelem, pvals);
pool_value_free(pvals[0]);
pool_query_resource_components(conf, reslist[0], &nelem, NULL);
printf("pool %s: %u cpu", my_pool_ name, nelem);
pool_conf_close(conf);
```

List All Resource Pools

The following example lists all resource pools defined in an application's pools pset.

The key points of the example include the following:

- Open the dynamic conf file read-only, PO_RDONLY. pool_query_pools() returns the list of pools in pl and the number of pools in nelem. For each pool, call pool_get_property() to get the pool.name property from the element into the pval value.
- pool_get_property() calls pool_to_elem() to convert the libpool entity to an opaque value. pool value get string() gets the string from the opaque pool value.

```
conf = pool_conf_alloc();
pool_conf_open(conf, pool_dynamic_location(), PO_RDONLY);
pl = pool_query_pools(conf, &nelem, NULL);
pval = pool_value_alloc();
for (i = 0; i < nelem; i++) {
    pool_get_property(conf, pool_to_elem(conf, pl[i]), "pool.name", pval);
    pool_value_get_string(pval, &fname);
    printf("%s\n", name);
}
pool_value_free(pval);
free(pl);
pool_conf_close(conf);</pre>
```

Report Pool Statistics for a Given Pool

The following example reports statistics for the designated pool.

The key points for the example include the following:

- pool_query_pool_resources() gets a list of all resources in rl. Because the last argument to pool_query_pool_resources() is NULL, all resources are returned. For each resource, the name, load and size properties are read, and printed.
- The call to strdup() allocates local memory and copies the string returned by get_string(). The call to get_string() returns a pointer that is freed by the next call to get_property(). If the call to strdup() is not included, subsequent references to the string(s) could cause the application to fail with a segmentation fault.

```
printf("pool %s\n:" pool name);
pool = pool_get_pool(conf, pool_name);
rl = pool_query_pool_resources(conf, pool, &nelem, NULL);
for (i = 0; i < nelem; i++) {
  pool get property(conf, pool resource to elem(conf, rl[i]), "type", pval);
  pool value get string(pval, &type);
  type = strdup(type);
  snprintf(prop_name, 32, "%s.%s", type, "name");
  pool_get_property(conf, pool_resource_to_elem(conf, rl[i]),
        prop_name, pval);
  pool value get string(val, &res name);
  res name = strdup(res name);
  snprintf(prop_name, 32, "%s.%s", type, "load");
  pool get property(conf, pool resource to elem(conf, rl[i]),
        prop name, pval);
  pool value get uint64(val, &load);
  snprintf(prop_name, 32, "%s.%s", type, "size");
 pool_get_property(conf, pool_resource_to_elem(conf, rl[i]),
        prop name, pval);
  pool value get uint64(val, &size);
  printf("resource %s: size %llu load %llu\n", res name, size, load);
  free(type);
  free(res name);
free(rl);
```

Set pool. comment Property and Add New Property

The following example sets the pool.comment property for the pset. The example also creates a new property in pool.newprop.

The key point for the example includes the following:

- In the call to pool_conf_open(), using PO_RDWR on a static configuration file, requires the caller to be root.
- To commit these changes to the pset after running this utility, issue a pooladm c command. To have the utility commit the changes, call pool_conf_commit() with a nonzero second argument.

