Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and [man\(1\)](#) for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.								
SYNOPSIS	<p>This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.</p> <p>The following special characters are used in this section:</p> <table><tr><td>[]</td><td>Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.</td></tr><tr><td>. . .</td><td>Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename...".</td></tr><tr><td> </td><td>Separator. Only one of the arguments separated by this character can be specified at a time.</td></tr><tr><td>{ }</td><td>Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</td></tr></table>	[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.	. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename...".		Separator. Only one of the arguments separated by this character can be specified at a time.	{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.								
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename...".								
	Separator. Only one of the arguments separated by this character can be specified at a time.								
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.								
PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.								
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.								
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called <code>ioctl</code> and generates its own								

	<p>heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code>.</p>
OPTIONS	<p>This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.</p>
OPERANDS	<p>This section lists the command operands and describes how they affect the actions of the command.</p>
OUTPUT	<p>This section describes the output – standard output, standard error, or output files – generated by the command.</p>
RETURN VALUES	<p>If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.</p>
ERRORS	<p>On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.</p>
USAGE	<p>This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:</p> <ul style="list-style-type: none">CommandsModifiersVariablesExpressionsInput Grammar

EXAMPLES	This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code> , or if the user must be superuser, <code>example#</code> . Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.
ENVIRONMENT VARIABLES	This section lists any environment variables that the command or function affects, followed by a brief description of the effect.
EXIT STATUS	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.
FILES	This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
ATTRIBUTES	This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.
SEE ALSO	This section lists references to other man pages, in-house documentation, and outside publications.
DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

REFERENCE

Introduction

Name Intro – introduction to commands and application programs

Description This section describes, in alphabetical order, commands available with this operating system.

Pages of special interest are categorized as follows:

- 1B Commands found only in the *SunOS/BSD Compatibility Package*.
- 1C Commands for communicating with other systems.
- 1F Commands associated with *Form and Menu Language Interpreter* (FMLI).
- 1S Commands specific to SunOS.

OTHER SECTIONS See the following sections of the SunOS Reference Manual for more information.

- Section 1M for system maintenance commands.
- Section 4 for information on file formats.
- Section 5 for descriptions of publicly available files and miscellaneous information pages.

For tutorial information about these commands and procedures, see [Solaris Advanced User's Guide](#).

Manual Page Command Syntax Unless otherwise noted, commands described in the SYNOPSIS section of a manual page accept options and other arguments according to the following syntax and should be interpreted as explained below.

name [- *option*...] [*cmdarg*...] where:

- [] Surround an *option* or *cmdarg* that is not required.
- ... Indicates multiple occurrences of the *option* or *cmdarg*.
- name* The name of an executable file.
- { } The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
- option* (Always preceded by a “-.”) *noargletter*... or, *argletter optarg*[, ...]
- noargletter* A single letter representing an option without an option-argument. Notice that more than one *noargletter* option can be grouped after one “-” (Guideline 5, below).
- argletter* A single letter representing an option requiring an option-argument.
- optarg* An option-argument (character string) satisfying a preceding *argletter*. Notice that groups of *optargs* following an *argletter* must be separated by commas, or separated by a tab or space character and quoted (Guideline 8, below).
- cmdarg* Path name (or other command argument) *not* beginning with “-”, or “-” by itself indicating the standard input.

Unless otherwise specified, whenever an operand or option-argument is, or contains, a numeric value:

- The number is interpreted as a decimal integer.
- Numerals in the range 0 to 2147483647 are syntactically recognized as numeric values.
- When the utility description states that it accepts negative numbers as operands or option-arguments, numerals in the range -2147483647 to 2147483647 are syntactically recognized as numeric values.
- Ranges greater than those listed here are allowed.

Command Syntax
Standard: Guidelines

These command syntax guidelines are not followed by all current commands, but new commands are likely to obey them. `getopts(1)` should be used by all shell procedures to parse positional parameters and to check for legal options. It supports Guidelines 3-10 below. The enforcement of the other guidelines must be done by the command itself.

1. Command names (*name* above) should be between two and nine characters long.
2. Command names should include only lower-case letters and digits.
3. Option names (*option* above) must be one character long.
4. All options must be preceded by “-”.
5. Options with no arguments can be grouped after a single “-”.
6. The first option-argument (*optarg* above) following an option must be preceded by a tab or space character.
7. Option-arguments cannot be optional.
8. Groups of option-arguments following an option must either be separated by commas or separated by tab or space character and quoted (-o xxx,z,yy or -o“xxx z yy”).
9. All options must precede operands (*cmdarg* above) on the command line.
10. “- -” can be used to indicate the end of the options.
11. The order of the options relative to one another should not matter.
12. The relative order of the operands (*cmdarg* above) can affect their significance in ways determined by the command with which they appear.
13. “-” preceded and followed by a white space character should only be used to mean standard input.

An expanded set of guidelines referred to as CLIP for Command Line Interface Paradigm has been developed for Solaris and other Sun products. Its intent is to provide a command line syntax more closely aligned with the GNU command line syntax popular on Linux systems. There is no intent to retrofit existing utilities or even to apply this to all new utilities. It is only intended to be applied to sets of utilities being developed when appropriate.

CLIP is a full superset of the guidelines discussed above which are closely aligned with IEEE Std. 1003.1-2001 (SUSv3). It does not include all the GNU syntax. The GNU syntax allows constructs that either conflict with the IEEE rules or are ambiguous. These constructs are not allowed.

The expanded CLIP command line syntax is:

```
utility_name -a --longopt1 -c option_argument \  
    -f option_argument --longopt2=option_argument \  
    --longopt3 option_argument operand
```

The utility in the example is named `utility_name`. It is followed by options, option-arguments, and operands, collectively referred to as arguments. The arguments that consist of a hyphen followed a single letter or digit, such as `-a`, are known as short-options. The arguments that consist of two hyphens followed by a series of letters, digits and hyphens, such as `--longopt1`, are known as long-options. Collectively, short-options and long-options are referred to as options (or historically, flags). Certain options are followed by an option-argument, as shown with `-c option_argument`. The arguments following the last options and option-arguments are named operands. Once the first operand is encountered, all subsequent arguments are interpreted to be operands.

Option-arguments are sometimes shown separated from their short-options by BLANKSs, sometimes directly adjacent. This reflects the situation that in some cases an option-argument is included within the same argument string as the option; in most cases it is the next argument. This specification requires that the option be a separate argument from its option-argument, but there are some exceptions to ensure continued operation of historical applications:

- If the SYNOPSIS of a utility shows a SPACE between a short-option and option-argument (as with `-c option_argument` in the example), the application uses separate arguments for that option and its option-argument.
- If a SPACE is not shown (as with `-f option_argument` in the example), the application expects an option and its option-argument directly adjacent in the same argument string, without intervening BLANKs.
- Notwithstanding the preceding requirements, an application should accept short-options and option-arguments as a single argument or as separate arguments whether or not a SPACE is shown on the synopsis line.
- Long-options with option-arguments are always documented as using an equals sign as the separator between the option name and the option-argument. If the OPTIONS section of a utility shows an equals sign (=) between a long-option and its option-argument (as with `--longopt2= option_argument` in the example), a application shall also permit the use of separate arguments for that option and its option-argument (as with `--longopt1 option_argument` in the example).

CLIP expands the guidelines discussed with the following additional guidelines:

14. The form `command subcommand [options] [operands]` is appropriate for grouping similar operations. Subcommand names should follow the same conventions as command names as specified in guidelines 1 and 2.
15. Long-options should be preceded by `--` and should include only alphanumeric characters and hyphens from the portable character set. Option names are typically one to three words long, with hyphens to separate words.
16. `--name=argument` should be used to specify an option-argument for a long-option. The form `--name argument` is also accepted.
17. All utilities should support two standard long-options: `--version` (with the short-option synonym `-V`) and `--help` (with the short-option synonym `-?`). The short option synonyms for `--version` can vary if the preferred synonym is already in use (but a synonym shall be provided). Both of these options stop further argument processing when encountered and after displaying the appropriate output, the utility successfully exits.
18. Every short-option should have exactly one corresponding long-option and every long-option should have exactly one corresponding short-option. Synonymous options can be allowed in the interest of compatibility with historical practice or community versions of equivalent utilities.
19. The short-option name should get its name from the long-option name according to these rules:
 1. Use the first letter of the long-option name for the short-option name.
 2. If the first letter conflicts with other short-option names, choose a prominent consonant.
 3. If the first letter and the prominent consonant conflict with other shortoption names, choose a prominent vowel.
 4. If none of the letters of the long-option name are usable, select an arbitrary character.
20. If a long-option name consists of a single character, it must use the same character as the short-option name. Single character long-options should be avoided. They are only allowed for the exceptionally rare case that a single character is the most descriptive name.
21. The subcommand in the form described in guideline 1 of the additional CLIP guidelines is generally required. In the case where it is omitted, the command shall take no operands and only options which are defined to stop further argument processing when encountered are allowed. Invoking a command of this form without a subcommand and no arguments is an error. This guideline is provided to allow the common forms `command --help`, `command -?`, `command --version`, and `command -V` to be accepted in the command-subcommand construct.

Several of these guidelines are only of interest to the authors of utilities. They are provided here for the use of anyone wanting to author utilities following this syntax.

Attributes See [attributes\(5\)](#) for a discussion of the attributes listed in this section.

See Also [getopts\(1\)](#), [wait\(1\)](#), [exit\(2\)](#), [getopt\(3C\)](#), [wait\(3UCB\)](#), [attributes\(5\)](#)

Diagnostics Upon termination, each command returns two bytes of status, one supplied by the system and giving the cause for termination, and (in the case of “normal” termination) one supplied by the program [see [wait\(3UCB\)](#) and [exit\(2\)](#)]. The former byte is 0 for normal termination. The latter byte is customarily 0 for successful execution and non-zero to indicate troubles such as erroneous parameters, or bad or inaccessible data. It is called variously “exit code”, “exit status”, or “return code”, and is described only where special conventions are involved.

Warnings Some commands produce unexpected results when processing files containing null characters. These commands often treat text input lines as strings and therefore become confused upon encountering a null character (the string terminator) within a line.

REFERENCE

User Commands

Name acctcom – search and print process accounting files

Synopsis acctcom [-abfhikmqrtv] [-C *sec*] [-e *time*] [-E *time*]
[-g *group*] [-H *factor*] [-I *chars*] [-l *line*]
[-n *pattern*] [-o *output-file*] [-O *sec*] [-s *time*]
[-S *time*] [-u *user*] [*filename*]...

Description The acctcom utility reads *filenames*, the standard input, or /var/adm/pacct, in the form described by [acct.h\(3HEAD\)](#) and writes selected records to standard output. Each record represents the execution of one process. The output shows the COMMAND NAME, USER, TTYNAME, START TIME, END TIME, REAL (SEC), CPU (SEC), MEAN SIZE (K), and optionally, F (the fork()/exec() flag: 1 for fork() without exec()), STAT (the system exit status), HOG FACTOR, KCORE MIN, CPU FACTOR, CHARS TRNSFD, and BLOCKS READ (total blocks read and written).

A '#' is prepended to the command name if the command was executed with super-user privileges. If a process is not associated with a known terminal, a '?' is printed in the TTYNAME field.

If no *filename* is specified, and if the standard input is associated with a terminal or /dev/null (as is the case when using '&' in the shell), /var/adm/pacct is read; otherwise, the standard input is read.

If any *filename* arguments are given, they are read in their respective order. Each file is normally read forward, that is, in chronological order by process completion time. The file /var/adm/pacct is usually the current file to be examined; a busy system may need several such files of which all but the current file are found in /var/adm/pacctincr.

Options The following options are supported:

- a Show some average statistics about the processes selected. The statistics will be printed after the output records.
- b Read backwards, showing latest commands first. This option has no effect when standard input is read.
- f Print the fork()/exec() flag and system exit status columns in the output. The numeric output for this option will be in octal.
- h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This "hog factor" is computed as (total CPU time)/(elapsed time).
- i Print columns containing the I/O counts in the output.
- k Instead of memory size, show total kcore-minutes.
- m Show mean core size (the default).
- q Do not print any output records, just print the average statistics as with the -a option.

-r	Show CPU factor (user-time/(system-time + user-time)).
-t	Show separate system and user CPU times.
-v	Exclude column headings from the output.
-C <i>sec</i>	Show only processes with total CPU time (system-time + user-time) exceeding <i>sec</i> seconds.
-e <i>time</i>	Select processes existing at or before <i>time</i> .
-E <i>time</i>	Select processes ending at or before <i>time</i> . Using the same <i>time</i> for both -S and -E shows the processes that existed at <i>time</i> .
-g <i>group</i>	Show only processes belonging to <i>group</i> . The <i>group</i> may be designated by either the group ID or group name.
-H <i>factor</i>	Show only processes that exceed <i>factor</i> , where <i>factor</i> is the “hog factor” as explained in option -h above.
-I <i>chars</i>	Show only processes transferring more characters than the cutoff number given by <i>chars</i> .
-l <i>line</i>	Show only processes belonging to terminal /dev/term/line.
-n <i>pattern</i>	Show only commands matching <i>pattern</i> that may be a regular expression as in regcmp(3C) , except + means one or more occurrences.
-o <i>output-file</i>	Copy selected process records in the input data format to <i>output-file</i> ; suppress printing to standard output.
-O <i>sec</i>	Show only processes with CPU system time exceeding <i>sec</i> seconds.
-s <i>time</i>	Select processes existing at or after <i>time</i> , given in the format <i>hr</i> [<i>:min</i> [<i>:sec</i>]].
-S <i>time</i>	Select processes starting at or after <i>time</i> .
-u <i>user</i>	Show only processes belonging to <i>user</i> . The user may be specified by a user ID, a login name that is then converted to a user ID, '#' (which designates only those processes executed with superuser privileges), or '?' (which designates only those processes associated with unknown user IDs).

Files	/etc/group	system group file
	/etc/passwd	system password file
	/var/adm/pacctincr	active processes accounting file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

System Administration Guide: Basic Administration

Notes `acctcom` reports only on processes that have terminated; use [ps\(1\)](#) for active processes.

Name adb – general-purpose debugger

Synopsis adb [-kw] [-I *dir*] [-P *prompt*] [-V *mode*] [*object* [*core*]]

Description The adb utility is an interactive, general-purpose debugger. It can be used to examine files and provides a controlled environment for the execution of programs.

The adb utility is now implemented as a link to the [mdb\(1\)](#) utility. mdb(1) is a low-level debugging utility that can be used to examine user processes as well as the live operating system or operating system crash dumps. The new mdb(1) utility provides complete backwards compatibility with the existing syntax and features of adb, including support for processing adb macro files. The [Solaris Modular Debugger Guide](#) and mdb(1) man page describes the features of mdb, including its adb compatibility mode. This mode will be activated by default when the adb link is executed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdb

See Also [mdb\(1\)](#), [attributes\(5\)](#)

[Solaris Modular Debugger Guide](#)

Name addbib – create or extend a bibliographic database

Synopsis addbib [-a] [-p *promptfile*] *database*

Description When addbib starts up, answering y to the initial Instructions? prompt yields directions. Typing n (or RETURN) skips the directions. addbib then prompts for various bibliographic fields, reads responses from the terminal, and sends output records to *database*. A null response (just RETURN) means to leave out that field. A '-' (minus sign) means to go back to the previous field. A trailing backslash allows a field to be continued on the next line. The repeating Continue? prompt allows the user either to resume by typing y (or RETURN), to quit the current session by typing n or q, or to edit *database* with any system editor (see vi(1), ex(1), ed(1)).

Options The following options are supported:

- a Suppresses prompting for an abstract. Asking for an abstract is the default. Abstracts are ended with a Control-D.
- p *promptfile* Uses a new prompting skeleton, defined in *promptfile*. This file should contain prompt strings, a TAB, and the key-letters to be written to the *database*.

Usage

Bibliography Key Letters The most common key-letters and their meanings are given below. addbib insulates you from these key-letters, since it gives you prompts in English, but if you edit the bibliography file later on, you will need to know this information.

- %A Author's name
- %B Book containing article referenced
- %C City (place of publication)
- %D Date of publication
- %E Editor of book containing article referenced
- %F Footnote number or label (supplied by refer)
- %G Government order number
- %H Header commentary, printed before reference
- %I Issuer (publisher)
- %J Journal containing article
- %K Keywords to use in locating reference
- %L Label field used by -k option of refer
- %M Bell Labs Memorandum (undefined)

%N	Number within volume
%O	Other commentary, printed at end of reference
%P	Page number(s)
%Q	Corporate or Foreign Author (unreversed)
%R	Report, paper, or thesis (unpublished)
%S	Series title
%T	Title of article or book
%V	Volume number
%X	Abstract — used by roffbib, not by refer
%Y,Z	Ignored by refer

Examples EXAMPLE 1 Editing the bibliography file

Except for A, each field should be given just once. Only relevant fields should be supplied.

```
%A   Mark Twain
%T   Life on the Mississippi
%I   Penguin Books
%C   New York
%D   1978
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

See Also [ed\(1\)](#), [ex\(1\)](#), [indxbib\(1\)](#), [lookbib\(1\)](#), [refer\(1\)](#), [roffbib\(1\)](#), [sortbib\(1\)](#), [vi\(1\)](#), [attributes\(5\)](#)

Name alias, unalias – create or remove a pseudonym or shorthand for a command or series of commands

Synopsis /usr/bin/alias [*alias-name* [= *string*]...]

/usr/bin/unalias *alias-name*...

/usr/bin/unalias -a

csh alias [*name* [*def*]]

unalias *pattern*

ksh alias [-tx] [*name* [= *value*]]...

unalias *name*...

unalias [-a]

Description The alias and unalias utilities create or remove a pseudonym or shorthand term for a command or series of commands, with different functionality in the C-shell and Korn shell environments.

/usr/bin/alias The alias utility creates or redefines alias definitions or writes the values of existing alias definitions to standard output. An alias definition provides a string value that replaces a command name when it is encountered.

An alias definition affects the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this document, the alias definition will not affect the parent process of the current shell nor any utility environment invoked by the shell.

/usr/bin/unalias The unalias utility removes the definition for each alias name specified. The aliases are removed from the current shell execution environment. The -a option removes all alias definitions from the current execution environment.

csh alias assigns *def* to the alias *name*. The assigned *def* is a list of words that may contain escaped history-substitution metasyntax. *name* is not allowed to be alias or unalias. If *def* is omitted, the alias *name* is displayed along with its current definition. If both *name* and *def* are omitted, all aliases are displayed.

Because of implementation restrictions, an alias definition must have been entered on a previous command line before it can be used.

unalias discards aliases that match (filename substitution) *pattern*. All aliases may be removed by 'unalias *'.

ksh alias with no arguments prints the list of aliases in the form *name=value* on standard output. An alias is defined for each name whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The -t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value

becomes undefined when the value of `PATH` is reset but the aliases remained tracked. Without the `-t` flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The `-x` flag is used to set or print *exported aliases*. An exported alias is defined for scripts invoked by *name*. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.

The aliases given by the list of *names* may be removed from the alias list with `unalias`.

Options The following option is supported by `unalias`:

`-a` Removes all alias definitions from the current shell execution environment.

`ksh` The following option is supported by `alias`:

`-t` Sets and lists tracked aliases.

Operands The following operands are supported:

<code>alias</code>	<i>alias-name</i>	Write the alias definition to standard output.
<code>unalias</code>	<i>alias-name</i>	The name of an alias to be removed.
	<i>alias-name=string</i>	Assign the value of <i>string</i> to the alias <i>alias-name</i> .

If no operands are given, all alias definitions will be written to standard output.

Output The format for displaying aliases (when no operands or only *name* operands are specified) is:

```
"%s=%s\n" name, value
```

The *value* string will be written with appropriate quoting so that it is suitable for reinput to the shell.

Examples **EXAMPLE 1** Modifying a command's output

This example specifies that the output of the `ls` utility is columnated and more annotated:

```
example% alias ls="ls -CF"
```

EXAMPLE 2 Repeating previous entries in the command history file

This example creates a simple “redo” command to repeat previous entries in the command history file:

```
example% alias r='fc -s'
```

EXAMPLE 3 Specifying a command's output options

This example provides that the `du` utility summarize disk output in units of 1024 bytes:

```
example% alias du="du -k"
```

EXAMPLE 4 Dealing with an argument that is itself an alias name

This example sets up the `nohup` utility so that it can deal with an argument that is itself an alias name:

```
example% alias nohup="nohup "
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `alias` and `unalias`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- `0` Successful completion.
- `alias >0` One of the *alias-name* operands specified did not have an alias definition, or an error occurred.
- `unalias >0` One of the *alias-name* operands specified did not represent a valid alias definition, or an error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

See Also [csh\(1\)](#), [ksh\(1\)](#), [shell_builtins\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name allocate – device allocation

Synopsis allocate [-s] [-w] [-F] [-U *uname*] [-z *zonename*] *device*
 allocate [-s] [-w] [-F] [-U *uname*] [-z *zonename*] -g *dev-type*

Description The `allocate` utility manages the ownership of devices through its allocation mechanism. It ensures that each device is used by only one qualified user at a time.

The *device* argument specifies the device to be manipulated. To preserve the integrity of the device's owner, the `allocate` operation is executed on all the device special files associated with that device.

The default `allocate` operation allocates the device special files associated with *device* to the `uid` of the current process.

Only authorized users may allocate a device. The required authorizations are specified in [device_allocate\(4\)](#).

When the system is configured with Trusted Extensions, `allocate` runs the `clean` program for the device before it grants access to the caller to that device. For devices with removable media that have a mountable file system, `allocate` mounts the media if the caller chooses.

Options The following options are supported:

- F *device* Force allocates either free or pre-allocated devices. This option is often used with the -U option to allocate/reallocate devices to a specific user. Only those users that have `solaris.device.revoke` authorization are allowed to use this option.
- g *dev-type* Allocates devices with a device-type matching *dev-type*. The *dev-type* argument specifies the device type to be operated on.
- s Silent. Suppresses any diagnostic output.
- U *uname* Uses the user ID *uname* instead of the user ID of the current process when performing the `allocate` operation. Only a user with the `solaris.device.revoke` authorization is permitted to use this option.

The following options are supported with Trusted Extensions:

- w Runs the device cleaning program in a windowing environment. If a windowing version of the program exists, it is used. Otherwise, the standard version is run in a terminal window.
- z *zonename* Allocates device to the zone specified by *zonename*.

Operands The following operands are supported:

- device* Specifies the name of the device to be allocated.

Exit Status The following exit values are returned:

- 0** Successful completion.
- 20** No entry for the specified device.
- other value* An error occurred.

Files /etc/security/device_allocate
/etc/security/device_maps
/etc/security/dev/*
/etc/security/lib/*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also [deallocate\(1\)](#), [list_devices\(1\)](#), [bsmconv\(1M\)](#), [dminfo\(1M\)](#), [mkdevalloc\(1M\)](#), [mkdevmaps\(1M\)](#), [device_allocate\(4\)](#), [device_maps\(4\)](#), [attributes\(5\)](#)

Controlling Access to Devices

Notes The functionality described in this man page is available only if Solaris Auditing has been enabled. See [bsmconv\(1M\)](#) for more information.

On systems configured with Trusted Extensions, the functionality is enabled by default.

/etc/security/dev, [mkdevalloc\(1M\)](#), and [mkdevmaps\(1M\)](#) might not be supported in a future release of the Solaris Operating Environment.

Name amt – run abstract machine test

Synopsis amt [-s]

Description The amt command is for use in a Common Criteria security certified system. The command is used to verify that the low level functions necessary to enforce the object reuse requirements of the Controlled Access Protection Profile are working correctly. /usr/bin/amt is a shell script that executes tests specific to your system. For a 32-bit system, the tests run as a 32-bit application. For a 64-bit system, the tests run twice; once as a 32-bit application and once as a 64-bit application.

amt lists test results with a "pass" or "fail" for each test it performs, unless output is suppressed with the -s option.

Options The following option is supported:

-s Suppresses output.

Exit Status The following error values are returned:

0 All tests passed.

>0 Count of the number of tests that failed.

<0 Incorrect command line argument.

Name answerbook2 – online documentation system

Synopsis /usr/dt/bin/answerbook2 [-h]

Description The AnswerBook2 server product is no longer included with Solaris or the Solaris Documentation CD products. Solaris documentation is now provided in HTML and PDF format on the Documentation CD and does not require the AnswerBook2 server to be viewed.

The answerbook2 utility opens the default web browser and displays an HTML page that shows a link to locally installed documentation, and, if the AnswerBook2 server has been defined, a link to AnswerBook2 collections.

To define a default AnswerBook2 server, use the environment variable, AB2_DEFAULTSERVER.

This functionality is also accessible through the AnswerBook2 option on the CDE front panel Help menu.

If you need an AnswerBook2 server, you can download the AnswerBook2 server software from <http://www.sun.com>.

Options The following option is supported:

-h Displays a usage statement.

Environment Variables AB2_DEFAULTSERVER Fully-qualified URL that identifies the default AnswerBook2 server to use. For example: <http://imaserver.eng.sun.com:8888/>

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	http://www.sun.com

See Also [attributes\(5\)](#)

Notes Use the online Help system to find out more about the AnswerBook2 product, once the web browser is opened and the AnswerBook2 library can be viewed.

Name appcert – examine application-level products for unstable use of Solaris interfaces

Synopsis appcert [-h] [-n] [-f *infile*] [-w *working_dir*] [-B] [-L]
 [-S] {*obj* | *dir*}...

Description The appcert utility examines an application's conformance to the Solaris Application Binary Interface (ABI). The Solaris ABI defines the runtime library interfaces in Solaris that are safe and stable for application use. More specifically, appcert identifies any dependencies on unstable runtime interfaces, as well as certain other risks that could cause the product to fail to work on a subsequent release of Solaris.

appcert checks for:

- *Private symbol usage in Solaris libraries.* These are private symbols, that is, functions or data, that are not intended for developer consumption. They are interfaces that Solaris libraries use to call one another. These symbols might change their semantic behavior or even disappear altogether (so-called "demoted" symbols), so it is a good practice to make sure your application does not depend upon any of them.
- *Static linking.* In particular, this refers to static linking of archives `libc.a`, `libsocket.a`, and `libnsl.a`, that is, instead of dynamically linking the corresponding shared object `.so`'s. Because the semantics of private symbol calls from one Solaris library to another can change from one release to another, it is not a good practice to "hardwire" library code into your binary objects.
- *Unbound symbols.* These are library symbols (that is, functions or data) that the dynamic linker could not resolve when appcert was run. This might be an environment problem (for example, `LD_LIBRARY_PATH`) or a build problem (for example, not specifying `-llib` and/or `-z defs` with compiling). They are flagged to point these problems out and in case a more serious problem is indicated.

An entire product can be readily examined by appcert (that is, if the product is a collection of many programs and supporting shared objects) by referring appcert to the directories where the product is installed.

To perform its task, appcert constructs a profile of interface dependencies for each object file within the product (whether an executable object or shared object), to determine all the Solaris system interfaces that are depended upon. (Notice that appcert uses the Solaris runtime linker to make this determination.) These dependency profiles are then compared to a definition of the Solaris ABI to identify any interfaces that are Private (unsafe and unstable for application-level use).

appcert generates a simple roll-up report that indicates which of the product's components, if any, had liabilities and what those liabilities were. The report aids developers who are examining their product's release-to-release stability.

Notice that appcert produces complete interface dependency information, both the Public (safe and stable) Solaris interfaces and the Private (non-ABI) interfaces. This information can also be examined for each product component, if you want.

IMPORTANT: appcert must run in the same environment in which the application being checked runs. See NOTES.

Options The following options are supported:

- B If appcert is run in "batch" mode, the output report will contain one line per binary, beginning with PASS if no problems were detected for the binary, FAIL if any problems were found, or INC if the binary could not be completely checked. Do not interpret these labels too literally. For example, PASS just means that none of the appcert warnings were triggered. These strings are flush left and so can be selected via `grep ^FAIL . . .`, and so forth.
- f *infile* Specifies the file *infile* that contains a list of files (one per line) to check. This list is appended to the list determined from the command line operands (see OPERANDS below).
- h Prints out the usage information.
- L appcert examines your product for the presence of shared objects. If it finds some, it appends the directories they reside in to LD_LIBRARY_PATH. Use this flag to prevent appcert from doing this.
- n When searching directories for binaries to check, this option does not follow symbolic links. See [find\(1\)](#).
- S Appends Solaris library directories (that is, /usr/openwin/lib:/usr/dt/lib) to LD_LIBRARY_PATH.
- w *working_dir* Identifies the directory in which to run the library components and create temporary files (default is /tmp).

Operands The following operands are supported:

- { *obj* | *dir* } ... A complete list of objects and/or directories that contain the objects constituting the product to be checked. appcert recursively searches directories looking for object files; non-object files are ignored.

Exit Status The following exit values are returned:

- 0 appcert ran successfully and found no potential binary stability problems.
- 1 appcert failed to run successfully.
- 2 Some of the objects checked have potential binary stability problems.
- 3 No binary objects were located that could be checked.

Limitations If the object file to be examined depends on libraries, those dependencies must be recorded in it (by using the compiler's -l switch).

If the object file to be examined depends on other shared libraries, those libraries must be accessible via `LD_LIBRARY_PATH` or `RPATH` when `appcert` is run.

To check 64-bit applications, the machine must be running the 64-bit Solaris kernel. See [isalist\(1\)](#). Also, the checks for static linking are currently not done on 64-bit applications.

`appcert` cannot examine:

- Object files that are completely or partially statically linked.

Completely statically linked objects are reported as unstable.

- Executable files that do not have execute permission set.

These are skipped. Shared objects without execute permission are not skipped.

- Object files that are `setuid` root.

Due to limitations in [ldd\(1\)](#), these are skipped. Copy and/or change the permissions to check them.

- Non-ELF file executables such as shell scripts.
- Non-C language interfaces to Solaris; for example, C++ and Java.

The code itself need not be in C as long as the calls to Solaris libraries are in C.

Output Files `appcert` records its findings in the following files in the working directory (`/tmp/appcert.?????` by default):

Index	A mapping between checked binaries and the subdirectory in the working directory in which the output specific to that binary can be found.
Report	A copy of the rollup report that was displayed on stdout when <code>appcert</code> was run.
Skipped	A list of binaries that <code>appcert</code> was asked to check but had to skip, along with a brief reason why each was skipped.

In addition, there is per-object information in the subdirectories under `appcert.????/objects/`, in the following files:

<code>check.demoted_symbols</code>	A list of symbols suspected to be demoted Solaris symbols.
<code>check.dynamic.private</code>	A list of private Solaris symbols to which the object makes direct bindings.
<code>check.dynamic.public</code>	A list of public Solaris symbols to which the object makes direct bindings.

<code>check.dynamic.unbound</code>	A list of symbols not bound by the dynamic linker when <code>ldd -r</code> was run. For convenience, <code>ldd</code> output lines containing "file not found" are also included.
<code>summary.dynamic</code>	A pretty-printed summary of dynamic bindings for the objects examined, including tables of Public and Private symbols used from each Solaris library.

Other files are temporary files used internally by `appcert`.

Output Messages

Private Symbol Use Private symbols are functions or data variables in a Solaris library that are not intended for developer or external use. These symbols are interfaces that the Solaris libraries use to call and communicate with one another. They are marked in [pvs\(1\)](#) output with the symbol version name "SUNWprivate".

Private symbols can change their semantic behavior or even disappear altogether ("demoted" or "deprecated" symbols), so your application should not depend upon any of them.

Demoted Symbols Demoted symbols are functions or data variables in a Solaris library that were once private to that library and have been removed (or possibly scoped local to the library) in a later Solaris release. If your application directly calls one of these demoted symbols, it will fail to run (relocation error) on the release in which the symbol was removed and releases thereafter.

In some rare cases, a demoted symbol will return in a later release, but nevertheless there are still some releases on which the application will not run.

Sun Microsystems Inc. performed most of the library scoping in the transition from Solaris 2.5.1 to 2.6. This action was done to increase binary stability. By making these completely internal interfaces invisible (that is, they cannot be dynamically linked against), a developer cannot accidentally or intentionally call these interfaces. For more information, see the [Linker and Libraries Guide](#), in particular the chapter on versioning. This document may be found online at <http://docs.sun.com>.

Unbound Symbols Unbound symbols are library symbols (that is, functions or data) referenced by the application that the dynamic linker could not resolve when `appcert` was run. *Note:* `appcert` does not actually run your application, so some aspect of the environment that affects dynamic linking might not be set properly.

Unbound symbols do not necessarily indicate a potential binary stability problem. They only mean that when `appcert` was run, the runtime dynamic linker could not resolve these symbols.

Unbound symbols might be due to `LD_LIBRARY_PATH` not being correctly set. Make sure it is set, so that all of your binary objects can find all of the libraries they depend on (either your product's own libraries, Solaris libraries, or those of a third party). Then re-run `appcert`.

You might find it useful to write a shell script that sets up the environment correctly and then runs `appcert` on the binaries you want to check.

Another common cause for unbound symbols is when a shared object under test has not recorded its dynamic dependencies, that is, at build time the `-l` switch was *not* supplied to the compiler and `ld(1)`. So the shared object requires that the *executables* that link against it have the correct dependencies recorded.

Notice that such a shared object can either be linked in the standard way (that is, specified at an executable's build time) or dynamically opened (for example, an executable calls `dlopen(3C)` on the shared object sometimes when running). Either case can give rise to unbound symbols when `appcert` is run. The former can usually be resolved by setting `LD_LIBRARY_PATH` appropriately before running `appcert`. The latter (`dlopen`) is usually difficult to resolve. Under some circumstances, you might be able to set `LD_PRELOAD` appropriately to preload the needed libraries, but this procedure does not always work.

How do you know if the environment has been set up correctly so that there will be no unbound symbols? It must be set up so that running `ldd -r` on the binary yields no “file not found” or “symbol not found” errors. See `ld.so.1(1)` and `ldd(1)` for more information on dynamic linking.

In any event, `appcert` flags unbound symbols as a warning in case they might indicate a more serious problem. Unbound symbols can be an indicator of dependencies on demoted symbols (symbols that have been removed from a library or scoped local to it). Dependencies on demoted symbols will lead to serious binary stability problems.

However, setting up the environment properly should remove most unbound symbols. In general, it is good practice to record library dependencies at build time whenever possible because it helps make the binary object better defined and self-contained. Also recommended is using the `-z defs` flag when building shared objects, to force the resolution of all symbols during compilation. See `ld(1)` for more information.

No Bindings Found `appcert` runs `/bin/ldd -r` on each binary object to be tested. It sets the environment variable `LD_DEBUG=“files,bindings”`. (See `ldd(1)` and `ld.so.1(1)` for more information). If that command fails for some reason, `appcert` will have no dynamic symbol binding information and will find “no bindings”.

`appcert` can fail if any of the following is true:

- The binary object does not have read permission.
- The binary object is SUID or SGID and the user does not have sufficient privileges.

- The binary object is an executable without the execute permission bit set.
- The binary object is completely statically linked.
- The binary object has no library dependency information recorded.

Other cases exist as well (for example, out of memory). In general, this flag means that appcert could not completely examine the object due to permissions or environment. Try to modify the permissions or environment so that the dynamic bindings can be recorded.

Obsolete Library An obsolete library is one whose use is deprecated and that might, in some future release, be removed from Solaris altogether. appcert flags these because applications depending on them might not run in future releases of Solaris. All interfaces, including Private ones, in an obsolete library are frozen and will not change.

Use of sys_errlist/sys_nerr Direct use of the symbols `sys_errlist` or `sys_nerr` presents a risk in which reference might be made past the end of the `sys_errlist` array. These symbols are deprecated in 32-bit versions of Solaris and are absent altogether in 64-bit versions. Use [strerror\(3C\)](#) instead.

Use of Strong vs. Weak Symbols The “strong” symbols (for example, `_socket`) associated with “weak” symbols (for example, `socket`) are reserved as private (their behavior could change in the future). Your application should only directly reference the weak symbol (usually the strong symbols begin with “_”).

Note: Under certain build environments, the strong/private symbol dependency gets recorded into your binary instead of the weak/public one, even though the source code doesn't appear to reference the private symbol. Nevertheless, steps should be taken to trace down why this is occurring and fix the dependency.

Notes appcert needs to run in the same environment in which the application being checked runs. Otherwise it might not be able to resolve references correctly to interfaces in the Solaris libraries. Take the following steps:

1. Make sure that `LD_LIBRARY_PATH` and any other aspects of the environment are set to whatever settings are used when the application is run. Also make sure that it contains the directories containing any non-Solaris shared objects that are part of the product, so that they can be found when referenced.
2. Make sure that all the binaries to be checked:
 - Are dynamically linked ELF objects
 - Have execute permission set on executables (this is not necessary for shared objects)
 - Are not SUID root (otherwise you will have to be root to check them; make non-SUID copies and check those if necessary).

You might find it useful to write a shell script that sets up the environment correctly and then runs appcert.

Some potential problems that can be encountered are:

- appcert reports unbound symbols that appear to be part of Solaris libraries.

This is probably caused when the application uses `dlopen(3C)` to access a shared object that does not have its Solaris dependencies recorded. appcert cannot resolve symbol use in such cases, since the dynamic linker is never invoked on the shared object, and there is no other dependency information that could be used to resolve the Solaris symbol bindings. This can also occur with non-Solaris symbols.

To avoid this problem, make sure that when a shared object is built, its dependencies on Solaris libraries are explicitly recorded by using the `-lib` option on the compile line (see `cc(1)` and `ld(1)`).

- appcert reports that the application uses a Solaris private symbol that is not referenced in the application's source code.

This problem is most likely due to static linking of a Solaris library that references that symbol. Since appcert uses the dynamic linker to resolve symbols, statically linked libraries appear to appcert to be part of the application code (which, in a sense, they are). This can also sometimes happen as a result of macro substitution in a Solaris header file.

To avoid this problem, whenever possible do not statically link Solaris library archives into your application.

- appcert does not recognize a library as part of Solaris.

Some obsolete Solaris libraries are so old that they were obsoleted before their symbols could be versioned. Consequently, appcert cannot recognize them as being part of Solaris.

Bugs The use of the terms “public” and “private” as equivalent to “stable” and “unstable” is unfortunately somewhat confusing. In particular, experimental or evolving interfaces are public in the sense that they are documented and their use is encouraged. But they are unstable, because an application built with them might not run on subsequent releases. Thus, they are classified as private for appcert's purposes until they are no longer evolving. Conversely, obsolete interfaces will eventually disappear, and so are unstable, even though they have been public and stable in the past and are still treated as public by appcert. Fortunately, these two situations are rare.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Linker and Libraries Guide

Name apptrace – trace application function calls to Solaris shared libraries

Synopsis apptrace [-f] [-F [!]*tracefromlist*] [-T [!]*tracetolist*]
[-o *outputfile*] [[-tv] [!] *call* , ...] *command*
[*command arguments*]

Description The appt race utility runs the executable program specified by *command* and traces all function calls that the program *command* makes to the Solaris shared libraries. For each function call that is traceable, appt race reports the name of the library interface called, the values of the arguments passed, and the return value.

By default, appt race traces calls directly from the executable object to any of the shared objects it depends on. Indirect calls (that is, calls made between shared objects that the executable depends upon) are not reported by default.

Calls from or to additional shared objects may be traced using the -F or -T options (see below).

The default reporting format is a single line per call, with no formatted printing of arguments passed by reference or of data structures.

Formatted printing providing additional argument details is obtained using the -v option (see below).

By default, every interface provided by a shared object is traced if called. However, the set of interfaces to be traced can be restricted, using the -t and/or -v options.

Since it is generally possible to trace calls between any of the dynamic objects linked at runtime (the executable object and any of the shared objects depended upon), the report of each traced call gives the name of the object from which the call was made.

appt race traces all of the procedure calls that occur between dynamic objects via the procedure linkage table, so only those procedure calls which are bound via the table will be traced. See the [Linker and Libraries Guide](#).

Options The following options are supported:

- f Follows all children created by [fork\(2\)](#). This option will also cause the process id to be printed at the beginning of each line.
- F [!]*tracefromlist* Traces calls from a comma-separated list of shared objects. Only calls from these shared objects will be traced. The default is to trace calls from the main executable only. Only the basename of the shared object is required. For example, *libc* will match */usr/lib/libc.so.1*. Additionally, shell style wildcard characters are supported as described in [fnmatch\(5\)](#). A list preceded by a "!" defines a list of objects from which calls should not be traced. If the tracing of calls from *command* is required, then *command* must be a member of *tracefromlist*.

<code>-o outputfile</code>	apptrace output will be directed to the <i>outputfile</i> . By default, apptrace output is placed on the stderr stream of the process being traced.
<code>-t [!]call, . . .</code>	Traces or excludes function calls. Those calls specified in the comma-separated list <i>call</i> are traced. If the list begins with a <i>!</i> , the specified function calls are excluded from the trace output. The default is <code>-t *</code> . The use of shell style wildcards is allowed.
<code>-T [!]tracetolist</code>	Traces calls to a comma-separated list of shared objects. The default is to trace calls to all shared objects. As above, the basename is all that is required and wildcarding is allowed. A list preceded by a <i>!</i> denotes a list of objects to which calls should not be traced.
<code>-v [!]call, . . .</code>	Provides verbose, formatted output of the arguments and return values of the function calls specified (as above in the <code>-t</code> option). Unlike truss(1) , calls named by the <code>-v</code> option do not have to be named by the <code>-t</code> option. For example, <code>apptrace -v open</code> is equivalent to <code>truss -t open -v open</code> .

Examples EXAMPLE 1 Tracing the date command

```
% apptrace date
-> date      -> libc.so.1:atexit(0xff3bf9ac, 0x22000, 0x0) ** NR
-> date      -> libc.so.1:atexit(0x11550, 0xfefeeef80, 0xab268) ** NR
-> date      -> libc.so.1:setlocale(0x6, 0x11560, 0x0) ** NR
-> date      -> libc.so.1:textdomain(0x11564, 0xfefce156, 0xff160200) ** NR
-> date      -> libc.so.1:int getopt(int = 0x1,
                    const char * = 0xffbffa5c,
                    const char * = 0x11574 "a:u")
<- date      -> libc.so.1:getopt() = 0xffffffff
-> date      -> libc.so.1:time_t time(time_t * = 0x225c0)
<- date      -> libc.so.1:time() = 0x41ab6e82
-> date      -> libc.so.1:char * nl_langinfo(nl_item = 0x3a)
<- date      -> libc.so.1:nl_langinfo() = 0xfefd3e10
-> date      -> libc.so.1:struct tm * localtime(const time_t * = 0x225c0)
<- date      -> libc.so.1:localtime() = 0xff160240
-> date      -> libc_psr.so.1:memcpy(0xffbff9cc, 0xff160240, 0x24) ** NR
-> date      -> libc.so.1:size_t strftime(char * = 0x225c4 "",
                    size_t = 0x400,
                    const char * = 0xfefd3e10 "%a %b %e %T %Z %Y",
                    const struct tm * = 0xffbff9cc)
<- date      -> libc.so.1:strftime() = 0x1c
-> date      -> libc.so.1:int puts(const char * = 0x225c4
                    "Mon Nov 29 10:46:26 PST 2004")
                    Mon Nov 29 10:46:26 PST 2004
<- date      -> libc.so.1:puts() = 0x1d
-> date      -> libc.so.1:exit(0x0, 0x22400, 0x0) ** NR
```

EXAMPLE 2 Tracing a specific set of interfaces with verbosity set**% apptrace -v localtime,strftime,puts date**

```

-> date      -> libc.so.1:struct tm * localtime(const time_t * = 0x225c0)
    arg0 = (const time_t *) 0x225c0
    return = (struct tm *) 0xff160280 (struct tm) {
    tm_sec: (int) 0x4
    tm_min: (int) 0x34
    tm_hour: (int) 0xa
    tm_mday: (int) 0x1d
    tm_mon: (int) 0xa
    tm_year: (int) 0x68
    tm_wday: (int) 0x1
    tm_yday: (int) 0x14d
    tm_isdst: (int) 0
    }
<- date      -> libc.so.1:localtime() = 0xff160280
-> date      -> libc.so.1:size_t strftime(char * = 0x225c4 "",
    size_t = 0x400,
    const char * = 0xfefd3e10 "%a %b %e %T %Z %Y",
    const struct tm * = 0xffbff99c)
    arg0 = (char *) 0x225c4 ""
    arg1 = (size_t) 0x400
    arg2 = (const char *) 0xfefd3e10 "%a %b %e %T %Z %Y"
    arg3 = (const struct tm *) 0xffbff99c (struct tm) {
    tm_sec: (int) 0x4
    tm_min: (int) 0x34
    tm_hour: (int) 0xa
    tm_mday: (int) 0x1d
    tm_mon: (int) 0xa
    tm_year: (int) 0x68
    tm_wday: (int) 0x1
    tm_yday: (int) 0x14d
    tm_isdst: (int) 0
    }
    return = (size_t) 0x1c
<- date      -> libc.so.1:strftime() = 0x1c
-> date      -> libc.so.1:int puts(const char * = 0x225c4
    "Mon Nov 29 10:52:04 PST 2004")
    arg0 = (const char *) 0x225c4 "Mon Nov 29 10:52:04 PST 2004"
    Mon Nov 29 10:52:04 PST 2004
    return = (int) 0x1d
<- date      -> libc.so.1:puts() = 0x1d

```

**** NR** - The return value of a function call will not be traced.

Files Basic runtime support for `appt race` is provided by the link auditing feature of the Solaris runtime linker ([ld.so.1\(1\)](#)) and the `appt race` command's use of this facility relies on an auditing object (`appt race.so.1`) kept in `/usr/lib/abi`.

Limitations In general, `appt race` cannot trace calls to functions accepting variable argument lists. There has been some clever coding in several specific cases to work around this limitation, most notably in the `printf` and `scanf` families.

The `appt race` utility can not trace the return value of a function call whose return type is a `struct` or `union`.

Functions that attempt to probe the stack or otherwise extract information about the caller cannot be traced. Some examples are `[gs]etcontext()`, `[sig]longjmp()`, `[sig]setjmp()`, and `vfork()`.

Functions such as [exit\(2\)](#) that do not return will not be traced for their return values.

For security reasons, only those processes with appropriate privileges can use `appt race` to trace `setuid/setgid` programs.

Tracing functions whose usage requires the inclusion of `<varargs.h>`, such as [vwprintw\(3XCURSES\)](#) and [vwscanw\(3XCURSES\)](#), will not provide formatted printing of arguments.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Unstable

See Also [ld.so.1\(1\)](#), [truss\(1\)](#), [vwprintw\(3XCURSES\)](#), [vwscanw\(3XCURSES\)](#), [attributes\(5\)](#), [fnmatch\(5\)](#)

Linker and Libraries Guide

Name apropos – locate commands by keyword lookup

Synopsis apropos *keyword*...