```
pool_set_comment(const char *pool_name, const char *comment)
{
   pool_t *pool;
   pool_elem_t *pool_elem;
   pool_value_t *pval = pool_value_alloc();
   pool_conf_t *conf = pool_conf_alloc();
   /* NOTE: need to be root to use PO_RDWR on static configuration file */
   pool_conf_open(conf, pool_static_location(), PO_RDWR);
   pool = pool_get_pool(conf, pool_name);
   pool_value_set_string(pval, comment);
   pool_elem = pool_to_elem(conf, pool);
   pool_put_property(conf, pool_elem, "pool.comment", pval);
   printf("pool %s: pool.comment set to %s\n:" pool_name, comment);
   /* Now, create a new property, customized to installation site */
```

An alternative way of modifying a pool's comment and adding a new pool property is to use poolcfg(1M).

Programming Issues Associated With Resource Pools

Consider the following issues when writing your application.

- Each site can add its own list of properties to the pools configuration.
 Multiple configurations can be maintained in multiple configuration files. The system administrator can commit different files to reflect changes to the resource consumption at different time slots. These time slots can include different times of the day, week, month, or seasons depending on load conditions.
- Resource sets can be shared between pools, but a pool has only one resource set of a given type. So, the pset_default can be shared between the default and a particular application's database pools.
- Use pool_value_*() interfaces carefully. Keep in mind the memory allocation issues for string pool values. See "Report Pool Statistics for a Given Pool" on page 73.

◆ ◆ ◆ CHAPTER 7

Design Considerations for Resource Management Applications in Solaris Zones

This chapter provides a brief overview of Solaris zones technology and discusses potential problems that may be encountered by developers who are writing resource management applications. For more information on zones, see Part II, "Zones," in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*.

Zones Overview

A zone is a virtualized operating system environment that is created within a single instance of the Solaris Operating System. Zones are a partitioning technology that provides an isolated, secure environment for applications. When you create a zone, you produce an application execution environment in which processes are isolated from the rest of the system. This isolation prevents a process that is running in one zone from monitoring or affecting processes that are running in other zones. Even a process running with superuser credentials cannot view or affect activity in other zones. A zone also provides an abstract layer that separates applications from the physical attributes of the machine on which the zone is deployed. Examples of these attributes include physical device paths and network interface names.

By default, all systems have a *global zone*. The global zone has a global view of the Solaris environment in similar fashion to the superuser model. All other zones are referred to as *non-global zones*. A non-global zone is analogous to an unprivileged user in the superuser model. Processes in non-global zones can control only the processes and files within that zone. Typically, system administration work is mainly performed in the global zone. In rare cases where a system administrator needs to be isolated, privileged applications can be used in a non-global zone. In general, though, resource management activities take place in the global zone.

IP Networking in Zones

IP networking in a zone can be configured in two different ways, depending on whether the non-global zone is given its own exclusive IP instance or shares the IP layer configuration and state with the global zone. The shared-IP type is the default.

Exclusive-IP zones are assigned zero or more network interface names, and for those network interfaces they can send and receive any packets, snoop, and change the IP configuration, including IP addresses and the routing table. Note that those changes do not affect any of the other IP instances on the system.

Design Considerations for Resource Management Applications in Zones

All applications are fully functional in the global zone as they would be in a conventional Solaris environment. Most applications should run without problem in a non-global environment as long as the application does not need any privileges. If an application does require privileges, then the developer needs to take a close look at which privileges are needed and how a particular privilege is used. If a privilege is required, then a system administrator must assign the appropriate privilege to the application.