Description The apropos utility displays the man page name, section number, and a short description for each man page whose NAME line contains *keyword*. This information is contained in the /usr/share/man/windex database created by [catman\(1M\)](#). If [catman\(1M\)](#) was not run, or was run with the -n option, apropos fails. Each word is considered separately and the case of letters is ignored. Words which are part of other words are considered; for example, when looking for 'compile', apropos finds all instances of 'compiler' also.

apropos is actually just the -k option to the [man\(1\)](#) command.

Examples **EXAMPLE 1** To find a man page whose NAME line contains a keyword

Try

```
example% apropos password
```

and

```
example% apropos editor
```

If the line starts '*filename(section) . . .*' you can run

```
man -s section filename
```

to display the man page for *filename*.

EXAMPLE 2 To find the man page for the subroutine printf()

Try

```
example% apropos format
```

and then

```
example% man -s 3s printf
```

to get the manual page on the subroutine printf().

Files /usr/share/man/windex table of contents and keyword database

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	Enabled

See Also [man\(1\)](#), [whatis\(1\)](#), [catman\(1M\)](#), [attributes\(5\)](#)

Diagnostics /usr/share/man/windex: No such file or directory
This database does not exist. [catman\(1M\)](#) must be run to create it.

Name ar – maintain portable archive or library

Synopsis /usr/ccs/bin/ar -d [-Vv] *archive file*...

/usr/ccs/bin/ar -m [-abiVv] [*posname*] *archive file*...

/usr/ccs/bin/ar -p [-sVv] *archive* [*file*]...

/usr/xpg4/bin/ar -x [-CsTVv] *archive* [*file*]...

Description The ar utility maintains groups of files combined into a single archive file. Its main use is to create and update library files. However, it can be used for any similar purpose. The magic string and the file headers used by ar consist of printable ASCII characters. If an archive is composed of printable files, the entire archive is printable.

When ar creates an archive, it creates headers in a format that is portable across all machines. The portable archive format and structure are described in detail in [ar.h\(3HEAD\)](#). The archive symbol table described there is used by the link editor [ld\(1\)](#) to effect multiple passes over libraries of object files in an efficient manner. An archive symbol table is only created and maintained by ar when there is at least one object file in the archive. The archive symbol table is in a specially named file that is always the first file in the archive. This file is never mentioned or accessible to the user. Whenever the ar command is used to create or update the contents of such an archive, the symbol table is rebuilt. The -s option described below forces the symbol table to be rebuilt.

Options The following options are supported:

- a Positions new *files* in *archive* after the file named by the *posname* operand.
- b Positions new *files* in *archive* before the file named by the *posname* operand.
- c Suppresses the diagnostic message that is written to standard error by default when *archive* is created.

- C Prevents extracted files from replacing like-named files in the file system. This option is useful when -T is also used to prevent truncated file names from replacing files with the same prefix.
- d Deletes one or more *files* from *archive*.
- i Positions new *files* in *archive* before the file named by the *posname* operand. This option is equivalent to -b.
- m Moves *files*. If -a, -b, or -i with the *posname* operand are specified, the -m option moves *files* to the new position. Otherwise, -m moves *files* to the end of *archive*.
- p Prints the contents of *files* in *archive* to standard output. If no *files* are specified, the contents of all files in *archive* are written in the order of the archive.
- q Quickly appends *files* to the end of *archive*. Positioning options -a, -b, and -i are invalid. The command does not check whether the added *files* are already in *archive*. This option is useful to avoid quadratic behavior when creating a large archive piece-by-piece.
- r Replaces or adds *files* in *archive*. If *archive* does not exist, a new archive file is created and a diagnostic message is written to standard error, unless the -c option is specified. If no *files* are specified and the *archive* exists, the results are undefined. Files that replace existing files do not change the order of the archive. If the -u option is used with the -r option, only those files with dates of modification later than the archive files are replaced. If the -a, -b, or -i option is used, the *posname* argument must be present and specifies that new files are to be placed after (-a) or before (-b or -i) *posname*. Otherwise, the new files are placed at the end.
- s Forces the regeneration of the archive symbol table even if ar is not invoked with an option that will modify the archive contents. This command is useful to restore the archive symbol table after the `strip(1)` command has been used on the archive.
- t Prints a table of contents of *archive*. The files specified by the *file* operands are included in the written list. If no *file* operands are specified, all files in *archive* are included in the order of the archive.
- T Allows file name truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long is an error. In that case, a diagnostic message is written and the file is not extracted.
- u Updates older files. When used with the -r option, files within *archive* are replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file within *archive*.
- V Prints its version number on standard error.

<code>/usr/ccs/bin/ar -v</code>	Gives verbose output. When used with options <code>-d</code> , <code>-r</code> , or <code>-x</code> , the <code>-v</code> option writes a detailed file-by-file description of the archive creation and the constituent <i>files</i> , and maintenance activity. When used with <code>-p</code> , <code>-v</code> writes the name of the file to the standard output before writing the file itself to the standard output. When used with <code>-t</code> , <code>-v</code> includes a long listing of information about the files within the archive. When used with <code>-x</code> , <code>-v</code> prints the filename preceding each extraction. When writing to an archive, <code>-v</code> writes a message to the standard error.
<code>/usr/xpg4/bin/ar -v</code>	Same as the <code>/usr/ccs/bin/ar</code> version, except when writing to an archive, no message is written to the standard error.
<code>-x</code>	Extracts the files named by the <i>file</i> operands from <i>archive</i> . The contents of <i>archive</i> are not changed. If no <i>file</i> operands are given, all files in <i>archive</i> are extracted. If the file name of a file extracted from <i>archive</i> is longer than that supported in the directory to which it is being extracted, the results are undefined. The modification time of each <i>file</i> extracted is set to the time <i>file</i> is extracted from <i>archive</i> .

Operands The following operands are supported:

<i>archive</i>	A path name of the archive file.
<i>file</i>	A path name. Only the last component is used when comparing against the names of files in the archive. If two or more <i>file</i> operands have the same last path name component (see basename(1)), the results are unspecified. The implementation's archive format will not truncate valid file names of files added to or replaced in the archive.
<i>posname</i>	The name of a file in the archive file, used for relative positioning. See options <code>-m</code> and <code>-r</code> .

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ar`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

<code>TMPDIR</code>	Determine the pathname that overrides the default directory for temporary files, if any.
<code>TZ</code>	Determine the timezone used to calculate date and time strings written by <code>ar -tv</code> . If <code>TZ</code> is unset or null, an unspecified default timezone is used.

Exit Status The following exit values are returned:

<code>0</code>	Successful completion.
<code>>0</code>	An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/ccs/bin/ar	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWbtool
	Interface Stability	Stable

/usr/xpg4/bin/ar	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	Interface Stability	Standard

See Also [basename\(1\)](#), [cc\(1B\)](#), [cpio\(1\)](#), [ld\(1\)](#), [lorder\(1\)](#), [strip\(1\)](#), [tar\(1\)](#), [ar.h\(3HEAD\)](#), [a.out\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes If the same file is mentioned twice in an argument list, it may be put in the archive twice.

By convention, archives are suffixed with “.a”.

When an archive file contains a member file whose class is ELF_CLASS64, archive file members may be padded so the ELF_CLASS64 files will be placed in an 8-byte boundary. Only the ELF object files will be padded, if needed. The padding character is “\n”.

Name arch – display the architecture of the current host

Synopsis arch [-k | *archname*]

Description The arch utility displays the application architecture of the current host system. Due to extensive historical use of this command without any options, all SunOS 5.x SPARC based systems will return "sun4" as their application architecture. Use of this command is discouraged. See NOTES section below.

Systems can be broadly classified by their *architectures*, which define what executables will run on which machines. A distinction can be made between *kernel* architecture and *application* architecture (or, commonly, just “architecture”). Machines that run different kernels due to underlying hardware differences may be able to run the same application programs.

Options -k Displays the kernel architecture, such as sun4u. This defines which specific SunOS kernel will run on the machine, and has implications only for programs that depend on the kernel explicitly (for example, [ps\(1\)](#)).

Operands The following operand is supported:

archname Use *archname* to determine whether the application binaries for this application architecture can run on the current host system. The *archname* must be a valid application architecture, such as sun4, i86pc, and so forth.

If *application* binaries for *archname* can run on the current host system, TRUE (0) is returned. Otherwise, FALSE (1) is returned.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [mach\(1\)](#), [ps\(1\)](#), [uname\(1\)](#), [attributes\(5\)](#)

Notes This command is provided for compatibility with previous releases and its use is discouraged. Instead, the uname command is recommended. See [uname\(1\)](#) for usage information.

Name as – assembler

Synopsis

```
SPARC as [-b] [-i] [-K {pic,PIC}] [-L] [-m] [-n] [-o outfile]
        [-P] [-Dname] [-Dname=def] [-Ipath] [-Uname]... [-q]
        [-Qy | n] [-s] [-S [a | b | c | l | A | B | C | L]]
        [-T] [-V]
        [-xarch=v7 | -xarch=v8 | -xarch=v8a | -xarch=v8plus |
        -xarch=v8plusa | -xarch=v8plusb | -xarch=v8plusd |
        -xarch=v8plusv | -xarch=v9 | -xarch=v9a |
        -xarch=v9b | -xarch=v9d | -xarch=v9v]
        [-xF] [-Y dirname] filename...

x86 as [-b] [-i] [-K PIC] [-L] [-m] [-n] [-o outfile] [-P]
        [-Dname] [-Dname=def] [-Ipath] [-Uname]... [-Qy | n]
        [-s] [-S [a | b | c | l | A | B | C | L]] [-T] [-V]
        [-xarch=generic64 | -xarch=amd64] [-Y dirname]
        [-xmodel= [ SMALL | KERNEL ]] filename...
```

Description The as command creates object files from assembly language source files.

Options

Common Options The following flags are common to both SPARC and x86. They can be specified in any order:

-b	Generates extra symbol table information.
-i	Ignore line number information from preprocessor.
-K <i>pic</i> PIC	Generates position-independent code.
-L	Saves all symbols, including temporary labels that are normally discarded to save space, in the ELF symbol table.
-m	Runs the m4(1) macro processor on the input to the assembler.
-n	Suppresses all the warnings while assembling.
-o <i>outfile</i>	Puts the output of the assembly in <i>outfile</i> . By default, the output file name is formed by removing the .s suffix, if there is one, from the input file name and appending a .o suffix.
-P	Runs cpp(1) , the C preprocessor, on the files being assembled. The preprocessor is run separately on each input file, not on their concatenation. The preprocessor output is passed to the assembler.
-D <i>name</i>	
-D <i>name</i> = <i>def</i>	When the -P option is in effect, these options are passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, they are ignored.

-I <i>path</i>	When the -P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.
-U <i>name</i>	When the -P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.
-Q <i>y</i> <i>n</i>	If <i>y</i> is specified, this option produces the assembler version information in the comment section of the output object file. If <i>n</i> is specified, the information is suppressed.
-s	Places all stabs in the .stabs section. By default, stabs are placed in stabs.excl sections, which are stripped out by the static linker, ld(1) , during final execution. When the -s option is used, stabs remain in the final executable because .stab sections are not stripped by the static linker.
-S[<i>a b c l A B C L</i>]	<p>Produces a disassembly of the emitted code to the standard output. Adding each of the following characters to the -S option produces:</p> <ul style="list-style-type: none"><i>a</i> disassembling with address<i>b</i> disassembling with “.bof”<i>c</i> disassembling with comments<i>l</i> disassembling with line numbers <p>Capital letters turn the switch off for the corresponding option.</p>
-T	This is a migration option for 4.x assembly files to be assembled on 5.x systems. With this option, the symbol names in 4.x assembly files are interpreted as 5.x symbol names.
-V	Writes the version number of the assembler being run on the standard error output.
-xF	Allows function reordering by the Performance Analyzer. If you compile with the -xF option, and then run the Performance Analyzer, you can generate a map file that shows an optimized order for the functions. The subsequent link to build the executable file can be directed to use that map file by using the linker -M <i>mapfile</i> option. It places each function from the executable file into a separate section.
-Y <i>dirname</i>	Specify directory m4 and/or cm4def.

Options for SPARC only	-q	Performs a quick assembly. When the -q option is used, many error checks are not performed. This option disables many error checks. Use of this option to assemble handwritten assembly language is not recommended.
	-xarch=v7	This option instructs the assembler to accept instructions defined in the SPARC version 7 (V7) architecture. The resulting object code is in ELF format.
	-xarch=v8	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format.
	-xarch=v8a	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions and less the <i>fmuld</i> instruction. The resulting object code is in ELF format. This is the default choice of the -xarch= <i>options</i> .
	-xarch=v8plus	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format. It does not execute on a Solaris V8 system (a machine with a V8 processor). It executes on a Solaris V8+ system. This combination is a SPARC 64-bit processor and a 32-bit OS.
	-xarch=v8plusa	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions, plus the instructions in the Visual Instruction Set (VIS). The resulting object code is in V8+ ELF format. It does not execute on a Solaris V8 system (a machine with a V8 processor). It executes on a Solaris V8+ system
	-xarch=v8plusb	This option enables the assembler to accept instructions defined in the SPARC-V9 architecture, plus the instructions in the Visual Instruction Set (VIS), with UltraSPARC-III extensions. The resulting object code is in V8+ ELF32 format.
	-xarch=v8plUSD	This option enables the assembler to accept instructions DEFINed in UltraSPARC Architecture 2009. The resulting object code is in V8+ ELF32 format.
	-xarch=v8plusv	This option enables the assembler to accept instructions defined in UltraSPARC Architecture 2005, including the extensions dealing with the sun4v virtual machine model. The resulting object code is in V8+ ELF32 format.
	-xarch=v9	This option limits the instruction set to the SPARC-V9 architecture. The resulting .o object files are in 64-bit ELF format and can only be linked

with other object files in the same format. The resulting executable can only be run on a 64-bit SPARC processor running 64-bit Solaris with the 64-bit kernel.

- xarch=v9a This option limits the instruction set to the SPARC-V9 architecture, adding the Visual Instruction Set (VIS) and extensions specific to UltraSPARC processors. The resulting .o object files are in 64-bit ELF format and can only be linked with other object files in the same format. The resulting executable can only be run on a 64-bit SPARC processor running 64-bit Solaris with the 64-bit kernel.
- xarch=v9b This option enables the assembler to accept instructions defined in the SPARC-V9 architecture, plus the Visual Instruction Set (VIS), with UltraSPARC-III extensions. The resulting .o object files are in ELF64 format and can only be linked with other V9 object files in the same format. The resulting executable can only be run on a 64-bit processor running a 64-bit Solaris operating environment with the 64-bit kernel.
- xarch=v9d This option enables the assembler to accept instructions defined in UltraSPARC Architecture 2009. The resulting object code is in ELF64 format.
- xarch=v9v This option enables the assembler to accept instructions defined in UltraSPARC Architecture 2005, including the extensions dealing with the sun4v virtual machine model. The resulting object code is in ELF64 format.

- Options for x86 Only
- xarch>=generic64 Limits the instruction set to AMD64. The resulting object code is in 64-bit ELF format.
 - xarch=amd64 Limits the instruction set to AMD64. The resulting object code is in 64-bit ELF format.
 - xmodel=[SMALL | KERNEL] For AMD64 only, generate R_X86_64_32S relocatable type for static data access under KERNEL. Otherwise, generate R_X86_64_32 under SMALL. SMALL is the default.

Operands The following operand is supported:

filename Assembly language source file

Environment Variables TMPDIR The as command normally creates temporary files in the directory /tmp. Another directory can be specified by setting the environment variable TMPDIR to the chosen directory. (If TMPDIR is not a valid directory, then as uses /tmp).

Files By default, as creates its temporary files in /tmp.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

See Also [cc\(1B\)](#), [cpp\(1\)](#), [ld\(1\)](#), [m4\(1\)](#), [nm\(1\)](#), [strip\(1\)](#), [tmpnam\(3C\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

dbx and analyzer manual pages available with Sun Studio documentation.

Notes If the `-m` option, which invokes the [m4\(1\)](#) macro processor, is used, keywords for `m4` cannot be used as symbols (variables, functions, labels) in the input file, since `m4` cannot determine which keywords are assembler symbols and which keywords are real `m4` macros.

Whenever possible, access the assembler through a compilation system interface program such as [cc\(1B\)](#).

All undefined symbols are treated as global.

Name asa – convert FORTRAN carriage-control output to printable form

Synopsis asa [-f] [*file*]...

Description The asa utility will write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences.

The first character of every line will be removed from the input, and the following actions will be performed.

If the character removed is:

SPACE The rest of the line will be output without change.

0 It is replaced by a newline control sequence followed by the rest of the input line.

1 It is replaced by a newpage control sequence followed by the rest of the input line.

+ It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.

For any other character in the first column of an input line, asa skips the character and prints the rest of the line unchanged.

If asa is called without providing a *filename*, the standard input is used.

Options The following option is supported:

-f Start each file on a new page.

Operands The following operand is supported:

file A pathname of a text file used for input. If no file operands are specified, or ' - ' is specified, then the standard input will be used.

Examples The command

```
a.out | asa | lp
```

converts output from a.out to conform with conventional printers and directs it through a pipe to the printer.

The command

```
asa output
```

shows the contents of file *output* on a terminal as it would appear on a printer.

The following program is used in the next two examples:

```
write(*, '(" Blank")')
write(*, '("0Zero ")')
```

```

write(*,'("+      Plus ")')
write(*,'("10ne  ")')
end

```

Both of the following examples produce two pages of output:

Page 1:

Blank

ZeroPlus

Page 2:

One

EXAMPLE 1 Using actual files

```

a.out > MyOutputFile
asa < MyOutputFile | lp

```

EXAMPLE 2 Using only pipes

```

a.out | asa | lp

```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of asa: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 All input files were output successfully.
 >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

See Also [lp\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name at, batch – execute commands at a later time

Synopsis /usr/bin/at [-c | -k | -s] [-m] [-f *file*] [-p *project*]
 [-q *queue**name*] -t *time*
 /usr/bin/at [-c | -k | -s] [-m] [-f *file*] [-p *project*]
 [-q *queue**name*] *timespec*...
 /usr/bin/at -l [-p *project*] [-q *queue**name*] [*at_job_id* ...]
 /usr/bin/at -r *at_job_id* ...
 /usr/bin/batch [-p *project*]
 /usr/xpg4/bin/at [-c | -k | -s] [-m] [-f *file*] [-p *project*]
 [-q *queue**name*] -t *time*
 /usr/xpg4/bin/at [-c | -k | -s] [-m] [-f *file*] [-p *project*]
 [-q *queue**name*] *timespec*...
 /usr/xpg4/bin/at -l [-p *project*] [-q *queue**name*]
 [*at_job_id* ...]
 /usr/xpg4/bin/at -r *at_job_id* ...
 /usr/xpg4/bin/batch [-p *project*]

Description

at The at utility reads commands from standard input and groups them together as an *at-job*, to be executed at a later time.

The at-job is executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask (see [umask\(1\)](#)), and system resource limits (for sh and ksh only, see [ulimit\(1\)](#)) in effect when the at utility is executed is retained and used when the at-job is executed.

When the at-job is submitted, the *at_job_id* and scheduled time are written to standard error. The *at_job_id* is an identifier that is a string consisting solely of alphanumeric characters and the period character. The *at_job_id* is assigned by the system when the job is scheduled such that it uniquely identifies a particular job.

User notification and the processing of the job's standard output and standard error are described under the -m option.

Users are permitted to use at and batch (see below) if their name appears in the file /usr/lib/cron/at.allow. If that file does not exist, the file /usr/lib/cron/at.deny is checked to determine if the user should be denied access to at. If neither file exists, only a user with the solaris.jobs.user authorization is allowed to submit a job. If only at.deny exists and is empty, global usage is permitted. The at.allow and at.deny files consist of one user name per line.

cron and at jobs are not be executed if the user's account is locked. Only accounts which are not locked as defined in [shadow\(4\)](#) will have their job or process executed.

batch The batch utility reads commands to be executed at a later time.

Commands of the forms:

```
/usr/bin/batch [-p project]
/usr/xpg4/bin/batch [-p project]
```

are respectively equivalent to:

```
/usr/bin/at -q b [-p project] now
/usr/xpg4/bin/at -q b -m [-p project] now
```

where queue b is a special at queue, specifically for batch jobs. Batch jobs are submitted to the batch queue for immediate execution. Execution of submitted jobs can be delayed by limits on the number of jobs allowed to run concurrently. See [queuedefs\(4\)](#).

Options If the -c, -k, or -s options are not specified, the SHELL environment variable by default determines which shell to use.

For /usr/xpg4/bin/at and /usr/xpg4/bin/batch, if SHELL is unset or NULL, /usr/xpg4/bin/sh is used.

For usr/bin/at and /usr/bin/batch, if SHELL is unset or NULL, /bin/sh is used.

The following options are supported:

- c C shell. [csh\(1\)](#) is used to execute the at-job.
- k Korn shell. [ksh\(1\)](#) is used to execute the at-job.
- s Bourne shell. [sh\(1\)](#) is used to execute the at-job.
- f *file* Specifies the path of a file to be used as the source of the at-job, instead of standard input.
- l (The letter ell.) Reports all jobs scheduled for the invoking user if no *at_job_id* operands are specified. If *at_job_ids* are specified, reports only information for these jobs.
- m Sends mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job are mailed to the user as well, unless redirected elsewhere. Mail is sent even if the job produces no output.

If -m is not used, the job's standard output and standard error is provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the user is not notified of the job's completion.

- p *project*** Specifies under which project the `at` or batch job is run. When used with the `-l` option, limits the search to that particular project. Values for *project* is interpreted first as a project name, and then as a possible project ID, if entirely numeric. By default, the user's current project is used.
- q *queue*** Specifies in which queue to schedule a job for submission. When used with the `-l` option, limits the search to that particular queue. Values for *queue* are limited to the lower case letters a through z. By default, `at-jobs` are scheduled in queue `a`. In contrast, queue `b` is reserved for batch jobs. Since queue `c` is reserved for cron jobs, it can not be used with the `-q` option.
- r *at_job_id*** Removes the jobs with the specified *at_job_id* operands that were previously scheduled by the `at` utility.
- t *time*** Submits the job to be run at the time specified by the *time* option-argument, which must have the format as specified by the [touch\(1\)](#) utility.

Operands The following operands are supported:

- at_job_id*** The name reported by a previous invocation of the `at` utility at the time the job was scheduled.
- timespec*** Submit the job to be run at the date and time specified. All of the *timespec* operands are interpreted as if they were separated by space characters and concatenated. The date and time are interpreted as being in the timezone of the user (as determined by the `TZ` variable), unless a timezone name appears as part of *time* below.

In the "C" locale, the following describes the three parts of the time specification string. All of the values from the `LC_TIME` categories in the "C" locale are recognized in a case-insensitive manner.

- time*** The *time* can be specified as one, two or four digits. One- and two-digit numbers are taken to be hours, four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning *hour:minute*. An AM/PM indication (one of the values from the `am_pm` keywords in the `LC_TIME` locale category) can follow the time; otherwise, a 24-hour clock time is understood. A timezone name of GMT, UCT, or ZULU (case insensitive) can follow to specify that the time is in Coordinated Universal Time. Other timezones can be specified using the `TZ` environment variable. The *time* field can also be one of the following tokens in the "C" locale:

midnight Indicates the time 12:00 am (00:00).

noon	Indicates the time 12:00 pm.				
now	Indicate the current day and time. Invoking at now submits an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).				
<i>date</i>	An optional <i>date</i> can be specified as either a month name (one of the values from the mon or abmon keywords in the LC_TIME locale category) followed by a day number (and possibly year number preceded by a comma) or a day of the week (one of the values from the day or abday keywords in the LC_TIME locale category). Two special days are recognized in the "C" locale: <table> <tr> <td>today</td><td>Indicates the current day.</td></tr> <tr> <td>tomorrow</td><td>Indicates the day following the current day.</td></tr> </table> <p>If no <i>date</i> is given, today is assumed if the given time is greater than the current time, and tomorrow is assumed if it is less. If the given month is less than the current month (and no year is given), next year is assumed.</p>	today	Indicates the current day.	tomorrow	Indicates the day following the current day.
today	Indicates the current day.				
tomorrow	Indicates the day following the current day.				
<i>increment</i>	The optional <i>increment</i> is a number preceded by a plus sign (+) and suffixed by one of the following: minutes, hours, days, weeks, months, or years. (The singular forms are also accepted.) The keyword next is equivalent to an increment number of + 1. For example, the following are equivalent commands: <pre>at 2pm + 1 week at 2pm next week</pre>				

Usage The format of the at command line shown here is guaranteed only for the "C" locale. Other locales are not supported for midnight, noon, now, mon, abmon, day, abday, today, tomorrow, minutes, hours, days, weeks, months, years, and next.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps and priority inherited from the invoking environment are lost.

Examples

```
at EXAMPLE1 Typical Sequence at a Terminal
This sequence can be used at a terminal:

$ at -m 0730 tomorrow
sort < file >outfile
<EOT>
```

EXAMPLE 2 Redirecting Output

This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
$ at now + 1 hour <<!  
diff file1 file2 2>&1 >outfile | mailx mygroup
```

EXAMPLE 3 Self-rescheduling a Job

To have a job reschedule itself, `at` can be invoked from within the `at`-job. For example, this "daily-processing" script named `my.daily` runs every day (although `crontab` is a more appropriate vehicle for such work):

```
# my.daily runs every day  
at now tomorrow < my.daily  
daily-processing
```

EXAMPLE 4 Various Time and Operand Presentations

The spacing of the three portions of the "C" locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentations include:

```
at 0815am Jan 24  
at 8 :15amjan24  
at now "+ 1day"  
at 5 pm FRIDay  
at '17  
    utc+  
    30minutes'
```

batch **EXAMPLE 5** Typical Sequence at a Terminal

This sequence can be used at a terminal:

```
$ batch  
sort <file >outfile  
<EOT>
```

EXAMPLE 6 Redirecting Output

This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
$ batch <<!  
diff file1 file2 2>&1 >outfile | mailx mygroup  
!
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `at` and `batch`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `LC_TIME`.

DATMSK	If the environment variable DATMSK is set, at uses its value as the full path name of a template file containing format strings. The strings consist of format specifiers and text characters that are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable LANG or LC_TIME. The list of allowable format specifiers is located in the getdate(3C) manual page. The formats described in the OPERANDS section for the <i>time</i> and <i>date</i> arguments, the special names noon, midnight, now, next, today, tomorrow, and the <i>increment</i> argument are not recognized when DATMSK is set.
SHELL	Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or NULL, sh is used. If it is set to a value other than sh, the implementation uses that shell; a warning diagnostic is printed telling which shell will be used.
TZ	Determine the timezone. The job is submitted for execution at the time specified by <i>timespec</i> or -t <i>time</i> relative to the timezone specified by the TZ variable. If <i>timespec</i> specifies a timezone, it overrides TZ. If <i>timespec</i> does not specify a timezone and TZ is unset or NULL, an unspecified default timezone is used.

Exit Status The following exit values are returned:

0	The at utility successfully submitted, removed or listed a job or jobs.
>0	An error occurred, and the job will not be scheduled.

Files	/usr/lib/cron/at.allow	names of users, one per line, who are authorized access to the at and batch utilities
	/usr/lib/cron/at.deny	names of users, one per line, who are denied access to the at and batch utilities

See Also [auths\(1\)](#), [crontab\(1\)](#), [csh\(1\)](#), [date\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [touch\(1\)](#), [ulimit\(1\)](#), [umask\(1\)](#), [cron\(1M\)](#), [getdate\(3C\)](#), [auth_attr\(4\)](#), [shadow\(4\)](#), [queuedefs\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes Regardless of queue used, [cron\(1M\)](#) has a limit of 100 jobs in execution at any time.

There can be delays in `cron` at job execution. In some cases, these delays can compound to the point that `cron` job processing appears to be hung. All jobs are executed eventually. When the delays are excessive, the only workaround is to kill and restart `cron`.

Name atq – display the jobs queued to run at specified times

Synopsis atq [-c] [-n] [*username*]...

Description The atq utility displays the at jobs queued up for the current user. [at\(1\)](#) is a utility that allows users to execute commands at a later date. If invoked by a user with the `solaris.jobs.admin` authorization, atq will display all jobs in the queue.

If no options are given, the jobs are displayed in chronological order of execution.

When an authorized user invokes atq without specifying *username*, the entire queue is displayed; when a *username* is specified, only those jobs belonging to the named user are displayed.

Options The following options are supported:

- c Displays the queued jobs in the order they were created (that is, the time that the at command was given).
- n Displays only the total number of jobs currently in the queue.

Files /var/spool/cron/atjobs spool area for at jobs.

Availability	SUNWcsu

See Also [at\(1\)](#), [atrm\(1\)](#), [auths\(1\)](#), [cron\(1M\)](#), [auth_attr\(4\)](#), [attributes\(5\)](#)

Name atrm – remove jobs spooled by at or batch

Synopsis atrm [-afi] [*job #*] [*user*]...

Description The atrm utility removes delayed-execution jobs that were created with the [at\(1\)](#) command, but have not yet executed. The list of these jobs and associated job numbers can be displayed by using [atq\(1\)](#).

atrm removes each job-number you specify, and/or all jobs belonging to the user you specify, provided that you own the indicated jobs.

You can only remove jobs belonging to other users if you have `solaris.jobs.admin` privileges.

Options The following options are supported:

- a All. Removes all unexecuted jobs that were created by the current user. If invoked by the privileged user, the entire queue will be flushed.
- f Force. All information regarding the removal of the specified jobs is suppressed.
- i Interactive. atrm asks if a job should be removed. If you respond with a y, the job will be removed.

Files /var/spool/cron/atjobs spool area for at jobs

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name audioconvert – convert audio file formats

Synopsis audioconvert [-pF] [-f *outfmt*] [-o *outfile*]
 [[-i *infmt*] [*file*]...] ...

Description audioconvert converts audio data between a set of supported audio encodings and file formats. It can be used to compress and decompress audio data, to add audio file headers to raw audio data files, and to convert between standard data encodings, such as -law and linear PCM.

If no filenames are present, audioconvert reads the data from the standard input stream and writes an audio file to the standard output. Otherwise, input files are processed in order, concatenated, and written to the output file.

Input files are expected to contain audio file headers that identify the audio data format. If the audio data does not contain a recognizable header, the format must be specified with the -i option, using the rate, encoding, and channels keywords to identify the input data format.

The output file format is derived by updating the format of the first input file with the format options in the -f specification. If -p is not specified, all subsequent input files are converted to this resulting format and concatenated together. The output file will contain an audio file header, unless format=*raw* is specified in the output format options.

Input files may be converted in place by using the -p option. When -p is in effect, the format of each input file is modified according to the -f option to determine the output format. The existing files are then overwritten with the converted data.

The [file\(1\)](#) command decodes and prints the audio data format of Sun audio files.

Options The following options are supported:

- p *In Place*: The input files are individually converted to the format specified by the -f option and rewritten. If a target file is a symbolic link, the underlying file will be rewritten. The -o option may not be specified with -p.
- F *Force*: This option forces audioconvert to ignore any file header for input files whose format is specified by the -i option. If -F is not specified, audioconvert ignores the -i option for input files that contain valid audio file headers.
- f *outfmt* *Output Format*: This option is used to specify the file format and data encoding of the output file. Defaults for unspecified fields are derived from the input file format. Valid keywords and values are listed in the next section.
- o *outfile* *Output File*: All input files are concatenated, converted to the output format, and written to the named output file. If -o and -p are not specified, the concatenated output is written to the standard output. The -p option may not be specified with -o.

-i infmt *Input Format:* This option is used to specify the data encoding of raw input files. Ordinarily, the input data format is derived from the audio file header. This option is required when converting audio data that is not preceded by a valid audio file header. If *-i* is specified for an input file that contains an audio file header, the input format string will be ignored, unless *-F* is present. The format specification syntax is the same as the *-f* output file format.

Multiple input formats may be specified. An input format describes all input files following that specification, until a new input format is specified.

file *File Specification:* The named audio files are concatenated, converted to the output format, and written out. If no file name is present, or if the special file name '-' is specified, audio data is read from the standard input.

-? *Help:* Prints a command line usage message.

Format Specification The syntax for the input and output format specification is:

keyword=value[,keyword=value ...]

with no intervening whitespace. Unambiguous values may be used without the preceding *keyword=*.

rate The audio sampling rate is specified in samples per second. If a number is followed by the letter *k*, it is multiplied by 1000 (for example, 44.1k = 44100). Standard of the commonly used sample rates are: 8k, 16k, 32k, 44.1k, and 48k.

channels The number of interleaved channels is specified as an integer. The words *mono* and *stereo* may also be used to specify one and two channel data, respectively.

encoding This option specifies the digital audio data representation. Encodings determine precision implicitly (*ulaw* implies 8-bit precision) or explicitly as part of the name (for example, *linear16*). Valid encoding values are:

ulaw CCITT G.711 -law encoding. This is an 8-bit format primarily used for telephone quality speech.

alaw CCITT G.711 A-law encoding. This is an 8-bit format primarily used for telephone quality speech in Europe.

linear8,
linear16,

linear32 Linear Pulse Code Modulation (PCM) encoding. The name identifies the number of bits of precision. *linear16* is typically used for high quality audio data.

pcm Same as *linear16*.

g721 CCITT G.721 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 4-bit precision. It is primarily used for compressing -law voice data (achieving a 2:1 compression ratio).

g723 CCITT G.723 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 3-bit precision. It is primarily used for compressing -law voice data (achieving an 8:3 compression ratio). The audio quality is similar to G.721, but may result in lower quality when used for non-speech data.

The following encoding values are also accepted as shorthand to set the sample rate, channels, and encoding:

voice Equivalent to `encoding=ulaw,rate=8k,channels=mono`.

cd Equivalent to `encoding=linear16,rate=44.1k,channels=stereo`.

dat Equivalent to `encoding=linear16,rate=48k,channels=stereo`.

format This option specifies the audio file format. Valid formats are:

sun Sun compatible file format (the default).

raw Use this format when reading or writing raw audio data (with no audio header), or in conjunction with an `offset` to import a foreign audio file format.

offset (*-i only*) Specifies a byte offset to locate the start of the audio data. This option may be used to import audio data that contains an unrecognized file header.

Usage See [largefile\(5\)](#) for the description of the behavior of `audioconvert` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Recording and compressing voice data before storing it

Record voice data and compress it before storing it to a file:

```
example% audiorecord | audioconvert -f g721 > mydata.au
```

EXAMPLE 2 Concatenating two audio files

Concatenate two Sun format audio files, regardless of their data format, and output an 8-bit ulaw, 16 kHz, mono file:

```
example% audioconvert -f ulaw,rate=16k,mono -o outfile.au infile1 infile2
```

EXAMPLE 3 Converting a directory to Sun format

Convert a directory containing raw voice data files, in place, to Sun format (adds a file header to each file):

EXAMPLE 3 Converting a directory to Sun format *(Continued)*

example% **audioconvert -p -i voice -f sun *.au**

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC, x86
Availability	SUNWauda
Interface Stability	Evolving

See Also [audioplay\(1\)](#), [audiorecord\(1\)](#), [file\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Notes The algorithm used for converting multi-channel data to mono is implemented by simply summing the channels together. If the input data is perfectly in phase (as would be the case if a mono file is converted to stereo and back to mono), the resulting data may contain some distortion.

Name audioplay – play audio files

Synopsis audioplay [-iV] [-v *vol*] [-b *bal*]
 [-p *speaker* | *headphone* | *line*] [-d *dev*] [*file*]...

Description The audioplay utility copies the named audio files (or the standard input if no filenames are present) to the audio device. If no input file is specified and standard input is a tty, the port, volume, and balance settings specified on the command line will be applied and the program will exit.

The input files must contain a valid audio file header. The encoding information in this header is matched against the capabilities of the audio device and, if the data formats are incompatible, an error message is printed and the file is skipped. Compressed ADPCM (G.721) monaural audio data is automatically uncompressed before playing.

Minor deviations in sampling frequency (that is, less than 1%) are ordinarily ignored. This allows, for instance, data sampled at 8012 Hz to be played on an audio device that only supports 8000 Hz. If the -V option is present, such deviations are flagged with warning messages.

Options The following options are supported:

- i *Immediate*: If the audio device is unavailable (that is, another process currently has write access), audioplay ordinarily waits until it can obtain access to the device. When the -i option is present, audioplay prints an error message and exits immediately if the device is busy.
- V *Verbose*: Prints messages on the standard error when waiting for access to the audio device or when sample rate deviations are detected.
- v *vol* *Volume*: The output volume is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The *vol* argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the output volume remains at the level most recently set by any process.
- b *bal* *Balance*: The output balance is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The *bal* argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the output balance remains at the level most recently set by any process.

- p speaker | headphone | line

Output Port: Selects the built-in speaker (the default), headphone jack, or Line out as the destination of the audio output signal. If this argument is not specified, the output port will remain unchanged. *Please note:* Not all audio adapters support all of the output ports. If the named port does not exist, an appropriate substitute will be used.
- d dev

Device: The *dev* argument specifies an alternate audio device to which output should be directed. If the *-d* option is not specified, the `AUDIODEV` environment variable is consulted (see below). Otherwise, `/dev/audio` is used as the default audio device.
- \?

Help: Prints a command line usage message.

Operands *file* *File Specification:* Audio files named on the command line are played sequentially. If no filenames are present, the standard input stream (if it is not a tty) is played (it, too, must contain an audio file header). The special filename `'-'` may be used to read the standard input stream instead of a file. If a relative path name is supplied, the `AUDIOPATH` environment variable is consulted (see below).

Usage See [largefile\(5\)](#) for the description of the behavior of `audioplay` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

- Environment Variables

AUDIODEV

The full path name of the audio device to write to, if no *-d* argument is supplied. If the `AUDIODEV` variable is not set, `/dev/audio` is used.
- AUDIOPATH

A colon-separated list of directories in which to search for audio files whose names are given by relative pathnames. The current directory (".") may be specified explicitly in the search path. If the `AUDIOPATH` variable is not set, only the current directory will be searched.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC, x86
Availability	SUNWauda
Interface Stability	Evolving

See Also [audioconvert\(1\)](#), [audiorecord\(1\)](#), [mixerctl\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [usb_ac\(7D\)](#), [audio\(7I\)](#), [mixer\(7I\)](#)

Bugs `audioplay` currently supports a limited set of audio format conversions. If the audio file is not in a format supported by the audio device, it must first be converted. For example, to convert to voice format on the fly, use the command:

```
example% audioconvert -f voice myfile | audioplay
```

The format conversion will not always be able to keep up with the audio output. If this is the case, you should convert to a temporary file before playing the data.

Name audiorecord – record an audio file

Synopsis audiorecord [-af] [-v *vol*] [-b *bal*] [-m *monvol*]
[-p mic | line | internal-cd] [-c *channels*] [-s *rate*]
[-e *encoding*] [-t *time*] [-i *info*] [-d *dev*]
[-T au | aif[f] | wav] [*file*[.au|.aif[f]]|.wav]

Description The audiorecord utility copies audio data from the audio device to a named audio file, or to the standard output if no filename is present. If no output file is specified and standard output is a tty, the volume, balance, monitor volume, port, and audio format settings specified on the command line will be applied and the program will exit.

By default, monaural audio data is recorded at 8 kHz and encoded in -law format. If the audio device supports additional configurations, the -c, -s, and -e options may be used to specify the data format. The output file is prefixed by an audio file header that identifies the format of the data encoded in the file.

Recording begins immediately and continues until a SIGINT signal (for example, Control-c) is received. If the -t option is specified, audiorecord stops when the specified quantity of data has been recorded.

If the audio device is unavailable, that is, if another process currently has read access, audiorecord prints an error message and exits immediately.

Options The following options are supported:

- | | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| - \? | <i>Help:</i> Prints a command line usage message. |
| - a | <i>Append:</i> Appends the data on the end of the named audio file. The audio device must support the audio data format of the existing file. |
| - b <i>bal</i> | <i>Balance:</i> The recording balance is set to the specified value before recording begins, and is reset to its previous level when audiorecord exits. The <i>bal</i> argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the input balance will remain at the level most recently set by any process. |
| - c <i>channels</i> | <i>Channels:</i> Specifies the number of audio channels (1 or 2). The value may be specified as an integer or as the string mono or stereo. The default value is mono. |
| - d <i>dev</i> | <i>Device:</i> The <i>dev</i> argument specifies an alternate audio device from which input should be taken. If the -d option is not specified, the AUDIODEV environment variable is consulted (see below). Otherwise, /dev/audio is used as the default audio device. |

<code>-e encoding</code>	<i>Encoding</i> : Specifies the audio data encoding. This value may be one of <code>ulaw</code> , <code>alaw</code> , or <code>linear</code> . The default encoding is <code>ulaw</code> .
<code>-f</code>	<i>Force</i> : When the <code>-a</code> flag is specified, the sample rate of the audio device must match the sample rate at which the original file was recorded. If the <code>-f</code> flag is also specified, sample rate differences are ignored, with a warning message printed on the standard error.
<code>-i info</code>	<i>Information</i> : The 'information' field of the output file header is set to the string specified by the <i>info</i> argument. This option cannot be specified in conjunction with the <code>-a</code> argument.
<code>-m monvol</code>	<i>Monitor Volume</i> : The input monitor volume is set to the specified value before recording begins, and is reset to its previous level when <code>audiorecord</code> exits. The <i>monval</i> argument is an integer value between 0 and 100, inclusive. A non-zero value allows a directly connected input source to be heard on the output speaker while recording is in-progress. If this argument is not specified, the monitor volume will remain at the level most recently set by any process.
<code>-p mic line internal-cd</code>	<i>Input Port</i> : Selects the <code>mic</code> , <code>line</code> , or <code>internal-cd</code> input as the source of the audio output signal. If this argument is not specified, the input port will remain unchanged. <i>Please notice</i> : Some systems will not support all possible input ports. If the named port does not exist, this option is ignored.
<code>-s rate</code>	<i>Sample Rate</i> : Specifies the sample rate, in samples per second. If a number is followed by the letter <code>k</code> , it is multiplied by 1000 (for example, <code>44.1k</code> = 44100). The default sample rate is 8 kHz.
<code>-t time</code>	<i>Time</i> : The <i>time</i> argument specifies the maximum length of time to record. Time can be specified as a floating-point value, indicating the number of seconds, or in the form: <i>hh:mm:ss.dd</i> , where the hour and minute specifications are optional.
<code>-T au aif[f] wav</code>	Specifies the audio file type to create. If the <code>-a</code> option is used, the file type must match the file to which it is being appended. Regardless of the file suffix, the type will be set as specified in this option. If this option is not specified, the file suffix will determine the type.

-v vol

Volume: The recording gain is set to the specified value before recording begins, and is reset to its previous level when audiorecord exits. The vol argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the input volume will remain at the level most recently set by any process.

Operands

file[.au|.aif[f]].wav

File Specification: The named audio file is rewritten, or appended. If no filename is present, and standard output is not a tty, or if the special filename “-” is specified, output is directed to the the standard output.

If the -T option is not specified, the file suffix will determine the type of file. If the suffix is not recognized, the default is .au. If the -T option is specified, that file type is used regardless of the file suffix.

Usage

See [largefile\(5\)](#) for the description of the behavior of audiorecord when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Environment Variables

AUDIODEV

The full path name of the audio device to record from, if no -d argument is supplied. If the AUDIODEV variable is not set, /dev/audio is used.

Attributes

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name auths – print authorizations granted to a user

Synopsis auths [*user*]...

Description The auths command prints on standard output the authorizations that you or the optionally-specified user or role have been granted. Authorizations are rights that are checked by certain privileged programs to determine whether a user may execute restricted functionality.

Each user may have zero or more authorizations. Authorizations are represented by fully-qualified names, which identify the organization that created the authorization and the functionality that it controls. Following the Java convention, the hierarchical components of an authorization are separated by dots (.), starting with the reverse order Internet domain name of the creating organization, and ending with the specific function within a class of authorizations.

An asterisk (*) indicates all authorizations in a class.

A user's authorizations are looked up in [user_attr\(4\)](#) and in the `/etc/security/policy.conf` file (see [policy.conf\(4\)](#)). Authorizations may be specified directly in [user_attr\(4\)](#) or indirectly through [prof_attr\(4\)](#). Authorizations may also be assigned to every user in the system directly as default authorizations or indirectly as default profiles in the `/etc/security/policy.conf` file.

Examples EXAMPLE 1 Sample output

The auths output has the following form:

```
example% auths tester01 tester02
tester01 : solaris.system.date,solaris.jobs.admin
tester02 : solaris.system.*
example%
```

Notice that there is no space after the comma separating the authorization names in `tester01`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files `/etc/user_attr`
`/etc/security/auth_attr`
`/etc/security/policy.conf`
`/etc/security/prof_attr`

Name auto_ef – auto encoding finder

Synopsis /usr/bin/auto_ef [-e *encoding_list*] [-a] [-l *level*]
 [*file ...*]
 /usr/bin/auto_ef -h

Description The auto_ef utility identifies the encoding of a given file. The utility judges the encoding by using the iconv code conversion, determining whether a certain code conversion was successful with the file, and also by performing frequency analyses on the character sequences that appear in the file.

The auto_ef utility might produce unexpected output if the string is binary, a character table, a localized digit list, or a chronogram, or if the string or file is very small in size (for example, less than one 100 bytes).

By default, `auto_ef` returns a single, most likely encoding for text in a specified file. To get all possible encodings for the file, use the `-a` option.

Also by default, `auto_ef` uses the fastest process to examine the file. For more accurate results, use the `-l` option.

To examine data with a limited set of encodings, use the `-e` option.

Options The following options are supported:

`-a` Shows all possible encodings in order of possibility, with scores in the range between 0.0 and 1.0. A higher score means a higher possibility. For example,

```
example% auto_ef -a test_file
eucJP          0.89
zh_CN.euc      0.04
ko_KR.euc      0.01
```

Without this option, only one encoding with the highest score is shown.

`-e encoding_list` Examines data only with specified encodings. For example, when *encoding_list* is specified as "ko_KR.euc:ko_KR.cp949", `auto_ef` examines text only with CP949 and ko_KR.euc. Without this option, `auto_ef` examines text with all encodings. Multiple encodings can be specified by separating the encodings using a colon (:).

`-h` Shows the usage message.

`-l level` Specifies the level of judgment. The value of *level* can be 0, 1, 2, or 3. Level 3 produces the best result but can be slow. Level 0 is fastest but results can be less accurate than in higher levels. The default is level 0.

Operands The following operands are supported:

file File name to examine.

Examples EXAMPLE 1 Examining encoding of a file

```
example% auto_ef file_name
```

EXAMPLE 2 Examining encoding of a file at level 2.

```
example% auto_ef -l 2 file_name
```

EXAMPLE 3 Examining encoding of a file with only eucJP or ko_KR.euc

```
example% auto_ef -e "eucJP:ko_KR.euc" file_name
```

Exit Status The following exit values are returned:

- 0 Successful completion
- 1 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWautoef
Interface Stability	See below.

Interface Stability of output format, when option -a is specified, is Evolving. Other interfaces are Stable.

International Language Environments Guide

Name awk – pattern scanning and processing language

Synopsis /usr/bin/awk [-f *progfile*] [-Fc] [' *prog* '] [*parameters*]
[*filename*]. . .

/usr/xpg4/bin/awk [-FcERE] [-v *assignment*] . . . '*program*' -f *progfile* . . .
[*argument*] . . .

Description The /usr/xpg4/bin/awk utility is described on the [nawk\(1\)](#) manual page.

The /usr/bin/awk utility scans each input *filename* for lines that match any of a set of patterns specified in *prog*. The *prog* string must be enclosed in single quotes (`'`) to protect it from the shell. For each pattern in *prog* there can be an associated action performed when a line of a *filename* matches the pattern. The set of pattern-action statements can appear literally as *prog* or in a file specified with the -f *progfile* option. Input files are read in order; if there are no files, the standard input is read. The file name `'-'` means the standard input.

Options The following options are supported:

-f *progfile* awk uses the set of patterns it reads from *progfile*.

-Fc Uses the character *c* as the field separator (FS) character. See the discussion of FS below.

Usage

Input Lines Each input line is matched against the pattern portion of every pattern-action statement; the associated action is performed for each matched pattern. Any *filename* of the form *var=value* is treated as an assignment, not a filename, and is executed at the time it would have been opened if it were a filename. *Variables* assigned in this manner are not available inside a BEGIN rule, and are assigned after previously specified files have been read.

An input line is normally made up of fields separated by white spaces. (This default can be changed by using the FS built-in variable or the -Fc option.) The default is to ignore leading blanks and to separate fields by blanks and/or tab characters. However, if FS is assigned a value that does not include any of the white spaces, then leading blanks are not ignored. The fields are denoted \$1, \$2, . . . ; \$0 refers to the entire line.

Pattern-action Statements A pattern-action statement has the form:

pattern { *action* }

Either pattern or action can be omitted. If there is no action, the matching line is printed. If there is no pattern, the action is performed on every input line. Pattern-action statements are separated by newlines or semicolons.

Patterns are arbitrary Boolean combinations (`!`, `||`, `&&`, and parentheses) of relational expressions and regular expressions. A relational expression is one of the following:

expression relop expression
expression matchop regular_expression

where a *relop* is any of the six relational operators in C, and a *matchop* is either ~ (contains) or !~ (does not contain). An *expression* is an arithmetic expression, a relational expression, the special expression

var in array

or a Boolean combination of these.

Regular expressions are as in [egrep\(1\)](#). In patterns they must be surrounded by slashes. Isolated regular expressions in a pattern apply to the entire line. Regular expressions can also occur in relational expressions. A pattern can consist of two patterns separated by a comma; in this case, the action is performed for all lines between the occurrence of the first pattern to the occurrence of the second pattern.

The special patterns BEGIN and END can be used to capture control before the first input line has been read and after the last input line has been read respectively. These keywords do not combine with any other patterns.

Built-in Variables Built-in variables include:

FILENAME	name of the current input file
FS	input field separator regular expression (default blank and tab)
NF	number of fields in the current record
NR	ordinal number of the current record
OFMT	output format for numbers (default %.6g)
OFS	output field separator (default blank)
ORS	output record separator (default new-line)
RS	input record separator (default new-line)

An action is a sequence of statements. A statement can be one of the following:

```
if ( expression ) statement [ else statement ]
while ( expression ) statement
do statement while ( expression )
for ( expression ; expression ; expression ) statement
for ( var in array ) statement
break
continue
{ [ statement ] . . . }
expression      # commonly variable = expression
print [ expression-list ] [ >expression ]
```

```
printf format [ ,expression-list ] [ >expression ]
next          # skip remaining patterns on this input line
exit [expr]    # skip the rest of the input; exit status is expr
```

Statements are terminated by semicolons, newlines, or right braces. An empty *expression-list* stands for the whole input line. Expressions take on string or numeric values as appropriate, and are built using the operators `+`, `-`, `*`, `/`, `%`, `^` and concatenation (indicated by a blank). The operators `++`, `---`, `+=`, `-=`, `*=`, `/=`, `%=`, `^=`, `>`, `>=`, `<`, `<=`, `==`, `!=`, and `?:` are also available in expressions. Variables can be scalars, array elements (denoted `x[i]`), or fields. Variables are initialized to the null string or zero. Array subscripts can be any string, not necessarily numeric; this allows for a form of associative memory. String constants are quoted (`"`), with the usual C escapes recognized within.

The `print` statement prints its arguments on the standard output, or on a file if *>expression* is present, or on a pipe if `|cmd` is present. The output resulted from the `print` statement is terminated by the output record separator with each argument separated by the current output field separator. The `printf` statement formats its expression list according to the format (see [printf\(3C\)](#)).

Built-in Functions The arithmetic functions are as follows:

<code>cos(x)</code>	Return cosine of <i>x</i> , where <i>x</i> is in radians. (In <code>/usr/xpg4/bin/awk</code> only. See nawk(1) .)
<code>sin(x)</code>	Return sine of <i>x</i> , where <i>x</i> is in radians. (In <code>/usr/xpg4/bin/awk</code> only. See nawk(1) .)
<code>exp(x)</code>	Return the exponential function of <i>x</i> .
<code>log(x)</code>	Return the natural logarithm of <i>x</i> .
<code>sqrt(x)</code>	Return the square root of <i>x</i> .
<code>int(x)</code>	Truncate its argument to an integer. It is truncated toward 0 when <i>x</i> > 0.

The string functions are as follows:

<code>index(s, t)</code>	Return the position in string <i>s</i> where string <i>t</i> first occurs, or 0 if it does not occur at all.
<code>int(s)</code>	truncates <i>s</i> to an integer value. If <i>s</i> is not specified, \$0 is used.
<code>length(s)</code>	Return the length of its argument taken as a string, or of the whole line if there is no argument.
<code>split(s, a, fs)</code>	Split the string <i>s</i> into array elements <i>a</i> [1], <i>a</i> [2], . . . <i>a</i> [<i>n</i>], and returns <i>n</i> . The separation is done with the regular expression <i>fs</i> or with the field separator FS if <i>fs</i> is not given.

<code>sprintf(<i>fmt, expr, expr, ...</i>)</code>	Format the expressions according to the printf(3C) format given by <i>fmt</i> and returns the resulting string.
<code>substr(<i>s, m, n</i>)</code>	returns the <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> .

The input/output function is as follows:

<code>getline</code>	Set <code>\$0</code> to the next input record from the current input file. <code>getline</code> returns 1 for successful input, 0 for end of file, and -1 for an error.
----------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of `awk` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 Printing Lines Longer Than 72 Characters

The following example is an `awk` script that can be executed by an `awk -f examplescript` style command. It prints lines longer than seventy two characters:

```
length > 72
```

EXAMPLE 2 Printing Fields in Opposite Order

The following example is an `awk` script that can be executed by an `awk -f examplescript` style command. It prints the first two fields in opposite order:

```
{ print $2, $1 }
```

EXAMPLE 3 Printing Fields in Opposite Order with the Input Fields Separated

The following example is an `awk` script that can be executed by an `awk -f examplescript` style command. It prints the first two input fields in opposite order, separated by a comma, blanks or tabs:

```
BEGIN { FS = ",[ \t]*|[ \t]+" }  
      { print $2, $1 }
```

EXAMPLE 4 Adding Up the First Column, Printing the Sum and Average

The following example is an `awk` script that can be executed by an `awk -f examplescript` style command. It adds up the first column, and prints the sum and average:

```
{ s += $1 }  
END { print "sum is", s, " average is", s/NR }
```

EXAMPLE 5 Printing Fields in Reverse Order

The following example is an `awk` script that can be executed by an `awk -f examplescript` style command. It prints fields in reverse order:

```
{ for (i = NF; i > 0; --i) print $i }
```

EXAMPLE 6 Printing All lines Between start/stop Pairs

The following example is an awk script that can be executed by an `awk -f examplescript` style command. It prints all lines between start/stop pairs.

```
/start/, /stop/
```

EXAMPLE 7 Printing All Lines Whose First Field is Different from the Previous One

The following example is an awk script that can be executed by an `awk -f examplescript` style command. It prints all lines whose first field is different from the previous one.

```
$1 != prev { print; prev = $1 }
```

EXAMPLE 8 Printing a File and Filling in Page numbers

The following example is an awk script that can be executed by an `awk -f examplescript` style command. It prints a file and fills in page numbers starting at 5:

```
/Page/      { $2 = n++; }  
             { print }
```

EXAMPLE 9 Printing a File and Numbering Its Pages

Assuming this program is in a file named `prog`, the following example prints the file input numbering its pages starting at 5:

```
example% awk -f prog n=5 input
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of awk: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, NLSPATH, and PATH.

LC_NUMERIC Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing awk programs (including assignments in command-line arguments).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/awk	ATTRIBUTETYPE	ATTRIBUTE VALUE
	Availability	SUNWesu
	CSI	Not Enabled

/usr/xpg4/bin/awk

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Committed
Standard	See standards(5) .

See Also [egrep\(1\)](#), [grep\(1\)](#), [nawk\(1\)](#), [sed\(1\)](#), [printf\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number, add 0 to it. To force an expression to be treated as a string, concatenate the null string ("") to it.

Name banner – make posters

Synopsis banner *strings*

Description banner prints its arguments (each up to 10 characters long) in large letters on the standard output.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also [echo\(1\)](#), [attributes\(5\)](#)

Name basename, dirname – deliver portions of path names

Synopsis /usr/bin/basename *string* [*suffix*]
 /usr/xpg4/bin/basename *string* [*suffix*]
 dirname *string*

Description The basename utility deletes any prefix ending in / and the *suffix* (if present in *string*) from *string*, and prints the result on the standard output. It is normally used inside substitution marks (‘ ’) within shell procedures.

/usr/bin The *suffix* is a pattern defined on the [expr\(1\)](#) manual page.

/usr/xpg4/bin The *suffix* is a string with no special significance attached to any of the characters it contains.
 The *dirname* utility delivers all but the last level of the path name in *string*.

Examples EXAMPLE 1 Setting environment variables

The following example, invoked with the argument /home/sms/personal/mail sets the environment variable NAME to the file named mail and the environment variable MYMAILPATH to the string /home/sms/personal:

```
example% NAME='basename $HOME/personal/mail'
example% MYMAILPATH='dirname $HOME/personal/mail'
```

EXAMPLE 2 Compiling a file and moving the output

This shell procedure, invoked with the argument /usr/src/bin/cat.c, compiles the named file and moves the output to cat in the current directory:

```
example% cc $1
example% mv a.out 'basename $1 .c'
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of basename and dirname: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.
 >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcsu

/usr/xpg4/bin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

See Also [expr\(1\)](#), [basename\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name basename – display portions of pathnames

Synopsis /usr/ucb/basename *string* [*suffix*]

Description The basename utility deletes any prefix ending in '/' and the *suffix*, if present in *string*. It directs the result to the standard output, and is normally used inside substitution marks (' ') within shell procedures. The *suffix* is a string with no special significance attached to any of the characters it contains.

Examples EXAMPLE 1 Using the basename command.

This shell procedure invoked with the argument /usr/src/bin/cat.c compiles the named file and moves the output to cat in the current directory:

```
example% cc $1
example% mv a.out 'basename $1 .c'
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

See Also [sh\(1\)](#), [attributes\(5\)](#)

Name bc – arbitrary precision arithmetic language

Synopsis /usr/bin/bc [-c] [-l] [*file*]...
 /usr/xpg6/bin/bc [-c] [-l] [*file*]...

Description The bc utility implements an arbitrary precision calculator. It takes input from any files given, then reads from the standard input. If the standard input and standard output to bc are attached to a terminal, the invocation of bc is *interactive*, causing behavioral constraints described in the following sections. bc processes a language that resembles C and is a preprocessor for the desk calculator program dc, which it invokes automatically unless the -c option is specified. In this case the dc input is sent to the standard output instead.

Usage The syntax for bc programs is as follows:

L Means a letter a–z,

E Means an expression: a (mathematical or logical) value, an operand that takes a value, or a combination of operands and operators that evaluates to a value,

S Means a statement.

Comments Enclosed in /* and */.

Names (Operands) Simple variables: *L*.
 Array elements: *L* [*E*] (up to BC_DIM_MAX dimensions).
 The words *ibase*, *obase* (limited to BC_BASE_MAX), and *scale* (limited to BC_SCALE_MAX).

Other Operands Arbitrarily long numbers with optional sign and decimal point. Strings of fewer than BC_STRING_MAX characters, between double quotes ("). (*E*)

sqrt (*E*) Square root

length (*E*) Number of significant decimal digits.

scale (*E*) Number of digits right of decimal point.

L (*E*, ..., *E*)

Operators + − * / % ^ (% is remainder; ^ is power)

++ — (prefix and postfix; apply to names)

== <= >= != < >

= += -= *= /= %= ^=

Statements *E*
 { *S* ; ... ; *S* }
 if (*E*) *S*

```

while ( E ) S
for ( E ; E ; E ) S
null statement
break
quit

.string

```

Function Definitions

```

define L ( L , ... , L ) {
  auto L , ... , L
  S ; ... S
  return ( E )
}

```

Functions in -l Math Library

s(x)	sine
c(x)	cosine
e(x)	exponential
l(x)	log
a(x)	arctangent
j(n,x)	Bessel function

All function arguments are passed by value.

The value of a statement that is an expression is printed unless the main operator is an assignment. Either semicolons or new-lines may separate statements. Assignment to `scale` influences the number of digits to be retained on arithmetic operations in the manner of `dc`. Assignments to `ibase` or `obase` set the input and output number radix respectively.

The same letter may be used as an array, a function, and a simple variable simultaneously. All variables are global to the program. `auto` variables are stacked during function calls. When using arrays as function arguments or defining them as automatic variables, empty square brackets must follow the array name.

Options The following operands are supported:

- | | | |
|------------------|----|------------------------------------------------------------------------------------------------------------------------------------------|
| | -c | Compiles only. The output is <code>dc</code> commands that are sent to the standard output. |
| /usr/bin/bc | -l | Defines the math functions and initializes <code>scale</code> to 20, instead of the default zero. |
| /usr/xpg6/bin/bc | -l | Defines the math functions and initializes <code>scale</code> to 20, instead of the default zero. All math results have the scale of 20. |

Operands The following operands are supported:

file A pathname of a text file containing bc program statements. After all cases of *file* have been read, bc reads the standard input.

Examples **EXAMPLE 1** Setting the precision of a variable

In the shell, the following assigns an approximation of the first ten digits of π to the variable *x*:

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

EXAMPLE 2 Defining a computing function

Defines a function to compute an approximate value of the exponential function:

```
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
    for(i=1; 1==1; i++){
        a = a*x
        b = b*i
        c = a/b
        if(c == 0) return(s)
        s = s+c
    }
}
```

EXAMPLE 3 Printing the approximate values of the function

Prints approximate values of the exponential function of the first ten integers:

```
for(i=1; i<=10; i++) e(i)
```

or

```
for (i = 1; i <= 10; ++i) {          e(i) }
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of bc: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 All input files were processed successfully.

unspecified An error occurred.

Files	/usr/lib/lib.b	mathematical library
	/usr/include/limits.h	to define BC_ parameters

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

See Also [dc\(1\)](#), [awk\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes The bc command does not recognize the logical operators && and | |.

The for statement must have all three expressions (*E*'s).

Name bdiff – big diff

Synopsis bdiff *filename1 filename2* [*n*] [-s]

Description bdiff is used in a manner analogous to diff to find which lines in *filename1* and *filename2* must be changed to bring the files into agreement. Its purpose is to allow processing of files too large for diff. If *filename1* (*filename2*) is –, the standard input is read.

bdiff ignores lines common to the beginning of both files, splits the remainder of each file into *n*-line segments, and invokes diff on corresponding segments. If both optional arguments are specified, they must appear in the order indicated above.

The output of bdiff is exactly that of diff, with line numbers adjusted to account for the segmenting of the files (that is, to make it look as if the files had been processed whole). Note: Because of the segmenting of the files, bdiff does not necessarily find a smallest sufficient set of file differences.

- Options**
- n* The number of line segments. The value of *n* is 3500 by default. If the optional third argument is given and it is numeric, it is used as the value for *n*. This is useful in those cases in which 3500-line segments are too large for diff, causing it to fail.
 - s Specifies that no diagnostics are to be printed by bdiff (silent option). Note: However, this does not suppress possible diagnostic messages from diff, which bdiff calls.

Usage See [largefile\(5\)](#) for the description of the behavior of bdiff when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Files /tmp/bd????

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	enabled

See Also [diff\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Diagnostics Use `help` for explanations.

Name bfs – big file scanner

Synopsis /usr/bin/bfs [-] *filename*

Description The `bfs` command is (almost) like `ed(1)` except that it is read-only and processes much larger files. Files can be up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). `bfs` is usually more efficient than `ed(1)` for scanning a file, since the file is not copied to a buffer. It is most useful for identifying sections of a large file where `csplit(1)` can be used to divide it into more manageable pieces for editing.

Normally, the size of the file being scanned is printed, as is the size of any file written with the `w` (write) command. The optional `–` suppresses printing of sizes. Input is prompted with `*` if `P` and a carriage return are typed, as in `ed(1)`. Prompting can be turned off again by inputting another `P` and carriage return. Note that messages are given in response to errors if prompting is turned on.

All address expressions described under `ed(1)` are supported. In addition, regular expressions may be surrounded with two symbols besides `/` and `?`:

- `>` indicates downward search without wrap-around, and
- `<` indicates upward search without wrap-around.

There is a slight difference in mark names; that is, only the letters `a` through `z` may be used, and all 26 marks are remembered.

bfs Commands The `e`, `g`, `v`, `k`, `p`, `q`, `w`, `=`, `!`, and null commands operate as described under `ed(1)`. Commands such as `—`, `+++—`, `+++=`, `–12`, and `+4p` are accepted. Note that `1,10p` and `1,10` both print the first ten lines. The `f` command only prints the name of the file being scanned; there is no *remembered* filename. The `w` command is independent of output diversion, truncation, or crunching (see the `xo`, `xt`, and `xc` commands, below). The following additional commands are available:

- `xf file` Further commands are taken from the named `file`. When an end-of-file is reached, an interrupt signal is received or an error occurs, reading resumes with the file containing the `xf`. The `xf` commands may be nested to a depth of 10.
- `xn` List the marks currently in use (marks are set by the `k` command).
- `xo [file]` Further output from the `p` and null commands is diverted to the named `file`, which, if necessary, is created mode 666 (readable and writable by everyone), unless your `umask` setting (see `umask(1)`) dictates otherwise. If `file` is missing, output is diverted to the

	standard output. Note that each diversion causes truncation or creation of the file.
<code>: label</code>	This positions a <i>label</i> in a command file. The <i>label</i> is terminated by new-line, and blanks between the : (colon) and the start of the <i>label</i> are ignored. This command may also be used to insert comments into a command file, since labels need not be referenced.
<code>(., .)xb/regular expression/label</code>	<p>A jump (either upward or downward) is made to <i>label</i> if the command succeeds. It fails under any of the following conditions:</p> <ol style="list-style-type: none">1. Either address is not between 1 and \$.2. The second address is less than the first.3. The regular expression does not match at least one line in the specified range, including the first and last lines. <p>On success, . (dot) is set to the line matched and a jump is made to <i>label</i>. This command is the only one that does not issue an error message on bad addresses, so it may be used to test whether addresses are bad before other commands are executed. Note that the command, <code>xb/^/label</code>, is an unconditional jump.</p> <p>The <code>xb</code> command is allowed only if it is read from someplace other than a terminal. If it is read from a pipe, only a downward jump is possible.</p>
<code>xτ number</code>	Output from the <code>p</code> and <code>null</code> commands is truncated to, at most, <i>number</i> characters. The initial number is 255.
<code>xv[<i>digit</i>] [<i>spaces</i>] [<i>value</i>]</code>	<p>The variable name is the specified <i>digit</i> following the <code>xv</code>. The commands <code>xv5100</code> or <code>xv5 100</code> both assign the value 100 to the variable 5. The command <code>xv61,100p</code> assigns the value 1,100p to the variable 6. To reference a variable, put a % in front of the variable name. For example, using the above assignments for variables 5 and 6:</p> <pre>1,%5p 1,%5 %6</pre> <p>prints the first 100 lines.</p>

`g/%5/p`

would globally search for the characters `100` and print each line containing a match. To escape the special meaning of `%`, a `\` must precede it.

`g/".*\%[cds]/p`

could be used to match and list `%c`, `%d`, or `%s` formats (for example, `printf`-like statements) of characters, decimal integers, or strings. Another feature of the `xv` command is that the first line of output from a UNIX system command can be stored into a variable. The only requirement is that the first character of *value* be an `!`. For example:

```
.w junk
xv5!cat junk
!rm junk
!echo "%5"
xv6!expr %6 + 1
```

would put the current line into variable 35, print it, and increment the variable 36 by one. To escape the special meaning of `!` as the first character of *value*, precede it with a `\`.

`xv7\!date`

stores the value `!date` into variable 7.

`xbz label`
`xbn label`

These two commands test the last saved *return code* from the execution of a UNIX system command (`!` command) or nonzero value, respectively, to the specified label. The two examples below both search for the next five lines containing the string size:

Example 1:

```
xv55
: l
/size/
xv5!expr %5 - 1
!if 0%5 != 0 exit 2
xbn l
```

Example 2:

```
xv45
: l
/size/
xv4!expr %4 - 1
!if 0%4 = 0 exit 2
xbz l
```

`xc [switch]` If `switch` is 1, output from the `p` and null commands is crunched; if `switch` is 0, it is not. Without an argument, `xc` reverses `switch`. Initially, `switch` is set for no crunching. Crunched output has strings of tabs and blanks reduced to one blank and blank lines suppressed.

Operands The following operand is supported:

filename Any file up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). *filename* can be a section of a larger file which has been divided into more manageable sections for editing by the use of `csplit(1)`.

Exit Status The following exit values are returned:

- 0 Successful completion without any file or command errors.
- >0 An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

Diagnostics Message is ? for errors in commands, if prompting is turned off. Self-explanatory error messages are displayed when prompting is on.

Name biff – give notice of incoming mail messages

Synopsis /usr/ucb/biff [y | n]

Description biff turns mail notification on or off for the terminal session. With no arguments, biff displays the current notification status for the terminal.

If notification is allowed, the terminal rings the bell and displays the header and the first few lines of each arriving mail message. biff operates asynchronously. For synchronized notices, use the MAIL variable of [sh\(1\)](#) or the mail variable of [csh\(1\)](#).

A 'biff y' command can be included in your ~/.login or ~/.profile file for execution when you log in.

- Options**
- y Allow mail notification for the terminal.
 - n Disable notification for the terminal.

Files

- ~/.login User's login file
- ~/.profile User's profile file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name break, continue – shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop

Synopsis

```
sh  break [n]
    continue [n]
csh  break
     continue
ksh  *break [n]
     *continue [n]
```

Description

sh The break utility exits from the enclosing for or while loop, if any. If *n* is specified, break *n* levels.

The continue utility resumes the next iteration of the enclosing for or while loop. If *n* is specified, resume at the *n*-th enclosing loop.

csh The break utility resumes execution after the end of the nearest enclosing foreach or while loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of break commands, all on one line.

The continue utility continues execution of the next iteration of the nearest enclosing while or foreach loop.

ksh The break utility exits from the enclosed for, while, until, or select loop, if any. If *n* is specified, then break *n* levels. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be exited.

The continue utility resumes the next iteration of the enclosed for, while, until, or select loop. If *n* is specified then resume at the *n*-th enclosed loop. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be used.

On this man page, [ksh\(1\)](#) commands that are preceded by one or two * (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words that follow a command preceded by ** that are in the format of a variable assignment are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign, and also that word splitting and file name generation are not performed.

Name cal – display a calendar

Synopsis cal [*month*] *year*

Description The cal utility writes a Gregorian calendar to standard output. If the *year* operand is specified, a calendar for that year is written. If no operands are specified, a calendar for the current month is written.

Operands The following operands are supported:

month Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default is the current month.

year Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default is the current year.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cal: LANG, LC_ALL, LC_CTYPE, LC_TIME, LC_MESSAGES, and NLSPATH.

TZ Determine the timezone used to calculate the value of the current month.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

See Also [calendar\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes An unusual calendar is printed for September 1752. That is the month 11 days were skipped to make up for lack of leap year adjustments. To see this calendar, type:

```
cal 9 1752
```

The command cal 83 refers to the year 83, not 1983.

The year is always considered to start in January.

Name calendar – reminder service

Synopsis calendar [-]

Description The `calendar` utility consults the file `calendar` in the current directory and writes lines that contain today's or tomorrow's date anywhere in the line to standard output. Most reasonable month-day dates such as Aug. 24, august 24, 8/24, and so forth, are recognized, but not 24 August or 24/8. On Fridays and weekends “tomorrow” extends through Monday. `calendar` can be invoked regularly by using the `crontab(1)` or `at(1)` commands.

When the optional argument `-` is present, `calendar` does its job for every user who has a file `calendar` in his or her login directory and sends them any positive results by `mail(1)`. Normally this is done daily by facilities in the UNIX operating system (see `cron(1M)`).

If the environment variable `DATMSK` is set, `calendar` will use its value as the full path name of a template file containing format strings. The strings consist of conversion specifications and text characters and are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable `LANG` or `LC_TIME`; see `environ(5)`. See `strftime(3C)` for the list of allowable conversion specifications.

Examples **EXAMPLE 1** Possible contents of a template

The following example shows the possible contents of a template:

```
%B %eth of the year %Y
```

`%B` represents the full month name, `%e` the day of month and `%Y` the year (4 digits).

If `DATMSK` is set to this template, the following `calendar` file would be valid:

```
March 7th of the year 1989 <Reminder>
```

Environment Variables See `environ(5)` for descriptions of the following environment variables that affect the execution of `calendar`: `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TZ`.

Exit Status `0` Successful completion.
`>0` An error occurred.

Files `/etc/passwd` system password file
`/tmp/cal*` temporary files used by `calendar`
`/usr/lib/calprog` program used to determine dates for today and tomorrow

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also [at\(1\)](#), [crontab\(1\)](#), [mail\(1\)](#), [cron\(1M\)](#), [ypbind\(1M\)](#), [strftime\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Notes Appropriate lines beginning with white space will not be printed.

Your calendar must be public information for you to get reminder service.

calendar's extended idea of "tomorrow" does not account for holidays.

The - argument works only on calendar files that are local to the machine; calendar is intended not to work on calendar files that are mounted remotely with NFS. Thus, 'calendar -' should be run only on diskful machines where home directories exist; running it on a diskless client has no effect.

calendar is no longer in the default root crontab. Because of the network burden 'calendar -' can induce, it is inadvisable in an environment running [ypbind\(1M\)](#) with a large passwd.byname map. If, however, the usefulness of calendar outweighs the network impact, the super-user may run 'crontab -e' to edit the root crontab. Otherwise, individual users may wish to use 'crontab -e' to edit their own crontabs to have cron invoke calendar without the - argument, piping output to mail addressed to themselves.

Name	cancel – cancel print request
Synopsis	<pre>cancel [request-ID...] [destination]...</pre> <pre>cancel -u user... [destination]...</pre>
Description	<p>The <code>cancel</code> utility cancels print requests. There are two forms of the <code>cancel</code> command.</p> <p>The first form of <code>cancel</code> has two optional arguments: print requests (<i>request-ID</i>) and destinations (<i>destination</i>). Specifying <i>request-ID</i> with <i>destination</i> cancels <i>request-ID</i> on <i>destination</i>. Specifying only the destination cancels the current print request on <i>destination</i>. If <i>destination</i> is not specified, <code>cancel</code> cancels the requested print request on all destinations.</p> <p>The second form of <code>cancel</code> cancels a user's print requests on specific destinations.</p> <p>Users can only cancel print requests associated with their username. By default, users can only cancel print requests on the host from which the print request was submitted. If a super-user has set <code>user-equivalence=true</code> in <code>/etc/printers.conf</code> on the print server, users can cancel print requests associated with their username on any host. Super-users can cancel print requests on the host from which the print request was submitted. Superusers can also cancel print requests from the print server.</p> <p>The print client commands locate destination information using the <code>printers</code> database in the name service switch. See nsswitch.conf(4), printers(4), and printers.conf(4) for details.</p>
Options	<p>The following options are supported:</p> <p><code>-u user</code> The name of the user for which print requests are to be cancelled. Specify <i>user</i> as a username.</p>
Operands	<p>The following operands are supported:</p> <p><i>destination</i> The destination on which the print requests are to be canceled. <i>destination</i> is the name of a printer or class of printers (see lpadmin(1M)). If <i>destination</i> is not specified, <code>cancel</code> cancels the requested print request on all destinations. Specify <i>destination</i> using atomic, URI-style (<i>scheme://endpoint</i>), or POSIX-style (<i>server:destination</i>), names. See Notes for information regarding using URI-style or POSIX-style destination names with <code>cancel</code>. See printers.conf(4) for more information.</p> <p><i>request-ID</i> The print request to be canceled. Specify <i>request-ID</i> using LP-style request IDs (<i>destination-number</i>).</p> <p><i>user</i> The name of the user for which the print requests are to be cancelled. Specify <i>user</i> as a username.</p>
Exit Status	<p>The following exit values are returned:</p> <p><code>0</code> Successful completion.</p> <p>non-zero An error occurred.</p>

Files	/etc/printers.conf	System printer configuration database
	\$HOME/.printers	User-configurable printer database
	ou=printers	LDAP version of /etc/printers.conf
	printers.conf.byname	NIS version of /etc/printers.conf
	printers.org_dir	NIS+ version of /etc/printers.conf

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlp-cmds
Interface Stability	Obsolete

See Also [lp\(1\)](#), [lpq\(1B\)](#), [lpr\(1B\)](#), [lprm\(1B\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

Notes URI-style and POSIX-style destination names (*server:destination*) are treated as print requests if *destination* has the same format as an LP-style *request-ID*. See [standards\(5\)](#).

Some print servers send cancelation notification to job owners when their print jobs have been cancelled. This notification usually comes in the form of an email message. Cancelation notices cannot be disabled on a Solaris server.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

Name cat – concatenate and display files

Synopsis cat [-nbsuvet] [*file*]...

Description The cat utility reads each *file* in sequence and writes it on the standard output. Thus:

```
example% cat file
```

prints *file* on your terminal, and:

```
example% cat file1 file2 >file3
```

concatenates *file1* and *file2*, and writes the results in *file3*. If no input file is given, cat reads from the standard input file.

Options The following options are supported:

- n Precede each line output with its line number.
- b Number the lines, as -n, but omit the line numbers from blank lines.
- u The output is not buffered. (The default is buffered output.)
- s cat is silent about non-existent files.
- v Non-printing characters (with the exception of tabs, new-lines and form-feeds) are printed visibly. ASCII control characters (octal 000 – 037) are printed as ^*n*, where *n* is the corresponding ASCII character in the range octal 100 – 137 (@, A, B, C, . . . , X, Y, Z, [, \,], ^, and _); the DEL character (octal 0177) is printed ^?. Other non-printable characters are printed as M-*x*, where *x* is the ASCII character specified by the low-order seven bits.

When used with the -v option, the following options may be used:

- e A \$ character will be printed at the end of each line (prior to the new-line).
- t Tabs will be printed as ^I's and formfeeds to be printed as ^L's.

The -e and -t options are ignored if the -v option is not specified.

Operands The following operand is supported:

file A path name of an input file. If no *file* is specified, the standard input is used. If *file* is ' – ', cat will read from the standard input at that point in the sequence. cat will not close and reopen standard input when it is referenced in this way, but will accept multiple occurrences of ' – ' as *file*.

Usage See [largefile\(5\)](#) for the description of the behavior of cat when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Concatenating a file

The following command:

```
example% cat myfile
```

writes the contents of the file `myfile` to standard output.

EXAMPLE 2 Concatenating two files into one

The following command:

```
example% cat doc1 doc2 > doc.all
```

concatenates the files `doc1` and `doc2` and writes the result to `doc.all`.

EXAMPLE 3 Concatenating two arbitrary pieces of input with a single invocation

The command:

```
example% cat start - middle - end > file
```

when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of `cat`. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start - middle /dev/null end > file
```

because the entire contents of the file would be consumed by `cat` the first time ‘`-`’ was used as a *file* operand and an end-of-file condition would be detected immediately when ‘`-`’ was referenced the second time.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `cat`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 All input files were output successfully.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled
Interface Stability	Standard

See Also [touch\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes Redirecting the output of `cat` onto one of the files being read will cause the loss of the data originally in the file being read. For example,

example% `cat filename1 filename2 >filename1`

causes the original data in `filename1` to be lost.

Name	cc – C compiler	
Synopsis	<code>/usr/ucb/cc</code> [<i>options</i>]	
Description	<p><code>/usr/ucb/cc</code> is the interface to the BSD Compatibility Package C compiler. It is a script that looks for the link <code>/usr/ccs/bin/ucbcc</code> to the C compiler. The <code>/usr/ccs/bin/ucbcc</code> link is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code>. The <code>/usr/ucb/cc</code> interface is identical to <code>/usr/ccs/bin/ucbcc</code>, except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/acc.1</code> man page is available only with the SPROcc package.</p>	
Options	<p>The <code>/usr/ucb/cc</code> interface accepts the same options as <code>/usr/ccs/bin/ucbcc</code>, with the following exceptions:</p> <ul style="list-style-type: none"> -I<i>dir</i> Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for <code>#include</code> files in the directory containing <i>sourcefile</i>, and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code>, and finally, in <code>/usr/include</code>. -L<i>dir</i> Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ld</code> and <code>/usr/lib</code>. Directories specified with this option are searched before <code>/usr/ucblib</code> and <code>/usr/lib</code>. -Y P, <i>dir</i> Change the default directory used for finding libraries. 	
Exit Status	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful compilation or link edit. >0 An error occurred. 	
Files	<code>/usr/ccs/bin/ld</code>	link editor
	<code>/usr/lib/libc</code>	C library
	<code>/usr/ucbinclude</code>	BSD Compatibility directory for header files
	<code>/usr/ucblib</code>	BSD Compatibility directory for libraries
	<code>/usr/ucblib/libucb</code>	BSD Compatibility C library
	<code>/usr/lib/libsocket</code>	library containing socket routines
	<code>/usr/lib/libnsl</code>	library containing network functions
	<code>/usr/lib/libelf</code>	library containing routines to process ELF object files
	<code>/usr/lib/libaio</code>	library containing asynchronous I/O routines

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

See Also [ld\(1\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

Notes The `-Y P`, *dir* option may have unexpected results and should not be used.

Name cd, chdir, pushd, popd, dirs – change working directory

Synopsis /usr/bin/cd [*directory*]

sh cd [*argument*]

chdir [*argument*]

csch cd [*dir*]

chdir [*dir*]

pushd [+*n* | *dir*]

popd [+*n*]

dirs [-*l*]

ksh cd [-L] [-P] [*arg*]

cd *old new*

Description

/usr/bin/cd The /usr/bin/cd utility changes the current directory in the context of the cd utility only. This is in contrast to the version built into the shell. /usr/bin/cd has no effect on the invoking process but can be used to determine whether or not a given directory can be set as the current directory.

sh The Bourne shell built-in cd changes the current directory to *argument*. The shell parameter HOME is the default *argument*. The shell parameter CDPATH defines the search path for the directory containing *argument*. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *argument* begins with '/', '.', or './', the search path is not used. Otherwise, each directory in the path is searched for *argument*. cd must have execute (search) permission in *argument*. Because a new process is created to execute each command, cd would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the shell. (See [pwd\(1\)](#), [sh\(1\)](#), and [chdir\(2\)](#)).

chdir is just another way to call cd.

csch If *dir* is not specified, the C shell built-in cd uses the value of shell parameter HOME as the new working directory. If *dir* specifies a complete path starting with '/', '.', or './', *dir* becomes the new working directory. If neither case applies, cd tries to find the designated directory relative to one of the paths specified by the CDPATH shell variable. CDPATH has the same syntax as, and similar semantics to, the PATH shell variable. cd must have execute (search) permission in *dir*. Because a new process is created to execute each command, cd would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the C-shell. (See [pwd\(1\)](#), [sh\(1\)](#), and [chdir\(2\)](#)).

`chdir` changes the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the `cdpath` variable. If *dir* is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

`pushd` pushes a directory onto the directory stack. With no arguments, exchange the top two elements.

`+n` Rotate the *n*'th entry to the top of the stack and `cd` to it.

dir Push the current working directory onto the stack and change to *dir*.

`popd` pops the directory stack and `cd` to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

`+n` Discard the *n*'th entry in the stack.

`dirs` prints the directory stack, most recent to the left; the first directory shown is the current directory. With the `-l` argument, produce an unabbreviated printout; use of the `~` notation is suppressed.

ksh The Korn shell built-in `cd` command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is `-` the directory is changed to the previous directory. The shell variable `HOME` is the default *arg*. The environment variable `PWD` is set to the current directory. If the `PWD` is changed, the `OLDPWD` environment variable shall also be changed to the value of the old working directory, that is, the current working directory immediately prior to the call to change directory (`cd`). The shell variable `CDPATH` defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (`:`). The default path is `null` (specifying the current directory). The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a `' / '`, `' . '`, or `' . . '`, then the search path is not used. Otherwise, each directory in the path is searched for *arg*. If unsuccessful, `cd` attempts to change directories to the pathname formed by the concatenation of the value of `PWD`, a slash character, and *arg*.

-L Handles the operation dot-dot (`..`) logically. Symbolic link components are *not* resolved before dot-dot components are processed.

-P Handles the operand dot-dot physically. Symbolic link components *are* resolved before dot-dot components are processed.

If both **-L** and **-P** options are specified, the last option to be invoked is used and the other is ignored. If neither **-L** nor **-P** is specified, the operand is handled dot-dot logically.

The second form of `cd` substitutes the string *new* for the string *old* in the current directory name, `PWD` and tries to change to this new directory.

The `cd` command cannot be executed by `rksh`. Because a new process is created to execute each command, `cd` would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the Korn shell. (See [pwd\(1\)](#), [sh\(1\)](#), and [chdir\(2\)](#)).

Operands The following operands are supported:

directory An absolute or relative pathname of the directory that becomes the new working directory. The interpretation of a relative pathname by `cd` depends on the `CDPATH` environment variable.

Output If a non-empty directory name from `CDPATH` is used, an absolute pathname of the new working directory is written to the standard output as follows:

`"%s\n", <new directory>`

Otherwise, there is no output.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `cd`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

CDPATH A colon-separated list of pathnames that refer to directories. If the *directory* operand does not begin with a slash (/) character, and the first component is not dot or dot-dot, `cd` searches for *directory* relative to each directory named in the `CDPATH` variable, in the order listed. The new working directory sets to the first matching directory found. An empty string in place of a directory pathname represents the current directory. If `CDPATH` is not set, it is treated as if it were an empty string.

HOME The name of the home directory, used when no *directory* operand is specified.

OLDPWD A pathname of the previous working directory, used by `cd -`.

PWD A pathname of the current working directory, set by `cd` after it has changed to that directory.

Exit Status The following exit values are returned by `cd`:

`0` The directory was successfully changed.

`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

See Also [csh\(1\)](#), [ksh\(1\)](#), [pwd\(1\)](#), [sh\(1\)](#), [chdir\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name cdrw – CD read and write

Synopsis `cdrw -i [-vSC0] [-d device] [-p speed] [image-file]`
`cdrw -a [-vSC0] [-d device] [-p speed] [-T audio-type] audio-file1`
`[audio-file2]...`
`cdrw -x [-v] [-d device] [-T audio-type] track-number out-file`
`cdrw -c [-vSC] [-d device] [-p speed] [-m tmp-dir]`
`[-s src-device]`
`cdrw -b [-v] [-d device] all | session | fast`
`cdrw -L [-v] [-d device]`
`cdrw -M [-v] [-d device]`
`cdrw -l [-v]`
`cdrw -h`

Description The `cdrw` command provides the ability to create data and audio CDs. This command also provides the ability to extract audio tracks from an audio CD and to create data DVDs. The CD or DVD device must be MMC-compliant to create a CD or DVD with the `cdrw` command.

`cdrw` searches for a CD or DVD writer connected to the system, unless you specify a device with the `-d` option. If `cdrw` finds a single such device, it uses that device as the default CD or DVD writer for the command.

When more than one CD or DVD writer is connected to the system, use the `-d` option to indicate which device is desired. The device name can be specified in one of the following ways: `/dev/rdsd/cNtNdNsN`, `cNtNdNsN`, `cNtNdN`, or a name used by volume manager, such as `cdrom` or `cdrom1`. Using the `-l` option provides a list of CD or DVD writers.

For instructions on adding a USB-mass-storage-class-compliant CD-RW or DVD-RW device to your system, see [scsa2usb\(7D\)](#).

Creating Data CDs When creating data CDs, `cdrw` uses the Track-At-Once mode of writing. Use the `-i` option to specify a file that contains the data to write on CD media. If you don't specify this option, `cdrw` reads data from standard input.

In either case, the data is typically prepared by using the `mkisofs` command to convert the file and file information into the High Sierra format used on CDs. See the examples that include use of this command.

Creating Data DVDs `cdrw` can create single-session data DVDs on DVD+RW or DVD-RW devices using images generated from `mkisofs`. These disks can be mounted as HSFS file systems. When making data DVDs, `cdrw` uses Disk-At-Once (DAO) mode of writing, which closes the media when writing is completed and prevents any further sessions from being added. The image should be prepared in advance when writing an image to the DVD media since DAO mode requires that the size of the image be known in advance.

Creating Audio CDs Use the `-a` option to create an audio CD. Single or multiple audio files can be specified with this option. All of the audio files should be in a supported audio format. Currently approved formats are:

- `sun` Sun .au files with data in Red Book CDDA form
- `wav` RIFF (.wav) files with data in Red Book CDDA form
- `cda` .cda files having raw CD audio data (that is, 16 bit PCM stereo at 44.1 KHz sample rate in little-endian byte order)
- `aur` .aur files having raw CD data in big-endian byte order

If no audio format is specified, `cd rw` tries to identify the audio file format based on the file extension. The case of the characters in the extension is ignored. If a format is specified using the `-T` option, it is assumed to be the audio file type for all the files specified. Also, using the `-c` option closes the session after writing the audio tracks. Therefore, the tracks to be written should be specified in a single command line.

Extracting Audio `cd rw` can also be used for extracting audio data from an audio CD with the `-x` option. The CD should have tracks in Red Book CDDA form. By default, the output format is based on the file extension. A user can specify a `sun`, `wav`, `cda`, or `aur` output format with the `-T` option.

Copying CDs `cd rw` can be used to copy single session data CD-ROMs and Red Book audio CDs. When copying a CD, `cd rw` looks for a specified source device. If no source device is specified when using the `-c` option, the current CD writer is assumed to be the source. `cd rw` extracts the track or tracks into a temporary file and looks for a blank writable CD-R/RW media in the current CD writer. If no media is found, insert a blank writable CD media in the current CD writer. If the default temporary directory does not have enough space, an alternate directory can be specified by using the `-m` option.

Erasing CD-RW or DVD-RW Media Users have to erase the CD-RW media before it can be rewritten. With the `-b` option, the following flavors of erasing are currently supported:

- `session` Erases the last session.
- `fast` Minimally erases the media.
- `all` Erases the entire media.

If the session erasing type is used, `cd rw` erases the last session. If there is only one session recorded on the CD-RW (for example, a data or audio CD-RW created by this tool), then session erasing only erases the portion that is recorded, leaving behind a blank disk. This is faster than erasing the entire media. For DVD media, using the `-b session` erases the whole media.

The `fast` erasing type minimally erases the entire media by removing the PMA and TOC of the first session. It does not erase the user data and subsequent tracks on the media, but the media is treated as if it were a blank disk. If a complete erase of the media is necessary, use the `all` option.

The `all` erasing type should be used if it is a multisession disk, the last session is not closed, or disk status is unknown, and you want to erase the disk. With this type of erasing, `cdrw` erases the entire disk.

DVD+RW media does not support erasing. To re-use DVD+RW media, simply write a new image onto the media. `cdrw` formats and overwrites the existing media automatically.

Checking device-list or media-status You can list a system's CD or DVD writers by using the `-l` option. Also, for a particular media, you can get the blanking status and table of contents by using the `-M` option. The `-M` option also prints information about the last session's start address and the next writable address. This information, along with the `-O` option, can be used to create multisession CDs. Refer to the `mkisofs(8)` man page, (`/usr/share/man/man8/mkisofs.8`), in the `SUNWfsman` package for more information.

Options The following options are supported:

- a Creates an audio disk. At least one *audio-file* name must be specified. A CD can not have more than 99 audio tracks, so no more than 99 audio files can be specified. Also, the maximum audio data that can be written to the media by default is 74 minutes, unless `-C` is specified.
- b Blanks CD-RW or DVD-RW media. The type of erasing must be specified by the `all`, `fast`, or `session` argument. DVD+RW media does not support blanking, but can be rewritten without the need for blanking.
- c Copies a CD. If no other argument is specified, the default CD writing device is assumed to be the source device as well. In this case, the copy operation reads the source media into a temporary directory and prompts you to place a blank media into the drive for the copy operation to proceed.
- C Uses stated media capacity. Without this option, `cdrw` uses a default value for writable CD media, which is 74 minutes for an audio CD, 681984000 bytes for a data CD, or 4.7 Gbytes for a DVD.
- d Specifies the CD or DVD writing device.
- h Help. Prints usage message.
- i Specifies the image file for creating data CDs or DVDs. The file size should be less than what can be written on the media. Also, consider having the file locally available instead of having the file on an NFS-mounted file system. The CD writing process expects data to be available continuously without interruptions.

- l Lists all the CD or DVD writers available on the system.
- L Closes the disk. If the media was left in an open state after the last write operation, it is closed to prevent any further writing. This operation can only be done on re-writable CD-RW media.
- m Uses an alternate temporary directory instead of the default temporary directory for storing track data while copying a CD or DVD. An alternate temporary directory might be required because the amount of data on a CD can be huge. For example, the amount of data can be as much as 800 Mbytes for an 80 minute audio CD and 4.7 Gbytes for a DVD. The default temporary directory might not have that much space available.
- M Reports media status. `cdrw` reports if the media is blank or not, its table of contents, the last session's start address, and the next writable address if the disk is open. DVD+RW does not support erasing and always has some content on the media.
- O Keeps the disk open. `cdrw` closes the session, but it keeps the disk open so that another session can be added later on to create a multisession disk.
- p Sets the CD writing speed. For example, `-p 4` sets the speed to 4X. If this option is not specified, `cdrw` uses the default speed of the CD writer. If this option is specified, `cdrw` tries to set the drive write speed to this value, but there is no guarantee of the actual speed that is used by the drive.
- s Specifies the source device for copying a CD or DVD.
- S Simulation mode. In this mode, `cdrw` operates with the drive laser turned off, so nothing is written to the media. Use this option to verify if the system can provide data at a rate good enough for CD writing.