General Considerations When Writing Applications for Non-Global Zones

The known situations that a developer needs to investigate are as follows:

- System calls that change the system time require the PRIV_SYS_TIME privilege. These system calls include adjtime(2), ntp adjtime(2), and stime(2).
- System calls that need to operate on files that have the sticky bit set require the PRIV_SYS_CONFIG privilege. These system calls include chmod(2), creat(2), and open(2).
- The ioctl(2) system call requires the PRIV_SYS_NET_CONFIG privilege to be able to unlock an anchor on a STREAMS module. .
- The link(2) and unlink(2) system calls require the PRIV_SYS_LINKDIR privilege to create a link or unlink a directory in a non-global zone. Applications that install or configure software or that create temporary directories could be affected by this limitation.
- The PRIV_PROC_LOCK_MEMORY privilege is required for the mlock(3C), munlock(3C), mlockall(3C), munlockall(3C), and plock(3C) functions and the MC_LOCK, MC_LOCKAS, MC_UNLOCK, and MC_UNLOCKAS flags for the memcntl(2) system. This privilege is a default privilege in a non-global zone. See "Privileges in a Non-Global Zone" in System Administration Guide: Solaris Containers-Resource Management and Solaris Zones for more information.

- The mknod(2) system call requires the PRIV_SYS_DEVICES privilege to create a block (S_IFBLK) or character (S_IFCHAR) special file. This limitation affects applications that need to create device nodes on the fly.
- The IPC_SET flag in the msgctl(2) system call requires the PRIV_SYS_IPC_CONFIG
 privilege to increase the number of message queue bytes. This limitation affects any
 applications that need to resize the message queue dynamically.
- The nice(2) system call requires the PRIV_PROC_PRIOCNTL privilege to change the priority of a process. This privilege is available by default in a non-global zone. Another way to change the priority is to bind the non-global zone in which the application is running to a resource pool, although scheduling processes in that zone is ultimately decided by the Fair Share Scheduler.
- The P_ONLINE, P_OFFLINE, P_NOINTR, P_FAULTED, P_SPARE, and PZ-FORCED flags in the p_online(2) system call require the PRIV_SYS_RES_CONFIG privilege to return or change process operational status. This limitation affects applications that need to enable or disable CPUs.
- The PC_SETPARMS and PC_SETXPARMS flags in the priocntl(2)system call requires the PRIV_PROC_PRIOCNTL privilege to change the scheduling parameters of a lightweight process (LWP).
- System calls that need to manage processor sets (psets), including binding LWPs to psets and setting pset attributes require the PRIV_SYS_RES_CONFIG privilege. This limitation affects the following system calls: pset_assign(2), pset_bind(2), pset_create(2), pset_destroy(2), and pset_setattr(2).
- The SHM_LOCK and SHM_UNLOCK flags in the shmctl(2) system call require the PRIV_PROC_LOCK_MEMORY privilege to share memory control operations. If the application is locking memory for performance purposes, using the intimate shared memory (ISM) feature provides a potential workaround.
- The swapctl(2)system call requires the PRIV_SYS_CONFIG privilege to add or remove swapping resources. This limitation affects installation and configuration software.
- The uadmin(2) system call requires the PRIV_SYS_CONFIG privilege to use the A_REMOUNT, A_FREEZE, A_DUMP, and AD_IBOOT commands. This limitation affects applications that need to force crash dumps under certain circumstances.
- The clock_settime(3RT) function requires the PRIV_SYS_TIME privilege to set the CLOCK_REALTIME and CLOCK_HIRES clocks.
- The cpc_bind_cpu(3CPC) function requires the PRIV_CPC_CPU privilege to bind request sets to hardware counters. As a workaround, the cpc_bind_curlwp(3CPC) function can be used to monitor CPU counters for the LWP in question.
- The pthread_attr_setschedparam(3C) function requires the PRIV_PROC_PRIOCNTL privilege to change the underlying scheduling policy and parameters for a thread.
- The timer_create(3RT) function requires the PRIV_PROC_CLOCK_HIGHRES privilege to create a timer using the high-resolution system clock.