CD-R, CD-RW (not MRW formatted), DVD-R, and DVD-RW media support simulation mode (-S). DVD-RAM, DVD+R, DVD+RW, any MRW-formatted media, and some others do not support simulation mode (-S).
- T Audio format to use for extracting audio files or for reading audio files for audio CD creation. The *audio-type* can be `sun`, `wav`, `cda`, or `aur`.
- v Verbose mode.
- x Extracts audio data from an audio track.

Examples **EXAMPLE 1** Creating a Data CD or DVD

```
example% cdrw -i /local/iso_image
```

EXAMPLE 2 Creating a CD or DVD from a Directory

This example shows how to create a CD or DVD from the directory tree `/home/foo`.

```
example% mkisofs -r /home/foo 2>/dev/null | cdrw -i -p 1
```

EXAMPLE 3 Extracting an Audio Track Number

This example shows how to extract audio track number 1 to `/home/foo/song1.wav`.

```
example% cdrw -x -T wav 1 /home/foo/song1.wav
```

EXAMPLE 4 Using wav Files

This example shows how to create an audio CD from wav files on disk.

```
example% cdrw -a song1.wav song2.wav song3.wav song4.wav
```

EXAMPLE 5 Erasing CD-RW or DVD-RW Media

This example shows how to erase rewritable media.

```
example% cdrw -b all
```

EXAMPLE 6 Creating a Data CD or DVD with Multiple Drives

This example shows how to create a data CD or DVD on a system with multiple CD, DVD-R, or DVD-RW drives.

```
example% cdrw -d c1t6d0s2 -i /home/foo/iso-image
```

EXAMPLE 7 Checking Data Delivery Rate

This example shows how to verify that the system can provide data to a CD-RW or a DVD drive at a rate sufficient for the write operation.

```
example% cdrw -S -i /home/foo/iso-image
```

EXAMPLE 8 Running at a Higher Priority

This example shows how to run `cdrw` at a higher priority (for root user only).

```
example# priocntl -e -p 60 cdrw -i /home/foo/iso-image
```

EXAMPLE 9 Creating a Multi-session Disk

This examples shows how to create the first session image by using `mkisofs` and recording it onto the disk without closing the disk.

```
example% cdrw -O -i /home/foo/iso-image
```

Additional sessions can be added to an open disk by creating an image with `mkisofs` using the session start and next writable address reported by `cdrw`.

```
example% cdrw -M
```

Track No.	Type	Start address
1	Data	0

EXAMPLE 9 Creating a Multi-session Disk (Continued)

```

Leadout   |Data   | 166564

Last session start address: 162140
Next writable address: 173464

example% mkisofs -o /tmp/image2 -r -C 0,173464 -M \
/dev/rdisk/c0t2d0s2 /home/foo

```

System Administration Guide: Devices and File Systems

Notes The CD writing process requires data to be supplied at a constant rate to the drive. Keep I/O activity to a minimum and shut down any related I/O applications while writing CDs.

When making copies or extracting audio tracks, use an MMC compliant source CD-ROM drive. The CD writer can be used for this purpose.

Before writing a CD, ensure that the media is blank by using the `-M` option. You can use the `-S` simulation mode to test the system to make sure it can provide data at the required rate. `cdrw` turns on buffer underrun protection for drives that support it and recovers from most stalls. If the system is not able to provide data at a constant rate or frequent stalling occurs, you can lower the speed by using the `-p` option. You can also try to run `cdrw` at a higher priority by using the [priocntl\(1\)](#) command.

If you know that the CD-R/RW drive can operate at different write speeds, use the `-p` option. Some commercially available drives handle the drive speed setting command differently, so use this option judiciously.

Most commercially available drives allow writing beyond 74 minutes as long as the media has the capacity (such as 80-minute media). However, the ability to write beyond 74 minutes might not be supported by the drive in use. If the drive supports this feature, then use the `-C` option to indicate that the tool should rely on the capacity indicated by the media.

The `cdrw` command uses [rbac\(5\)](#) to control user access to the devices. By default, `cdrw` is accessible to all users but can be restricted to individual users. Refer to the *System Administration Guide: Devices and File Systems* for more information.

Name checknr – check nroff and troff input files; report possible errors

Synopsis checknr [-fs] [-a . x1 . y1 . x2 . y2xn .yn]
[-c . x1 . x2 . x3xn] [filename]...

Description checknr checks a list of [nroff\(1\)](#) or [troff\(1\)](#) input files for certain kinds of errors involving mismatched opening and closing delimiters and unknown commands. If no files are specified, checknr checks the standard input. Delimiters checked are:

- Font changes using \fx ... \fP.
- Size changes using \sx ... \s0.
- Macros that come in open ... close forms, for example, the .TS and .TE macros which must always come in pairs.

checknr knows about the [ms\(5\)](#) and [me\(5\)](#) macro packages.

checknr is intended to be used on documents that are prepared with checknr in mind. It expects a certain document writing style for \f and \s commands, in that each \fx must be terminated with \fP and each \sx must be terminated with \s0. While it will work to directly go into the next font or explicitly specify the original font or point size, and many existing documents actually do this, such a practice will produce complaints from checknr. Since it is probably better to use the \fP and \s0 forms anyway, you should think of this as a contribution to your document preparation style.

- Options**
- f Ignore \f font changes.
 - s Ignore \s size changes.
 - a .x1 .y1 ... Add pairs of macros to the list. The pairs of macros are assumed to be those (such as .DS and .DE) that should be checked for balance. The -a option must be followed by groups of six characters, each group defining a pair of macros. The six characters are a period, the first macro name, another period, and the second macro name. For example, to define a pair .BS and .ES, use '-a.BS.ES'
 - c .x1 ... Define commands which checknr would otherwise complain about as undefined.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

See Also [eqn\(1\)](#), [nroff\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [me\(5\)](#), [ms\(5\)](#)

Bugs There is no way to define a one-character macro name using the `-a` option.

Name chgrp – change file group ownership

Synopsis chgrp [-fhR] *group file...*
chgrp -R [f] [-H | -L | -P] *group file...*

Description The chgrp utility will set the group ID of the file named by each *file* operand to the group ID specified by the *group* operand.

For each *file* operand, it will perform actions equivalent to the [chown\(2\)](#) function, called with the following arguments:

- The *file* operand will be used as the *path* argument.
- The user ID of the file will be used as the *owner* argument.
- The specified group ID will be used as the *group* argument.

Unless chgrp is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file will be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

The operating system has a configuration option `_POSIX_CHOWN_RESTRICTED`, to restrict ownership changes. When this option is in effect, the owner of the file may change the group of the file only to a group to which the owner belongs. Only the super-user can arbitrarily change owner IDs, whether or not this option is in effect. To set this configuration option, include the following line in `/etc/system`:

```
set rstchown = 1
```

To disable this option, include the following line in `/etc/system`:

```
set rstchown = 0
```

`_POSIX_CHOWN_RESTRICTED` is enabled by default. See [system\(4\)](#) and [fpathconf\(2\)](#).

Options The following options are supported.

<div>/usr/bin/chgrp and /usr/xpg4/bin/chgrp</div>	<div>-f Force. Does not report errors.</div> <div>-h If the file is a symbolic link, this option changes the group of the symbolic link. Without this option, the group of the file referenced by the symbolic link is changed.</div> <div>-H If the file specified on the command line is a symbolic link referencing a file of type directory, this option changes the group of the directory referenced by the symbolic link and all the files in the file hierarchy below it. If a symbolic link is encountered when traversing a file hierarchy, the group of the target file is changed, but no recursion takes place.</div> <div>-L If the file is a symbolic link, this option changes the group of the file referenced by the symbolic link. If the file specified on the command line, or encountered during the traversal of the file hierarchy, is a symbolic link referencing a file of type directory, then this option changes the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.</div>
-------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

- P If the file specified on the command line or encountered during the traversal of a file hierarchy is a symbolic link, this option changes the group of the symbolic link. This option does not follow the symbolic link to any other part of the file hierarchy.

Specifying more than one of the mutually-exclusive options -H, -L, or -P is not considered an error. The last option specified determines the behavior of chgrp.

- /usr/bin/chgrp -R Recursive. chgrp descends through the directory, and any subdirectories, setting the specified group ID as it proceeds. When a symbolic link is encountered, the group of the target file is changed, unless the -h or -P option is specified. However, no recursion takes place, unless the -H or -L option is specified.
- /usr/xpg4/bin/chgrp -R Recursive. chgrp descends through the directory, and any subdirectories, setting the specified group ID as it proceeds. When a symbolic link is encountered, the group of the target file is changed, unless the -h or -P option is specified. Unless the -H, -L, or -P option is specified, the -L option is used as the default mode.

Operands The following operands are supported:

- group* A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the *file* operands. If a numeric *group* operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.
- file* A path name of a file whose group ID is to be modified.

Usage See [largefile\(5\)](#) for the description of the behavior of chgrp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of chgrp: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 The utility executed successfully and all requested changes were made.
- >0 An error occurred.

Files /etc/group group file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled (see NOTES)
Interface Stability	Standard

/usr/xpg4/bin/chgrp	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	CSI	Enabled (see NOTES)
	Interface Stability	Standard

See Also [chmod\(1\)](#), [chown\(1\)](#), [id\(1M\)](#), [chown\(2\)](#), [fpathconf\(2\)](#), [group\(4\)](#), [passwd\(4\)](#), [system\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes chgrp is CSI-enabled except for the *group* name.

Name chkey – change user's secure RPC key pair

Synopsis chkey [-p] [-s nisplus | nis | files | ldap]
[-m <mechanism>]

Description chkey is used to change a user's secure RPC public key and secret key pair. chkey prompts for the old secure-rpc password and verifies that it is correct by decrypting the secret key. If the user has not already used [keylogin\(1\)](#) to decrypt and store the secret key with [keyserv\(1M\)](#), chkey registers the secret key with the local [keyserv\(1M\)](#) daemon. If the secure-rpc password does not match the login password, chkey prompts for the login password. chkey uses the login password to encrypt the user's secret Diffie-Hellman (192 bit) cryptographic key. chkey can also encrypt other Diffie-Hellman keys for authentication mechanisms configured using [nisauthconf\(1M\)](#).

chkey ensures that the login password and the secure-rpc password(s) are kept the same, thus enabling password shadowing. See [shadow\(4\)](#).

The key pair can be stored in the /etc/publickey file (see [publickey\(4\)](#)), the NIS publickey map, or the NIS+ cred.org_dir table. If a new secret key is generated, it will be registered with the local [keyserv\(1M\)](#) daemon. However, only NIS+ can store Diffie-Hellman keys other than 192-bits.

Keys for specific mechanisms can be changed or reencrypted using the -m option followed by the authentication mechanism name. Multiple -m options can be used to change one or more keys. However, only mechanisms configured using [nisauthconf\(1M\)](#) can be changed with chkey.

If the source of the publickey is not specified with the -s option, chkey consults the publickey entry in the name service switch configuration file. See [nsswitch.conf\(4\)](#). If the publickey entry specifies one and only one source, then chkey will change the key in the specified name service. However, if multiple name services are listed, chkey can not decide which source to update and will display an error message. The user should specify the source explicitly with the -s option.

Non root users are not allowed to change their key pair in the files database.

Options The following options are supported:

- | | |
|----------------|--------------------------------------------------------------------|
| -p | Re-encrypt the existing secret key with the user's login password. |
| -s nisplus | Update the NIS+ database. |
| -s nis | Update the NIS database. |
| -s files | Update the files database. |
| -s ldap | Update the LDAP database. |
| -m <mechanism> | Changes or re-encrypt the secret key for the specified mechanism. |

Files /etc/nsswitch.conf
/etc/publickey

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [keylogin\(1\)](#), [keylogout\(1\)](#), [keyserv\(1M\)](#), [newkey\(1M\)](#), [nisaddcred\(1M\)](#), [nisauthconf\(1M\)](#), [nsswitch.conf\(4\)](#), [publickey\(4\)](#), [shadow\(4\)](#), [attributes\(5\)](#)

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

Name chmod – change the permissions mode of a file

Synopsis chmod [-fR] *absolute-mode* file...
 chmod [-fR] *symbolic-mode-list* file...
 chmod [-fR] *acl_operation* file...

Description The chmod utility changes or assigns the mode of a file.

chmod can also be used to modify Access Control Lists (ACLs) on files and directories.

Absolute Mode An absolute mode specification has the following format:

chmod [*options*] *absolute-mode* file...

where *absolute-mode* is specified using octal numbers *nnnn* defined as follows:

n a number from 0 to 7. An absolute mode is constructed from the OR of any of the following modes:

4000 Set user ID on execution.

20 # 0 Set group ID on execution if # is 7, 5, 3, or 1.

Enable mandatory locking if # is 6, 4, 2, or 0.

For directories, files are created with BSD semantics for propagation of the group ID. With this option, files and subdirectories created in the directory inherit the group ID of the directory, rather than of the current process. For directories, the set-gid bit can only be set or cleared by using symbolic mode.

1000 Turn on sticky bit. See [chmod\(2\)](#).

0400 Allow read by owner.

0200 Allow write by owner.

0100 Allow execute (search in directory) by owner.

0700 Allow read, write, and execute (search) by owner.

0040 Allow read by group.

0020 Allow write by group.

0010 Allow execute (search in directory) by group.

0070 Allow read, write, and execute (search) by group.

0004 Allow read by others.

0002 Allow write by others.

0001 Allow execute (search in directory) by others.

0007 Allow read, write, and execute (search) by others.

For directories, the `setgid` bit cannot be set (or cleared) in absolute mode; it must be set (or cleared) in symbolic mode using `g+s` (or `g-s`).

Symbolic Mode A symbolic mode specification has the following format:

`chmod [options] symbolic-mode-list file ...`

where *symbolic-mode-list* is a comma-separated list (with no intervening whitespace) of symbolic mode expressions of the form:

`[who] operator [permissions]`

Operations are performed in the order given. Multiple *permissions* letters following a single operator cause the corresponding operations to be performed simultaneously.

who zero or more of the characters `u`, `g`, `o`, and `a` specifying whose permissions are to be changed or assigned:

- `u` user's permissions
- `g` group's permissions
- `o` others' permissions
- `a` all permissions (user, group, and other)

If *who* is omitted, it defaults to `a`, but the setting of the file mode creation mask (see `umask` in [sh\(1\)](#) or [csh\(1\)](#) for more information) is taken into account. When *who* is omitted, `chmod` does not override the restrictions of your user mask.

operator either `+`, `-`, or `=`, signifying how permissions are to be changed:

- `+` Add permissions.

If *permissions* are omitted, nothing is added.

If *who* is omitted, add the file mode bits represented by *permissions*, *except* for the those with corresponding bits in the file mode creation mask.

If *who* is present, add the file mode bits represented by the *permissions*.

- `-` Take away permissions.

If *permissions* are omitted, do nothing.

If *who* is omitted, clear the file mode bits represented by *permissions*, *except* for those with corresponding bits in the file mode creation mask.

If *who* is present, clear the file mode bits represented by *permissions*.

= Assign permissions absolutely.

If *who* is omitted, clear all file mode bits; if *who* is present, clear the file mode bits represented by *who*.

If *permissions* are omitted, do nothing else.

If *who* is omitted, add the file mode bits represented by *permissions*, *except* for the those with corresponding bits in the file mode creation mask.

If *who* is present, add the file mode bits represented by *permissions*.

Unlike other symbolic operations, = has an absolute effect in that it resets all other bits represented by *who*. Omitting *permissions* is useful only with = to take away all permissions.

permission any compatible combination of the following letters:

- l mandatory locking
- r read permission
- s user or group set-ID
- t sticky bit
- w write permission
- x execute permission
- X execute permission if the file is a directory or if there is execute permission for one of the other user classes
- u,g,o indicate that *permission* is to be taken from the current user, group or other mode respectively.

Permissions to a file can vary depending on your user identification number (UID) or group identification number (GID). Permissions are described in three sequences each having three characters:

User	Group	Other
rwX	rwX	rwX

This example (user, group, and others all have permission to read, write, and execute a given file) demonstrates two categories for granting permissions: the access class and the permissions themselves.

The letter *s* is only meaningful with *u* or *g*, and *t* only works with *u*.

Mandatory file and record locking (*l*) refers to a file's ability to have its reading or writing permissions locked while a program is accessing that file.

In a directory which has the set-group-ID bit set (reflected as either *-----s---* or *-----l---* in the output of '*ls -ld*'), files and subdirectories are created with the group-ID of the parent directory—not that of current process.

It is not possible to permit group execution and enable a file to be locked on execution at the same time. In addition, it is not possible to turn on the set-group-ID bit and enable a file to be locked on execution at the same time. The following examples, therefore, are invalid and elicit error messages:

```
chmod g+x,+l file
chmod g+s,+l file
```

Only the owner of a file or directory (or the super-user) can change that file's or directory's mode. Only the super-user can set the sticky bit on a non-directory file. If you are not super-user, *chmod* masks the sticky-bit but does not return an error. In order to turn on a file's set-group-ID bit, your own group ID must correspond to the file's and group execution must be set.

ACL Operation An ACL Operation specification has the following format:

```
chmod [options] A[number]- file ...
chmod [options] A-acl_specification file ...
chmod [options] A[index]{+|=}acl_specification file ...
```

Where *acl_specification* is a comma-separated list (with no intervening whitespace) of an ACL specification of the form:

- | | |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A[index]+acl_specification</i> | Prepends the access control entries (ACE) specified in <i>acl_specification</i> to the beginning of the file's ACL. Depending on the file system, the ACL can be reordered when applied to the file. If “optional” number is specified then new ACEs are inserted before specified number. |
| <i>A-</i> | Removes all ACEs for current ACL on file and replaces current ACL with new ACL that represents only the current mode of the file. |
| <i>Aindex-</i> | Removes ACE specified by <i>index</i> number. |

<i>A=acl_specification</i>	Removes ACEs specified by <i>acl_specification</i> , if they exist in current file's ACL.
<i>A=acl_specification</i>	Replaces a files entire ACL with <i>acl_specification</i> .
<i>A[index]=acl_specification</i>	Replaces ACEs starting at a specific index number in the current ACL on the file. If multiple ACEs are specified, then each subsequent ACE in <i>acl_specification</i> replaces the corresponding ACE in the current ACL.

POSIX-draft ACL Specification (as supported by UFS)

POSIX-draft ACLs (as supported by UFS) are specified as colon (:) separated fields of the following.

<i>user::perms</i>	File owner permissions.
<i>user:username:perms</i>	Permissions for a specific user.
<i>group::perms</i>	File group owner permissions.
<i>group:groupname:perms</i>	Permissions for a specific group.
<i>other::perms</i>	Permissions for user other than the file owner or members of file group owner.
<i>mask:perms</i>	The ACL mask. The mask entry specifies the maximum permissions allowed for user (other than that the owner) and for groups.
<i>default:user::perms</i>	Default file owner permissions.
<i>default:user:username:perms</i>	Default permissions for a specific user.
<i>default:group::perms</i>	Default file group owner permissions.
<i>default:group:groupname:perms</i>	Default permissions for a specific group.
<i>default:other:perms</i>	Default permissions for user other than the file owner or members of the file group owner.
<i>default:mask:perms</i>	Default ACL mask.

The above specification allows for ACLs to be specified such as:

```
user:tom:rw-,mask:rwx,group:staff:r-x
```

NFSv4 ACL Specification (as supported by NFSv4 and ZFS)

NFSv4 ACLs provide richer ACL semantics. They provide both allow and deny entries, finer grained permissions, and enhanced inheritance control.

NFSv4 ACLs are specified as colon (:) separated fields of the following.

owner@:<perms>[:inheritance flags]:<allow|deny>

Permissions for file owner.

group@:<perms>[:inheritance flags]:<allow|deny>

Permissions for file group owner.

everyone@:<perms>[:inheritance flags]:<allow|deny>

Permissions for everyone, including file owner and group owner.

user:<username>:<perms>[:inheritance flags]:<allow|deny>

Permissions for a specific user.

group:<groupname>:<perms>[:inheritance flags]:<allow|deny>

Permissions for a specific group.

groupsid:<sid string>:<perms>[:inheritance flags]:<allow|deny>

Permissions for a specific group, but group is specified by SID.

sid:<sid string>:<perms>[:inheritance flags]:<allow|deny>

Permissions for a specific SID, but it doesn't matter if it is a user or a group.

Permissions can be specified in three different chmod ACL formats: verbose, compact, or positional. The verbose format uses words to indicate that the permissions are separated with a forward slash (/) character. Compact format uses the permission letters and positional format uses the permission letters or the hyphen (-) to identify no permissions.

The permissions for verbose mode and their abbreviated form in parentheses for compact and positional mode are described as follows:

read_data (r)	Permission to read the data of a file.
list_directory (r)	Permission to list the contents of a directory.
write_data (w)	Permission to modify a file's data. anywhere in the file's offset range.
add_file (w)	Permission to add a new file to a directory.
append_data (p)	The ability to modify a file's data, but only starting at EOF. Currently, this permission is not supported.
add_subdirectory (p)	Permission to create a subdirectory to a directory.
read_xattr (R)	Ability to read the extended attributes of a file.
write_xattr (A)	Ability to create extended attributes or write to the extended attribute directory.
execute (x)	Permission to execute a file.
read_attributes (a)	The ability to read basic attributes (non-ACLs) of a file.

<code>write_attributes (w)</code>	Permission to change the times associated with a file or directory to an arbitrary value.
<code>delete (d)</code>	Permission to delete a file.
<code>delete_child (D)</code>	Permission to delete a file within a directory.
<code>read_acl (c)</code>	Permission to read the ACL of a file.
<code>write_acl (C)</code>	Permission to write the ACL of a file.
<code>write_owner (o)</code>	Permission to change the owner of a file.
<code>synchronize (s)</code>	Permission to access file locally at server with synchronize reads and writes.

Currently, this permission is not supported.

Using the compact ACL format, permissions are specified by using 14 unique letters to indicate permissions.

Using the positional ACL format, permissions are specified as positional arguments similar to the `ls -V` format. The hyphen (-), which indicates that no permission is granted at that position, can be omitted and only the required letters have to be specified.

The letters above are listed in the order they would be specified in positional notation.

Permissions can be specified with these letters in the following way:

```
rwX--D-----
```

The hyphens can be removed to compact the string as follows:

```
rxwD
```

The optional inheritance flags can be specified in the three formats. The first format uses words to indicate the various inheritance flags separated with a forward slash (/) character.

<code>file_inherit (f)</code>	Inherit to all newly created files.
<code>dir_inherit (d)</code>	Inherit to all newly created directories.
<code>inherit_only (i)</code>	When placed on a directory, do not apply to the directory, only to newly created files and directories. This flag requires that either <code>file_inherit</code> and or <code>dir_inherit</code> is also specified.
<code>no_propagate (n)</code>	Indicates that ACL entries should be inherited to objects in a directory, but inheritance should stop after descending one level. This flag is dependent upon either <code>file_inherit</code> and or <code>dir_inherit</code> also being specified.

The inheritance flags listed can also be specified in the compact format or as positional arguments similar to the `ls -V` format. A hyphen character indicates that the inheritance flag at that position is not specified in the positional ACL format.

The inheritance flags can be specified with these letters in any of the following equivalent ways.

`file_inherit/dir_inherit/no_propagate`

`fd-n--`

`fdn`

With this inheritance model, an ACL entry can be specified such as:

`user:tom:read_data/write_data/read_attributes:file_inherit:allow`

`user:fred:read_data:file_inherit/dir_inherit:deny`

`user:bob:read_data:allow`

Options The following options are supported:

- f Force. `chmod` does not complain if it fails to change the mode of a file.
- R Recursively descends through directory arguments, setting the mode for each file as described above. When symbolic links are encountered, the mode of the target file is changed, but no recursion takes place.

Operands The following operands are supported:

absolute-mode

symbolic-mode-list Represents the change to be made to the file mode bits of each file named by one of the *file* operands. See [Absolute Mode](#) and [Symbolic Mode](#) above in the [Description](#) section for more information.

acl_operation

Represents the modification to be performed on the file's ACL. See [ACL Operation](#) in the [DESCRIPTION](#) section for more information.

acl_operation is one of the following:

`A[number] -`

`A-acl_specification`

`A[index]{+|=}acl_specification`

file

A path name of a file whose file mode bits are to be modified.

Usage See [largefile\(5\)](#) for the description of the behavior of `chmod` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 Denying execute Permission

The following example denies execute permission to everyone:

```
example% chmod a-x file
```

EXAMPLE 2 Allowing read-only Permission

The following example allows only read permission to everyone:

```
example% chmod 444 file
```

EXAMPLE 3 Making a File readable and writable

The following example makes a file readable and writable by the group and others:

```
example% chmod go+rw file
```

```
example% chmod 066 file
```

EXAMPLE 4 Locking a File From Access

The following example locks a file from access:

```
example% chmod +l file
```

EXAMPLE 5 Granting read, write, execute, and set group-ID Permission on a File

The following example grants everyone read, write, and execute permissions on the file, and turns on the set group-ID:

```
example% chmod a=rwx,g+s file
```

```
example% chmod 2777 file
```

EXAMPLE 6 Prepending a New ACL Entry on a ZFS File

The following example prepends a new ACL entry on a ZFS file.

First, display the current ACL:

```
example% ls -v file.3
-rw-r--r--  1 marks  staff           0 Oct  9 15:49 file.3
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow
```

Issue the following command:

EXAMPLE 6 Prepending a New ACL Entry on a ZFS File *(Continued)*

```
example% chmod A+user:lp:read_data:deny file.3
```

Display the new ACL:

```
example% ls -v file.3
-rw-r--r--+ 1 marks    staff          0 Oct  9 15:49 file.3
0:user:lp:read_data:deny
1:owner@:execute:deny
2:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
3:group@:write_data/append_data/execute:deny
4:group@:read_data:allow
5:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
6:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow
```

EXAMPLE 7 Prepending a New POSIX-draft ACL Entry on a UFS File

The following example prepends a new POSIX-draft ACL entry on a UFS file.

First, display the current ACL:

```
example% ls -v file.2
-rw-r--r-- 1 marks    staff          0 Oct  9 15:52 file.2
0:user::rw-
1:group::r--          #effective:r--
2:mask:r--
3:other:r--
```

Issue the following command:

```
example% chmod A+user:lp:-wx file.2
```

Display the new ACL:

```
example% ls -v file.2
-rw-r--r--+ 1 marks    staff          0 Oct  9 15:52 file.2
0:user::rw-
1:user:lp:-wx          #effective:---
2:group::r--          #effective:r--
3:mask:r--
4:other:r--
```

EXAMPLE 8 Inserting an ACL Entry in a Specific Position on a ZFS file

The following example inserts an ACL entry in a specific position on a ZFS file system. It also illustrates the compact ACL format.

EXAMPLE 8 Inserting an ACL Entry in a Specific Position on a ZFS file *(Continued)*

First, display the ACL to pick a location to insert a new ACE.

```
example% ls -V file.1
-rw-r--r--+ 1 root      root          0 Oct  6 12:16 file.1
  user:lp:rw-----:-----:allow
  owner@:--x-----:-----:deny
  owner@:rw-p---A-W-Co-:-----:allow
  group@:-w xp-----:-----:deny
  group@:r-----:-----:allow
  everyone@:-w xp---A-W-Co-:-----:deny
  everyone@:r-----a-R-c--s:-----:allow
```

Next, insert a new entry in location 3. This causes the entries that are currently in position 3 - 6 to be pushed down.

Issue the following command:

```
example% chmod A3+user:marks:r:deny file.1
```

Display the new ACL:

```
example% ls -V file.1
-rw-r--r--+ 1 root      staff          0 Feb  3 14:13 file.1
  user:lp:rw-----:-----:allow
  owner@:--x-----:-----:deny
  owner@:rw-p---A-W-Co-:-----:allow
  user:marks:r-----:-----:deny
  group@:-w xp-----:-----:deny
  group@:r-----:-----:allow
  everyone@:-w xp---A-W-Co-:-----:deny
  everyone@:r-----a-R-c--s:-----:allow
```

EXAMPLE 9 Inserting a POSIX-draft ACL in a Specific Position on a UFS File

The file system reorders ACLs when they are stored in the file system. The following example illustrates this behavior.

```
example% ls -v file.1
-rw-r--r--+ 1 root      root          0 Sep 29 16:10 file.1
  0:user::rw-
  1:user:lp:rw-      #effective:r--
  2:group::r--      #effective:r--
  3:mask:r--
  4:other:r--
```

Now, insert an entry at index position 3. The command works, but the file system reorders the ACL.

EXAMPLE 9 Inserting a POSIX-draft ACL in a Specific Position on a UFS File *(Continued)*

```
example% chmod A3+user:marks:rw- file.1
example% ls -v file.1
-rw-r--r--+ 1 root      root          0 Sep 29 16:10 file.1
 0:user::rw-
 1:user:lp:rw-          #effective:r--
 2:user:marks:rw-       #effective:r--
 3:group::r--           #effective:r--
 4:mask:r--
 5:other:r--
```

Rather than inserting the ACL entry in position 3 as requested, it actually ends up in position 2.

EXAMPLE 10 Removing an ACL Entry on a ZFS File

The following example removes the lp entry from an ACL:

```
example% ls -v file.3
-rw-r--r--+ 1 marks    staff          0 Oct  9 15:49 file.3
 0:user:lp:read_data:deny
 1:owner@:execute:deny
 2:owner@:read_data/write_data/append_data/write_xattr/
   write_attributes/write_acl/write_owner:allow
 3:group@:write_data/append_data/execute:deny
 4:group@:read_data:allow
 5:everyone@:write_data/append_data/write_xattr/execute/
   write_attributes/write_acl/write_owner:deny
 6:everyone@:read_data/read_xattr/read_attributes/read_acl/
   synchronize:allow

example% chmod A-user:lp:read_data:deny file.3
example% ls -v file.3
-rw-r--r-- 1 marks    staff          0 Oct  9 15:49 file.3
 0:owner@:execute:deny
 1:owner@:read_data/write_data/append_data/write_xattr/
   write_attributes/write_acl/write_owner:allow
 2:group@:write_data/append_data/execute:deny
 3:group@:read_data:allow
 4:everyone@:write_data/append_data/write_xattr/execute/
   write_attributes/write_acl/write_owner:deny
 5:everyone@:read_data/read_xattr/read_attributes/read_acl/
   synchronize:allow
```

EXAMPLE 11 Removing a POSIX-draft ACL on a UFS File

The following example removes the lp entry from an ACL:

EXAMPLE 11 Removing a POSIX-draft ACL on a UFS File *(Continued)*

```

example% ls -v file.2
-rw-r--r--+ 1 marks      staff          0 Oct  9 15:52 file.2
  0:user::rw-
  1:user:lp:-wx          #effective:---
  2:group::r--          #effective:r--
  3:mask:r--
  4:other:r--

example% chmod A-user:lp:-wx file.2
example% ls -v file.2
-rw-r--r--  1 marks      staff          0 Oct  9 15:52 file.2
  0:user::rw-
  1:group::r--          #effective:r--
  2:mask:r--
  3:other:r--

```

EXAMPLE 12 Removing a Specific ACL Entry by Index Number on a ZFS File

Consider the following ACL:

```

example% ls -v file
  0:group:staff:read_data/write_data/execute/read_acl:allow
  1:user:bin:read_data:deny
  2:user:bin:read_data:allow
  3:owner@:write_data/append_data:deny
  4:owner@:read_data/write_xattr/execute/write_attributes/write_acl
    /write_owner:allow
  5:group@:write_data/append_data:deny
  6:group@:read_data/execute:allow
  7:everyone@:write_data/append_data/write_xattr/write_attributes
    /write_acl/write_owner:deny
  8:everyone@:read_data/read_xattr/execute/read_attributes/read_acl
    /synchronize:allow

```

Remove the second user entry for bin.

```

example% chmod A2- file
example% ls -v file
  0:group:staff:read_data/write_data/execute/read_acl:allow
  1:user:bin:read_data:deny
  2:owner@:write_data/append_data:deny
  3:owner@:read_data/write_xattr/execute/write_attributes/write_acl
    /write_owner:allow
  4:group@:write_data/append_data:deny
  5:group@:read_data/execute:allow
  6:everyone@:write_data/append_data/write_xattr/write_attributes
    /write_acl/write_owner:deny

```

EXAMPLE 12 Removing a Specific ACL Entry by Index Number on a ZFS File *(Continued)*

```
7:everyone@:read_data/read_xattr/execute/read_attributes/read_acl
/synchronize:allow
```

EXAMPLE 13 Removing a Specific POSIX-draft ACL Entry on a UFS File

The following example removes the lp entry by index number from the following ACL:

```
example% ls -v file.1
-rw-r--r--+ 1 root      root          0 Sep 29 16:10 file.1
0:user::rw-
1:user:lp:rw-          #effective:r--
2:group::r--          #effective:r--
3:mask:r--
4:other:r--

example% chmod A1- file.1
example% ls -v
-rw-r--r--+ 1 root      root          0 Sep 29 16:10 file.1
0:user::rw-
1:group::r--          #effective:r--
2:mask:r--
3:other:r--
```

EXAMPLE 14 Removing All ACLs From a File

The following command works with either NFSv4/ZFS or POSIX-draft ACLs.

Consider the following ACL:

```
example% ls -v file.3
-rw-r--r--+ 1 marks    staff          0 Oct  9 15:49 file.3
0:user:lp:read_data/write_data:allow
1:user:marks:read_acl:allow
2:owner@:execute:deny
3:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
4:group@:write_data/append_data/execute:deny
5:group@:read_data:allow
6:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
7:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow
```

The existing ACL is effectively removed and is replaced with an ACL that represents the permission bits of the file.

EXAMPLE 14 Removing All ACLs From a File (Continued)

```
example% chmod A- file.3
example% ls -v file.3
-rw-r--r-- 1 marks    staff          0 Oct  9 15:49 file.3
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow
```

EXAMPLE 15 Replacing an Entire ACL Entry on a ZFS File

Use the following chmod syntax if you want to replace an ACL in its entirety:

```
example% chmod A=owner@:read_data/write_data:allow,group@:read_data/
  write_data:allow,user:lp:read_data:allow file.4
example% ls -v file.4
-rw-rw----+ 1 marks    staff          0 Oct  9 16:12 file.4
0:owner@:read_data/write_data:allow
1:group@:read_data/write_data:allow
2:user:lp:read_data:allow
```

EXAMPLE 16 Replacing an Entire POSIX-draft ACL on a UFS File

This operation is a little more complicated. The replacement ACL needs the necessary entries to represent the file owner, file group owner, other, mask and any additional entries you wish to set.

```
example% chmod A=user::rw-,group::rw-,other::---,mask:r--,
  user:lp:r-- file.3
example% ls -v file.3
-rw-r-----+ 1 root      root          0 Oct  9 16:14 file.3
0:user::rw-
1:user:lp:r--      #effective:r--
2:group::rw-      #effective:r--
3:mask:r--
4:other:---
```

EXAMPLE 17 Replacing a Specific Entry on a ZFS File

Consider the following ACL.

```
example% ls -v file.5
-rw-r--r--+ 1 marks    staff          0 Oct  9 16:18 file.5
```

EXAMPLE 17 Replacing a Specific Entry on a ZFS File (Continued)

```

0:user:marks:read_data:allow
1:owner@:execute:deny
2:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
3:group@:write_data/append_data/execute:deny
4:group@:read_data:allow
5:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
6:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow

```

Now, change the allow access to a deny for user marks:

```

example% chmod A0=user:marks:read_data:deny file.5
example% ls -v file.5
-rw-r--r--+ 1 marks  staff          0 Aug 23 09:11 file.5
0:user:marks:read_data:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
  /write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
  /write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
  :allow

```

EXAMPLE 18 Replacing a Specific POSIX-draft ACL on a UFS File

Consider the following ACL.

```

example% ls -v file.4
-rw-r--r--+ 1 marks  staff          0 Oct  9 16:21 file.4
0:user::rw-
1:user:lp:rw-      #effective:r--
2:group::r--      #effective:r--
3:mask:r--
4:other:r--

```

Now, change the permission on lp from rw- to r--:

```

example% chmod A1=user:lp:r-- file.4

example% ls -v file
-rw-r--r--+ 1 marks  staff          0 Oct  9 16:21 file.4
0:user::rw-
1:user:lp:r--      #effective:r--
2:group::r--      #effective:r--

```

EXAMPLE 18 Replacing a Specific POSIX-draft ACL on a UFS File (Continued)

```
3:mask:r--
4:other:r--
```

EXAMPLE 19 Setting ACL Inheritance Flags on a ZFS File

You can only set inheritance flags on ZFS files. When setting ACLs on directories, several inheritance flags can be optionally set.

Suppose you have an ACL entry for user `lp` that you want to be inherited to newly created files in a directory. First, you need to create an inheritable ACL entry on the directory:

```
example% chmod A+user:lp:read_data:file_inherit:allow test.dir
example% ls -dv test.dir
drwxr-xr-x+ 2 marks  staff          2 Aug 23 09:08 test.dir/
0:user:lp:read_data:file_inherit:allow
1:owner@::deny
2:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
  /append_data/write_xattr/execute/write_attributes/write_acl
  /write_owner:allow
3:group@:add_file/write_data/add_subdirectory/append_data:deny
4:group@:list_directory/read_data/execute:allow
5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
  /write_attributes/write_acl/write_owner:deny
6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
  /read_acl/synchronize:allow
```

The `lp` entry is inherited to newly created files in the directory `test.dir`.

```
example% touch test.dir/file.test
example% ls -v test.dir/file.test
-rw-r--r--+ 1 marks  staff          0 Oct  9 16:29 test.dir/file.test
0:user:lp::deny
1:user:lp:read_data:allow
2:owner@:execute:deny
3:owner@:read_data/write_data/append_data/write_xattr/
  write_attributes/write_acl/write_owner:allow
4:group@:write_data/append_data/execute:deny
5:group@:read_data:allow
6:everyone@:write_data/append_data/write_xattr/execute/
  write_attributes/write_acl/write_owner:deny
7:everyone@:read_data/read_xattr/read_attributes/read_acl/
  synchronize:allow
```

The user `lp` entry is inherited to the newly created file. Multiple combinations of the inheritance flags can be specified. For example, if you wanted the `lp` entry to also be inherited to directories, then the following command can be used:

EXAMPLE 19 Setting ACL Inheritance Flags on a ZFS File (Continued)

```
example% chmod A+user:lp:read_data:file_inherit/\
dir_inherit:allow test.dir
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of chmod: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

See Also [getfacl\(1\)](#), [ls\(1\)](#), [setfacl\(1\)](#), [chmod\(2\)](#), [acl\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes Absolute changes do not work for the set-group-ID bit of a directory. You must use g+s or g-s.

chmod permits you to produce useless modes so long as they are not illegal (for instance, making a text file executable). chmod does not check the file type to see if mandatory locking is meaningful.

If the filesystem is mounted with the *nosuid* option, *setuid* execution is not allowed.

If you use chmod to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions can change the effective permissions for additional users and groups who have ACL entries on the file. Use the [getfacl\(1\)](#) or [ls\(1\)](#) command to make sure the appropriate permissions are set for all ACL entries.

Name chown – change file ownership

Synopsis chown [-fhR] *owner[:group]* *file...*
 chown -R [-f] [-H | -L | -P] *owner[:group]* *file...*

Description The chown utility sets the user ID of the file named by each *file* to the user ID specified by *owner*, and, optionally, sets the group ID to that specified by *group*.

If chown is invoked by other than the super-user, the set-user-ID bit is cleared.

Only the owner of a file (or the super-user) can change the owner of that file.

The operating system has a configuration option { _POSIX_CHOWN_RESTRICTED }, to restrict ownership changes. When this option is in effect the owner of the file is prevented from changing the owner ID of the file. Only the super-user can arbitrarily change owner IDs whether or not this option is in effect. To set this configuration option, include the following line in /etc/system:

```
set rstchown = 1
```

To disable this option, include the following line in /etc/system:

```
set rstchown = 0
```

{ _POSIX_CHOWN_RESTRICTED } is enabled by default. See [system\(4\)](#) and [fpathconf\(2\)](#).

Options

/usr/bin/chown and
 /usr/xpg4/bin/chown

The following options are supported:

- f Force. Does not report errors.
- h If the file is a symbolic link, this option changes the owner of the symbolic link. Without this option, the owner of the file referenced by the symbolic link is changed.
- H If the file specified on the command line is a symbolic link referencing a file of type directory, this option changes the owner of the directory referenced by the symbolic link and all the files in the file hierarchy below it. If a symbolic link is encountered when traversing a file hierarchy, the owner of the target file is changed, but no recursion takes place.
- L If the file is a symbolic link, this option changes the owner of the file referenced by the symbolic link. If the file specified on the command line, or encountered during the traversal of the file hierarchy, is a symbolic link referencing a file of type directory, then this option changes the owner of the directory referenced by the symbolic link and all files in the file hierarchy below it.
- P If the file specified on the command line or encountered during the traversal of a file hierarchy is a symbolic link, this option changes the owner of the symbolic link. This option does not follow the symbolic link to any other part of the file hierarchy.

Specifying more than one of the mutually-exclusive options `-H`, `-L`, or `-P` is not considered an error. The last option specified determines the behavior of `chown`.

`/usr/bin/chown` The following options are supported:

- `-R` Recursive. `chown` descends through the directory, and any subdirectories, setting the specified ownership ID as it proceeds. When a symbolic link is encountered, the owner of the target file is changed, unless the `-h` or `-P` option is specified. However, no recursion takes place, unless the `-H` or `-L` option is specified.

`/usr/xpg4/bin/chown` The following options are supported:

- `-R` Recursive. `chown` descends through the directory, and any subdirectories, setting the specified ownership ID as it proceeds. When a symbolic link is encountered, the owner of the target file is changed, unless the `-h` or `-P` option is specified. Unless the `-H`, `-L`, or `-P` option is specified, the `-L` option is used as the default mode.

Operands The following operands are supported:

owner[:group] A user ID and optional group ID to be assigned to *file*. The *owner* portion of this operand must be a user name from the user database or a numeric user ID. Either specifies a user ID to be given to each file named by *file*. If a numeric *owner* exists in the user database as a user name, the user ID number associated with that user name is used as the user ID. Similarly, if the *group* portion of this operand is present, it must be a group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.

file A path name of a file whose user ID is to be modified.

Usage See [largefile\(5\)](#) for the description of the behavior of `chown` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Changing Ownership of All Files in the Hierarchy

The following command changes ownership of all files in the hierarchy, including symbolic links, but not the targets of the links:

```
example% chown -R -h owner[:group] file...
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `chown`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- `0` The utility executed successfully and all requested changes were made.

>0 An error occurred.

Files /etc/passwd System password file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/chown

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled. See NOTES.
Interface Stability	Standard

/usr/xpg4/bin/chown

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled. See NOTES.
Interface Stability	Standard

See Also [chgrp\(1\)](#), [chmod\(1\)](#), [chown\(2\)](#), [fpathconf\(2\)](#), [passwd\(4\)](#), [system\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes chown is CSI-enabled except for the *owner* and *group* names.

Name chown – change owner

Synopsis /usr/ucb/chown [-fR] owner[.group] filename...

Description chown changes the owner of the *filenames* to *owner*. The owner can be either a decimal user ID (UID) or a login name found in the password file. An optional *group* can also be specified. The group can be either a decimal group ID (GID) or a group name found in the GID file.

In the default case, only the super-user of the machine where the file is physically located can change the owner. The system configuration option {_POSIX_CHOWN_RESTRICTED} and the privileges PRIV_FILE_CHOWN and PRIV_FILE_CHOWN_SELF also affect who can change the ownership of a file. See [chown\(2\)](#) and [privileges\(5\)](#).

Options The following options are supported:

- f Do not report errors.
- R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed.

Usage See [largefile\(5\)](#) for the description of the behavior of chown when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Files /etc/passwd Password file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

- Name** ckdate, errdate, helpdate, valdate – prompts for and validates a date
- Synopsis** ckdate [-Q] [-W *width*] [-f *format*] [-d *default*] [-h *help*]
 [-e *error*] [-p *prompt*] [-k *pid* [-s *signal*]]
- /usr/sadm/bin/errdate [-W *width*] [-e *error*] [-f *format*]
 /usr/sadm/bin/helpdate [-W *width*] [-h *help*] [-f *format*]
 /usr/sadm/bin/valdate [-f *format*] *input*
- Description** The ckdate utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a date, text for help and error messages, and a default value (which will be returned if the user responds with a RETURN). The user response must match the defined format for a date.

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Three visual tool modules are linked to the ckdate command. They are errdate (which formats and displays an error message), helpdate (which formats and displays a help message), and valdate (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When format is defined in the errdate and helpdate modules, the messages will describe the expected format.

Options The following options are supported:

- d *default* Defines the default value as *default*. The default does not have to meet the format criteria.
- e *error* Defines the error message as *error*.
- f *format* Specifies the format against which the input will be verified. Possible formats and their definitions are:
 - %b = abbreviated month name (jan, feb, mar)
 - %B = full month name
 - %d = day of month (01 - 31)
 - %D = date as %m/%d/%y (the default format)
 - %e = day of month (1 - 31; single digits are preceded by a blank)
 - %h = abbreviated month name, identical to %b%
 - %m = month number (01 - 12)

- `%y` = year within century (for instance, 89)
- `%Y` = year as CCYY (for instance, 1989)
- `-h help` Defines the help messages as *he lp*.
- `-k pid` Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- `-p prompt` Defines the prompt message as *prompt*.
- `-Q` Specifies that quit will not be allowed as a valid response.
- `-s signal` Specifies that the process ID *pid* defined with the `-k` option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- `-W width` Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified against format criteria.

- Exit Status** The following exit values are returned:
- 0 Successful execution.
 - 1 EOF on input, or negative width on `-W` option, or usage error.
 - 3 User termination (quit).
 - 4 Garbled format argument.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for `ckdate` is:

Enter the date [?,q]:

The default error message is:

ERROR - Please enter a date. Format is <format>.

The default help message is:

Please enter a date. Format is <format>.

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. The `valdate` module will not produce any output. It returns zero for success and non-zero for failure.

Name ckgid, errgid, helpgid, valgid – prompts for and validates a group id

Synopsis ckgid [-Q] [-W *width*] [-m] [-d *default*] [-h *help*]
[-e *error*] [-p *prompt*] [-k *pid* [-s *signal*]]

/usr/sadm/bin/errgid [-W *width*] [-e *error*]

/usr/sadm/bin/helpgid [-W *width*] [-m] [-h *help*]

/usr/sadm/bin/valgid *input*

Description ckgid prompts a user and validates the response. It defines, among other things, a prompt message whose response should be an existing group ID, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Three visual tool modules are linked to the ckgid command. They are *errgid* (which formats and displays an error message), *helpgid* (which formats and displays a help message), and *valgid* (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt.

Options The following options are supported:

- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- h *help* Defines the help messages as *help*.
- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- m Displays a list of all groups when help is requested or when the user makes an error.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified against /etc/group.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for ckgid is:

Enter the name of an existing group [?,q]:

The default error message is:

ERROR: Please enter one of the following group names: [*List*]

If the -m option of ckgid is used, a list of valid groups is displayed here.

The default help message is:

ERROR: Please enter one of the following group names: [*List*]

If the -m option of ckgid is used, a list of valid groups is displayed here.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The `valgid` module will not produce any output. It returns 0 for success and non-zero for failure.

Name ckint, errint, helpint, valint – display a prompt; verify and return an integer value

Synopsis ckint [-Q] [-W *width*] [-b *base*] [-d *default*] [-h *help*]
 [-e *error*] [-p *prompt*] [-k *pid* [-s *signal*]]

 /usr/sadm/bin/errint [-W *width*] [-b *base*] [-e *error*]
 /usr/sadm/bin/helpint [-W *width*] [-b *base*] [-h *help*]
 /usr/sadm/bin/valint [-b *base*] *input*

Description The ckint utility prompts a user, then validates the response. It defines, among other things, a prompt message whose response should be an integer, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Three visual tool modules are linked to the ckint command. They are errint (which formats and displays an error message), helpint (which formats and displays a help message), and valint (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When *base* is defined in the errint and helpint modules, the messages will include the expected base of the input.

Options The following options are supported:

- b *base* Defines the base for input. Must be 2 to 36, default is 10.
- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- h *help* Defines the help messages as *help*.
- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified against *base* criterion.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default base 10 prompt for ckint is:

Enter an integer [?,q]:

The default base 10 error message is:

ERROR - Please enter an integer.

The default base 10 help message is:

Please enter an integer.

The messages are changed from "integer" to "base *base* integer" if the base is set to a number other than 10.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The `valint` module will not produce any output. It returns 0 for success and non-zero for failure.

Name ckitem, erritem, helpitem – build a menu; prompt for and return a menu item

Synopsis ckitem [-Q] [-W *width*] [-uno] [-f *filename*] [-l *label*]
[[-i *invis*] [,]...] [-m *max*] [-d *default*] [-h *help*]
[-e *error*] [-p *prompt*] [-k *pid*] [-s *signal*]]
[*choice* [...]]

/usr/sadm/bin/erritem [-W *width*] [-e *error*] [*choice* [...]]

/usr/sadm/bin/helpitem [-W *width*] [-h *help*] [*choice* [...]]

Description The ckitem utility builds a menu and prompts the user to choose one item from a menu of items. It then verifies the response. Options for this command define, among other things, a prompt message whose response will be a menu item, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).

By default, the menu is formatted so that each item is prepended by a number and is printed in columns across the terminal. Column length is determined by the longest choice. Items are alphabetized.

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Two visual tool modules are linked to the ckitem command. They are erritem (which formats and displays an error message) and helpitem (which formats and displays a help message). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When *choice* is defined in these modules, the messages will describe the available menu choice (or choices).

Options The following options are supported:

- d *default* Define the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Define the error message as *error*.
- f *filename* Define a file, *filename*, which contains a list of menu items to be displayed. (The format of this file is: token<tab>description. Lines beginning with a pound sign (#) are designated as comments and ignored.)
- h *help* Define the help messages as *help*.
- i *invis* Define invisible menu choices (those which will not be printed in the menu). (For example, "all" used as an invisible choice would mean it is a legal option

but does not appear in the menu. Any number of invisible choices may be defined.) Invisible choices should be made known to a user either in the prompt or in a help message.

- k *pid* Specify that the process ID *pid* is to be sent a signal if the user chooses to abort.
- l *label* Define a label, *label*, to print above the menu.
- m *max* Define the maximum number of menu choices that the user can choose. The default is 1.
- n Specify that menu items should not be displayed in alphabetical order.
- o Specify that only one menu token will be returned.
- p *prompt* Define the prompt message as *prompt*.
- Q Specify that quit will not be allowed as a valid response.
- s *signal* Specify that process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- u Specify that menu items should be displayed as an unnumbered list.
- W *width* Specify that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

choice Define menu items. Items should be separated by white space or newline.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or inability to open file on -f option, or usage error.
- 3 User termination (quit).
- 4 No choices from which to choose.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The user may input the number of the menu item if choices are numbered or as much of the string required for a unique identification of the item. Long menus are paged with 10 items per page.

When menu entries are defined both in a file (by using the `-f` option) and also on the command line, they are usually combined alphabetically. However, if the `-n` option is used to suppress alphabetical ordering, then the entries defined in the file are shown first, followed by the options defined on the command line.

The default prompt for ckitem is:

```
Enter selection [?,??,q]:
```

One question mark will give a help message and then redisplay the prompt. Two question marks will give a help message and then redisplay the menu label, the menu and the prompt.

The default error message if you typed a number is:

```
ERROR: Bad numeric choice specification
```

The default error message if you typed a string is:

```
ERROR: Entry does not match available menu selection. Enter the number
of the menu item you wish to select, the token which is associated
with the menu item, or a partial string which uniquely identifies the
token for the menu item. Enter ?? to reprint the menu.
```

The default help message is:

```
Enter the number of the menu item you wish to select, the token
which is associated with the menu item, or a partial string which
uniquely identifies the token for the menu item. Enter ? to
reprint the menu.
```

When the quit option is chosen (and allowed), q is returned along with the return code 3.

Name ckkeywd – prompts for and validates a keyword

Synopsis ckkeywd [-Q] [-W *width*] [-d *default*] [-h *help*] [-e *error*]
 [-p *prompt*] [-k *pid* [-s *signal*]] *keyword* [...]

Description ckkeywd prompts a user and validates the response. It defines, among other things, a prompt message whose response should be one of a list of keywords, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return). The answer returned from this command must match one of the defined list of keywords.

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.

Options The following options are supported:

- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- h *help* Defines the help messages as *help*.
- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

- keyword* Defines the keyword, or list of keywords, against which the answer will be verified.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or no keywords from which to choose, or usage error.

3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for ckkeywd is:

Enter appropriate value [*keyword*,[. . .],?,q]:

The default error message is:

ERROR: Please enter one of the following keywords: *keyword*,[. . .],q

The default help message is:

keyword,[. . .],q

When the quit option is chosen (and allowed), q is returned along with the return code 3.

Name ckpath, errpath, helppath, valpath – display a prompt; verify and return a pathname

Synopsis ckpath [-Q] [-W *width*] [-a | l] [-b | c | f | y]
 [-n [o | z]] [-rtwx] [-d *default*] [-h *help*] [-e *error*]
 [-p *prompt*] [-k *pid*] [-s *signal*]]

/usr/sadm/bin/errpath [-W *width*] [-a | l] [-b | c
 | f | y] [-n [o | z]] [-rtwx] [-e *error*]

/usr/sadm/bin/helppath [-W *width*] [-a | l] [-b
 | c | f | y] [-n [o | z]] [-rtwx] [-h *help*]

/usr/sadm/bin/valpath [-a | l] [-b | c | f | y]
 [-n [o | z]] [-rtwx] *input*

Description The ckpath utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a pathname, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).

The pathname must obey the criteria specified by the first group of options. If no criteria is defined, the pathname must be for a normal file that does not yet exist. If neither -a (absolute) or -l (relative) is given, then either is assumed to be valid.

All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single white space character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under EXAMPLES) is displayed.

Three visual tool modules are linked to the ckpath command. They are errpath (which formats and displays an error message on the standard output), helppath (which formats and displays a help message on the standard output), and valpath (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.

Options The following options are supported:

- a Pathname must be an absolute path.
- b Pathname must be a block special file.
- c Pathname must be a character special file.
- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- f Pathname must be a regular file.

-h <i>help</i>	Defines the help message as <i>help</i> .
-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.
-l	Pathname must be a relative path.
-n	Pathname must not exist (must be new).
-o	Pathname must exist (must be old).
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specifies that <code>quit</code> is not allowed as a valid response.
-r	Pathname must be readable.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-t	Pathname must be creatable (touchable). Pathname will be created if it does not already exist.
-w	Pathname must be writable.
-W <i>width</i>	Specify that prompt, help and error messages be formatted to a line length of <i>width</i> .
-x	Pathname must be executable.
-y	Pathname must be a directory.
-z	Pathname must have a file having a size greater than zero bytes.

Operands The following operand is supported:

input Input to be verified against validation options.

Examples The text of the default messages for `ckpath` depends upon the criteria options that have been used.

EXAMPLE 1 Default prompt

An example default prompt for `ckpath` (using the -a option) is:

```
example% ckpath -a
Enter an absolute pathname [?,q]
```

EXAMPLE 2 Default error message

An example default error message (using the -a option) is:

EXAMPLE 2 Default error message *(Continued)*

```
example% /usr/sadm/bin/errpath -a
ERROR: A pathname is a filename, optionally preceded by parent directories.
The pathname you enter: - must begin with a slash (/)
```

EXAMPLE 3 Default help message

An example default help message (using the -a option) is:

```
example% /usr/sadm/bin/helppath -a
A pathname is a filename, optionally preceded by parent directories.
The pathname you enter: - must begin with a slash (/)
```

EXAMPLE 4 The quit option

When the quit option is chosen (and allowed), q is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 5 Using the valpath module

The valpath module will produce a usage message on stderr. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valpath
usage: valpath [-a|l][b|c|f|y][n|[o|z]]rtwx] input
.
.
.
```

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 2 Mutually exclusive options.
- 3 User termination (quit).
- 4 Mutually exclusive options.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [face\(1\)](#), [signal.h\(3HEAD\)](#), [attributes\(5\)](#)

Name ckrange, errrange, helprange, valrange – prompts for and validates an integer

Synopsis ckrange [-Q] [-W *width*] [-l *lower*] [-u *upper*] [-b *base*]
[-d *default*] [-h *help*] [-e *error*] [-p *prompt*] [-k *pid*]
[-s *signal*]]

/usr/sadm/bin/errrange [-W *width*] [-e *error*] [-l *lower*]
[-u *upper*] [-b *base*]

/usr/sadm/bin/helprange [-W *width*] [-h *help*] [-l *lower*]
[-u *upper*] [-b *base*]

/usr/sadm/bin/valrange [-l *lower*] [-u *upper*] [-b *base*]
input

Description The ckrange utility prompts a user for an integer between a specified range and determines whether this response is valid. It defines, among other things, a prompt message whose response should be an integer in the range specified, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).

This command also defines a range for valid input. If either the lower or upper limit is left undefined, then the range is bounded on only one end.

All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single whitespace character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under EXAMPLES) is displayed.

Three visual tool modules are linked to the ckrange command. They are *errange* (which formats and displays an error message on the standard output), *helprange* (which formats and displays a help message on the standard output), and *valrange* (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.

Note: Negative "input" arguments confuse getopt in *valrange*. By inserting a "-" before the argument, getopt processing will stop. See [getopt\(1\)](#) and [Intro\(1\)](#) about getopt parameter handling. getopt is used to parse positional parameters and to check for legal options.

Options The following options are supported:

- | | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -b <i>base</i> | Defines the base for input. Must be 2 to 36, default is 10. Base conversion uses strtol(3C) . Output is always base 10. |
| -d <i>default</i> | Defines the default value as <i>default</i> . <i>default</i> is converted using strtol(3C) in the desired base. Any characters invalid in the specified base will terminate the <code>strtol</code> conversion without error. |

-e <i>error</i>	Defines the error message as <i>error</i> .
-h <i>help</i>	Defines the help message as <i>help</i> .
-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.
-l <i>lower</i>	Defines the lower limit of the range as <i>lower</i> . Default is the machine's largest negative long.
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specifies that quit will not be allowed as a valid response.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-u <i>upper</i>	Defines the upper limit of the range as <i>upper</i> . Default is the machine's largest positive long.
-W <i>width</i>	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

Operands The following operand is supported:

input Input to be verified against upper and lower limits and base.

Examples **EXAMPLE 1** Default base 10 prompt

The default base 10 prompt for ckrange is:

```
example% ckrange
Enter an integer between lower_bound and
upper_bound [lower_bound–upper_bound,?,q]:
```

EXAMPLE 2 Default base 10 error message

The default base 10 error message is:

```
example% /usr/sadm/bin/errrange
ERROR: Please enter an integer between lower_bound \
and upper_bound.
```

EXAMPLE 3 Default base 10 help message

The default base 10 help message is:

```
example% /usr/sadm/bin/helprange
Please enter an integer between lower_bound and upper_bound.
```

EXAMPLE 4 Changing messages for a base other than 10

The messages are changed from “integer” to “base *base* integer” if the base is set to a number other than 10. For example,

```
example% /usr/sadm/bin/helprange -b 36
```

EXAMPLE 5 Using the quit option

When the quit option is chosen (and allowed), q is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 6 Using the valrange module

The valrange module will produce a usage message on stderr. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valrange
usage: valrange [-l lower] [-u upper] [-b base] input
```

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 2 Usage error.
- 3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

Name ckstr, errstr, helpstr, valstr – display a prompt; verify and return a string answer

Synopsis ckstr [-Q] [-W *width*] [[-r *regex*] [...] [-l *length*]
 [-d *default*] [-h *help*] [-e *error*] [-p *prompt*] [-k *pid*
 [-s *signal*]]

/usr/sadm/bin/errstr [-W *width*] [-e *error*] [-l *length*]
 [[-r *regex*] [...]]

/usr/sadm/bin/helpstr [-W *width*] [-h *help*] [-l *length*]
 [[-r *regex*] [...]]

/usr/sadm/bin/valstr [-l *length*] [[-r *regex*] [...]]
input

Description The ckstr utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a string, text for help and error messages, and a default value (which are returned if the user responds with a RETURN).

The answer returned from this command must match the defined regular expression and be no longer than the length specified. If no regular expression is given, valid input must be a string with a length less than or equal to the length defined with no internal, leading or trailing white space. If no length is defined, the length is not checked.

All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single white space character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under EXAMPLES) is displayed.

Three visual tool modules are linked to the ckstr command. They are errstr (which formats and displays an error message on the standard output), helpstr (which formats and displays a help message on the standard output), and valstr (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.

Options The following options are supported:

- | | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| -d <i>default</i> | Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria. |
| -e <i>error</i> | Defines the error message as <i>error</i> . |
| -h <i>help</i> | Defines the help message as <i>help</i> . |
| -k <i>pid</i> | Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit. |
| -l <i>length</i> | Specifies the maximum length of the input. |

-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specifies that <code>quit</code> will not be allowed as a valid response.
-r <i>regexp</i>	Specifies a regular expression, <i>regexp</i> , against which the input should be validated. May include white space. If multiple expressions are defined, the answer need match only one of them.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the <code>-k</code> option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-W <i>width</i>	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

Operands The following operand is supported:

<i>input</i>	Input to be verified against format length and/or regular expression criteria.
--------------	--------------------------------------------------------------------------------

Examples **EXAMPLE 1** Default prompt

The default prompt for `ckstr` is:

```
example% ckstr
Enter an appropriate value [?,q]:
```

EXAMPLE 2 Default error message

The default error message is dependent upon the type of validation involved. The user will be told either that the length or the pattern matching failed. The default error message is:

```
example% /usr/sadm/bin/errstr
ERROR: Please enter a string which contains no embedded,
leading or trailing spaces or tabs.
```

EXAMPLE 3 Default help message

The default help message is also dependent upon the type of validation involved. If a regular expression has been defined, the message is:

```
example% /usr/sadm/bin/helpstr -r regexp
Please enter a string which matches the following pattern:
regexp
```

Other messages define the length requirement and the definition of a string.

EXAMPLE 4 Using the quit option

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 5 Using the valstr module

The `valstr` module will produce a usage message on `stderr`. It returns `0` for success and non-zero for failure.

```
example% /usr/sadm/bin/valstr
usage: valstr [-l length] [[-r regexp] [ . . . ]] input
```

Exit Status The following exit values are returned:

- `0` Successful execution.
- `1` EOF on input, or negative width on `-W` option, or usage error.
- `2` Invalid regular expression.
- `3` User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [face\(1\)](#), [signal.h\(3HEAD\)](#), [attributes\(5\)](#)

Name cksum – write file checksums and sizes

Synopsis cksum [*file*]...

Description The cksum command calculates and writes to standard output a cyclic redundancy check (CRC) for each input file, and also writes to standard output the number of octets in each file.

For each file processed successfully, cksum will write in the following format:

"%u %d %s\n" <checksum>, <# of octets>, <path name>

If no *file* operand was specified, the path name and its leading space will be omitted.

The CRC used is based on the polynomial used for CRC error checking in the referenced Ethernet standard.

The encoding for the CRC checksum is defined by the generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Mathematically, the CRC value corresponding to a given file is defined by the following procedure:

1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer is used.
2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31 .
3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.
4. The bit sequence is complemented and the result is the CRC.

Operands The following operand is supported:

file A path name of a file to be checked. If no *file* operands are specified, the standard input is used.

Usage The cksum command is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are astronomically small; deliberate deception is difficult, but probably not impossible.

Although input files to cksum can be any type, the results need not be what would be expected on character special device files. Since this document does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.

The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as moving 8-bit characters into 9-bit bytes or changing “Little Endian” byte ordering to “Big Endian”), identical CRC values cannot be expected. Implementations performing such transformations may extend cksum to handle such situations.

See [largefile\(5\)](#) for the description of the behavior of cksum when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cksum: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 All files were processed successfully.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

See Also [digest\(1\)](#), [sum\(1\)](#), [bart\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Name cktime, errtime, helptime, valtime – display a prompt; verify and return a time of day

Synopsis cktime [-Q] [-W *width*] [-f *format*] [-d *default*] [-h *help*]
 [-e *error*] [-p *prompt*] [-k *pid* [-s *signal*]]

 /usr/sadm/bin/errtime [-W *width*] [-e *error*] [-f *format*]

 /usr/sadm/bin/helptime [-W *width*] [-h *help*] [-f *format*]

 /usr/sadm/bin/valtime [-f *format*] *input*

Description The cktime utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a time, text for help and error messages, and a default value (which is returned if the user responds with a RETURN). The user response must match the defined format for the time of day.

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including NEWLINE) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.

Three visual tool modules are linked to the cktime command. They are *errtime* (which formats and displays an error message), *helptime* (which formats and displays a help message), and *valtime* (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When format is defined in the *errtime* and *helptime* modules, the messages will describe the expected format.

Options The following options are supported:

-d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.

-e *error* Defines the error message as *error*.

-f *format* Specifies the format against which the input will be verified. Possible formats and their definitions are:

```
%H = hour (00 - 23)
%I = hour (00 - 12)
%M = minute (00 - 59)
%p = ante meridian or post meridian
%r = time as %I:%M:%S %p
%R = time as %H:%M (the default format)
%S = seconds (00 - 59)
%T = time as %H:%M:%S
```

-h *help* Defines the help messages as *help*.

- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified against format criteria.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error .
- 3 User termination (quit) .
- 4 Garbled format argument.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for `cktime` is:

Enter a time of day [?,q]:

The default error message is:

ERROR: Please enter the time of day. Format is <format>.

The default help message is:

Please enter the time of day. Format is <format>.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The `valtime` module will not produce any output. It returns 0 for success and non-zero for failure.

Name ckuid, erruid, helpuid, valuid – prompts for and validates a user ID

Synopsis ckuid [-Q] [-W *width*] [-m] [-d *default*] [-h *help*]
 [-e *error*] [-p *prompt*] [-k *pid* [-s *signal*]]

 /usr/sadm/bin/erruid [-W *width*] [-e *error*]

 /usr/sadm/bin/helpuid [-W *width*] [-m] [-h *help*]

 /usr/sadm/bin/valuid *input*

Description The ckuid utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be an existing user ID, text for help and error messages, and a default value (which are returned if the user responds with a RETURN).

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including NEWLINE) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.

Three visual tool modules are linked to the ckuid command. They are *erruid* (which formats and displays an error message), *helpuid* (which formats and displays a help message), and *valuid* (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt.

Options The following options are supported:

- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- h *help* Defines the help messages as *help*.
- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- m Displays a list of all logins when help is requested or when the user makes an error.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified against /etc/passwd.

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 2 Usage error.
- 3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for ckuid is:

Enter the login name of an existing user [?,q]:

The default error message is:

ERROR - Please enter the login name of an existing user.

If the -m option is used, the default error message is:

ERROR: Please enter one of the following login names: <List>

The default help message is:

Please enter the login name of an existing user.

If the -m option is used, the default help message is:

Please enter one of the following login names: <List>

When the quit option is chosen (and allowed), q is returned along with the return code 3. The valuid module will not produce any output. It returns 0 for success and non-zero for failure.

Name ckyorn, erryorn, helpyorn, valyorn – prompts for and validates yes/no

Synopsis ckyorn [-Q] [-W *width*] [-d *default*] [-h *help*] [-e *error*]
 [-p *prompt*] [-k *pid* [-s *signal*]]

 /usr/sadm/bin/erryorn [-W *width*] [-e *error*]
 /usr/sadm/bin/helpyorn [-W *width*] [-h *help*]
 /usr/sadm/bin/valyorn *input*

Description ckyorn prompts a user and validates the response. It defines, among other things, a prompt message for a yes or no answer, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).

All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.

If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.

Three visual tool modules are linked to the ckyorn command. They are erryorn (which formats and displays an error message), helpyorn (which formats and displays a help message), and valyorn (which validates a response). These modules should be used in conjunction with FACE objects. In this instance, the FACE object defines the prompt.

Options The following options are supported:

- d *default* Defines the default value as *default*. The default is not validated and so does not have to meet any criteria.
- e *error* Defines the error message as *error*.
- h *help* Defines the help messages as *help*.
- k *pid* Specifies that process ID *pid* is to be sent a signal if the user chooses to abort.
- p *prompt* Defines the prompt message as *prompt*.
- Q Specifies that quit will not be allowed as a valid response.
- s *signal* Specifies that the process ID *pid* defined with the -k option is to be sent signal *signal* when quit is chosen. If no signal is specified, SIGTERM is used.
- W *width* Specifies that prompt, help and error messages will be formatted to a line length of *width*.

Operands The following operand is supported:

input Input to be verified as y, yes, or n, no (in any combination of upper- and lower-case letters).

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on -W option, or usage error.
- 2 Usage error.
- 3 User termination (quit).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Notes The default prompt for ckyorn is:

Yes or No [y,n,?,q]:

The default error message is:

ERROR - Please enter yes or no.

The default help message is:

To respond in the affirmative, enter y, yes, Y, or YES.

To respond in the negative, enter n, no, N, or NO.

When the quit option is chosen (and allowed), q is returned along with the return code 3. The valyorn module will not produce any output. It returns 0 for success and non-zero for failure.

Name clear – clear the terminal screen

Synopsis clear [*term*]

Description The `clear` utility clears the terminal screen if this is possible. It looks in the environment for the terminal type, if this is not already specified by the *term* operand, and then looks up the terminfo database to figure out how to clear the screen.

Operands *term* Indicates the type of terminal. Normally, this operand is unnecessary because the default is taken from the environment variable `TERM`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [tput\(1\)](#), [attributes\(5\)](#)

-
- Name** cmp – compare two files
- Synopsis** cmp [-l] [-s] *file1 file2* [*skip1*] [*skip2*]
- Description** The cmp utility compares two files. cmp will write no output if the files are the same. Under default options, if they differ, it writes to standard output the byte and line numbers at which the first difference occurred. Bytes and lines are numbered beginning with 1. If one file is an initial subsequence of the other, that fact is noted. *skip1* and *skip2* are initial byte offsets into *file1* and *file2* respectively, and may be either octal or decimal; a leading 0 denotes octal.
- Options** The following options are supported:
- l Write the byte number (decimal) and the differing bytes (octal) for each difference.
 - s Write nothing for differing files; return exit statuses only.
- Operands** The following operands are supported:
- file1* A path name of the first file to be compared. If *file1* is –, the standard input will be used.
- file2* A path name of the second file to be compared. If *file2* is –, the standard input will be used.
- If both *file1* and *file2* refer to standard input or refer to the same FIFO special, block special or character special file, an error results.
- Usage** See [largefile\(5\)](#) for the description of the behavior of cmp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
- Examples** **EXAMPLE 1** Comparing files byte for byte
- The following example:
- ```
example% cmp file1 file2 0 1024
```
- does a byte for byte comparison of *file1* and *file2*. It skips the first 1024 bytes in *file2* before starting the comparison.
- Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cmp: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.
- Exit Status** The following error values are returned:
- 0 The files are identical.
  - 1 The files are different; this includes the case where one file is identical to the first part of the other.
  - >1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|

**Name** col – reverse line-feeds filter

**Synopsis** col [-bfp $x$ ]

**Description** The col utility reads from the standard input and writes to the standard output. It performs the line overlays implied by reverse line-feeds, and by forward and reverse half-line-feeds. Unless -x is used, all blank characters in the input will be converted to tab characters wherever possible. col is particularly useful for filtering multi-column output made with the .rt command of [nroff\(1\)](#) and output resulting from use of the [tbl\(1\)](#) preprocessor.

The ASCII control characters SO and SI are assumed by col to start and end text in an alternative character set. The character set to which each input character belongs is remembered, and on output SI and SO characters are generated as appropriate to ensure that each character is written in the correct character set.

On input, the only control characters accepted are space, backspace, tab, carriage-return and newline characters, SI, SO, VT, reverse line-feed, forward half-line-feed and reverse half-line-feed. The VT character is an alternative form of full reverse line-feed, included for compatibility with some earlier programs of this type. The only other characters to be copied to the output are those that are printable.

The ASCII codes for the control functions and line-motion sequences mentioned above are as given in the table below. ESC stands for the ASCII escape character, with the octal code 033; ESC– means a sequence of two characters, ESC followed by the character x.

|                        |       |
|------------------------|-------|
| reverse line-feed      | ESC–7 |
| reverse half-line-feed | ESC–8 |
| forward half-line-feed | ESC–9 |
| vertical-tab (VT)      | 013   |
| start-of-text (SO)     | 016   |
| end-of-text (SI)       | 017   |

- Options**
- b Assume that the output device in use is not capable of backspacing. In this case, if two or more characters are to appear in the same place, only the last one read will be output.
  - f Although col accepts half-line motions in its input, it normally does not emit them on output. Instead, text that would appear between lines is moved to the next lower full-line boundary. This treatment can be suppressed by the -f (fine) option; in this case, the output from col may contain forward half-line-feeds (ESC-9), but will still never contain either kind of reverse line motion.
  - p Normally, col will ignore any escape sequences unknown to it that are found in its input; the -p option may be used to cause col to output these sequences as regular

characters, subject to overprinting from reverse line motions. The use of this option is highly discouraged unless the user is fully aware of the textual position of the escape sequences.

- x Prevent col from converting blank characters to tab characters on output wherever possible. Tab stops are considered to be at each column position *n* such that *n* modulo 8 equals 1.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of col: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following error values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | enabled         |

**See Also** [nroff\(1\)](#), [tbl\(1\)](#), [ascii\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** The input format accepted by col matches the output produced by nroff with either the -T37 or -Tlp options. Use -T37 (and the -f option of col) if the ultimate disposition of the output of col will be a device that can interpret half-line motions, and -Tlp otherwise.

col cannot back up more than 128 lines or handle more than 800 characters per line.

Local vertical motions that would result in backing up over the first line of the document are ignored. As a result, the first line must not have any superscripts.

- 
- Name** comm – select or reject lines common to two files
- Synopsis** comm [-123] *file1 file2*
- Description** The comm utility reads *file1* and *file2*, which must be ordered in the current collating sequence, and produces three text columns as output: lines only in *file1*; lines only in *file2*; and lines in both files.
- If the input files were ordered according to the collating sequence of the current locale, the lines written will be in the collating sequence of the original lines. If not, the results are unspecified.
- Options** The following options are supported:
- 1 Suppresses the output column of lines unique to *file1*.
  - 2 Suppresses the output column of lines unique to *file2*.
  - 3 Suppresses the output column of lines duplicated in *file1* and *file2*.
- Operands** The following operands are supported:
- file1* A path name of the first file to be compared. If *file1* is –, the standard input is used.
- file2* A path name of the second file to be compared. If *file2* is –, the standard input is used.
- Usage** See [largefile\(5\)](#) for the description of the behavior of comm when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).
- Examples** **EXAMPLE 1** Printing a list of utilities specified by files
- If *file1*, *file2*, and *file3* each contain a sorted list of utilities, the command
- ```
example% comm -23 file1 file2 | comm -23 - file3
```
- prints a list of utilities in *file1* not specified by either of the other files. The entry:
- ```
example% comm -12 file1 file2 | comm -12 - file3
```
- prints a list of utilities specified by all three files. And the entry:
- ```
example% comm -12 file2 file3 | comm -23 -file1
```
- prints a list of utilities specified by both *file2* and *file3*, but not specified in *file1*.
- Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of comm: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.
- Exit Status** The following exit values are returned:
- 0 All input files were successfully output as specified.
 - >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	enabled
Interface Stability	Standard

See Also [cmp\(1\)](#), [diff\(1\)](#), [sort\(1\)](#), [uniq\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Name `command` – execute a simple command

Synopsis `command [-p] command_name [argument] ...`
`command [-v | -V] command_name`

Description The `command` utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup.

If the *command_name* is the same as the name of one of the special built-in utilities, the special properties will not occur. In every other respect, if *command_name* is not the name of a function, the effect of `command` (with no options) will be the same as omitting `command`.

The `command` utility also provides information concerning how a command name will be interpreted by the shell. See `-v` and `-V`.

Options The following options are supported:

- p Performs the command search using a default value for `PATH` that is guaranteed to find all of the standard utilities.
- v Writes a string to standard output that indicates the path or command that will be used by the shell, in the current shell execution environment to invoke *command_name*, but does not invoke *command_name*.
 - Utilities, regular built-in utilities, *command_names* including a slash character, and any implementation-provided functions that are found using the `PATH` variable will be written as absolute path names.
 - Shell functions, special built-in utilities, regular built-in utilities not associated with a `PATH` search, and shell reserved words will be written as just their names.
 - An alias will be written as a command line that represents its alias definition.
 - Otherwise, no output will be written and the exit status will reflect that the name was not found.
- V Writes a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment, but does not invoke *command_name*. Although the format of this string is unspecified, it will indicate in which of the following categories *command_name* falls and include the information stated:
 - Utilities, regular built-in utilities, and any implementation-provided functions that are found using the `PATH` variable will be identified as such and include the absolute path name in the string.
 - Other shell functions will be identified as functions.
 - Aliases will be identified as aliases and their definitions will be included in the string.
 - Special built-in utilities will be identified as special built-in utilities.

- Regular built-in utilities not associated with a `PATH` search will be identified as regular built-in utilities.
- Shell reserved words will be identified as reserved words.

Operands The following operands are supported:

argument One of the strings treated as an argument to *command_name*.
command_name The name of a utility or a special built-in utility.

Examples **EXAMPLE 1** Making a version of `cd` that always prints out the new working directory exactly once

```
cd() {  
    command cd "$@" >/dev/null  
    pwd  
}
```

EXAMPLE 2 Starting off a “secure shell script” in which the script avoids being spoofed by its parent

```
IFS=  
,  
# The preceding value should be <space><tab><newline>.  
# Set IFS to its default value.  
\unalias -a  
# Unset all possible aliases.  
# Note that unalias is escaped to prevent an alias  
# being used for unalias.  
unset -f command  
# Ensure command is not a user function.  
PATH="$(command -p getconf _CS_PATH):$PATH"  
# Put on a reliable PATH prefix.  
# ...
```

At this point, given correct permissions on the directories called by `PATH`, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked. This capability is not specified by this document, but it is not prohibited as an extension. For example, the `ENV` variable precedes the invocation of the script with a user startup script. Such a script could define functions to spoof the application.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `command`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH` Determine the search path used during the command search, except as described under the `-p` option.

Exit Status When the `-v` or `-V` options are specified, the following exit values are returned:

`0` Successful completion.

>0 The *command_name* could not be found or an error occurred.

Otherwise, the following exit values are returned:

126 The utility specified by *command_name* was found but could not be invoked.

127 An error occurred in the command utility or the utility specified by *command_name* could not be found.

Otherwise, the exit status of command will be that of the simple command specified by the arguments to command.

Name compress, uncompress, zcat – compress, uncompress files or display expanded files

Synopsis compress [-fv] [-b *bits*] [*file*]...

compress [-cfv] [-b *bits*] [*file*]

uncompress [-cfv] [*file*]...

zcat [*file*]...

Description

compress The compress utility will attempt to reduce the size of the named files by using adaptive Lempel-Ziv coding. Except when the output is to the standard output, each file will be replaced by one with the extension .Z, while keeping the same ownership modes, change times and modification times. If appending the .Z to the file pathname would make the pathname exceed 1023 bytes, the command will fail. If no files are specified, the standard input will be compressed to the standard output.

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50–60%. Compression is generally much better than that achieved by Huffman coding (as used in [pack\(1\)](#)) and it takes less time to compute. The *bits* parameter specified during compression is encoded within the compressed file, along with a magic number to ensure that neither decompression of random data nor recompression of compressed data is subsequently allowed.

uncompress The uncompress utility will restore files to their original state after they have been compressed using the compress utility. If no files are specified, the standard input will be uncompressed to the standard output.

This utility supports the uncompressing of any files produced by compress. For files produced by compress on other systems, uncompress supports 9- to 16-bit compression (see -b).

zcat The zcat utility will write to standard output the uncompressed form of files that have been compressed using compress. It is the equivalent of uncompress -c. Input files are not affected.

Options The following options are supported:

- c Writes to the standard output; no files are changed and no .Z files are created. The behavior of zcat is identical to that of 'uncompress -c'.
- f When compressing, forces compression of *file*, even if it does not actually reduce the size of the file, or if the corresponding *file*.Z file already exists. If the -f option is not given, and the process is not running in the background, prompts to verify whether an existing *file*.Z file should be overwritten. When uncompressing, does not prompt for overwriting files. If the -f option is not given, and the process is not running in the background, prompts to verify whether an existing file should be overwritten. If the standard input is not a terminal and -f is not given, writes a diagnostic message to standard error and exits with a status greater than 0.

- v Verbose. Writes to standard error messages concerning the percentage reduction or expansion of each file.
- b *bits* Sets the upper limit (in bits) for common substring codes. *bits* must be between 9 and 16 (16 is the default). Lowering the number of bits will result in larger, less compressed files.

Operands The following operand is supported:

file A path name of a file to be compressed by `compress`, uncompressed by `uncompress`, or whose uncompressed form is written to standard out by `zcat`. If *file* is `-`, or if no *file* is specified, the standard input will be used.

Usage See [largefile\(5\)](#) for the description of the behavior of `compress`, `uncompress`, and `zcat` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `compress`, `uncompress`, and `zcat`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLS_PATH`.

Exit Status The following error values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 One or more files were not compressed because they would have increased in size (and the `-f` option was not specified).
- >2 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled
Interface Stability	Standard

See Also [ln\(1\)](#), [pack\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics Usage: `compress [-fvc] [-b maxbits] [file ...]`
Invalid options were specified on the command line.

Missing maxbits
Maxbits must follow `-b`, or invalid maxbits, not a numeric value.

file: not in compressed format
The file specified to `uncompress` has not been compressed.

file: compressed with *xx*bits, can only handle *yy*bits

file was compressed by a program that could deal with more *bits* than the compress code on this machine. Recompress the file with smaller *bits*.

file: already has .Z suffix -- no change

The file is assumed to be already compressed. Rename the file and try again.

file: already exists; do you wish to overwrite (y or n)?

Respond y if you want the output file to be replaced; n if not.

uncompress: corrupt input

A SIGSEGV violation was detected, which usually means that the input file is corrupted.

Compression: *xx.xx*%

Percentage of the input saved by compression. (Relevant only for -v.)

-- not a regular file: unchanged

When the input file is not a regular file, (such as a directory), it is left unaltered.

-- has *xx* other links: unchanged

The input file has links; it is left unchanged. See [ln\(1\)](#) for more information.

-- file unchanged

No savings are achieved by compression. The input remains uncompressed.

filename too long to tack on .Z

The path name is too long to append the .Z suffix.

Notes Although compressed files are compatible between machines with large memory, -b 12 should be used for file transfer to architectures with a small process data space (64KB or less).

compress should be more flexible about the existence of the .Z suffix.

Name coproc, cocreate, cosend, cocheck, coreceive, codestroy – communicate with a process

Synopsis cocreate [-r *rpath*] [-w *wpath*] [-i *id*] [-R *refname*]
 [-s *send_string*] [-e *expect_string*] *command*
 cosend [-n] *proc_id string*
 cocheck *proc_id*
 coreceive *proc_id*
 codestroy [-R *refname*] *proc_id [string]*

Description These co-processing functions provide a flexible means of interaction between FMLI and an independent process; especially, they enable FMLI to be responsive to asynchronous activity.

The *cocreate* function starts *command* as a co-process and initializes communications by setting up pipes between FMLI and the standard input and standard output of *command*. The argument *command* must be an executable and its arguments (if any). This means that *command* expects strings on its input (supplied by *cosend*) and sends information on its output that can be handled in various ways by FMLI.

The *cosend* function sends *string* to the co-process identified by *proc_id* via the pipe set up by *cocreate* (optionally *wpath*), where *proc_id* can be either the *command* or *id* specified in *cocreate*. By default, *cosend* blocks, waiting for a response from the co-process. Also by default, FMLI does not send a *send_string* and does not expect an *expect_string* (except a newline). That is, it reads only one line of output from the co-process. If *-e expect_string* was not defined when the pipe was created, then the output of the co-process is any single string followed by a newline: any other lines of output remain on the pipe. If the *-e* option was specified when the pipe was created, *cosend* reads lines from the pipe until it reads a line starting with *expect_string*. All lines except the line starting with *expect_string* become the output of *cosend*.

The *cocheck* function determines if input is available from the process identified by *proc_id*, where *proc_id* can be either the *command* or *id* specified in *cocreate*. It returns a Boolean value, which makes *cocheck* useful in *if* statements and in other backquoted expressions in Boolean descriptors. *cocheck* receives no input from the co-process; it simply indicates if input is available from the co-process. You must use *coreceive* to actually accept the input. The *cocheck* function can be called from a *reread* descriptor to force a frame to update when new data is available. This is useful when the default value of a field in a form includes *coreceive*.

The *coreceive* function is used to read input from the co-process identified by *proc_id*, where *proc_id* can be either the *command* or *id* specified in *cocreate*. It should only be used when it has been determined, using *cocheck*, that input is actually available. If the *-e* option was used when the co-process was created, *coreceive* will continue to return lines of input until *expect_string* is read. At this point, *coreceive* will terminate. The output of *coreceive* is all the lines that were read excluding the line starting with *expect_string*. If the *-e* option was not

used in the `cocreate`, each invocation of `coreceive` will return exactly one line from the co-process. If no input is available when `coreceive` is invoked, it will simply terminate without producing output.

The `codestroy` function terminates the read/write pipes to *proc-id*, where *proc-id* can be either the *command* or *id* specified in `cocreate`. It generates a SIGPIPE signal to the (child) co-process. This kills the co-process, unless the co-process ignores the SIGPIPE signal. If the co-process ignores the SIGPIPE, it will not die, even after the FMLI process terminates (the parent process id of the co-process will be 1).

The optional argument *string* is sent to the co-process before the co-process dies. If *string* is not supplied, a NULL string is passed, followed by the normal *send_string* (newline by default). That is, `codestroy` will call `cosend proc-id string`: this implies that `codestroy` will write any output generated by the co-process to *stdout*. For example, if an interactive co-process is written to expect a "quit" string when the communication is over, the `close` descriptor could be defined; `close='codestroy ID 'quit' | message'` and any output generated by the co-process when the string `quit` is sent to it via `codestroy` (using `cosend`) would be redirected to the message line.

The `codestroy` function should usually be given the `-R` option, since you may have more than one process with the same name, and you do not want to kill the wrong one. `codestroy` keeps track of the number of *refnames* you have assigned to a process with `cocreate`, and when the last instance is killed, it kills the process (*id*) for you. `codestroy` is typically called as part of a `close` descriptor because `close` is evaluated when a frame is closed. This is important because the co-process will continue to run if `codestroy` is not issued.

When writing programs to use as co-processes, the following tips may be useful. If the co-process program is written in C language, be sure to flush output after writing to the pipe. (Currently, `awk(1)` and `sed(1)` cannot be used in a co-process program because they do not flush after lines of output.) Shell scripts are well-mannered, but slow. C language is recommended. If possible, use the default *send_string*, *rpath* and *wpath*. In most cases, *expect_string* will have to be specified. This, of course, depends on the co-process.

In the case where asynchronous communication from a co-process is desired, a co-process program should use `vsig` to force strings into the pipe and then signal FMLI that output from the co-process is available. This causes the `reread` descriptor of all frames to be evaluated immediately.

Options `cocreate` options are:

- | | |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-r rpath</code> | If <code>-r</code> is specified, <i>rpath</i> is the pathname from which FMLI reads information. This option is usually used to set up communication with processes that naturally write to a certain path. If <code>-r</code> is not specified, <code>cocreate</code> will choose a unique path in <code>/var/tmp</code> . |
| <code>-w wpath</code> | If <code>-w</code> is specified, <i>wpath</i> is the pathname to which <code>cosend</code> writes information. This option is usually used so that one process can talk to |

- many different FMLI processes through the same pipe. If `-w` is not specified, `cocreate` will choose a unique path in `/var/tmp`.
- i *id*** If `-i` is specified, *id* is an alternative name for the co-process initialized by this `cocreate`. If `-i` is not specified, *id* defaults to *command*. The argument *id* can later be used with the other co-processing functions rather than *command*. This option is typically used, since it facilitates the creation of two or more co-processes generated from the same *command*. (For example, `cocreate -i ID1 program args` and `cocreate -i ID2 program different_args`).
- R *refname*** If `-R` is specified, *refname* is a local name for the co-process. Since the `cocreate` function can be issued more than once, a *refname* is useful when the same co-process is referenced a second or subsequent time. With the `-R` option, if the co-process already exists a new one will not be created: the same pipes will be shared. Then, *refname* can be used as an argument to the `-R` option to `codestroy` when you want to end a particular connection to a co-process and leave other connections undisturbed. (The co-process is only killed after `codestroy -R` has been called as many times as `cocreate -R` was called.)
- s *send_string*** The `-s` option specifies *send_string* as a string that will be appended to all output sent to the co-process using `cosend`. This option allows a co-process to know when input from FMLI has completed. The default *send_string* is a newline if `-s` is not specified.
- e *expect_string*** The `-e` option specifies *expect_string* as a string that identifies the end of all output returned by the co-process. (Note: *expect_string* need only be the initial part of a line, and there must be a newline at the end of the co-process output.) This option allows FMLI to know when output from the co-process has completed. The default *expect_string* is a newline if `-e` is not specified.

`cosend` options are:

- n** If the `-n` option is specified, `cosend` will not wait for a response from the co-process. It simply returns, providing no output. If the `-n` option is not used, a co-process that does not answer will cause FMLI to permanently hang, waiting for input from the co-process.

Examples **EXAMPLE 1** Sample commands

```
.
.
.
init='cocreate -i BIGPROCESS initialize'
close='codestroy BIGPROCESS'
```

EXAMPLE 1 Sample commands (Continued)

```
.
.
.
reread='cocheck BIGPROCESS'

name='cosend -n BIGPROCESS field1'
.
.
.
name="Receive field"
inactive=TRUE
value='coreceive BIGPROCESS'
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [awk\(1\)](#), [cat\(1\)](#), [sed\(1\)](#), [vsig\(1F\)](#), [attributes\(5\)](#)

Notes If cosend is used without the -n option, a co-process that does not answer will cause FMLI to permanently hang.

The use of non-alphabetic characters in input and output strings to a co-process should be avoided because they may not get transferred correctly.

Name cp – copy files

Synopsis /usr/bin/cp [-fip@] *source_file* *target_file*
 /usr/bin/cp [-fip@] *source_file*... *target*
 /usr/bin/cp -r | -R [-H | -L | -P] [-fip@] *source_dir*... *target*
 /usr/xpg4/bin/cp [-fip@] *source_file* *target_file*
 /usr/xpg4/bin/cp [-fip@] *source_file*... *target*
 /usr/xpg4/bin/cp -r | -R [-H | -L | -P] [-fip@] *source_dir*... *target*

Description In the first synopsis form, neither *source_file* nor *target_file* are directory files, nor can they have the same name. The cp utility copies the contents of *source_file* to the destination path named by *target_file*. If *target_file* exists, cp overwrites its contents, but the mode (and ACL if applicable), owner, and group associated with it are not changed. The last modification time of *target_file* and the last access time of *source_file* are set to the time the copy was made. If *target_file* does not exist, cp creates a new file named *target_file* that has the same mode as *source_file* except that the sticky bit is not set unless the user is super-user. In this case, the owner and group of *target_file* are those of the user, unless the setgid bit is set on the directory containing the newly created file. If the directory's setgid bit is set, the newly created file has the group of the containing directory rather than of the creating user. If *target_file* is a link to another file, cp overwrites the link destination with the contents of *source_file*; the link(s) from *target_file* remains.

In the second synopsis form, one or more *source_files* are copied to the directory specified by *target*. It is an error if any *source_file* is a file of type directory, if *target* either does not exist or is not a directory.

In the third synopsis form, one or more directories specified by *source_dir* are copied to the directory specified by *target*. Either -r or -R must be specified. For each *source_dir*, cp copies all files and subdirectories.

Options The following options are supported for both /usr/bin/cp and /usr/xpg4/bin/cp:

- f Unlink. If a file descriptor for a destination file cannot be obtained, this option attempts to unlink the destination file and proceed.
- H Takes actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

If the *source_file* operand is a symbolic link, then cp copies the file referenced by the symbolic link for the *source_file* operand. All other symbolic links encountered during traversal of a file hierarchy are preserved.

- i Interactive. cp prompts for confirmation whenever the copy would overwrite an existing *target*. A y answer means that the copy should proceed. Any other answer prevents cp from overwriting *target*.

- L Takes actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic links encountered during traversal of a file hierarchy.

Copies files referenced by symbolic links. Symbolic links encountered during traversal of a file hierarchy are not preserved.

- P Takes actions on any symbolic link specified as a *source_file* operand or any symbolic link encountered during traversal of a file hierarchy.

Copies symbolic links. Symbolic links encountered during traversal of a file hierarchy are preserved.

- r Recursive. cp copies the directory and all its files, including any subdirectories and their files to *target*. Unless the -H, -L, or -P option is specified, the -L option is used as the default mode.

- R Same as -r, except pipes are replicated, not read from.

- @ Preserves extended attributes. cp attempts to copy all of the source file's extended attributes along with the file data to the destination file.

Specifying more than one of the mutually-exclusive options -H, -L, and -P is not considered an error. The last option specified determines the behavior of the utility.

/usr/bin/cp The following option is supported for /usr/bin/cp only:

- p Preserve. cp duplicates not only the contents of *source_file*, but also preserves the owner and group id, permission modes, modification and access time, ACLs, and extended attributes, if applicable. The command can fail if ACLs are copied to a file system without appropriate support. The command does not fail if unable to preserve extended attributes, modification and access time, or permission modes. If unable to preserve owner and group id, cp does not fail, and it clears S_ISUID and S_ISGID bits in the target. cp prints a diagnostic message to `stderr` and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions. This includes being superuser or the same owner id as the destination file.

When both -p and -@ options are specified, the -p option determines the behavior. However, the command can fail if unable to preserve extended attributes.

/usr/xpg4/bin/cp The following option is supported for /usr/xpg4/bin/cp only:

- p Preserve. cp duplicates not only the contents of *source_file*, but also preserves the owner and group id, permission modes, modification and access time, ACLs, and extended attributes, if applicable. The command can fail if ACLs are copied to a file

system without appropriate support. The command does not fail if unable to preserve extended attributes. If unable to duplicate the modification and access time or the permission modes, cp prints a diagnostic message to `stderr` and return a non-zero exit status. If unable to preserve owner and group id, cp does not fail, and it clears `S_ISUID` and `S_ISGID` bits in the target. cp prints a diagnostic message to `stderr` and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions. This includes being superuser or the same owner id as the destination file.

When both `-p` and `-@` options are specified, the last specified `-p` or `-@` option determines the behavior.

Operands The following operands are supported:

<i>source_file</i>	A pathname of a regular file to be copied.
<i>source_dir</i>	A pathname of a directory to be copied.
<i>target_file</i>	A pathname of an existing or non-existing file, used for the output when a single file is copied.
<i>target</i>	A pathname of a directory to contain the copied files.

Usage See [largefile\(5\)](#) for the description of the behavior of cp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Copying a File

The following example copies a file:

```
example% cp goodies goodies.old
```

```
example% ls goodies*
goodies goodies.old
```

EXAMPLE 2 Copying a List of Files

The following example copies a list of files to a destination directory:

```
example% cp ~/src/* /tmp
```

EXAMPLE 3 Copying a Directory

The following example copies a directory, first to a new, and then to an existing destination directory

```
example% ls ~/bkup
/usr/example/fred/bkup not found
```

EXAMPLE 3 Copying a Directory *(Continued)*

```
example% cp -r ~/src ~/bkup

example% ls -R ~/bkup
x.c y.c z.sh

example% cp -r ~/src ~/bkup

example% ls -R ~/bkup
src x.c y.c z.sh
src:
x.c y.c z.s
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cp: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 All files were copied successfully.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/cp

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

/usr/xpg4/bin/cp

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

See Also [chmod\(1\)](#), [chown\(1\)](#), [setfacl\(1\)](#), [utime\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes The permission modes of the source file are preserved in the copy.