- The APIs that are provided by the following list of libraries are not supported in a non-global zone. The shared objects are present in the zone's /usr/lib directory, so no link time errors occur if your code includes references to these libraries. You can inspect your make files to determine if your application has explicit bindings to any of these libraries and use pmap(1) while the application is executing to verify that none of these libraries are dynamically loaded.
 - libdevinfo(3LIB)
 - libcfgadm(3LIB)
 - libpool(3LIB)
 - libtnfctl(3LIB)
 - libsysevent(3LIB)
- Zones have a restricted set of devices, consisting primarily of pseudo devices that form part of the Solaris programming API. These pseudo devices include /dev/null, /dev/zero, /dev/poll, /dev/random, /dev/tcp, and so on. Physical devices are not directly accessible from within a zone unless the device has been configured by a system administrator. Since devices, in general, are shared resources in a system, to make devices available in a zone requires some restrictions so system security will not be compromised, as follows:
 - The /dev name space consists of symbolic links, that is, logical paths, to the physical paths in /devices. The /devices name space, which is available only in the global zone, reflects the current state of attached device instances that have been created by the driver. Only the logical path /dev is visible in a non-global zone.
 - Processes within a non-global zone cannot create new device nodes. For example, mknod(2) cannot create special files in a non-global zone. The creat(2), link(2), mkdir(2), rename(2), symlink(2), and unlink(2) system calls fail with EACCES if a file in /dev is specified. You can create a symbolic link to an entry in /dev, but that link cannot be created in /dev.
 - Devices that expose system data are only available in the global zone. Examples of such devices include dtrace(7D), kmem(7D), kmdb(7d), ksyms(7D), lockstat(7D), and trapstat(1M).
 - The /dev name space consists of device nodes made up of a default, "safe" set of drivers as well as device nodes that have been specified for the zone by the zonecfg(1M) command.

Specific Considerations for Shared-IP Non-Global Zones

For non-global zones that are configured to use the shared-IP instance, the following restrictions apply.

The socket(3SOCKET) function requires the PRIV_NET_RAWACCESS privilege to create a raw socket with the protocol set to IPPROTO_RAW or IPPROTO_IGMP. This limitation affects applications that use raw sockets or need to create or inspect TCP/IP headers.

- The t_open(3NSL) function requires the PRIV_NET_RAWACCESS privilege to establish a transport endpoint. This limitation affects applications that use the /dev/rawip device to implement network protocols as wall as applications that operate on TCP/IP headers.
- No NIC devices that support the DLPI programming interface are accessible in a shared-IP non-global zone, for example, hme(7D) and ce(7D).
- Each non-global shared-IP zone has its own logical network and loopback interface. Bindings between upper layer streams and logical interfaces are restricted such that a stream may only establish bindings to logical interfaces in the same zone. Likewise, packets from a logical interface can only be passed to upper layer streams in the same zone as the logical interface. Bindings to the loopback address are kept within a zone with one exception: When a stream in one zone attempts to access the IP address of an interface in another zone. While applications within a zone can bind to privileged network ports, they have no control over the network configuration, including IP addresses and the routing table.

Note that these restrictions do not apply to exclusive-IP zones.

Configuration Examples

This chapter show example configurations for the /etc/project file.

- "Configure Resource Controls" on page 84
- "Configure Resource Pools" on page 84
- "Configure FSS project.cpu-shares for a Project" on page 84
- "Configure Five Applications with Different Characteristics" on page 85

/etc/project Project File

The project file is a local source of project information. The project file can be used in conjunction with other project sources, including the NIS maps project. byname and project.byname and the LDAP database project. Programs use the getprojent(3PROJECT) routines to access this information.

Define Two Projects

/etc/project defines two projects: database and appserver. The *user* defaults are user.database and user.appserver. The *admin* default can switch between user.database or user.appserver.

hostname# cat /etc/project