A - - permits the user to mark the end of any command line options explicitly, thus allowing cp to recognize filename arguments that begin with a -.

Name cpio – copy file archives in and out

Synopsis `cpio -i [-bBcdfkmPrsStuvV6,t;] [-C bufsize] [-E file]
 [-H header] [-I [-M message]] [-R id] [pattern]....`
`cpio -o [-aABcLPvV,t;] [-C bufsize] [-H header]
 [-O file] [-M message]]`
`cpio -p [-adlLmPuvV,t;] [-R id] directory`

Description The cpio command copies files into and out of a cpio archive. The cpio archive may span multiple volumes. The -i, -o, and -p options select the action to be performed. The following list describes each of the actions. These actions are mutually exclusive.

Copy In Mode `cpio -i` (copy in) extracts files from the standard input, which is assumed to be the product of a previous `cpio -o` command. Only files with names that match one of the *patterns* are selected. See [sh\(1\)](#) and OPERANDS for more information about *pattern*. Extracted files are conditionally copied into the current directory tree, based on the options described below. The permissions of the files will be those of the previous `cpio -o` command. The owner and group will be the same as the current user, unless the current user is the super-user. If this is the case, owner and group will be the same as those resulting from the previous `cpio -o` command. Notice that if `cpio -i` tries to create a file that already exists and the existing file is the same age or younger (newer), cpio will output a warning message and not replace the file. The -u option can be used to unconditionally overwrite the existing file.

Copy Out Mode `cpio -o` (copy out) reads a list of file path names from the standard input and copies those files to the standard output, together with path name and status information in the form of a cpio archive. Output is padded to an 8192-byte boundary by default or to the user-specified block size (with the -B or -C options) or to some device-dependent block size where necessary (as with the CTC tape).

Pass Mode `cpio -p` (pass) reads a list of file path names from the standard input and conditionally copies those files into the destination directory tree, based on the options described below.

If the underlying file system of the source file supports detection of holes as reported by [pathconf\(2\)](#), the file is a sparse file, and the destination file is seekable, then holes in sparse files are preserved in pass mode, otherwise holes are filled with zeros.

cpio assumes four-byte words.

If, when writing to a character device (-o) or reading from a character device (-i), cpio reaches the end of a medium (such as the end of a diskette), and the -O and -I options are not used, cpio prints the following message:

To continue, type device/file name when ready.

To continue, you must replace the medium and type the character special device name (/dev/rdiskette for example) and press RETURN. You may want to continue by directing

cpio to use a different device. For example, if you have two floppy drives you may want to switch between them so cpio can proceed while you are changing the floppies. Press RETURN to cause the cpio process to exit.

Options The following options are supported:

- i (copy in) Reads an archive from the standard input and conditionally extracts the files contained in it and places them into the current directory tree.
- o (copy out) Reads a list of file path names from the standard input and copies those files to the standard output in the form of a cpio archive.
- p (pass) Reads a list of file path names from the standard input and conditionally copies those files into the destination directory tree.

The following options can be appended in any sequence to the -i, -o, or -p options:

- a Resets access times of input files after they have been copied, making cpio's access invisible. Access times are not reset for linked files when cpio -pla is specified.
- A Appends files to an archive. The -A option requires the -O option. Valid only with archives that are files, or that are on floppy diskettes or hard disk partitions. The effect on files that are linked in the existing portion of the archive is unpredictable.
- b Reverses the order of the bytes within each word. Use only with the -i option.
- B Blocks input/output 5120 bytes to the record. The default buffer size is 8192 bytes when this and the -C options are not used. -B does not apply to the -p (pass) option.
- c Reads or writes header information in ASCII character form for portability. There are no UID or GID restrictions associated with this header format. Use this option between SVR4-based machines, or the -H odc option between unknown machines. The -c option implies the use of expanded device numbers, which are only supported on SVR4-based systems. When transferring files between SunOS 4 or Interactive UNIX and the Solaris 2.6 Operating environment or compatible versions, use -H odc.
- C *bufsize* Blocks input/output *bufsize* bytes to the record, where *bufsize* is replaced by a positive integer. The default buffer size is 8192 bytes when this and -B options are not used. -C does not apply to the -p (pass) option.
- d Creates directories as needed.
- E *file* Specifies an input file (*file*) that contains a list of filenames to be extracted from the archive (one filename per line).

- f Copies in all files except those in *patterns*. See OPERANDS for a description of *pattern*.
- H *header* Reads or writes header information in *header* format. Always use this option or the -c option when the origin and the destination machines are different types. This option is mutually exclusive with options -c and -6.
- Valid values for *header* are:
- | | |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bar | bar head and format. Used only with the -i option (read only). |
| crc CRC | ASCII header with expanded device numbers and an additional per-file checksum. There are no UID or GID restrictions associated with this header format. |
| odc | ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the header formats. It is the official format for transferring files between POSIX-conforming systems (see standards(5)). Use this format to communicate with SunOS 4 and Interactive UNIX. This header format allows UIDs and GIDs up to 262143 to be stored in the header. |
| tar TAR | tar header and format. This is an older tar header format that allows UIDs and GIDs up to 2097151 to be stored in the header. It is provided for the reading of legacy archives only, that is, in conjunction with option -i. |
| | Specifying this archive format with option -o has the same effect as specifying the “ustar” format: the output archive is in ustar format, and must be read using -H ustar. |
| ustar USTAR | IEEE/P1003 Data Interchange Standard tar header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header. |
- Files with UIDs and GIDs greater than the limit stated above will be archived with the UID and GID of 60001. To transfer a large file (8 Gb — 1 byte), the header format can be tar | TAR, ustar | USTAR, or odc only.
- I *file* Reads the contents of *file* as an input archive, instead of the standard input. If *file* is a character special device, and the current medium has been completely read, replace the medium and press RETURN to continue to the next medium. This option is used only with the -i option.

- k Attempts to skip corrupted file headers and I/O errors that may be encountered. If you want to copy files from a medium that is corrupted or out of sequence, this option lets you read only those files with good headers. For `cpio` archives that contain other `cpio` archives, if an error is encountered, `cpio` may terminate prematurely. `cpio` will find the next good header, which may be one for a smaller archive, and terminate when the smaller archive's trailer is encountered. Use only with the `-i` option.
- l In pass mode, makes hard links between the source and destination whenever possible. If the `-L` option is also specified, the hard link will be to the file referred to by the symbolic link. Otherwise, the hard link will be to the symbolic link itself. Use only with the `-p` option.
- L Follows symbolic links. If a symbolic link to a directory is encountered, archives the directory referred to by the link, using the name of the link. Otherwise, archives the file referred to by the link, using the name of the link.
- m Retains previous file modification time. This option is ineffective on directories that are being copied.
- M *message* Defines a *message* to use when switching media. When you use the `-O` or `-I` options and specify a character special device, you can use this option to define the message that is printed when you reach the end of the medium. One `%d` can be placed in *message* to print the sequence number of the next medium needed to continue.
- O *file* Directs the output of `cpio` to *file*, instead of the standard output. If *file* is a character special device and the current medium is full, replace the medium and type a carriage return to continue to the next medium. Use only with the `-o` option.
- P Preserves ACLs. If the option is used for output, existing ACLs are written along with other attributes, except for extended attributes, to the standard output. ACLs are created as special files with a special file type. If the option is used for input, existing ACLs are extracted along with other attributes from standard input. The option recognizes the special file type. Notice that errors will occur if a `cpio` archive with ACLs is extracted by previous versions of `cpio`. This option should not be used with the `-c` option, as ACL support may not be present on all systems, and hence is not portable. Use ASCII headers for portability.
- r Interactively renames files. If the user types a carriage return alone, the file is skipped. If the user types a ".", the original pathname will be retained. Not available with `cpio -p`.
- R *id* Reassigns ownership and group information for each file to *user ID*. (*ID* must be a valid login ID from `/etc/passwd`.) This option is valid only for the super-user.
- s Swaps bytes within each half word.

- S Swaps halfwords within each word.
- t Prints a table of contents of the input. If any file in the table of contents has extended attributes, these are also listed. No files are created. -t and -V are mutually exclusive.
- u Copies unconditionally. Normally, an older file will not replace a newer file with the same name, although an older directory will update a newer directory.
- v Verbose. Prints a list of file and extended attribute names. When used with the -t option, the table of contents looks like the output of an `ls -l` command (see [ls\(1\)](#)).
- V Special verbose. Prints a dot for each file read or written. Useful to assure the user that `cpio` is working without printing out all file names.
- 6 Processes a UNIX System Sixth Edition archive format file. Use only with the -i option. This option is mutually exclusive with -c and -H.
- @ Includes extended attributes in archive. By default, `cpio` does not place extended attributes in the archive. With this flag, `cpio` will look for extended attributes on the files to be placed in the archive and add them, as regular files, to the archive. The extended attribute files go in the archive as special files with special file types. When the -@ flag is used with -i or -p, it instructs `cpio` to restore extended attribute data along with the normal file data. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

Operands The following operands are supported:

- directory* A path name of an existing directory to be used as the target of `cpio -p`.
- pattern* Expressions making use of a pattern-matching notation similar to that used by the shell (see [sh\(1\)](#)) for filename pattern matching, and similar to regular expressions. The following metacharacters are defined:
 - * Matches any string, including the empty string.
 - ? Matches any single character.
 - [. . .] Matches any one of the enclosed characters. A pair of characters separated by '-' matches any symbol between the pair (inclusive), as defined by the system default collating sequence. If the first character following the opening '[' is a '!', the results are unspecified.
 - ! The ! (exclamation point) means *not*. For example, the `!abc*` pattern would exclude all files that begin with `abc`.

In *pattern*, metacharacters `?`, `*`, and `[...]` match the slash (`/`) character, and backslash (`\`) is an escape character. Multiple cases of *pattern* can be specified and if no *pattern* is specified, the default for *pattern* is `*` (that is, select all files).

Each pattern must be enclosed in double quotes. Otherwise, the name of a file in the current directory might be used.

Usage See [largefile\(5\)](#) for the description of the behavior of `cpio` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples The following examples show three uses of `cpio`.

EXAMPLE 1 Using standard input

```
example% ls | cpio -oc > ../newfile
```

When standard input is directed through a pipe to `cpio -o`, as in the example above, it groups the files so they can be directed (`>`) to a single file (`../newfile`). The `-c` option insures that the file will be portable to other machines (as would the `-H` option). Instead of [ls\(1\)](#), you could use [find\(1\)](#), [echo\(1\)](#), [cat\(1\)](#), and so on, to pipe a list of names to `cpio`. You could direct the output to a device instead of a file.

EXAMPLE 2 Extracting files into directories

```
example% cat newfile | cpio -icd "memo/a1" "memo/b*"
```

In this example, `cpio -i` uses the output file of `cpio -o` (directed through a pipe with `cat`), extracts those files that match the patterns (`memo/a1`, `memo/b*`), creates directories below the current directory as needed (`-d` option), and places the files in the appropriate directories. The `-c` option is used if the input file was created with a portable header. If no patterns were given, all files from `newfile` would be placed in the directory.

EXAMPLE 3 Copying or linking files to another directory

```
example% find . -depth -print | cpio -pdlmv newdir
```

In this example, `cpio -p` takes the file names piped to it and copies or links (`-l` option) those files to another directory, `newdir`. The `-d` option says to create directories as needed. The `-m` option says to retain the modification time. (It is important to use the `-depth` option of [find\(1\)](#) to generate path names for `cpio`. This eliminates problems that `cpio` could have trying to create files under read-only directories.) The destination directory, `newdir`, must exist.

Notice that when you use `cpio` in conjunction with `find`, if you use the `-L` option with `cpio`, you must use the `-follow` option with `find` and vice versa. Otherwise, there will be undesirable results.

For multi-reel archives, dismount the old volume, mount the new one, and continue to the next tape by typing the name of the next device (probably the same as the first reel). To stop, type a RETURN and cpio will end.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cpio: LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_TIME, TZ, and NLSPATH.

TMPDIR cpio creates its temporary file in /var/tmp by default. Otherwise, it uses the directory specified by TMPDIR.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

See Also [ar\(1\)](#), [cat\(1\)](#), [echo\(1\)](#), [find\(1\)](#), [ls\(1\)](#), [pax\(1\)](#), [setfacl\(1\)](#), [sh\(1\)](#), [tar\(1\)](#), [vold\(1M\)](#), [archives.h\(3HEAD\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes The maximum path name length allowed in a cpio archive is determined by the header type involved. The following table shows the proper value for each supported archive header type.

Header type	Command line options	Maximum path name length
BINARY	“-o”	256
POSIX	“-oH odc”	256
ASCII	“-oc”	1023
CRC	“-oH crc”	1023
USTAR	“-oH ustar”	255

When the command line options “-o -H tar” are specified, the archive created is of type USTAR. This means that it is an error to read this same archive using the command line options “-i -H tar”. The archive should be read using the command line options “-i -H ustar”. The options “-i -H tar” refer to an older tar archive format.

An error message is output for files whose UID or GID are too large to fit in the selected header format. Use `-H crc` or `-c` to create archives that allow all UID or GID values.

Only the super-user can copy special files.

Blocks are reported in 512-byte quantities.

If a file has `000` permissions, contains more than 0 characters of data, and the user is not root, the file will not be saved or restored.

The inode number stored in the header (`/usr/include/archives.h`) is an unsigned short, which is 2 bytes. This limits the range of inode numbers from 0 to 65535. Files which are hard linked must fall in this inode range. This could be a problem when moving `cpio` archives between different vendors' machines.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, `/dev/rdiskette`) may not succeed. See [vold\(1M\)](#) for further details.

You must use the same blocking factor when you retrieve or copy files from the tape to the hard disk as you did when you copied files from the hard disk to the tape. Therefore, you must specify the `-B` or `-C` option.

During `-p` and `-o` processing, `cpio` buffers the file list presented on `stdin` in a temporary file.

The new [pax\(1\)](#) format, with a command that supports it (for example, `pax`, `tar`, or `cpio`), should be used for large files. The `cpio` command is no longer part of the current POSIX standard and is deprecated in favor of `pax`.

Name cpp – the C language preprocessor

Synopsis /usr/lib/cpp [-BCHMpPRT] [-undef] [-Dname] [-Dname = def]
 [-Idirectory] [-Uname] [-Ydirectory]
 [input-file [output-file]]

Description cpp is the C language preprocessor. It is invoked as the first pass of any C compilation started with the [cc\(1B\)](#) command. However, cpp can also be used as a first-pass preprocessor for other Sun compilers.

Although cpp can be used as a macro processor, this is not normally recommended, as its output is geared toward that which would be acceptable as input to a compiler's second pass. Thus, the preferred way to invoke cpp is through the [cc\(1B\)](#) command, or some other compilation command. For general-purpose macro-processing, see [m4\(1\)](#).

cpp optionally accepts two filenames as arguments. *input-file* and *output-file* are, respectively, the input and output files for the preprocessor. They default to the standard input and the standard output.

Options The following options are supported:

- B Supports the C++ comment indicator / /. With this indicator, everything on the line after the / / is treated as a comment.
- C Passes all comments (except those that appear on cpp directive lines) through the preprocessor. By default, cpp strips out C-style comments.
- H Prints the pathnames of included files, one per line on the standard error.
- M Generates a list of makefile dependencies and write them to the standard output. This list indicates that the object file which would be generated from the input file depends on the input file as well as the include files referenced.
- p Uses only the first eight characters to distinguish preprocessor symbols, and issue a warning if extra tokens appear at the end of a line containing a directive.
- P Preprocesses the input without producing the line control information used by the next pass of the C compiler.
- R Allows recursive macros.
- T Uses only the first eight characters for distinguishing different preprocessor names. This option is included for backward compatibility with systems which always use only the first eight characters.
- undef Removes initial definitions for all predefined symbols.
- Dname Defines *name* as 1 (one). This is the same as if a -Dname=1 option appeared on the cpp command line, or as if a

```
#define name 1
```

line appeared in the source file that cpp is processing.

- D*name*=*def* Defines *name* as if by a `#define` directive. This is the same as if a `#define name def` line appeared in the source file that cpp is processing. The -D option has lower precedence than the -U option. That is, if the same name is used in both a -U option and a -D option, the name is undefined regardless of the order of the options.
- Idirectory Inserts *directory* into the search path for `#include` files with names not beginning with `/`. *directory* is inserted ahead of the standard list of include directories. Thus, `#include` files with names enclosed in double-quotes (") are searched for first in the directory of the file with the `#include` line, then in directories named with -I options, and lastly, in directories from the standard list. For `#include` files with names enclosed in angle-brackets (< >), the directory of the file with the `#include` line is not searched. See Details below for exact details of this search order.
- U*name* Removes any initial definition of *name*, where *name* is a symbol that is predefined by a particular preprocessor. Here is a partial list of symbols that can be predefined, depending upon the architecture of the system:

Operating System:	ibm, gcos, os, tss and unix
Hardware:	interdata, pdp11, u370, u3b, u3b2, u3b5, u3b15, u3b20d, vax, ns32000, iAPX286, i386, sparc, and sun
UNIX system variant:	RES, and RT
The lint command:	lint

The symbols sun, sparc and unix are defined for all Sun systems.
- Y*directory* Uses *directory* in place of the standard list of directories when searching for `#include` files.

Usage

Directives All cpp directives start with a hash symbol (#) as the first character on a line. White space (SPACE or TAB characters) can appear after the initial # for proper indentation.

`#define name token-string`

Replace subsequent instances of *name* with *token-string*.

`#define name(argument [, argument] . . .) token-string`

There can be no space between *name* and the (. Replace subsequent instances of *name*, followed by a parenthesized list of arguments, with *token-string*, where each occurrence of

an *argument* in the *token-string* is replaced by the corresponding token in the comma-separated list. When a macro with arguments is expanded, the arguments are placed into the expanded *token-string* unchanged. After the entire *token-string* has been expanded, cpp re-starts its scan for names to expand at the beginning of the newly created *token-string*.

#undef *name*

Remove any definition for the symbol *name*. No additional tokens are permitted on the directive line after *name*.

#include "*filename*"

#include <*filename*>

Read in the contents of *filename* at this location. This data is processed by cpp as if it were part of the current file. When the <*filename*> notation is used, *filename* is only searched for in the standard include directories. See the -I and -Y options above for more detail. No additional tokens are permitted on the directive line after the final " or >.

#line *integer-constant* "*filename*"

Generate line control information for the next pass of the C compiler. *integer-constant* is interpreted as the line number of the next line and *filename* is interpreted as the file from where it comes. If "*filename*" is not given, the current filename is unchanged. No additional tokens are permitted on the directive line after the optional *filename*.

#if *constant-expression*

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** directive, appear in the output only if *constant-expression* yields a nonzero value. All binary non-assignment C operators, including **&&**, **|**, and **,**, are legal in *constant-expression*. The **?:** operator, and the unary **~**, **!**, and **~** operators, are also legal in *constant-expression*.

The precedence of these operators is the same as that for C. In addition, the unary operator **defined**, can be used in *constant-expression* in these two forms: **defined (*name*)** or **defined *name***. This allows the effect of **#ifdef** and **#ifndef** directives (described below) in the **#if** directive. Only these operators, integer constants, and names that are known by cpp should be used within *constant-expression*. In particular, the **sizeof** operator is not available.

#ifdef *name*

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** appear in the output only if *name* has been defined, either with a **#define** directive or a **-D** option, and in the absence of an intervening **#undef** directive. Additional tokens after *name* on the directive line is silently ignored.

#ifndef *name*

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** appear in the output only if *name* has *not* been defined, or if its definition has been removed with an **#undef** directive. No additional tokens are permitted on the directive line after *name*.

`#elif` *constant-expression*

Any number of `#elif` directives can appear between an `#if`, `#ifdef`, or `#ifndef` directive and a matching `#else` or `#endif` directive. The lines following the `#elif` directive appear in the output only if all of the following conditions hold:

- The *constant-expression* in the preceding `#if` directive evaluated to zero, the *name* in the preceding `#ifdef` is not defined, or the *name* in the preceding `#ifndef` directive was defined.
- The *constant-expression* in all intervening `#elif` directives evaluated to zero.
- The current *constant-expression* evaluates to non-zero.

If the *constant-expression* evaluates to non-zero, subsequent `#elif` and `#else` directives are ignored up to the matching `#endif`. Any *constant-expression* allowed in an `#if` directive is allowed in an `#elif` directive.

`#else`

This inverts the sense of the conditional directive otherwise in effect. If the preceding conditional would indicate that lines are to be included, then lines between the `#else` and the matching `#endif` are ignored. If the preceding conditional indicates that lines would be ignored, subsequent lines are included in the output. Conditional directives and corresponding `#else` directives can be nested.

`#endif`

End a section of lines begun by one of the conditional directives `#if`, `#ifdef`, or `#ifndef`. Each such directive must have a matching `#endif`.

Macros Formal parameters for macros are recognized in `#define` directive bodies, even when they occur inside character constants and quoted strings. For instance, the output from:

```
#define abc(a) | 'a|  
abc(xyz)
```

is:

```
# 1 ""  
| 'xyz |
```

The second line is a NEWLINE. The last seven characters are `| 'xyz |` (vertical-bar, backquote, vertical-bar, x, y, z, vertical-bar). Macro names are not recognized within character constants or quoted strings during the regular scan. Thus:

```
#define abc xyz  
printf("abc");
```

does not expand `abc` in the second line, since it is inside a quoted string that is not part of a `#define` macro definition.

Macros are not expanded while processing a `#define` or `#undef`. Thus:

```
#define abc zingo
#define xyz abc
#undef abc
xyz
```

produces `abc`. The token appearing immediately after an `#ifdef` or `#ifndef` is not expanded.

Macros are not expanded during the scan which determines the actual parameters to another macro call. Thus:

```
#define reverse(first,second)second first
#define greeting hello
reverse(greeting,
#define greeting goodbye
)
```

produces `#define hello goodbye hello`.

Output Output consists of a copy of the input file, with modifications, plus lines of the form:

```
#lineno " filename" "level"
```

indicating the original source line number and filename of the following output line and whether this is the first such line after an include file has been entered (*level*=1), the first such line after an include file has been exited (*level*=2), or any other such line (*level* is empty).

Details This section contains usage details.

Directory Search Order `#include` files are searched for in the following order:

1. The directory of the file that contains the `#include` request (that is, `#include` is relative to the file being scanned when the request is made).
2. The directories specified by `-I` options, in left-to-right order.
3. The standard directory(s) (`/usr/include` on UNIX systems).

Special Names Two special names are understood by `cpp`. The name `__LINE__` is defined as the current line number (a decimal integer) as known by `cpp`, and `__FILE__` is defined as the current filename (a C string) as known by `cpp`. They can be used anywhere (including in macros) just as any other defined name.

Newline Characters A NEWLINE character terminates a character constant or quoted string. An escaped NEWLINE (that is, a backslash immediately followed by a NEWLINE) can be used in the body of a `#define` statement to continue the definition onto the next line. The escaped NEWLINE is not included in the macro value.

Comments Comments are removed (unless the `-C` option is used on the command line). Comments are also ignored, except that a comment terminates a token.

Exit Status The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

See Also [cc\(1B\)](#), [m4\(1\)](#), [attributes\(5\)](#)

Diagnostics The error messages produced by `cpp` are intended to be self-explanatory. The line number and filename where the error occurred are printed along with the diagnostic.

Notes When NEWLINE characters were found in argument lists for macros to be expanded, some previous versions of `cpp` put out the NEWLINE characters as they were found and expanded. The current version of `cpp` replaces them with SPACE characters.

Because the standard directory for included files might be different in different environments, this form of `#include` directive:

```
#include <file.h>
```

should be used, rather than one with an absolute path, like:

```
#include "/usr/include/file.h"
```

`cpp` warns about the use of the absolute pathname.

While the compiler allows 8-bit strings and comments, 8-bits are not allowed anywhere else.

Name cputrack – monitor process and LWP behavior using CPU performance counters

Synopsis `cputrack -c eventspec [-c eventspec]... [-efntvD]
 [-N count] [-o pathname] [-T interval] command [args]
cputrack -c eventspec [-c eventspec]... -p pid [-efntvD]
 [-N count] [-o pathname] [-T interval]
cputrack -h`

Description The `cputrack` utility allows CPU performance counters to be used to monitor the behavior of a process or family of processes running on the system. If *interval* is specified with the `-T` option, `cputrack` samples activity every *interval* seconds, repeating forever. If a *count* is specified with the `-N` option, the statistics are repeated *count* times for each process tracked. If neither are specified, an interval of one second is used. If *command* and optional *args* are specified, `cputrack` runs the command with the arguments given while monitoring the specified CPU performance events. Alternatively, the process ID of an existing process can be specified using the `-p` option.

Because `cputrack` is an unprivileged program, it is subject to the same restrictions that apply to [truss\(1\)](#). For example, [setuid\(2\)](#) executables cannot be tracked.

Options The following options are supported:

`-c eventspec` Specifies a set of events for the CPU performance counters to monitor. The syntax of these event specifications is:

```
[picn=]eventn[,attr[n]=[val]][, [picn=]eventn  

  [,attr[n]=[val]],...]
```

You can use the `-h` option to obtain a list of available events and attributes. This causes generation of the usage message. You can omit an explicit counter assignment, in which case `cpustat` attempts to choose a capable counter automatically.

Attribute values can be expressed in hexadecimal, octal, or decimal notation, in a format suitable for [strtoll\(3C\)](#). An attribute present in the event specification without an explicit value receives a default value of 1. An attribute without a corresponding counter number is applied to all counters in the specification.

The semantics of these event specifications can be determined by reading the CPU manufacturer's documentation for the events.

Multiple `-c` options can be specified, in which case `cputrack` cycles between the different event settings on each sample.

`-D` Enables debug mode.

`-e` Follows all [exec\(2\)](#), or [execve\(2\)](#) system calls.

- f Follows all children created by [fork\(2\)](#), [fork1\(2\)](#), or [vfork\(2\)](#) system calls.
- h Prints an extended help message on how to use the utility, how to program the processor-dependent counters, and where to look for more detailed information.
- n Omits all header output (useful if `cputrack` is the beginning of a pipeline).
- N *count* Specifies the maximum number of CPU performance counter samples to take before exiting.
- o *outfile* Specifies file to be used for the `cputrack` output.
- p *pid* Interprets the argument as the process ID of an existing process to which process counter context should be attached and monitored.
- t Prints an additional column of processor cycle counts, if available on the current architecture.
- T *interval* Specifies the interval between CPU performance counter samples in seconds. Very small intervals may cause some samples to be skipped. See **WARNINGS**.
- v Enables more verbose output.

Usage The operating system enforces certain restrictions on the tracing of processes. In particular, a command whose object file cannot be read by a user cannot be tracked by that user; `set-uid` and `set-gid` commands can only be tracked by a privileged user. Unless it is run by a privileged user, `cputrack` loses control of any process that performs an `exec()` of a `set-id` or unreadable object file. Such processes continue normally, though independently of `cputrack`, from the point of the `exec()`.

The system may run out of per-user process slots when the `-f` option is used, since `cputrack` runs one controlling process for each process being tracked.

The times printed by `cputrack` correspond to the wallclock time when the hardware counters were actually sample. The time is derived from the same timebase as [gethrtime\(3C\)](#).

The `cputrack` utility attaches performance counter context to each process that it examines. The presence of this context allows the performance counters to be multiplexed between different processes on the system, but it cannot be used at the same time as the [cpustat\(1M\)](#) utility.

Once an instance of the `cpustat` utility is running, further attempts to run `cputrack` will fail until all instances of `cpustat` terminate.

Sometimes `cputrack` provides sufficient flexibility and prints sufficient statistics to make adding the observation code to an application unnecessary. However, more control is occasionally desired. Because the same performance counter context is used by both the

application itself and by the agent LWP injected into the application by `cputrack`, it is possible for an application to interact with the counter context to achieve some interesting capabilities. See `cpc_enable(3CPC)`.

The processor cycle counts enabled by the `-t` option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

The output of `cputrack` is designed to be readily parseable by `nawk(1)` and `perl(1)`, thereby allowing performance tools to be composed by embedding `cputrack` in scripts. Alternatively, tools may be constructed directly using the same APIs that `cputrack` is built upon, using the facilities of `libcpc(3LIB)` and `libpctx(3LIB)`. See `cpc(3CPC)`.

Although `cputrack` uses performance counter context to maintain separate performance counter values for each LWP, some of the events that can be counted will inevitably be impacted by other activities occurring on the system, particularly for limited resources that are shared between processes (for example, cache miss rates). For such events, it may also be interesting to observe overall system behavior with `cpustat(1M)`.

For the `-T interval` option, if *interval* is specified as zero, no periodic sampling is performed. The performance counters are only sampled when the process creates or destroys an LWP, or it invokes `fork(2)`, `exec(2)`, or `exit(2)`.

Examples

SPARC EXAMPLE 1 Using Performance Counters to Count Clock Cycles

In this example, the utility is being used on a machine containing an UltraSPARC-III+ processor. The counters are set to count processor clock cycles and instructions dispatched in user mode while running the `sleep(1)` command.

```
example% cputrack -c pic0=Cycle_cnt,pic1=Instr_cnt sleep 10
```

time	lwp	event	pic0	pic1
1.007	1	tick	765308	219233
2.007	1	tick	0	0
4.017	1	tick	0	0
6.007	1	tick	0	0
8.007	1	tick	0	0
10.007	1	tick	0	0
10.017	1	exit	844703	228058

EXAMPLE 2 Counting External Cache References and Misses

This example shows more verbose output while following the `fork()` and `exec()` of a simple shell script on an UltraSPARC machine. The counters are measuring the number of external cache references and external cache misses. Notice that the explicit `pic0` and `pic1` names can be omitted where there are no ambiguities.

```
example% cputrack -fev -c EC_ref,EC_hit /bin/ulimit -c
```

```

time    pid lwp      event    pic0      pic1
0.007 101142  1   init_lwp   805286    20023
0.023 101142  1      fork                # 101143
0.026 101143  1   init_lwp   1015382    24461
0.029 101143  1   fini_lwp   1025546    25074
0.029 101143  1      exec   1025546    25074
0.000 101143  1      exec                \
                                # '/usr/bin/sh /usr/bin/basename\
                                /bin/ulimit'
0.039 101143  1   init_lwp   1025546    25074
0.050 101143  1   fini_lwp   1140482    27806
0.050 101143  1      exec   1140482    27806
0.000 101143  1      exec                # '/usr/bin/expr \
//bin/ulimit : \(.*[^\]\)/.*$ : .*\/(..*)$ : \(.*\) $ | //bin/ulimi'
0.059 101143  1   init_lwp   1140482    27806
0.075 101143  1   fini_lwp   1237647    30207
0.075 101143  1      exit   1237647    30207
unlimited
0.081 101142  1   fini_lwp   953383    23814
0.081 101142  1      exit   953383    23814

```

x86 EXAMPLE 3 Counting Instructions

This example shows how many instructions were executed in the application and in the kernel to print the date on a Pentium III machine:

```
example% cputrack -c inst_retired,inst_retired,nouser1,sys1 date
```

```

time lwp      event    pic0      pic1
Fri Aug 20 20:03:08 PDT 1999
0.072  1      exit   246725    339666

```

EXAMPLE 4 Counting TLB Hits

This example shows how to use processor-specific attributes to count TLB hits on a Pentium 4 machine:

```
example% cputrack -c ITLB_reference,emask=1 date
```

EXAMPLE 4 Counting TLB Hits (Continued)

```

time lwp      event      pic0
Fri Aug 20 20:03:08 PDT 1999
0.072  1      exit      246725

```

Warnings By running any instance of the [cpustat\(1M\)](#) utility, all existing performance counter context is forcibly invalidated across the machine. This may in turn cause all invocations of the `cputrack` command to exit prematurely with unspecified errors.

If `cpustat` is invoked on a system that has CPU performance counters which are not supported by Solaris, the following message appears:

```
cputrack: cannot access performance counters - Operation not applicable
```

This error message implies that `cpc_open()` has failed and is documented in [cpc_open\(3CPC\)](#). Review this documentation for more information about the problem and possible solutions.

If a short interval is requested, `cputrack` may not be able to keep up with the desired sample rate. In this case, some samples may be dropped.

Name crle – configure runtime linking environment

Synopsis crle [-64] [-a name] [-A name] [-c conf] [-e env] [-E env]
[-f flags] [-i name] [-I name] [-g name] [-G name] [-l dir]
[-o dir] [-s dir] [-t [ELF | AOUT]] [-u] [-v]

Description The crle utility provides for the creation and display of a runtime linking configuration file. The configuration file is read and interpreted by the runtime linker, [ld.so.1\(1\)](#), during process start-up. Without any arguments, or with just the -c option, crle displays configuration information. This information includes the contents of a configuration file, any system defaults and the command-line required to regenerate the configuration file. When used with any other options, a new configuration file is created or updated.

For 32-bit objects, the default configuration file is /var/ld/ld.config. For 64-bit objects, the default configuration file is /var/ld/64/ld.config.

When creating a new configuration file, first create the file in a temporary location. The environment variable LD_CONFIG can then be set to this new configuration file. This setting causes the new configuration to be used by the runtime linker instead of any default. After verification, the new configuration file can be moved to the default location if desired. At any time, the environment variable LD_NOCONFIG can be set to any value to instruct the runtime linker to ignore any configuration files. This setting can prove useful during experimentation.

A configuration file can contain the following information.

Default Search Paths

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. This search path starts with the components of any LD_LIBRARY_PATH definition, followed by the components of an object's runpath. Finally, any default search paths specific to the object's type are used. This last component of the search path can be expressed within the configuration file. Typically, use of this facility should be augmented with any system defaults. See the -l option.

Trusted Directories

When processing a secure application, the runtime linker restricts the use of LD_LIBRARY_PATH and the directories from which preload and audit libraries can be used. This processing is restricted to known trusted directories. Trusted directories can be expressed within the configuration file. Typically, use of this facility should be augmented with any system defaults. See the -s option.

Directory Cache

The location of shared objects within defined directories can be maintained as a cache within the configuration file. This directory cache can reduce the overhead of searching for application dependencies.

Alternative Objects

In conjunction with the directory cache, shared objects can have alternative objects specified for use at runtime. These alternate objects, can be supplied by the user.

Alternative objects can also be created by `crle` as copies of shared objects fixed to known memory locations. These fixed alternative objects can require less processing at runtime than their original shared object counterpart.

Environment Variables

Any environment variable interpreted by the runtime linker can be specified within the configuration file.

Defining alternative default search paths, or additional trusted directories can be useful for administrators who wish to install third party software in a central location, or otherwise alter the search path of applications that might not have been coded with suitable runpaths.

The declaration of alternative objects, provides a means of replacing dependencies other than by using symbolic links, or requiring `LD_LIBRARY_PATH` settings.

The declaration of environment variables that are interpreted by the runtime linker, provides a means of centralizing their definition for all applications.

The directory cache, and `crle` generated alternate objects, can provide a means of reducing the runtime start-up overhead of applications. Alternative objects can be useful for applications that require many dependencies, or whose dependencies are expensive to relocate. Shared objects that contain position-*dependent* code are often expensive to relocate.

When alternate objects that are generated by `crle` are specified within a configuration file, `ld.so.1(1)` performs some minimal consistency verification. The alternative objects are verified against their originating objects. This verification is intended to avert application failure should an applications configuration information become out-of-sync with the underlying system components. When this situation arises the flexibility offered by dynamic linking system components can be compromised. This type of application failure can be very difficult to diagnose. No verification of directory cache information is performed. Any changes to the directory structure are not seen by a process until the cache is rebuilt.

System shared objects are often well tuned, and can show little benefit from being cached. The directory cache and alternative object features are typically applicable to user applications and shared objects.

`crle` creates alternate objects for the shared objects that are discovered when using the `-I` and `-G` options, by calls to `dldump(3C)`. The alternate object is created in the directory specified by the preceding `-o` option, or defaults to the directory in which the configuration file is created. The flags used for the `dldump()` are specified using the `-f` option, or default to `RTLD_REL_RELATIVE`.

Options The following options are supported.

`-64`

Specify to process 64-bit objects, the default is 32-bit.

-a *name*

Create an alternative pathname for *name*. The alternative pathname is added to the configuration file.

The actual alternative file must be supplied by the user. Multiple occurrences of this option are permitted. If *name* is a directory, each shared object within the directory is added to the cache. If *name* does not exist, then *name* is marked in the cache as a nonexistent file.

Typically, this option is used with the -o option.

-A *name*

Create an optional alternative pathname for *name*. This alternative pathname is added to the configuration file.

This option mimics the -a option, except that if the alternative is unavailable at runtime, the original object *name* is used. This model mimics the use of auxiliary filters. See the [Linker and Libraries Guide](#).

Typically, this option is used with the -o option.

-c *conf*

Specify to use the configuration file name *conf*. If this option is not supplied, the default configuration file is used.

-e *env*

Specify a *replaceable* environment variable, *env*. Only environment variables that are applicable to the runtime linker are meaningful. Multiple occurrences of this option are permitted. This option is similar to the -E option. However, the options differs in how configuration file definitions, and process environment definitions of the same name are resolved at runtime.

A definition established in a configuration file can be *overridden* by a process environment definition, or be *suppressed* by a null-value process environment definition.

In other words, these configuration file definitions can be replaced, or removed by the process environment at runtime.

-E *env*

Specify a *permanent* environment variable, *env*. Only environment variables that are applicable to the runtime linker are meaningful. Multiple occurrences of this option are permitted. This option is similar to the -e option. However, the option differs in how configuration file definitions, and process environment definitions of the same name are resolved at runtime.

Environment variable definitions that are meaningful to the runtime linker fall into one of two categories. Singular definitions are definitions such as LD_NOLAZYLOAD=1 and LD_DEBUG_OUTPUT=*file*. List definitions, which can take one or more values, are definitions such as LD_LIBRARY_PATH=*path*, and LD_DEBUG=*files,details*.

A singular definition that is established in a configuration file takes precedence over a process environment definition. A list definition that is established in a configuration file is *appended* to a process environment definition. Any definition that is established in a configuration file can *not* be suppressed by a null-value process environment definition.

In other words, these configuration file definitions can *not* be replaced, or removed by the process environment at runtime.

-f *flags*

Provide the symbolic *flags* argument to the `dlldump(3C)` calls used to generate alternate objects. Any of the RTLD_REL flags that are defined in `/usr/include/dlfcn.h` can be used. Multiple flags can be or'ed together using the “|” character. In this case, the string should be quoted to avoid expansion by the shell. If no *flags* values are provided the default flag is RTLD_REL_RELATIVE.

-i *name*

Add an individual *name* to the configuration cache. Multiple occurrences of this option are permitted. *name* can be a shared object or a directory. If *name* is a directory, each shared object within the directory is added to the cache. If *name* does not exist, the *name* is marked in the cache as a nonexistent directory.

-I *name*

Mimic the -i, and in addition any shared object that is processed has an alternative created using `dlldump(3C)`. If the -f flag contains RTLD_REL_EXEC, then *name* can be a dynamic executable, for which an alternative is created. Only one dynamic executable can be specified in this manner, as the cache that is created is specific to this application.

-g *name*

Add the group *name* to the configuration cache. Each object is expanded to determine its dependencies. Multiple occurrences of this option are permitted. *name* can be a dynamic executable, shared object or a directory. If *name* is a shared object, the shared object and its dependencies are added to the cache. If *name* is a directory, each shared object within the directory, and its dependencies, are added to the cache.

-G *name*

Mimic the -g option, and in addition any shared object that is processed has an alternative created using `dlldump(3C)`. If *name* is a dynamic executable, and the -f flag contains RTLD_REL_EXEC, then an alternative for the dynamic executable is also created. Only one dynamic executable can be specified in this manner as the cache that is created is specific to this application.

-l *dir*

Specify a new default search directory *dir* for ELF or AOUT objects. Multiple occurrences of this option are permitted. The type of object that is applicable to the search, is specified by the preceding -t option, or defaults to ELF.

The default search paths for 32-bit ELF objects are `/lib` followed by `/usr/lib`. For 64-bit ELF objects, the default search paths are `/lib/64` followed by `/usr/lib/64`.

The default search paths for AOUT objects are `/usr/4lib`, followed by `/usr/lib` and finally `/usr/local/lib`.

Use of this option *replaces* the default search path. Therefore, a `-l` option is normally required to specify the original system default in relation to any new paths that are being applied. However, if the `-u` option is in effect, and a configuration file does *not* exist, the system defaults are added to the new configuration file. These defaults are added before the new paths specified with the `-l` option.

-o *dir*

When used with either the `-a` or `-A` options, specifies the directory *dir* in which any alternate objects exist. When alternative objects are created by `crle`, this option specifies where the alternative are created. Without this option, alternate objects exist in the directory in which the configuration file is created. Multiple occurrences of this option are permitted, the directory *dir* being used to locate alternatives for any following command-line options. Alternative objects are not permitted to override their associated originals.

Typically, this option is used with the `-a` or `-A` options.

-s *dir*

Specify a new trusted directory *dir* for *secure* ELF or AOUT objects. See SECURITY in [ld.so.1\(1\)](#) for a definition of secure objects.

Multiple occurrences of this option are permitted. The type of object that is applicable to the search is specified by the preceding `-t` option, or defaults to ELF.

The default trusted directories for secure 32-bit ELF objects are `/lib/secure` followed by `/usr/lib/secure`. For 64-bit secure ELF objects, the default trusted directories are `/lib/secure/64` followed by `/usr/lib/secure/64`.

The default trusted directories for secure AOUT objects are `/usr/4lib`, followed by `/usr/lib`, followed by `/usr/ucblib`, and finally `/usr/local/lib`.

Use of this option *replaces* the default trusted directories. Therefore, a `-s` option is normally required to specify the original system default in relation to any new directories that are being applied. However, if the `-u` option is in effect, and a configuration file does *not* exist, the system defaults are added to the new configuration file. These defaults are added before the new directories specified with the `-l` option.

-t ELF | AOUT

Toggle the object type that is applicable to any `-l` or `-s` options that follow. The default object type is ELF.

-u

Request that a configuration file be updated, possibly with the addition of new information. Without other options, any existing configuration file is inspected and its contents recomputed. Additional arguments allow information to be appended to the recomputed contents. See NOTES.

If a configuration file does not exist, the configuration file is created as directed by the other arguments. In the case of the `-l` and `-s` options, any system defaults are first applied to the configuration file before the directories specified with these options.

-v

Specify verbose mode. When creating a configuration file, a trace of the files that are being processed is written to the standard out. When printing the contents of a configuration file, more extensive directory and file information is provided.

By default, the runtime linker attempts to read the configuration file `/var/ld/ld.config` for each 32-bit application processed. `/var/ld/64/ld.config` is read for each 64-bit application. When processing an alternative application, the runtime linker uses a `$ORIGIN/ld.config.app-name` configuration file if present. See NOTES. Applications can reference an alternative configuration file by setting the `LD_CONFIG` environment variable. See [ld.so.1\(1\)](#). An alternative configuration file can also be specified by recording the configuration file name in the application at the time the application is built. See the `-c` option of [ld\(1\)](#).

Examples **EXAMPLE 1** Updating and Displaying a New Default Search Path for ELF Objects

The following example updates and displays a new default search path for ELF objects:

```
example% crle -u -l /local/lib
example% crle
```

```
Configuration file [version 4]: /var/ld/ld.config
Default Library Path (ELF):  /lib:/usr/lib:/local/lib
Trusted Directories (ELF):  /lib/secure:/usr/lib/secure (system default)
```

```
Command line:
crle -l /lib:/usr/lib:/local/lib
```

```
example% crle -u -l /usr/local/lib
example% crle
```

```
Configuration file [version 4]: /var/ld/ld.config
Default Library Path (ELF):  /lib:/usr/lib:/local/lib:/usr/local/lib
Trusted Directories (ELF):  /lib/secure:/usr/lib/secure (system default)
```

```
Command line:
crle -l /lib:/usr/lib:/local/lib:/usr/local/lib
```

In this example, the default configuration file initially did not exist. Therefore, the new search path `/local/lib` is appended to the system default. The next update appends the search path `/usr/local/lib` to those paths already established in the configuration file.

EXAMPLE 2 Creating and Displaying a New Default Search Path and New Trusted Directory for ELF Objects

The following example creates and displays a new default search path and new trusted directory for ELF objects:

```
example% crle -l /local/lib -l /lib -l /usr/lib -s /local/lib
example% crle
```

```
Configuration file [version 4]: /var/ld/ld.config
  Default Library Path (ELF):  /local/lib:/lib:/usr/lib
  Trusted Directories (ELF):   /local/lib
```

Command line:

```
crle -l /local/lib:/lib:/usr/lib -s /local/lib
```

With this configuration, third party applications could be installed in `/local/bin` and their associated dependencies in `/local/lib`. The default search path allows the applications to locate their dependencies without the need to set `LD_LIBRARY_PATH`. The default trusted directories have also been replaced with this example.

EXAMPLE 3 Creating a Directory Cache for ELF Objects

The following example creates a directory cache for ELF objects:

```
example% crle -i /usr/dt/lib -i /usr/openwin/lib -i /lib -i /usr/lib \
-c config
```

```
example% ldd -s ./main
```

```
....
  find object=libc.so.1; required by ./main
  search path=/usr/dt/lib:/usr/openwin/lib (RPATH ./main)
  trying path=/usr/dt/lib/libc.so.1
  trying path=/usr/openwin/lib/libc.so.1
  search path=/lib (default)
  trying path=/lib/libc.so.1
    libc.so.1 => /lib/libc.so.1
```

```
example% LD_CONFIG=config ldd -s ./main
```

```
....
  find object=libc.so.1; required by ./main
  search path=/usr/dt/lib:/usr/openwin/lib (RPATH ./main)
  search path=/lib (default)
  trying path=/lib/libc.so.1
    libc.so.1 => /lib/libc.so.1
```

With this configuration, the cache reflects that the system library `libc.so.1` does not exist in the directories `/usr/dt/lib` or `/usr/openwin/lib`. Therefore, the search for this system file ignores these directories even though the application's runpath indicates these paths should be searched.

EXAMPLE 4 Creating an Alternative Object Cache for an ELF Executable

The following example creates an alternative object cache for an ELF executable:

```
example% crle -c /local/$HOST/.xterm/ld.config.xterm \
-f RTLD_REL_ALL -G /usr/openwin/bin/xterm
example% ln -s /local/$HOST/.xterm/xterm /local/$HOST/xterm
example% ldd /usr/local/$HOST/xterm
libXaw.so.5 => /local/$HOST/.xterm/libWaw.so.5 (alternate)
libXmu.so.4 => /local/$HOST/.xterm/libXmu.so.4 (alternate)
....
libc.so.1 => /local/$HOST/.xterm/libc.so.1 (alternate)
....
```

With this configuration, a new xterm and its dependencies are created. These new objects are fully relocated to each other, and result in faster start-up than the originating objects. The execution of this application uses its own specific configuration file. This model is generally more flexible than using the environment variable `LD_CONFIG`, as the configuration file can not be erroneously used by other applications such as `ldd(1)` or `truss(1)`.

EXAMPLE 5 Creating an Alternative Object Cache to Replace an ELF Shared Object

The following example creates an alternative object cache to replace an ELF shared object:

```
example% ldd /usr/bin/vi
libcurses.so.1 => /lib/libcurses.so.1
....
```

```
example% crle -a /lib/libcurses.so.1 -o /usr/ucblib
example% crle
```

```
Configuration file [version 4]: /var/ld/ld.config
Default Library Path (ELF): /lib:/usr/lib (system default)
Trusted Directories (ELF): /lib/secure:/usr/lib/secure (system default)
```

```
Directory: /lib
libcurses.so.1 (alternate: /usr/ucblib/libcurses.so.1)
....
```

```
example% ldd /usr/bin/vi
libcurses.so.1 => /usr/ucblib/libcurses.so.1 (alternate)
....
```

With this configuration, any dependency that would normally resolve to `/usr/lib/libcurses.so.1` instead resolves to `/usr/ucblib/libcurses.so.1`.

EXAMPLE 6 Setting Replaceable and Permanent Environment Variables

The following example sets replaceable and permanent environment variables:

EXAMPLE 6 Setting Replaceable and Permanent Environment Variables (Continued)

```

example% crle -e LD_LIBRARY_PATH=/local/lib \
             -E LD_PRELOAD=preload.so.1
example% crle
.....
Environment Variables:
  LD_LIBRARY_PATH=/local/lib  (replaceable)
  LD_PRELOAD=preload.so.1    (permanent)

.....
example% LD_DEBUG=files LD_PRELOAD=preload.so.2 ./main
.....
18764: file=preload.so.2;  preloaded
18764: file=/local/lib/preload.so.2  [ ELF ]; generating link map
.....
18764: file=preload.so.1;  preloaded
18764: file=/local/lib/preload.so.1  [ ELF ]; generating link map
.....

```

With this configuration file, a replaceable search path has been specified together with a permanent preload object which becomes appended to the process environment definition.

Exit Status The creation or display of a configuration file results in a 0 being returned. Otherwise, any error condition is accompanied with a diagnostic message and a non-zero value being returned.

Notes The ability to tag an alternative application to use an application-specific configuration file, is possible if the original application contains one of the *dynamic* tags `DT_FLAGS_1` or `DT_FEATURE_1`. Without these entries, a configuration file must be specified using the `LD_CONFIG` environment variable. Care should be exercised with this latter method as this environment variable is visible to any forked applications.

The use of the `-u` option requires at least version 2 of `crle`. This version level is evident from displaying the contents of a configuration file:

```

example% crle

Configuration file [2]: /var/ld/ld.config
.....

```

With a version 2 configuration file, `crle` is capable of constructing the command-line arguments required to regenerate the configuration file. This command-line construction, provides full update capabilities using the `-u` option. Although a version 1 configuration file update is possible, the configuration file contents might be insufficient for `crle` to compute the entire update requirements.

Files `/var/ld/ld.config`
 Default configuration file for 32-bit applications.

`/var/ld/64/ld.config`
 Default configuration file for 64-bit applications.

`/var/tmp`
 Default location for temporary configuration file. See [tempnam\(3C\)](#).

`/usr/lib/lddstub`
 Stub application that is employed to [dldump\(3C\)](#) 32-bit objects.

`/usr/lib/64/lddstub`
 Stub application that is employed to [dldump\(3C\)](#) 64-bit objects.

`/usr/lib/libcrle.so.1`
 Audit library that is employed to [dldump\(3C\)](#) 32-bit objects.

`/usr/lib/64/libcrle.so.1`
 Audit library that is employed to [dldump\(3C\)](#) 64-bit objects.

Linker and Libraries Guide

Name crontab – user crontab file

Synopsis /usr/bin/crontab [*filename*]
/usr/bin/crontab -e [*username*]
/usr/bin/crontab -l [*username*]
/usr/bin/crontab -r [*username*]
/usr/xpg4/bin/crontab [*filename*]
/usr/xpg4/bin/crontab -e [*username*]
/usr/xpg4/bin/crontab -l [*username*]
/usr/xpg4/bin/crontab -r [*username*]
/usr/xpg6/bin/crontab [*filename*]
/usr/xpg6/bin/crontab -e [*username*]
/usr/xpg6/bin/crontab -l [*username*]
/usr/xpg6/bin/crontab -r [*username*]

Description The crontab utility manages a user's access with cron (see [cron\(1M\)](#)) by copying, creating, listing, and removing crontab files. If invoked without options, crontab copies the specified file, or the standard input if no file is specified, into a directory that holds all users' crontabs.

If crontab is invoked with *filename*, this overwrites an existing crontab entry for the user that invokes it.

crontab Access Control Users: Access to crontab is allowed:

- if the user's name appears in `/etc/cron.d/cron.allow`.
- if `/etc/cron.d/cron.allow` does not exist and the user's name is not in `/etc/cron.d/cron.deny`.

Users: Access to crontab is denied:

- if `/etc/cron.d/cron.allow` exists and the user's name is not in it.
- if `/etc/cron.d/cron.allow` does not exist and user's name is in `/etc/cron.d/cron.deny`.
- if neither file exists, only a user with the `solaris.jobs.user` authorization is allowed to submit a job.
- if BSM audit is enabled, the user's shell is not audited and the user is not the crontab owner. This can occur if the user logs in by way of a program, such as some versions of SSH, which does not set audit parameters.

The rules for `allow` and `deny` apply to root only if the `allow/deny` files exist.

The `allow/deny` files consist of one user name per line.

crontab Entry Format A crontab file consists of lines of six fields each. The fields are separated by spaces or tabs. The first five are integer patterns that specify the following:

```
minute (0–59),
hour (0–23),
day of the month (1–31),
month of the year (1–12),
day of the week (0–6 with 0=Sunday).
```

Each of these patterns can be either an asterisk (meaning all legal values) or a list of elements separated by commas. An element is either a number or two numbers separated by a minus sign (meaning an inclusive range). Time specified here is interpreted in the timezone of the [cron\(1M\)](#) daemon, which is set system-wide in `/etc/default/init`. Entries do not use the invoking user's timezone. The specification of days can be made by two fields (day of the month and day of the week). Both are adhered to if specified as a list of elements. See **EXAMPLES**.

The sixth field of a line in a crontab file is a string that is executed by the shell at the specified times. A percent character in this field (unless escaped by `\`) is translated to a **NEWLINE** character.

Only the first line (up to a `' % '` or end of line) of the command field is executed by the shell. Other lines are made available to the command as standard input. Any blank line or line beginning with a `' # '` is a comment and is ignored.

The shell is invoked from your `$HOME` directory with an `arg0` of `sh`. Users who desire to have their `.profile` executed must explicitly do so in the crontab file. `cron` supplies a default environment for every shell, defining `HOME`, `LOGNAME`, `SHELL` (`=/bin/sh`), `TZ`, and `PATH`. The default `PATH` for user cron jobs is `/usr/bin`; while root cron jobs default to `/usr/sbin:/usr/bin`. The default `PATH` can be set in `/etc/default/cron` (see [cron\(1M\)](#)).

If you do not redirect the standard output and standard error of your commands, any generated output or errors are mailed to you.

Setting cron Jobs Across Timezones The timezone of the `cron` daemon sets the system-wide timezone for `cron` entries. This, in turn, is by set by default system-wide using `/etc/default/init`.

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

Options The following options are supported:

- e Edits a copy of the current user's crontab file, or creates an empty file to edit if crontab does not exist. When editing is complete, the file is installed as the user's crontab file.

The environment variable `EDITOR` determines which editor is invoked with the `-e` option. All crontab jobs should be submitted using `crontab`. Do not add jobs by just editing the crontab file, because `cron` is not aware of changes made this way.

If all lines in the crontab file are deleted, the old crontab file is restored. The correct way to delete all lines is to remove the crontab file using the `-r` option.

If *username* is specified, the specified user's crontab file is edited, rather than the current user's crontab file. This can only be done by root or by a user with the `solaris.jobs.admin` authorization.

- l Lists the crontab file for the invoking user. Only root or a user with the `solaris.jobs.admin` authorization can specify a username following the `-l` option to list the crontab file of the specified user.
- r Removes a user's crontab from the crontab directory. Only root or a user with the `solaris.jobs.admin` authorization can specify a username following the `-r` option to remove the crontab file of the specified user.

Examples **EXAMPLE 1** Cleaning up Core Files

This example cleans up core files every weekday morning at 3:15 am:

```
15 3 * * 1-5 find $HOME-namecore 2>/dev/null | xargs rm-f
```

EXAMPLE 2 Mailing a Birthday Greeting

This example mails a birthday greeting:

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

EXAMPLE 3 Specifying Days of the Month and Week

This example runs a command on the first and fifteenth of each month, as well as on every Monday:

```
0 0 1,15 * 1
```

To specify days by only one field, the other field should be set to `*`. For example:

```
0 0 * * 1
```

would run a command only on Mondays.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of crontab: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

<code>/usr/bin/crontab</code>	EDITOR	Determine the editor to be invoked when the <code>-e</code> option is specified. This is overridden by the <code>VISUAL</code> environmental variable. The default editor is ed(1) .
	PATH	The search path used to find the default <code>ed</code> utility.
	VISUAL	Determine the visual editor to be invoked when the <code>-e</code> option is specified. If <code>VISUAL</code> is not specified, then the environment variable <code>EDITOR</code> is used. If that is not set, the default is ed(1) .

- /usr/xpg4/bin/crontabEDITOR

Determine the editor to be invoked when the -e option is specified. The default editor is /usr/xpg4/bin/vi(1).
- /usr/xpg6/bin/crontabEDITOR

Determine the editor to be invoked when the -e option is specified. The default editor is /usr/xpg6/bin/vi(1).

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

- Files

/etc/cron.d

main cron directory

/etc/cron.d/cron.allow

list of allowed users

/etc/default/cron

contains cron default settings

/etc/cron.d/cron.deny

list of denied users

/var/cron/log

accounting information

/var/spool/cron/crontabs

spool area for crontab

See Also [atq\(1\)](#), [atrm\(1\)](#), [auths\(1\)](#), [ed\(1\)](#), [sh\(1\)](#), [vi\(1\)](#), [cron\(1M\)](#), [su\(1M\)](#), [auth_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes If you inadvertently enter the crontab command with no arguments, do not attempt to get out with Control-d. This removes all entries in your crontab file. Instead, exit with Control-c.

When updating `cron`, check first for existing `crontab` entries that can be scheduled close to the time of the update. Such entries can be lost if the update process completes after the scheduled event. This can happen because, when `cron` is notified by `crontab` to update the internal view of a user's `crontab` file, it first removes the user's existing internal `crontab` and any internal scheduled events. Then it reads the new `crontab` file and rebuilds the internal `crontab` and events. This last step takes time, especially with a large `crontab` file, and can complete *after* an existing `crontab` entry is scheduled to run if it is scheduled too close to the update. To be safe, start a new job at least 60 seconds after the current date and time.

Simultaneous modifications of the same `crontab` file may lead to unexpected results.

Name crypt – encode or decode a file

Synopsis crypt [*password*]

Description The crypt utility encrypts and decrypts the contents of a file. crypt reads from the standard input and writes on the standard output. The *password* is a key that selects a particular transformation. If no *password* is given, crypt demands a key from the terminal and turns off printing while the key is being typed in. crypt encrypts and decrypts with the same key:

```
example% crypt key < clear.file > encrypted.file
```

```
example% crypt key < encrypted.file | pr
```

prints the contents of clear.file.

Files encrypted by crypt are compatible with those treated by the editors [ed\(1\)](#), [ex\(1\)](#), and [vi\(1\)](#) in encryption mode.

The security of encrypted files depends on three factors: the fundamental method must be hard to solve; direct search of the key space must be infeasible; “sneak paths” by which keys or cleartext can become visible must be minimized.

crypt implements a one-rotor machine designed along the lines of the German Enigma, but with a 256-element rotor. Methods of attack on such machines are widely known, thus crypt provides minimal security.

The transformation of a key into the internal settings of the machine is deliberately designed to be expensive, that is, to take a substantial fraction of a second to compute. However, if keys are restricted to (say) three lower-case letters, then encrypted files can be read by expending only a substantial fraction of five minutes of machine time.

Since the key is an argument to the crypt command, it is potentially visible to users executing [ps\(1\)](#) or a derivative command. To minimize this possibility, crypt takes care to destroy any record of the key immediately upon entry. No doubt the choice of keys and key security are the most vulnerable aspect of crypt.

Files /dev/tty for typed key

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name csh – shell command interpreter with a C-like syntax

Synopsis csh [-bcefinstvVxX] [*argument*]...

Description csh, the C shell, is a command interpreter with a syntax reminiscent of the C language. It provides a number of convenient features for interactive use that are not available with the Bourne shell, including filename completion, command aliasing, history substitution, job control, and a number of built-in commands. As with the Bourne shell, the C shell provides variable, command and filename substitution.

Initialization and Termination When first started, the C shell normally performs commands from the `.cshrc` file in your home directory, provided that it is readable and you either own it or your real group ID matches its group ID. If the shell is invoked with a name that starts with `'-'`, as when started by [login\(1\)](#), the shell runs as a login shell.

If the shell is a login shell, this is the sequence of invocations: First, commands in `/etc/.login` are executed. Next, commands from the `.cshrc` file your home directory are executed. Then the shell executes commands from the `.login` file in your home directory; the same permission checks as those for `.cshrc` are applied to this file. Typically, the `.login` file contains commands to specify the terminal type and environment. (For an explanation of file interpreters, see [Command Execution](#) and [exec\(2\)](#).)

As a login shell terminates, it performs commands from the `.logout` file in your home directory; the same permission checks as those for `.cshrc` are applied to this file.

Interactive Operation After startup processing is complete, an interactive C shell begins reading commands from the terminal, prompting with `hostname%` (or `hostname#` for the privileged user). The shell then repeatedly performs the following actions: a line of command input is read and broken into *words*. This sequence of words is placed on the history list and then parsed, as described under [USAGE](#). Finally, the shell executes each command in the current line.

Noninteractive Operation When running noninteractively, the shell does not prompt for input from the terminal. A noninteractive C shell can execute a command supplied as an *argument* on its command line, or interpret commands from a file, also known as a script.

Options The following options are supported:

- b Forced a “break” from option processing. Subsequent command line arguments are not interpreted as C shell options. This allows the passing of options to a script without confusion. The shell does not run `set-user-ID` or `set-group-ID` scripts unless this option is present.
- c Executes the first *argument*, which must be present. Remaining arguments are placed in `argv`, the argument-list variable, and passed directly to `csh`.
- e Exits if a command terminates abnormally or yields a nonzero exit status.
- f Fast start. Reads neither the `.cshrc` file, nor the `.login` file (if a login shell) upon startup.

- i Forced interactive. Prompts for command line input, even if the standard input does not appear to be a terminal (character-special device).
- n Parses (interprets), but does not execute commands. This option can be used to check C shell scripts for syntax errors.
- s Takes commands from the standard input.
- t Reads and executes a single command line. A ‘\’ (backslash) can be used to escape each newline for continuation of the command line onto subsequent input lines.
- v Verbose. Sets the verbose predefined variable. Command input is echoed after history substitution, but before other substitutions and before execution.
- V Sets verbose before reading .cshrc.
- x Echo. Sets the echo variable. Echoes commands after all substitutions and just before execution.
- X Sets echo before reading .cshrc.

Except with the options -c, -i, -s, or -t, the first nonoption *argument* is taken to be the name of a command or script. It is passed as argument zero, and subsequent arguments are added to the argument list for that command or script.

Usage

- Filename Completion** When enabled by setting the variable `filec`, an interactive C shell can complete a partially typed filename or user name. When an unambiguous partial filename is followed by an ESC character on the terminal input line, the shell fills in the remaining characters of a matching filename from the working directory.
- If a partial filename is followed by the EOF character (usually typed as Control-d), the shell lists all filenames that match. It then prompts once again, supplying the incomplete command line typed in so far.
- When the last (partial) word begins with a tilde (~), the shell attempts completion with a user name, rather than a file in the working directory.
- The terminal bell signals errors or multiple matches. This bell signal can be inhibited by setting the variable `nobeep`. You can exclude files with certain suffixes by listing those suffixes in the variable `ignore`. If, however, the only possible completion includes a suffix in the list, it is not ignored. `ignore` does not affect the listing of filenames by the EOF character.
- Lexical Structure** The shell splits input lines into words at space and tab characters, except as noted below. The characters `&`, `|`, `;`, `<`, `>`, `(`, and `)` form separate words; if paired, the pairs form single words. These shell metacharacters can be made part of other words, and their special meaning can be suppressed by preceding them with a ‘\’ (backslash). A newline preceded by a \ is equivalent to a space character.

In addition, a string enclosed in matched pairs of single-quotes ('), double-quotes ("), or backquotes (`), forms a partial word. Metacharacters in such a string, including any space or tab characters, do not form separate words. Within pairs of backquote (`) or double-quote (") characters, a newline preceded by a `\' (backslash) gives a true newline character. Additional functions of each type of quote are described, below, under *Variable Substitution*, *Command Substitution*, and *Filename Substitution*.

When the shell's input is not a terminal, the character # introduces a comment that continues to the end of the input line. Its special meaning is suppressed when preceded by a \ or enclosed in matching quotes.

Command Line Parsing A *simple command* is composed of a sequence of words. The first word (that is not part of an I/O redirection) specifies the command to be executed. A simple command, or a set of simple commands separated by | or |& characters, forms a *pipeline*. With |, the standard output of the preceding command is redirected to the standard input of the command that follows. With | &, both the standard error and the standard output are redirected through the pipeline.

Pipelines can be separated by semicolons (;), in which case they are executed sequentially. Pipelines that are separated by && or | | form conditional sequences in which the execution of pipelines on the right depends upon the success or failure, respectively, of the pipeline on the left.

A pipeline or sequence can be enclosed within parentheses '(') to form a simple command that can be a component in a pipeline or sequence.

A sequence of pipelines can be executed asynchronously or "in the background" by appending an '&'; rather than waiting for the sequence to finish before issuing a prompt, the shell displays the job number (see *Job Control*, below) and associated process IDs and prompts immediately.

History Substitution History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size of which is controlled by the `history` variable. The most recent command is retained in any case. A history substitution begins with a ! (although you can change this with the `histchars` variable) and may occur anywhere on the command line; history substitutions do not nest. The ! can be escaped with \ to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

Event Designators An event designator is a reference to a command line entry in the history list.

!	Start a history substitution, except when followed by a space character, tab, newline, = or (.
!!	Refer to the previous command. By itself, this substitution repeats the previous command.
!n	Refer to command line <i>n</i> .
!-n	Refer to the current command line minus <i>n</i> .
!str	Refer to the most recent command starting with <i>str</i> .
!?str?	Refer to the most recent command containing <i>str</i> .
!?str? <i>additional</i>	Refer to the most recent command containing <i>str</i> and append <i>additional</i> to that referenced command.
!{command} <i>additional</i>	Refer to the most recent command beginning with <i>command</i> and append <i>additional</i> to that referenced command.
^previous_word^replacement^	Repeat the previous command line replacing the string <i>previous_word</i> with the string <i>replacement</i> . This is equivalent to the history substitution: !:s/previous_word/replacement/. To re-execute a specific previous command AND make such a substitution, say, re-executing command #6, !:6s/previous_word/replacement/.

Word Designators A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, \$, *, - or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, !!:1 and !:1 both refer to the first word of the previous command, while !!\$ and !\$ both refer to the last word in the previous command. Word designators include:

#	The entire command line typed so far.
0	The first input word (command).
n	The <i>n</i> 'th argument.
^	The first argument, that is, 1.

\$	The last argument.
%	The word matched by the ?s search.
x-y	A range of words; -y abbreviates 0-y.
*	All the arguments, or a null value if there is just one word in the event.
x*	Abbreviates x-\$.
x-	Like x* but omitting word \$.

Modifiers After the optional word designator, you can add one of the following modifiers, preceded by a `:`.

h	Remove a trailing pathname component, leaving the head.
r	Remove a trailing suffix of the form '.xxx', leaving the basename.
e	Remove all but the suffix, leaving the Extension.
s/l/r/	Substitute <i>r</i> for <i>l</i> .
t	Remove all leading pathname components, leaving the tail.
&	Repeat the previous substitution.
g	Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, g&).
p	Print the new command but do not execute it.
q	Quote the substituted words, escaping further substitutions.
x	Like q, but break into words at each space character, tab or newline.

Unless preceded by a *g*, the modification is applied only to the first string that matches *l*; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of `/`. A backslash quotes the delimiter character. The character `&`, in the right hand side, is replaced by the text from the left-hand-side. The `&` can be quoted with a backslash. A null *l* uses the previous string either from a *l* or from a contextual scan string *s* from `! ?s`. You can omit the rightmost delimiter if a newline immediately follows *r*; the rightmost `?` in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

Quick Substitution `^l^r^` This is equivalent to the history substitution:
`! : s/l/r/ .`

Aliases The C shell maintains a list of aliases that you can create, display, and modify using the `alias` and `unalias` commands. The shell checks the first word in each command to see if it matches the name of an existing alias. If it does, the command is reprocessed with the alias definition replacing its name; the history substitution mechanism is made available as though that command were the previous input line. This allows history substitutions, escaped with a backslash in the definition, to be replaced with actual command line arguments when the alias is used. If no history substitution is called for, the arguments remain unchanged.

Aliases can be nested. That is, an alias definition can contain the name of another alias. Nested aliases are expanded before any history substitutions is applied. This is useful in pipelines such as

```
alias lm 'ls -l \!* | more'
```

which when called, pipes the output of `ls(1)` through `more(1)`.

Except for the first word, the name of the alias may not appear in its definition, nor in any alias referred to by its definition. Such loops are detected, and cause an error message.

I/O Redirection The following metacharacters indicate that the subsequent word is the name of a file to which the command's standard input, standard output, or standard error is redirected; this word is variable, command, and filename expanded separately from the rest of the command.

<

Redirect the standard input.

< < *word*

Read the standard input, up to a line that is identical with *word*, and place the resulting lines in a temporary file. Unless *word* is escaped or quoted, variable and command substitutions are performed on these lines. Then, the pipeline is invoked with the temporary file as its standard input. *word* is not subjected to variable, filename, or command substitution, and each line is compared to it before any substitutions are performed by the shell.

> > ! >& >& !

Redirect the standard output to a file. If the file does not exist, it is created. If it does exist, it is overwritten; its previous contents are lost.

When set, the variable `noclobber` prevents destruction of existing files. It also prevents redirection to terminals and `/dev/null`, unless one of the `!` forms is used. The `&` forms redirect both standard output and the standard error (diagnostic output) to the file.

> >> >& >> > ! > >& !

Append the standard output. Like `>`, but places output at the end of the file rather than overwriting it. If `noclobber` is set, it is an error for the file not to exist, unless one of the `!` forms is used. The `&` forms append both the standard error and standard output to the file.

Variable Substitution The C shell maintains a set of *variables*, each of which is composed of a *name* and a *value*. A variable name consists of up to 20 letters and digits, and starts with a letter (the underscore is considered a letter). A variable's value is a space-separated list of zero or more words.

To refer to a variable's value, precede its name with a '\$'. Certain references (described below) can be used to select specific words from the value, or to display other information about the variable. Braces can be used to insulate the reference from other characters in an input-line word.

Variable substitution takes place after the input line is analyzed, aliases are resolved, and I/O redirections are applied. Exceptions to this are variable references in I/O redirections (substituted at the time the redirection is made), and backquoted strings (see Command Substitution).

Variable substitution can be suppressed by preceding the \$ with a \, except within double-quotes where it always occurs. Variable substitution is suppressed inside of single-quotes. A \$ is escaped if followed by a space character, tab or newline.

Variables can be created, displayed, or destroyed using the set and unset commands. Some variables are maintained or used by the shell. For instance, the argv variable contains an image of the shell's argument list. Of the variables used by the shell, a number are toggles; the shell does not care what their value is, only whether they are set or not.

Numerical values can be operated on as numbers (as with the @ built-in command). With numeric operations, an empty value is considered to be zero. The second and subsequent words of multiword values are ignored. For instance, when the verbose variable is set to any value (including an empty value), command input is echoed on the terminal.

Command and filename substitution is subsequently applied to the words that result from the variable substitution, except when suppressed by double-quotes, when noglob is set (suppressing filename substitution), or when the reference is quoted with the :q modifier. Within double-quotes, a reference is expanded to form (a portion of) a quoted string; multiword values are expanded to a string with embedded space characters. When the :q modifier is applied to the reference, it is expanded to a list of space-separated words, each of which is quoted to prevent subsequent command or filename substitutions.

Except as noted below, it is an error to refer to a variable that is not set.

`$var`

`${var}` These are replaced by words from the value of *var*, each separated by a space character. If *var* is an environment variable, its value is returned (but ':' modifiers and the other forms given below are not available).

`$var[index]`

`${var[index]}` These select only the indicated words from the value of *var*. Variable substitution is applied to *index*, which may consist of (or result in) a either single number, two numbers separated by a '-', or an asterisk.

Words are indexed starting from 1; a '*' selects all words. If the first number of a range is omitted (as with `$argv[-2]`), it defaults to 1. If the last number of a range is omitted (as with `$argv[1-]`), it defaults to `$#var` (the word count). It is not an error for a range to be empty if the second argument is omitted (or within range).

<code>\$#name</code>	
<code>\${#name}</code>	These give the number of words in the variable.
<code>\$0</code>	This substitutes the name of the file from which command input is being read except for setuid shell scripts. An error occurs if the name is not known.
<code>\$n</code>	
<code>\${n}</code>	Equivalent to <code>\$argv[n]</code> .
<code>\$*</code>	Equivalent to <code>\$argv[*]</code> .

The modifiers `:e`, `:h`, `:q`, `:r`, `:t`, and `:x` can be applied (see History Substitution), as can `:gh`, `:gt`, and `:gr`. If `{ }` (braces) are used, then the modifiers must appear within the braces. The current implementation allows only one such modifier per expansion.

The following references may not be modified with `:` modifiers.

<code>\$?var</code>	
<code>\${?var}</code>	Substitutes the string 1 if <code>var</code> is set or 0 if it is not set.
<code>\$?0</code>	Substitutes 1 if the current input filename is known or 0 if it is not.
<code>\$\$_</code>	Substitutes the process number of the (parent) shell.
<code>\$<</code>	Substitutes a line from the standard input, with no further interpretation thereafter. It can be used to read from the keyboard in a C shell script.

Command and Filename Substitutions	Command and filename substitutions are applied selectively to the arguments of built-in commands. Portions of expressions that are not evaluated are not expanded. For non-built-in commands, filename expansion of the command name is done separately from that of the argument list; expansion occurs in a subshell, after I/O redirection is performed.
Command Substitution	A command enclosed by backquotes (<code>`...`</code>) is performed by a subshell. Its standard output is broken into separate words at each space character, tab and newline; null words are discarded. This text replaces the backquoted string on the current command line. Within double-quotes, only newline characters force new words; space and tab characters are preserved. However, a final newline is ignored. It is therefore possible for a command substitution to yield a partial word.
Filename Substitution	Unquoted words containing any of the characters <code>*</code> , <code>?</code> , <code>[</code> or <code>{</code> , or that begin with <code>~</code> , are expanded (also known as <i>globbing</i>) to an alphabetically sorted list of filenames, as follows:

<code>*</code>	Match any (zero or more) characters.
<code>?</code>	Match any single character.
<code>[...]</code>	Match any single character in the enclosed list(s) or range(s). A list is a string of characters. A range is two characters separated by a dash (<code>-</code>), and includes all the characters in between in the ASCII collating sequence (see ascii(5)).
<code>{str, str, ...}</code>	Expand to each string (or filename-matching pattern) in the comma-separated list. Unlike the pattern-matching expressions above, the expansion of this construct is not sorted. For instance, <code>{b, a}</code> expands to <code>'b' 'a'</code> , (not <code>'a' 'b'</code>). As special cases, the characters <code>{</code> and <code>}</code> , along with the string <code>{ }</code> , are passed undisturbed.
<code>~[user]</code>	Your home directory, as indicated by the value of the variable <code>home</code> , or that of <code>user</code> , as indicated by the password entry for <code>user</code> .

Only the patterns `*`, `?` and `[...]` imply pattern matching; an error results if no filename matches a pattern that contains them. The `'.'` (dot character), when it is the first character in a filename or pathname component, must be matched explicitly. The `/` (slash) must also be matched explicitly.

Expressions and Operators A number of C shell built-in commands accept expressions, in which the operators are similar to those of C and have the same precedence. These expressions typically appear in the `@`, `exit`, `if`, `set` and `while` commands, and are often used to regulate the flow of control for executing commands. Components of an expression are separated by white space.

Null or missing values are considered `0`. The result of all expressions is a string, which may represent decimal numbers.

The following C shell operators are grouped in order of precedence:

<code>(...)</code>	grouping
<code>>~</code>	one's complement
<code>!</code>	logical negation
<code>* / %</code>	multiplication, division, remainder. These are right associative, which can lead to unexpected results. Combinations should be grouped explicitly with parentheses.
<code>+ -</code>	addition, subtraction (also right associative)
<code><< >></code>	bitwise shift left, bitwise shift right
<code>< > <= >=</code>	less than, greater than, less than or equal to, greater than or equal to

<code>=</code> <code>!=</code> <code>=~</code> <code>!~</code>	equal to, not equal to, filename-substitution pattern match (described below), filename-substitution pattern mismatch
<code>&</code>	bitwise AND
<code>^</code>	bitwise XOR (exclusive or)
<code> </code>	bitwise inclusive OR
<code>&&</code>	logical AND
<code> </code>	logical OR

The operators `==`, `!=`, `=~`, and `!~` compare their arguments as strings; other operators use numbers. The operators `=~` and `!~` each check whether or not a string to the left matches a filename substitution pattern on the right. This reduces the need for `switch` statements when pattern-matching between strings is all that is required.

Also available are file inquiries:

<code>-r filename</code>	Return true, or 1 if the user has read access. Otherwise it returns false, or 0.
<code>-w filename</code>	True if the user has write access.
<code>-x filename</code>	True if the user has execute permission (or search permission on a directory).
<code>-e filename</code>	True if <i>filename</i> exists.
<code>-o filename</code>	True if the user owns <i>filename</i> .
<code>-z filename</code>	True if <i>filename</i> is of zero length (empty).
<code>-f filename</code>	True if <i>filename</i> is a plain file.
<code>-d filename</code>	True if <i>filename</i> is a directory.

If *filename* does not exist or is inaccessible, then all inquiries return false.

An inquiry as to the success of a command is also available:

<code>{ command }</code>	If <i>command</i> runs successfully, the expression evaluates to true, 1. Otherwise, it evaluates to false, 0. <i>Note:</i> Conversely, <i>command</i> itself typically returns 0 when it runs successfully, or some other value if it encounters a problem. If you want to get at the status directly, use the value of the <code>status</code> variable rather than this expression.
--------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Control Flow The shell contains a number of commands to regulate the flow of control in scripts and within limits, from the terminal. These commands operate by forcing the shell either to reread input (to *loop*), or to skip input under certain conditions (to *branch*).

Each occurrence of a `foreach`, `switch`, `while`, `if...then` and `else` built-in command must appear as the first word on its own input line.

If the shell's input is not seekable and a loop is being read, that input is buffered. The shell performs seeks within the internal buffer to accomplish the rereading implied by the loop. (To the extent that this allows, backward `goto` commands will succeed on nonseekable inputs.)

Command Execution If the command is a C shell built-in command, the shell executes it directly. Otherwise, the shell searches for a file by that name with execute access. If the command name contains a `/`, the shell takes it as a pathname, and searches for it. If the command name does not contain a `/`, the shell attempts to resolve it to a pathname, searching each directory in the `path` variable for the command. To speed the search, the shell uses its hash table (see the `rehash` built-in command) to eliminate directories that have no applicable files. This hashing can be disabled with the `-c` or `-t`, options, or the `unhash` built-in command.

As a special case, if there is no `/` in the name of the script and there is an alias for the word `shell`, the expansion of the `shell` alias is prepended (without modification) to the command line. The system attempts to execute the first word of this special (late-occurring) alias, which should be a full pathname. Remaining words of the alias's definition, along with the text of the input line, are treated as arguments.

When a pathname is found that has proper execute permissions, the shell forks a new process and passes it, along with its arguments, to the kernel using the `execve()` system call (see [exec\(2\)](#)). The kernel then attempts to overlay the new process with the desired program. If the file is an executable binary (in [a.out\(4\)](#) format) the kernel succeeds and begins executing the new process. If the file is a text file and the first line begins with `#!`, the next word is taken to be the pathname of a shell (or command) to interpret that script. Subsequent words on the first line are taken as options for that shell. The kernel invokes (overlays) the indicated shell, using the name of the script as an argument.

If neither of the above conditions holds, the kernel cannot overlay the file and the `execve()` call fails (see [exec\(2\)](#)). The C shell then attempts to execute the file by spawning a new shell, as follows:

- If the first character of the file is a `#`, a C shell is invoked.
- Otherwise, a Bourne shell is invoked.

Signal Handling The shell normally ignores `QUIT` signals. Background jobs are immune to signals generated from the keyboard, including hangups (`HUP`). Other signals have the values that the C shell inherited from its environment. The shell's handling of interrupt and terminate signals within scripts can be controlled by the `onintr` built-in command. Login shells catch the `TERM` signal. Otherwise, this signal is passed on to child processes. In no case are interrupts allowed when a login shell is reading the `.logout` file.

Job Control The shell associates a numbered *job* with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals (typically Control-z). When a command or command sequence (semicolon separated list) is started in the background using the & metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the *current* job and is indicated with a '+'. The previous job is indicated with a '-'. When the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands.

A reference to a job begins with a '%'. By itself, the percent-sign refers to the current job.

`%+ %%` The current job.

`%-` The previous job.

`%j` Refer to job *j* as in: '`kill -9 %j`'. *j* can be a job number, or a string that uniquely specifies the command line by which it was started; '`fg %vi`' might bring a stopped `vi` job to the foreground, for instance.

`%?string` Specify the job for which the command line uniquely contains *string*.

A job running in the background stops when it attempts to read from the terminal.

Background jobs can normally produce output, but this can be suppressed using the '`stty tostop`' command.

Status Reporting While running interactively, the shell tracks the status of each job and reports whenever the job finishes or becomes blocked. It normally displays a message to this effect as it issues a prompt, in order to avoid disturbing the appearance of your input. When set, the `notify` variable indicates that the shell is to report status changes immediately. By default, the `notify` command marks the current process; after starting a background job, type `notify` to mark it.

Commands Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell.

:

Null command. This command is interpreted, but performs no action.

`alias [name [def]]`

Assign *def* to the alias *name*. *def* is a list of words that may contain escaped history-substitution metasyntax. *name* is not allowed to be `alias` or `unalias`. If *def* is omitted, the current definition for the alias *name* is displayed. If both *name* and *def* are omitted, all aliases are displayed with their definitions.

bg [*%job* . . .]

Run the current or specified jobs in the background.

break

Resume execution after the end of the nearest enclosing `foreach` or `while` loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of `break` commands, all on one line.

breaksw

Break from a `switch`, resuming after the `endsw`.

case *label*:

A label in a `switch` statement.

cd [*dir*]

chdir [*dir*]

Change the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the `cdpath` variable. If *dir* is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

continue

Continue execution of the next iteration of the nearest enclosing `while` or `foreach` loop.

default:

Labels the default case in a `switch` statement. The default should come after all case labels. Any remaining commands on the command line are first executed.

dirs [-*l*]

Print the directory stack, most recent to the left. The first directory shown is the current directory. With the `-l` argument, produce an unabbreviated printout; use of the `~` notation is suppressed.

echo [-*n*] *list*

The words in *list* are written to the shell's standard output, separated by space characters. The output is terminated with a newline unless the `-n` option is used. `csh` will, by default, invoke its built-in `echo`, if `echo` is called without the full pathname of a Unix command, regardless of the configuration of your `PATH` (see [echo\(1\)](#)).

eval *argument* . . .

Reads the arguments as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution. See [tset\(1B\)](#) for an example of how to use `eval`.

exec *command*

Execute *command* in place of the current shell, which terminates.

exit [(*expr*)]

The calling shell or shell script exits, either with the value of the status variable or with the value specified by the expression *expr*.

`fg [%job]`

Bring the current or specified *job* into the foreground.

`foreach var (wordlist)`

...

`end`

The variable *var* is successively set to each member of *wordlist*. The sequence of commands between this command and the matching `end` is executed for each new value of *var*. Both `foreach` and `end` must appear alone on separate lines.

The built-in command `continue` may be used to terminate the execution of the current iteration of the loop and the built-in command `break` may be used to terminate execution of the `foreach` command. When this command is read from the terminal, the loop is read once prompting with `?` before any statements in the loop are executed.

`glob wordlist`

Perform filename expansion on *wordlist*. Like `echo`, but no `\` escapes are recognized.

Words are delimited by NULL characters in the output.

`goto label`

The specified *label* is a filename and a command expanded to yield a label. The shell rewinds its input as much as possible and searches for a line of the form *label*: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a `while` or `for` built-in command and its corresponding `end`.

`hashstat`

Print a statistics line indicating how effective the internal hash table for the *path* variable has been at locating commands (and avoiding execs). An `exec` is attempted for each component of the *path* where the hash function indicates a possible hit and in each component that does not begin with a `/`. These statistics only reflect the effectiveness of the *path* variable, not the *cdpath* variable.

`history [-hr] [n]`

Display the history list; if *n* is given, display only the *n* most recent events.

-r Reverse the order of printout to be most recent first rather than oldest first.

-h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the `-h` option to *source*.

`if (expr) command`

If the specified expression evaluates to true, the single *command* with arguments is executed. Variable substitution on *command* happens early, at the same time it does for the rest of the `if` command. *command* must be a simple command, not a pipeline, a command list, or a parenthesized command list. *Note*: I/O redirection occurs even if *expr* is false, when *command* is *not* executed (this is a bug).

```
if (expr) then
...
else if (expr2) then
...
else
...
endif
```

If *expr* is true, commands up to the first `else` are executed. Otherwise, if *expr2* is true, the commands between the `else if` and the second `else` are executed. Otherwise, commands between the `else` and the `endif` are executed. Any number of `else if` pairs are allowed, but only one `else`. Only one `endif` is needed, but it is required. The words `else` and `endif` must be the first nonwhite characters on a line. The `if` must appear alone on its input line or after an `else`.

`jobs [-l]`

List the active jobs under job control.

`-l` List process IDs, in addition to the normal information.

`kill [sig] [pid] [%job] . . .`

`kill -l`

Send the TERM (terminate) signal, by default, or the signal specified, to the specified process ID, the *job* indicated, or the current *job*. Signals are either given by number or by name. There is no default. Typing `kill` does not send a signal to the current job. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal as well.

`-l` List the signal names that can be sent.

`limit [-h] [resource [max-use]]`

Limit the consumption by the current process or any process it spawns, each not to exceed *max-use* on the specified *resource*. The string `unlimited` requests that the current limit, if any, be removed. If *max-use* is omitted, print the current limit. If *resource* is omitted, display all limits. Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported by `sysdef` are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command.

`-h` Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

resource is one of:

<code>cputime</code>	Maximum CPU seconds per process.
----------------------	----------------------------------

<code>filesize</code>	Largest single file allowed. Limited by the size and capabilities of the filesystem. See <code>df(1M)</code> .
-----------------------	----------------------------------------------------------------------------------------------------------------

<code>datasize (heapsize)</code>	Maximum data size (including stack) for the process. This is the size of your virtual memory See swap(1M) .
<code>stacksize</code>	Maximum stack size for the process. The default stack size is 2 ⁶⁴ bytes. You can use limit(1) to change this default within a shell.
<code>coredumpsize</code>	Maximum size of a core dump (file). This is limited by the size of the filesystem.
<code>descriptors</code>	Maximum number of file descriptors. Run sysdef(1M) .
<code>memorysize</code>	Maximum size of virtual memory.

max-use is a number, with an optional scaling factor, as follows:

<i>nh</i>	Hours (for <code>cputime</code>).
<i>nk</i>	<i>n</i> kilobytes. This is the default for all but <code>cputime</code> .
<i>nm</i>	<i>n</i> megabytes or minutes (for <code>cputime</code>).
<i>mm:ss</i>	Minutes and seconds (for <code>cputime</code>).

Example of limit: To limit the size of a core file dump to 0 Megabytes, type the following:

```
limit coredumpsize 0M
```

`login [username | -p]`

Terminate a login shell and invoke [login\(1\)](#). The `.logout` file is not processed. If *username* is omitted, `login` prompts for the name of a user.

`-p` Preserve the current environment (variables).

`logout`

Terminate a login shell.

`nice [+n | -n] [command]`

Increment the process priority value for the shell or for *command* by *n*. The higher the priority value, the lower the priority of a process, and the slower it runs. When given, *command* is always run in a subshell, and the restrictions placed on commands in simple if commands apply. If *command* is omitted, `nice` increments the value for the current shell. If no increment is specified, `nice` sets the process priority value to 4. The range of process priority values is from -20 to 20. Values of *n* outside this range set the value to the lower, or to the higher boundary, respectively.

`+n` Increment the process priority value by *n*.

`-n` Decrement by *n*. This argument can be used only by the privileged user.

nohup [*command*]

Run *command* with HUPs ignored. With no arguments, ignore HUPs throughout the remainder of a script. When given, *command* is always run in a subshell, and the restrictions placed on commands in simple `if` statements apply. All processes detached with `&` are effectively nohup'd.

notify [%*job*]. . .

Notify the user asynchronously when the status of the current job or specified jobs changes.

onintr [-] [*label*]

Control the action of the shell on interrupts. With no arguments, `onintr` restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the `-` argument, the shell ignores all interrupts. With a *label* argument, the shell executes a `goto label` when an interrupt is received or a child process terminates because it was interrupted.

popd [+*n*]

Pop the directory stack and `cd` to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

+*n* Discard the *n*'th entry in the stack.

pushd [+*n*] [*dir*]

Push a directory onto the directory stack. With no arguments, exchange the top two elements.

+*n* Rotate the *n*'th entry to the top of the stack and `cd` to it.

dir Push the current working directory onto the stack and change to *dir*.

rehash

Recompute the internal hash table of the contents of directories listed in the *path* variable to account for new commands added. Recompute the internal hash table of the contents of directories listed in the *cdpath* variable to account for new directories added.

repeat *count command*

Repeat *command* *count* times. *command* is subject to the same restrictions as with the one-line `if` statement.

set [*var* [= *value*]]**set** *var*[*n*] = *word*

With no arguments, `set` displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, `set` assigns an empty (null) value to the variable *var*. With arguments of the form *var* = *value* `set` assigns *value* to *var*, where *value* is one of:

word A single word (or quoted string).

(*wordlist*) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form `set var[n]` = *word* replaces the *n*'th word in a multiword value with *word*.

`setenv [VAR [word]]`

With no arguments, `setenv` displays all environment variables. With the *VAR* argument, `setenv` sets the environment variable *VAR* to have an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both *VAR* and *word* arguments, `setenv` sets the environment variable *NAME* to the value *word*, which must be either a single word or a quoted string. The most commonly used environment variables, `USER`, `TERM`, and `PATH`, are automatically imported to and exported from the `csh` variables `user`, `term`, and `path`. There is no need to use `setenv` for these. In addition, the shell sets the `PWD` environment variable from the `csh` variable `cwd` whenever the latter changes.

The environment variables `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY` take immediate effect when changed within the C shell.

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of `csh` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the C (U.S. style) locale determines how `csh` behaves.

<code>LC_CTYPE</code>	Determines how <code>csh</code> handles characters. When <code>LC_CTYPE</code> is set to a valid value, <code>csh</code> can display and handle text and filenames containing valid characters for that locale.
<code>LC_MESSAGES</code>	Determines how diagnostic and informative messages are presented. This includes the language and style of the messages and the correct form of affirmative and negative responses. In the C locale, the messages are presented in the default form found in the program itself (in most cases, U.S./English).
<code>LC_NUMERIC</code>	Determines the value of the radix character (decimal point (.) in the C locale) and thousand separator (empty string (" ") in the C locale).

`shift [variable]`

The components of `argv`, or *variable*, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

`source [-h] name`

Reads commands from *name*. `source` commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested `source` commands.

`-h` Place commands from the file *name* on the history list without executing them.