```
. . . user.database:2001:Database backend:admin:: user.appserver:2002:Application Server frontend:admin:: .
```

Configure Resource Controls

The /etc/project file shows the resource controls for the application.

hostname# cat /etc/project

```
.
.
.
development:2003:Developers:::task.ax-lwps=(privileged,10,deny);
process.max-addressspace=(privileged,209715200,deny)
.
```

Configure Resource Pools

The /etc/project file shows the resource pools for the application.

hostname# cat /etc/project

```
.
.
batch:2001:Batch project:::project.pool=batch_pool
process:2002:Process control:::project.pool=process_pool
.
```

Configure FSS project.cpu-shares for a Project

Set up FSS for two projects: *database* and *appserver*. The *database* project has 20 CPU shares. The *appserver* project has 10 CPU shares.

hostname# cat /etc/project

Note – The line break in the lines that precede "20,deny" and "(privileged," is not valid in an /etc/project file. The line breaks are shown here only to allow the example to display on a printed or displayed page. Each entry in the /etc/project file must be on a single line.

If the FSS is enabled but each user and application is not assigned to a unique project, then the users and applications will all run in the same project. By running in the same project, all compete for the same share, in a timeshare fashion. This occurs because shares are assigned to projects, not to users or processes. To take advantage of the FSS scheduling capabilities, assign each user and application to a unique project.

To configure a project, see "Local /etc/project File Format" in System Administration Guide: Solaris Containers-Resource Management and Solaris Zones.

Configure Five Applications with Different Characteristics

The following example configures five applications with different characteristics.

TABLE 8-1 Target Applications and Characteristics

Application Type and Name	Characteristics
Application server, app_server.	Negative scalability beyond two CPUs. Assign a two-CPU processor set to app_server. Use TS scheduling class.
Database instance, app_db.	Heavily multithreaded. Use FSS scheduling class.
Test and development, development.	Motif based. Hosts untested code execution. Interactive scheduling class ensures user interface responsiveness. Use process.max-address-space to impose memory limitations and minimize the effects of antisocial processing.
Transaction processing engine, tp_engine.	Response time is paramount. Assign a dedicated set of at least two CPUs to ensure response latency is kept to a minimum. Use timeshare scheduling class.
Standalone database instance, geo_db.	Heavily multithreaded. Serves multiple time zones. Use FSS scheduling class. $ \\$

Note – Consolidate database applications (app.db and geo_db) onto a single processor set of at least four CPUs. Use FSS scheduling class. Application app_db gets 25% of the project.cpu-shares. Application geo_db gets 75% of the project.cpu-shares.

Edit the /etc/project file. Map users to resource pools for the app_server, app_db, development, tp engine, and geo db project entries.

hostname# cat /etc/project

```
.
.
.
.
user.app_server:2001:Production Application Server::
    project.pool=appserver_pool
user.app_db:2002:App Server DB:::project.pool=db_pool,
    project.cpu-shares=(privileged,1,deny)
development:2003:Test and delopment::staff:project.pool=dev.pool,
    process.max-addressspace=(privileged,536870912,deny)
user.tp_engine:Transaction Engine:::project.pool=tp_pool
user.geo_db:EDI DB:::project.pool=db_pool;
    project.cpu-shares=(privileged,3,deny)
```

Note – The line break in the lines that begin with "project.pool", "project.cpu-shares=", "process.max-addressspace", and "project.cpu-shares=" is not valid in a project file. The line breaks are shown here only to allow the example to display on a printed or displayed page. Each entry must be on one and only one line.

Create the pool. host script and add entries for resource pools.

hostname# cat pool.host

```
create system host
create pset dev_pset (unit pset.max = 2)
create pset tp_pset (unit pset.min = 2)
create pset db_pset (unit pset.min = 4; uint pset.max = 6)
create pset app_pset (unit pset.min = 1; uint pset.max = 2)
create pool dev_pool (string pool.scheduler="IA")
create pool appserver_pool (string pool.scheduler="TS")
create pool db_pool (string pool.scheduler="TS")
create pool tp_pool (string pool.scheduler="TS")
associate pool pool_default (pset pset_default)
associate pool dev_pool (pset dev_pset)
associate pool db_pool (pset db_pset)
associate pool db_pool (pset db_pset)
associate pool tp_pool (pset tp_pset)
```

Note – The line break in the line that begins with "boolean" is not valid in a pool. host file. The line break is shown here only to allow the example to display on a printed or displayed page. Each entry must be on one and only one line.

Run the pool.host script and modify the configuration as specified in the pool.host file.

```
hostname# poolcfg -f pool.host
```

Read the pool . host resource pool configuration file and initialize the resource pools on the system.

hostname# **pooladm -c**