`stop %jobid . . .`

Stop the current or specified background job.

`stop pid . . .`

Stop the specified process, *pid*. (see [ps\(1\)](#)).

`suspend`

Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by `su`.

`switch (string)`

`case label:`

`...`

`breaksw`

`...`

`default:`

`...`

`breaksw`

`endsw`

Each *label* is successively matched, against the specified *string*, which is first command and filename expanded. The file metacharacters *, ? and [. . .] may be used in the case labels, which are variable expanded. If none of the labels match before a “default” label is found, execution begins after the default label. Each case statement and the default statement must appear at the beginning of a line. The command `breaksw` continues execution after the `endsw`. Otherwise control falls through subsequent case and default statements as with C. If no label matches and there is no default, execution continues after the `endsw`.

`time [command]`

With no argument, print a summary of time used by this C shell and its children. With an optional *command*, execute *command* and print a summary of the time it uses. As of this writing, the `time` built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value 0 for these fields.

```
example %time ls -R
```

```
9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w
```

(See the Environment Variables and Predefined Shell Variables sub-section on the `time` variable.)

`umask [value]`

Display the file creation mask. With *value*, set the file creation mask. With *value* given in octal, the user can turn off any bits, but cannot turn on bits to allow new permissions. Common values include 077, restricting all permissions from everyone else; 002, giving complete access to the group, and read (and directory search) access to others; or 022, giving read (and directory search) but not write permission to the group and others.

`unalias pattern`

Discard aliases that match (filename substitution) *pattern*. All aliases are removed by `'unalias *'`.

`unhash`

Disable the internal hash tables for the *path* and *cdpath* variables.

`unlimit [-h] [resource]`

Remove a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.

`-h` Remove corresponding hard limits. Only the privileged user may do this.

`unset pattern`

Remove variables whose names match (filename substitution) *pattern*. All variables are removed by ‘unset *’; this has noticeably distasteful side effects.

`unsetenv variable`

Remove *variable* from the environment. As with `unset`, pattern matching is not performed.

`wait`

Wait for background jobs to finish (or for an interrupt) before prompting.

`while (expr)`

...

`end`

While *expr* is true (evaluates to nonzero), repeat commands between the `while` and the matching `end` statement. `break` and `continue` may be used to terminate or continue the loop prematurely. The `while` and `end` must appear alone on their input lines. If the shell's input is a terminal, it prompts for commands with a question-mark until the `end` command is entered and then performs the commands in the loop.

`% [job] [&]`

Bring the current or indicated *job* to the foreground. With the ampersand, continue running *job* in the background.

`@ [var=expr]`

`@ [var[n]=expr]`

With no arguments, display the values for all shell variables. With arguments, set the variable *var*, or the *n*'th word in the value of *var*, to the value that *expr* evaluates to. (If [*n*] is supplied, both *var* and its *n*'th component must already exist.)

If the expression contains the characters `>`, `<`, `&`, or `|`, then at least this part of *expr* must be placed within parentheses.

The operators `*`, `+=`, and so forth, are available as in C. The space separating the name from the assignment operator is optional. Spaces are, however, mandatory in separating components of *expr* that would otherwise be single words.

Special postfix operators, `++` and `--`, increment or decrement *name*, respectively.

Environment Variables and Predefined Shell Variables

Unlike the Bourne shell, the C shell maintains a distinction between environment variables, which are automatically exported to processes it invokes, and shell variables, which are not. Both types of variables are treated similarly under variable substitution. The shell sets the variables `argv`, `cwd`, `home`, `path`, `prompt`, `shell`, and `status` upon initialization. The shell

copies the environment variable `USER` into the shell variable `user`, `TERM` into `term`, and `HOME` into `home`, and copies each back into the respective environment variable whenever the shell variables are reset. `PATH` and `path` are similarly handled. You need only set `path` once in the `.cshrc` or `.login` file. The environment variable `PWD` is set from `cwd` whenever the latter changes. The following shell variables have predefined meanings:

<code>argv</code>	Argument list. Contains the list of command line arguments supplied to the current invocation of the shell. This variable determines the value of the positional parameters <code>\$1</code> , <code>\$2</code> , and so on.				
<code>cdpath</code>	Contains a list of directories to be searched by the <code>cd</code> , <code>chdir</code> , and <code>popd</code> commands, if the directory argument each accepts is not a subdirectory of the current directory.				
<code>cwd</code>	The full pathname of the current directory.				
<code>echo</code>	Echo commands (after substitutions) just before execution.				
<code>fignore</code>	A list of filename suffixes to ignore when attempting filename completion. Typically the single word <code>‘.o’</code> .				
<code>filec</code>	Enable filename completion, in which case the Control-d character EOT and the ESC character have special significance when typed in at the end of a terminal input line: <table><tr><td>EOT</td><td>Print a list of all filenames that start with the preceding string.</td></tr><tr><td>ESC</td><td>Replace the preceding string with the longest unambiguous extension.</td></tr></table>	EOT	Print a list of all filenames that start with the preceding string.	ESC	Replace the preceding string with the longest unambiguous extension.
EOT	Print a list of all filenames that start with the preceding string.				
ESC	Replace the preceding string with the longest unambiguous extension.				
<code>hardpaths</code>	If set, pathnames in the directory stack are resolved to contain no symbolic-link components.				
<code>histchars</code>	A two-character string. The first character replaces <code>!</code> as the history-substitution character. The second replaces the carat (<code>^</code>) for quick substitutions.				
<code>history</code>	The number of lines saved in the history list. A very large number may use up all of the C shell's memory. If not set, the C shell saves only the most recent command.				
<code>home</code>	The user's home directory. The filename expansion of <code>~</code> refers to the value of this variable.				
<code>ignoreeof</code>	If set, the shell ignores EOF from terminals. This protects against accidentally killing a C shell by typing a Control-d.				
<code>mail</code>	A list of files where the C shell checks for mail. If the first word of the value is a number, it specifies a mail checking interval in seconds (default 5 minutes).				

nobeeep	Suppress the bell during command completion when asking the C shell to extend an ambiguous filename.						
noclobber	Restrict output redirection so that existing files are not destroyed by accident. > redirections can only be made to new files. >> redirections can only be made to existing files.						
noglob	Inhibit filename substitution. This is most useful in shell scripts once filenames (if any) are obtained and no further expansion is desired.						
nomatch	Return the filename substitution pattern, rather than an error, if the pattern is not matched. Malformed patterns still result in errors.						
notify	If set, the shell notifies you immediately as jobs are completed, rather than waiting until just before issuing a prompt.						
path	The list of directories in which to search for commands. path is initialized from the environment variable PATH, which the C shell updates whenever path changes. A null word (") specifies the current directory. The default is typically (/usr/bin .). One may override this initial search path upon csh start-up by setting it in .cshrc or .login (for login shells only). If path becomes unset, only full pathnames will execute. An interactive C shell will normally hash the contents of the directories listed after reading .cshrc, and whenever path is reset. If new commands are added, use the rehash command to update the table.						
prompt	<p>The string an interactive C shell prompts with. Noninteractive shells leave the prompt variable unset. Aliases and other commands in the .cshrc file that are only useful interactively, can be placed after the following test: 'if (\$?prompt == 0) exit', to reduce startup time for noninteractive shells. A ! in the prompt string is replaced by the current event number. The default prompt is <i>hostname%</i> for mere mortals, or <i>hostname#</i> for the privileged user.</p> <p>The setting of \$prompt has three meanings:</p> <table> <tr> <td>\$prompt not set</td><td>non-interactive shell, test \$?prompt.</td></tr> <tr> <td>\$prompt set but == ""</td><td>.cshrc called by the which(1) command.</td></tr> <tr> <td>\$prompt set and != ""</td><td>normal interactive shell.</td></tr> </table>	\$prompt not set	non-interactive shell, test \$?prompt.	\$prompt set but == ""	.cshrc called by the which(1) command.	\$prompt set and != ""	normal interactive shell.
\$prompt not set	non-interactive shell, test \$?prompt.						
\$prompt set but == ""	.cshrc called by the which(1) command.						
\$prompt set and != ""	normal interactive shell.						
savehist	The number of lines from the history list that are saved in ~/.history when the user logs out. Large values for savehist slow down the C shell during startup.						

shell	The file in which the C shell resides. This is used in forking shells to interpret files that have execute bits set, but that are not executable by the system.																								
status	The status returned by the most recent command. If that command terminated abnormally, 0200 is added to the status. Built-in commands that fail return exit status 1; all other built-in commands set status to 0.																								
time	<p>Control automatic timing of commands. Can be supplied with one or two values. The first is the reporting threshold in CPU seconds. The second is a string of tags and text indicating which resources to report on. A tag is a percent sign (%) followed by a single upper-case letter (unrecognized tags print as text):</p> <table><tr><td>%D</td><td>Average amount of unshared data space used in Kilobytes.</td></tr><tr><td>%E</td><td>Elapsed (wallclock) time for the command.</td></tr><tr><td>%F</td><td>Page faults.</td></tr><tr><td>%I</td><td>Number of block input operations.</td></tr><tr><td>%K</td><td>Average amount of unshared stack space used in Kilobytes.</td></tr><tr><td>%M</td><td>Maximum real memory used during execution of the process.</td></tr><tr><td>%O</td><td>Number of block output operations.</td></tr><tr><td>%P</td><td>Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.</td></tr><tr><td>%S</td><td>Number of seconds of CPU time consumed by the kernel on behalf of the user's process.</td></tr><tr><td>%U</td><td>Number of seconds of CPU time devoted to the user's process.</td></tr><tr><td>%W</td><td>Number of swaps.</td></tr><tr><td>%X</td><td>Average amount of shared memory used in Kilobytes.</td></tr></table> <p>The default summary display outputs from the %U, %S, %E, %P, %X, %D, %I, %O, %F, and %W tags, in that order.</p>	%D	Average amount of unshared data space used in Kilobytes.	%E	Elapsed (wallclock) time for the command.	%F	Page faults.	%I	Number of block input operations.	%K	Average amount of unshared stack space used in Kilobytes.	%M	Maximum real memory used during execution of the process.	%O	Number of block output operations.	%P	Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.	%S	Number of seconds of CPU time consumed by the kernel on behalf of the user's process.	%U	Number of seconds of CPU time devoted to the user's process.	%W	Number of swaps.	%X	Average amount of shared memory used in Kilobytes.
%D	Average amount of unshared data space used in Kilobytes.																								
%E	Elapsed (wallclock) time for the command.																								
%F	Page faults.																								
%I	Number of block input operations.																								
%K	Average amount of unshared stack space used in Kilobytes.																								
%M	Maximum real memory used during execution of the process.																								
%O	Number of block output operations.																								
%P	Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.																								
%S	Number of seconds of CPU time consumed by the kernel on behalf of the user's process.																								
%U	Number of seconds of CPU time devoted to the user's process.																								
%W	Number of swaps.																								
%X	Average amount of shared memory used in Kilobytes.																								
verbose	Display each command after history substitution takes place.																								

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of csh when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Files	~/.cshrc	Read at beginning of execution by each shell.
	~/.login	Read by login shells after .cshrc at login.
	~/.logout	Read by login shells at logout.
	~/.history	Saved history for use at next login.
	/usr/bin/sh	The Bourne shell, for shell scripts not starting with a '#'.
	/tmp/sh*	Temporary file for '<<'.
	/etc/passwd	Source of home directories for '~name'.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [bc\(1\)](#), [echo\(1\)](#), [limit\(1\)](#), [login\(1\)](#), [ls\(1\)](#), [more\(1\)](#), [pfcsh\(1\)](#), [pfexec\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [shell_builtins\(1\)](#), [tset\(1B\)](#), [which\(1\)](#), [df\(1M\)](#), [swap\(1M\)](#), [sysdef\(1M\)](#), [access\(2\)](#), [exec\(2\)](#), [fork\(2\)](#), [pipe\(2\)](#), [a.out\(4\)](#), [environ\(4\)](#), [ascii\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [termio\(7I\)](#)

Diagnostics You have stopped jobs.
 You attempted to exit the C shell with stopped jobs under job control. An immediate second attempt to exit will succeed, terminating the stopped jobs.

Warnings The use of setuid shell scripts is *strongly* discouraged.

Notes Words can be no longer than 1024 bytes. The system limits argument lists to 1,048,576 bytes. However, the maximum number of arguments to a command for which filename expansion applies is 1706. Command substitutions may expand to no more characters than are allowed in the argument list. To detect looping, the shell restricts the number of alias substitutions on a single line to 20.

When a command is restarted from a stop, the shell prints the directory it started in if this is different from the current directory; this can be misleading (that is, wrong) as the job may have changed directories internally.

Shell built-in functions are not stoppable/restartable. Command sequences of the form *a ; b ; c* are also not handled gracefully when stopping is attempted. If you suspend *b*, the shell never executes *c*. This is especially noticeable if the expansion results from an alias. It can be avoided by placing the sequence in parentheses to force it into a subshell.

Commands within loops, prompted for by *?*, are not placed in the *history* list.

Control structures should be parsed rather than being recognized as built-in commands. This would allow control commands to be placed anywhere, to be combined with `|`, and to be used with `&` and `;` metasyntax.

It should be possible to use the `:` modifiers on the output of command substitutions. There are two problems with `:` modifier usage on variable substitutions: not all of the modifiers are available, and only one modifier per substitution is allowed.

The `g` (global) flag in history substitutions applies only to the first match in each word, rather than all matches in all words. The common text editors consistently do the latter when given the `g` flag in a substitution command.

Quoting conventions are confusing. Overriding the escape character to force variable substitutions within double quotes is counterintuitive and inconsistent with the Bourne shell.

Symbolic links can fool the shell. Setting the `hardpaths` variable alleviates this.

It is up to the user to manually remove all duplicate pathnames accrued from using built-in commands as

```
set path = pathnames
```

or

```
setenv PATH = pathnames
```

more than once. These often occur because a shell script or a `.cshrc` file does something like

```
'set path=(/usr/local /usr/hosts $path)'
```

to ensure that the named directories are in the pathname list.

The only way to direct the standard output and standard error separately is by invoking a subshell, as follows:

```
command > outfile ) >& errorfile
```

Although robust enough for general use, adventures into the esoteric periphery of the C shell may reveal unexpected quirks.

If you start `csh` as a login shell and you do not have a `.login` in your home directory, then the `csh` reads in the `/etc/.login`.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

Bugs As of this writing, the `time` built-in command does *not* compute the last 6 fields of output, rendering the output to erroneously report the value `0` for these fields:

```
example %time ls -R
9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w
```

Name csplit – split files based on context

Synopsis csplit [-ks] [-f *prefix*] [-n *number*] *file* *arg1*... *argn*

Description The `csplit` utility reads the file named by the *file* operand, writes all or part of that file into other files as directed by the *arg* operands, and writes the sizes of the files.

Options The following options are supported:

- f *prefix* Names the created files *prefix00*, *prefix01*, ..., *prefixn*. The default is *xx00* ... *xxn*. If the *prefix* argument would create a file name exceeding 14 bytes, an error results. In that case, `csplit` exits with a diagnostic message and no files are created.
- k Leaves previously created files intact. By default, `csplit` removes created files if an error occurs.
- n *number* Uses *number* decimal digits to form filenames for the file pieces. The default is 2.
- s Suppresses the output of file size messages.

Operands The following operands are supported:

file The path name of a text file to be split. If *file* is -, the standard input will be used.

The operands *arg1* ... *argn* can be a combination of the following:

- /rexp* [*offset*] Create a file using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with *offset*, if any, applied. The regular expression *rexp* must follow the rules for basic regular expressions. Regular expressions can include the use of '\/' and '\%'. These forms must be properly quoted with single quotes, since “\” is special to the shell. The optional *offset* must be a positive or negative integer value representing a number of lines. The integer value must be preceded by + or -. If the selection of lines from an offset expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line will be set to the line that results from the evaluation of the regular expression with any offset applied. The pattern match of *rexp* always is applied from the current line to the end of the file.
- %*rexp*% [*offset*] This operand is the same as */rexp* [*offset*], except that no file will be created for the selected section of the input file.
- line_no* Create a file from the current line up to (but not including) the line number *line_no*. Lines in the file will be numbered starting at one. The current line becomes *line_no*.
- {*num*} Repeat operand. This operand can follow any of the operands described previously. If it follows a *rexp* type operand, that operand will be applied *num* more times. If it follows a *line_no* operand, the file will be split every

line_no lines, *num* times, from that point.

An error will be reported if an operand does not reference a line between the current position and the end of the file.

Usage See [largefile\(5\)](#) for the description of the behavior of `csplit` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Splitting and combining files

This example creates four files, `cobol00...cobol03`.

```
example% csplit -f cobol filename \
        '/procedure division/' /par5./ /par16./
```

After editing the *split* files, they can be recombined as follows:

```
example% cat cobol0[0-3] > filename
```

This example overwrites the original file.

EXAMPLE 2 Splitting a file into equal parts

This example splits the file at every 100 lines, up to 10,000 lines. The `-k` option causes the created files to be retained if there are less than 10,000 lines; however, an error message would still be printed.

```
example% csplit -k filename 100 {99}
```

EXAMPLE 3 Creating a file for separate C routines

If `prog.c` follows the normal C coding convention (the last line of a routine consists only of a `}` in the first character position), this example creates a file for each separate C routine (up to 21) in `prog.c`.

```
example% csplit -k prog.c '%main(%' '/^}/+1' {20}
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `csplit`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled
Interface Stability	Standard

See Also [sed\(1\)](#), [split\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics The diagnostic messages are self-explanatory, except for the following:

arg – out of range The given argument did not reference a line between the current position and the end of the file.

Name ct – spawn login to a remote terminal

Synopsis ct [*options*] *telno*...

Description The ct utility dials the telephone number of a modem that is attached to a terminal and spawns a login process to that terminal. The *telno* is a telephone number, with equal signs for secondary dial tones and minus signs for delays at appropriate places. (The set of legal characters for *telno* is 0 through 9, -, =, *, and #. The maximum length *telno* is 31 characters). If more than one telephone number is specified, ct will try each in succession until one answers; this is useful for specifying alternate dialing paths.

ct will try each line listed in the file /etc/uucp/Devices until it finds an available line with appropriate attributes, or runs out of entries.

After the user on the destination terminal logs out, there are two things that could occur depending on what type of port monitor is monitoring the port. In the case of no port monitor, ct prompts: Reconnect? If the response begins with the letter n, the line will be dropped; otherwise, ttymon will be started again and the login: prompt will be printed. In the second case, where a port monitor is monitoring the port, the port monitor reissues the login: prompt.

The user should log out properly before disconnecting.

Options The following options are supported:

- h Normally, ct will hang up the current line so that it can be used to answer the incoming call. The -h option will prevent this action. The -h option will also wait for the termination of the specified ct process before returning control to the user's terminal.
- sspeed The data rate may be set with the -s option. *speed* is expressed in baud rates. The default baud rate is 1200.
- v If the -v (verbose) option is used, ct will send a running narrative to the standard error output stream.
- wn If there are no free lines ct will ask if it should wait, and for how many minutes, before it gives up. ct will continue to try to open the dialers at one-minute intervals until the specified limit is exceeded. This dialogue may be overridden by specifying the -wn option. *n* is the maximum number of minutes that ct is to wait for a line.
- xn This option is used for debugging; it produces a detailed output of the program execution on stderr. *n* is a single number between 0 and 9. As *n* increases to 9, more detailed debugging information is given.

Files /etc/uucp/Devices
/var/adm/ctlog

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

See Also [cu\(1C\)](#), [login\(1\)](#), [uucp\(1C\)](#), [ttymon\(1M\)](#), [attributes\(5\)](#)

Notes The ct program will not work with a DATAKIT Multiplex interface.

For a shared port, one used for both dial-in and dial-out, the ttymon program running on the line must have the -r and -b options specified (see [ttymon\(1M\)](#)).

Name ctags – create a tags file for use with ex and vi

Synopsis /usr/bin/ctags [-aBFtuvwx] [-f *tagsfile*] *file*...
 /usr/xpg4/bin/ctags [-aBFuvwx] [-f *tagsfile*] *file*...

Description The ctags utility makes a tags file for [ex\(1\)](#) from the specified C, C++, Pascal, FORTRAN, [yacc\(1\)](#), and [lex\(1\)](#) sources. A tags file gives the locations of specified objects (in this case functions and typedefs) in a group of files. Each line of the tags file contains the object name, the file in which it is defined, and an address specification for the object definition. Functions are searched with a pattern, typedefs with a line number. Specifiers are given in separate fields on the line, separated by SPACE or TAB characters. Using the tags file, ex can quickly find these objects' definitions.

Normally, ctags places the tag descriptions in a file called tags; this may be overridden with the -f option.

Files with names ending in .c or .h are assumed to be either C or C++ source files and are searched for C/C++ routine and macro definitions. Files with names ending in .cc, .C, or .cxx, are assumed to be C++ source files. Files with names ending in .y are assumed to be yacc source files. Files with names ending in .l are assumed to be lex files. Others are first examined to see if they contain any Pascal or FORTRAN routine definitions; if not, they are processed again looking for C definitions.

The tag main is treated specially in C or C++ programs. The tag formed is created by prepending M to *file*, with a trailing .c, .cc, .C, or .cxx removed, if any, and leading path name components also removed. This makes use of ctags practical in directories with more than one program.

Options The precedence of the options that pertain to printing is -x, -v, then the remaining options. The following options are supported:

- a Appends output to an existing tags file.
- B Uses backward searching patterns (?..?).
- f *tagsfile* Places the tag descriptions in a file called *tagsfile* instead of tags.
- F Uses forward searching patterns (/.../) (default).
- t Creates tags for typedefs. /usr/xpg4/bin/ctags creates tags for typedefs by default.
- u Updates the specified files in tags, that is, all references to them are deleted, and the new values are appended to the file. Beware: this option is implemented in a way that is rather slow; it is usually faster to simply rebuild the tags file.
- v Produces on the standard output an index listing the function name, file name, and page number (assuming 64 line pages). Since the output will be sorted into lexicographic order, it may be desired to run the output through sort -f.

- w Suppresses warning diagnostics.
- x Produces a list of object names, the line number and file name on which each is defined, as well as the text of that line and prints this on the standard output. This is a simple index which can be printed out as an off-line readable function index.

Operands The following *file* operands are supported:

- file.c* Files with basenames ending with the .c suffix are treated as C-language source code.
- file.h* Files with basenames ending with the .h suffix are treated as C-language source code.
- file.f* Files with basenames ending with the .f suffix are treated as FORTRAN-language source code.

Usage The -v option is mainly used with `vgrend` which will be part of the optional BSD Compatibility Package.

Examples **EXAMPLE 1** Producing entries in alphabetical order

Using `ctags` with the -v option produces entries in an order which may not always be appropriate for `vgrend`. To produce results in alphabetical order, you may want to run the output through `sort -f`.

```
example% ctags -v filename.c filename.h | sort -f > index
example% vgrind -x index
```

EXAMPLE 2 Building a tags file

To build a tags file for C sources in a directory hierarchy rooted at *sourcedir*, first create an empty tags file, and then run [find\(1\)](#)

```
example% cd sourcedir ; rm -f tags ; touch tags
example% find . \( -name SCCS -prune -name \
    '*.c' -o -name '*.h' \) -exec ctags -u {} \;
```

Notice that spaces must be entered exactly as shown.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ctags`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files tags output tags file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/ctags

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Notes Recognition of functions, subroutines, and procedures for FORTRAN and Pascal is done in a very simpleminded way. No attempt is made to deal with block structure; if you have two Pascal procedures in different blocks with the same name, you lose.

The method of deciding whether to look for C or Pascal and FORTRAN functions is a hack.

The ctags utility does not know about `#ifdefs`.

The ctags utility should know about Pascal types. Relies on the input being well formed to detect typedefs. Use of `-tx` shows only the last line of typedefs.

Name ctrn – execute command in a process contract

Synopsis /usr/bin/ctrn [*options*] *command* [*argument*]...

Description The `ctrn` utility starts a command in a newly created process contract. `ctrn` holds the contract and can be instructed to output or respond to events that occur within the contract.

For additional information about process contracts, see [contract\(4\)](#) and [process\(4\)](#).

Options The following options are supported:

-i *event*, [*event* ...]

-f *event*, [*event* ...]

Sets the informative and fatal events, respectively.

The following are valid *events*:

`core` A member process dumped core.

`core` events are informative by default.

`empty` The last member of the process contract exited.

`exit` A member process exited.

`fork` A process was added to the process contract.

`hwerr` A member process encountered a hardware error.

`hwerr` events are fatal by default.

`signal` A member process received a fatal signal from a process in a different process contract.

Only `core`, `hwerr`, and `signal` events can be made fatal.

More events can be delivered than requested if `ctrn` requires them for its own purposes. For example, `empty` messages are always requested if a lifetime of contract is specified. See `-l`.

-l *lifetime*

The following valid *lifetime* values are supported:

`child` `ctrn` exits when the command exits, regardless of whether the contract is empty.

`contract` `ctrn` exits only when the contract exits. This is the default.

`none` `ctrn` exits immediately, orphaning the contract.

-o *option*, [*option* ...]

The following *options* are supported:

`noorphan` Kills all processes in the contract if the holder (`ctrn`) exits.

	This option is invalid when a lifetime of none is specified.
<code>pgrponly</code>	If a fatal error occurs, kills at most the process group of which the errant process is a member.
<code>regent</code>	The contract inherits inheritable contracts when abandoned by member processes.
<code>-r count</code>	If the contract encounters a fault, this option attempts to restart the command <i>count</i> times. If <i>count</i> is 0, the attempt to restart continues indefinitely. By default, <code>ctrun</code> does not attempt to restart the command.
	This option is invalid if a lifetime other than <code>contract</code> is specified or if the <code>pgrponly</code> option is used.
<code>-t</code>	If the contract created by <code>ctrun</code> inherited subcontracts from its member processes, attempts to transfer them to the new contract when restarting.
	This option is invalid unless <code>-r</code> is also specified.
<code>-v</code>	Displays contract events and <code>ctrun</code> actions as they occur.
<code>-V</code>	Displays verbose contract events, as are displayed by the <code>-v</code> option of <code>ctwatch</code> . Implies <code>-v</code> .

Operands The following operands are supported:

<i>argument</i>	One of the strings treated as an argument to <i>command</i> .
<i>command</i>	The command to be passed to <code>execvp(2)</code> . See exec(2) .

Examples **EXAMPLE 1** Running a Shell in a New Process Contract

The following example runs a shell in a new process contract:

```
example% ctrun -l child -o pgrponly ksh
```

The `-l child` option argument is specified so that `ctrun` won't wait until all children of the shell have exited. `-o pgrponly` is specified because an interactive `ksh` puts each job in a new process group, and an error in one job is unlikely to affect the others.

EXAMPLE 2 Running a Simple Server

The following example runs a simple server:

```
example% ctrun -r 0 -t -f hwerr,core,signal server
```

EXAMPLE 2 Running a Simple Server (Continued)

The `-r 0` and `-t` options are specified to indicate that if the server encounters a fatal error, `ctrun` should try to restart it. The `-f` option makes “hwerr”, “core”, and “signal” fatal events.

Exit Status If *command* is specified and successfully invoked (see [exec\(2\)](#)), the exit status of `ctrun` is the exit status of *command*. Otherwise, `ctrun` exits with one of the following values:

- 123 The child process exited abnormally.
- 124 `ctrun` encountered an internal error.
- 125 Invalid arguments were provided to `ctrun`.
- 126 *command* was found but could not be invoked.
- 127 *command* could not be found.

Files `/system/contract/process/*`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

Human Readable Output is Unstable. Invocation is Evolving.

See Also [ctstat\(1\)](#), [ctwatch\(1\)](#), [exec\(2\)](#), [contract\(4\)](#), [process\(4\)](#), [attributes\(5\)](#)

Name ctstat – display active system contracts

Synopsis /usr/bin/ctstat [-a] [-i *contractid...*] [-t *type...*] [-v]
[*interval* [*count*]]

Description The ctstat utility allows a user to observe the contracts active on a system.

Unless you specify the -i or -t option, ctstat displays statistics on all contracts in the system.

Options The following options are supported:

- a Display all contracts regardless of state. By default, only those contracts which are in the owned, inherited, or orphan states are displayed.
- i *contractid...* Request status on the specified contracts, identified by their numeric contract identifier (*contract_id*).

This option accepts lists as arguments . Items in the list can be separated by commas, or enclosed in quotes and separated by commas or spaces.
- t *type...* Request status on contracts of the specified type (*type*).

This option accepts lists as arguments. Items in the list can be separated by commas, or enclosed in quotes and separated by commas or spaces.

The following types are supported:
process Process contracts
- v Verbose output.

Operands The following operands are supported:

- interval* Report once each *interval* seconds.
- count* Print only *count* reports.

Output The following list defines the column headings and the meanings of a ctstat report:

- CTID The contract ID of the contract.
- ZONEID The zone ID of the contract's creator.
- TYPE The contract type.
- STATE The state of the contract:
 - owned Contract is owned by a process.
 - inherited The contract owner has exited abnormally and the contract has been inherited by the owner's process contract.

	orphan	The contract owner has abandoned the contract, the contract owner exited abnormally and the contract was not inherited by the owner's process contract, or the process contract which had inherited the contract was abandoned by its owner.
	dead	The contract is no longer active. It is removed from the system automatically when all references to it (open file descriptors, contract templates, and events) have been released.
HOLDER		If the contract is in the owned state, the pid of the process that owns the contract. If the contract is in the inherited state, the id of the regent process contract.
EVENTS		The number of unacknowledged critical events pending.
QTIME		The time until quantum ends, or - if no negotiation is in progress.
NTIME		The time until negotiation ends, or - if no negotiation is in progress.

Examples **EXAMPLE 1** Reporting on all Contracts in the System

The following example reports on all contracts in the system:

```
example% ctstat -a
```

CTID	TYPE	STATE	HOLDER	EVENTS	QTIME	NTIME
1	process	owned	100579	0	-	-
2	process	dead	-	1	-	-
3	process	inherit	1	3	-	-
4	process	orphan	-	0	-	-

EXAMPLE 2 Obtaining a Verbose Report of All Contracts in the System

The following example obtains a verbose report of all contracts in the system:

```
example% ctstat -av
```

CTID	TYPE	STATE	HOLDER	EVENTS	QTIME	NTIME
1	process	owned	100579	0	-	-
	informative event set:			none		
	critical event set:			hwerr core		
	fatal event set:			hwerr		
	parameter set:			none		
	member processes:			100600 100601		
2	inherited ctids:			none		
	process	dead	-	1	-	-
	informative event set:			none		
	critical event set:			none		
	fatal event set:			hwerr core		
	parameter set:			pgrponly		
	member processes:			none		

EXAMPLE 2 Obtaining a Verbose Report of All Contracts in the System *(Continued)*

```
inherited ctids:      none
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid arguments.

Files /system/contract/*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

See Also [ctrun\(1\)](#), [ctwatch\(1\)](#), [contract\(4\)](#), [process\(4\)](#), [attributes\(5\)](#)

Name ctwatch – watch events in a contract or group of contracts

Synopsis /usr/bin/ctwatch [-f] [-r] [-v] *contract-type*... | *contract-id*...

Description The ctwatch utility allows a user to observe the events occurring within a set of contracts or contract types. By default, ctwatch watches all contracts.

Options The following options are supported:

- f Report events starting at the front of the event queue. Normally, ctwatch reports only events which occur after it has been invoked. With the -f option, any events that still exist in the contracts' event queues when ctwatch is invoked (for example, unacknowledged critical events) are also reported.
- r Reliably watches all messages. Normally, the system may drop informative events and acknowledged critical events at any time, so ctwatch isn't guaranteed to see them all. This option may only be used if the ctwatch is invoked with the {PRIV_CONTRACT_EVENT} privilege asserted in its effective set.
- v Request verbose event descriptions.

Operands The following operands are supported:

contract-type Valid contract types are:
process Process contracts.

contract-id A valid contract id.

Output The following list defines the column headings and the meanings of a ctwatch report:

CTID	The contract ID generating the event.
EVID	The event ID.
CRIT	Whether the event is informative, critical, or initiates an exit negotiation. Values are info, crit, or neg, respectively.
ACK	The event has been acknowledged. Values are yes or "no".
CTTYPE	The contract type.
SUMMARY	A type-specific summary of the event.

Examples **EXAMPLE 1** Watching a process contract

example% **ctwatch -r 1**

CTID	EVID	CRIT	ACK	CTTYPE	SUMMARY
1	2	crit	no	process	pid 100569 was created
1	3	info	no	process	pid 100569 encountered hardware error
1	4	info	no	process	pid 100568 exited
1	5	info	no	process	pid 100569 exited

EXAMPLE 1 Watching a process contract *(Continued)*

```
1      6      crit no process contract empty
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid arguments.

Files /system/contract/*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

Human Readable Output is Unstable. Invocation is Evolving.

See Also [ctrun\(1\)](#), [ctstat\(1\)](#), [contract\(4\)](#), [process\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#)

Notes Ordering of events is only guaranteed within a single contract, or within a single type when a type is specified.

ctwatch can only observe those events which are generated by contracts owned or authored by processes with the same effective user ID as ctwatch, unless the {PRIV_CONTRACT_OBSERVER} privilege is asserted in its effective set.

Name cu – call another UNIX system

Synopsis cu [-c *device* | -l *line*] [-s *speed*] [-b *bits*] [-h] [-n]
 [-t] [-d] [-o | -e] [-L] [-C] [-H] *telno* | *systemname*
 [*local-cmd*]

Description The command cu calls up another UNIX system, a terminal, or possibly a non-UNIX system. It manages an interactive conversation with possible transfers of files. It is convenient to think of cu as operating in two phases. The first phase is the connection phase in which the connection is established. cu then enters the conversation phase. The -d option is the only one that applies to both phases.

Options cu accepts many options. The -c, -l, and -s options play a part in selecting the medium. The remaining options are used in configuring the line.

- b *bits* Forces *bits* to be the number of bits processed on the line. *bits* is either 7 or 8. This allows connection between systems with different character sizes. By default, the character size of the line is set to the same value as the current local terminal, but the character size setting is affected by LC_CTYPE also.
- c *device* Forces cu to use only entries in the "Type" field (the first field in the /etc/uucp/Devices file) that match the user specified *device*, usually the name of a local area network.
- C Runs the *local-cmd* specified at the end of the command line instead of entering interactive mode. The stdin and stdout of the command that is run refer to the remote connection.
- d Prints diagnostic traces.
- e Sets an EVEN data parity. This option designates that EVEN parity is to be generated for data sent to the remote system.
- h Sets communication mode to half-duplex. This option emulates local echo in order to support calls to other computer systems that expect terminals to be set to half-duplex mode.
- H Ignores one hangup. This allows the user to remain in cu while the remote machine disconnects and places a call back to the local machine. This option should be used when connecting to systems with callback or dialback modems. Once the callback occurs subsequent hangups will cause cu to terminate. This option can be specified more than once. For more information about dialback configuration, see [remote\(4\)](#) and [System Administration Guide: IP Services](#)
- l *line* Specifies a device name to use as the communication line. This can be used to override the search that would otherwise take place for the first available line having the right speed. When the -l option is used without the -s option, the speed of a line is taken from the /etc/uucp/Devices file record in which *line* matches the second field (the Line field). When the -l and -s options are both

used together, cu will search the /etc/uucp/Devices file to check if the requested speed for the requested line is available. If so, the connection will be made at the requested speed, otherwise, an error message will be printed and the call will not be made. In the general case where a specified device is a directly connected asynchronous line (for instance, /dev/term/a), a telephone number (*telno*) is not required. The specified device need not be in the /dev directory. If the specified device is associated with an auto dialer, a telephone number must be provided.

- L Goes through the login chat sequence specified in the /etc/uucp/Systems file. For more information about the chat sequence, see [System Administration Guide: IP Services](#)
- n Requests user prompt for telephone number. For added security, this option will prompt the user to provide the telephone number to be dialed, rather than taking it from the command line.
- o Sets an ODD data parity. This option designates that ODD parity is to be generated for data sent to the remote system.
- s *speed* Specifies the transmission speed (300, 1200, 2400, 4800, 9600, 19200, 38400). The default value is "Any" speed which will depend on the order of the lines in the /etc/uucp/Devices file.
- t Dials a terminal which has been set to auto answer. Appropriate mapping of carriage-return to carriage-return-line-feed pairs is set.

Operands The following operands are supported:

- telno* When using an automatic dialler, specifies the telephone number with equal signs for secondary dial tone or minus signs placed appropriately for delays of 4 seconds.
- systemname* Specifies a uucp system name, which can be used rather than a telephone number; in this case, cu will obtain an appropriate direct line or telephone number from a system file.

Usage

Connection Phase cu uses the same mechanism that [uucp\(1C\)](#) does to establish a connection. This means that it will use the uucp control files /etc/uucp/Devices and /etc/uucp/Systems. This gives cu the ability to choose from several different media to establish the connection. The possible media include telephone lines, direct connections, and local area networks (LAN). The /etc/uucp/Devices file contains a list of media that are available on your system. The /etc/uucp/Systems file contains information for connecting to remote systems, but it is not generally readable.

Note: cu determines which `/etc/uucp/Systems` and `/etc/uucp/Devices` files to use based upon the name used to invoke cu. In the simple case, this name will be "cu", but you could also have created a link to cu with another name, such as "pppcu", in which case cu would then look for a "service=pppcu" entry in the `/etc/uucp/Sysfiles` file to determine which `/etc/uucp/Systems` file to use.

The *telno* or *systemname* parameter from the command line is used to tell cu what system you wish to connect to. This parameter can be blank, a telephone number, a system name, or a LAN specific address.

telephone number	A telephone number is a string consisting of the tone dial characters (the digits 0 through 9, *, and #) plus the special characters = and -. The equal sign designates a secondary dial tone and the minus sign creates a 4 second delay.
system name	A system name is the name of any computer that uucp can call; the uname(1C) command prints a list of these names.
LAN address	The documentation for your LAN will show the form of the LAN specific address.

If cu's default behavior is invoked (not using the `-c` or `-l` options), cu will use the *telno* or *systemname* parameter to determine which medium to use. If a telephone number is specified, cu will assume that you wish to use a telephone line and it will select an automatic call unit (ACU). Otherwise, cu will assume that it is a system name. cu will follow the uucp calling mechanism and use the `/etc/uucp/Systems` and `/etc/uucp/Devices` files to obtain the best available connection. Since cu will choose a speed that is appropriate for the medium that it selects, you may not use the `-s` option when this parameter is a system name.

The `-c` and `-l` options modify this default behavior. `-c` is most often used to select a LAN by specifying a Type field from the `/etc/uucp/Devices` file. You must include either a *telno* or *systemname* value when using the `-c` option. If the connection to *systemname* fails, a connection will be attempted using *systemname* as a LAN specific address. The `-l` option is used to specify a device associated with a direct connection. If the connection is truly a direct connection to the remote machine, then there is no need to specify a *systemname*. This is the only case where a *telno* or *systemname* parameter is unnecessary. On the other hand, there may be cases in which the specified device connects to a dialer, so it is valid to specify a telephone number. The `-c` and `-l` options should not be specified on the same command line.

Conversation Phase After making the connection, cu runs as two processes. The *transmit* process reads data from the standard input and, except for lines beginning with ~, passes it to the remote system. The *receive* process accepts data from the remote system and, except for lines beginning with ~, passes it to the standard output. Normally, an automatic DC3/DC1 protocol is used to control input from the remote so the buffer is not overrun. Lines beginning with ~ have special meanings.

Commands The *transmit* process interprets the following user initiated commands:

~.	Terminates the conversation.
~!	Escapes to an interactive shell on the local system.
~!cmd . . .	Runs <i>cmd</i> on the local system (via <i>sh -c</i>).
~\$cmd . . .	Runs <i>cmd</i> locally and send its output to the remote system.
~%cd	Changes the directory on the local system. Note: ~!cd will cause the command to be run by a sub-shell, probably not what was intended.
~%take from [to]	Copies file <i>from</i> (on the remote system) to file <i>to</i> on the local system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.
~%put from [to]	Copies file <i>from</i> (on local system) to file <i>to</i> on remote system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.
~~ line	Sends the line ~ <i>line</i> to the remote system.
~%break	Transmits a BREAK to the remote system (which can also be specified as ~%b).
~%debug	Toggles the -d debugging option on or off (which can also be specified as ~%d).
~t	Prints the values of the termio structure variables for the user's terminal (useful for debugging).
~l	Prints the values of the termio structure variables for the remote communication line (useful for debugging).
~%ifc	Toggles between DC3/DC1 input control protocol and no input control. This is useful when the remote system does not respond properly to the DC3 and DC1 characters (can also be specified as ~%nostop).
~%ofc	Toggles the output flow control setting. When enabled, outgoing data may be flow controlled by the remote host (can also be specified as ~%nostop).
~%divert	Allows/disallows unsolicited diversions. That is, diversions not specified by ~%take.
~%old	Allows/disallows old style syntax for received diversions.
~%nostop	Same as ~%ifc.

The *receive* process normally copies data from the remote system to the standard output of the local system. It may also direct the output to local files.

The use of `~%put` requires `stty(1)` and `cat(1)` on the remote side. It also requires that the current erase and kill characters on the remote system be identical to these current control characters on the local system. Backslashes are inserted at appropriate places.

The use of `~%take` requires the existence of `echo(1)` and `cat(1)` on the remote system, and that the remote system must be using the Bourne shell, `sh`. Also, `tabs` mode (see `stty(1)`) should be set on the remote system if tabs are to be copied without expansion to spaces.

When `cu` is used on system X to connect to system Y and subsequently used on system Y to connect to system Z, commands on system Y can be executed by using `~`. Executing a tilde command reminds the user of the local system `uname`. For example, `uname` can be executed on Z, X, and Y as follows:

```
uname
Z
~[X] !uname
X
~~[Y] !uname
Y
```

In general, `~` causes the command to be executed on the original machine. `~ ~` causes the command to be executed on the next machine in the chain.

Examples **EXAMPLE 1** Dialling a system

To dial a system whose telephone number is 9 1 201 555 1234 using 1200 baud (where dialtone is expected after the 9):

```
example% cu -s 1200 9=12015551234
```

If the speed is not specified, "Any" is the default value.

EXAMPLE 2 Logging in to a system on a direct line

To login to a system connected by a direct line:

```
example% cu -l /dev/term/b
```

or

```
example% cu -l term/b
```

EXAMPLE 3 Dialling a system with specific line and speed

To dial a system with a specific line and speed:

```
example% cu -s 1200 -l term/b
```

EXAMPLE 4 Using a system name

To use a system name:

```
example% cu systemname
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cu: LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files

/etc/uucp/Devices	device file
/etc/uucp/Sysfiles	system file
/etc/uucp/Systems	system file
/var/spool/locks/*	lock file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

See Also [cat\(1\)](#), [echo\(1\)](#), [stty\(1\)](#), [tip\(1\)](#), [uname\(1\)](#), [ct\(1C\)](#), [uuname\(1C\)](#), [uucp\(1C\)](#), [remote\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

System Administration Guide: IP Services

Notes The cu utility takes the default action upon receipt of signals, with the exception of:

SIGHUP Close the connection and terminate.

SIGINT Forward to the remote system.

SIGQUIT Forward to the remote system.

SIGUSR1 Terminate the cu process without the normal connection closing sequence.

The cu command does not do any integrity checking on data it transfers. Data fields with special cu characters may not be transmitted properly. Depending on the interconnection hardware, it may be necessary to use a ~. to terminate the conversion, even if stty 0 has been used. Non-printing characters are not dependably transmitted using either the ~%put or ~%take commands. ~%put and ~%take cannot be used over multiple links. Files must be moved one link at a time.

There is an artificial slowing of transmission by `cu` during the `~%put` operation so that loss of data is unlikely. Files transferred using `~%take` or `~%put` must contain a trailing newline, otherwise, the operation will hang. Entering a Control-D command usually clears the hang condition.

Name cut – cut out selected fields of each line of a file

Synopsis cut -b *list* [-n] [*file*] ...
 cut -c *list* [*file*] ...
 cut -f *list* [-d *delim*] [-s] [*file*] ...

Description Use the cut utility to cut out columns from a table or fields from each line of a file; in data base parlance, it implements the projection of a relation. The fields as specified by *list* can be fixed length, that is, character positions as on a punched card (-c option) or the length can vary from line to line and be marked with a field delimiter character like TAB (-f option). cut can be used as a filter.

Either the -b, -c, or -f option must be specified.

Use [grep\(1\)](#) to make horizontal “cuts” (by context) through a file, or [paste\(1\)](#) to put files together column-wise (that is, horizontally). To reorder columns in a table, use cut and paste.

Options The following options are supported:

- list* A comma-separated or blank-character-separated list of integer field numbers (in increasing order), with optional – to indicate ranges (for instance, 1,4,7; 1–3,8;–5,10 (short for 1–5,10); or 3– (short for third through last field)).
- b *list* The *list* following -b specifies byte positions (for instance, -b1-72 would pass the first 72 bytes of each line). When -b and -n are used together, *list* is adjusted so that no multi-byte character is split.
- c *list* The *list* following -c specifies character positions (for instance, -c1-72 would pass the first 72 characters of each line).
- d *delim* The character following -d is the field delimiter (-f option only). Default is *tab*. Space or other characters with special meaning to the shell must be quoted. *delim* can be a multi-byte character.
- f *list* The *list* following -f is a list of fields assumed to be separated in the file by a delimiter character (see -d); for instance, -f1,7 copies the first and seventh field only. Lines with no field delimiters will be passed through intact (useful for table subheadings), unless -s is specified.
- n Do not split characters. When -b *list* and -n are used together, *list* is adjusted so that no multi-byte character is split.
- s Suppresses lines with no delimiter characters in case of -f option. Unless specified, lines with no delimiters will be passed through untouched.

Operands The following operands are supported:

file A path name of an input file. If no *file* operands are specified, or if a *file* operand is `–`, the standard input will be used.

Usage See [largefile\(5\)](#) for the description of the behavior of cut when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Examples **EXAMPLE 1** Mapping user IDs
A mapping of user IDs to names follows:
example% `cut -d: -f1,5 /etc/passwd`

EXAMPLE 2 Setting current login name
To set name to current login name:
example\$ `name=`who am i` | cut -f1 -d' '``

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of cut: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:
`0` All input files were output successfully.
`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

See Also [grep\(1\)](#), [paste\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics cut: -n may only be used with -b
cut: -d may only be used with -f
cut: -s may only be used with -f

cut: cannot open <i><file></i>	Either <i>file</i> cannot be read or does not exist. If multiple files are present, processing continues.
cut: no delimiter specified	Missing <i>delim</i> on -d option.

cut: invalid delimiter

cut: no *list* specified

Missing *list* on -b, -c, or -f option.

cut: invalid range specifier

cut: too many ranges specified

cut: range must be increasing

cut: invalid character in range

cut: internal error processing input

cut: invalid multibyte character

cut: unable to allocate enough memory

Name date – write the date and time

Synopsis /usr/bin/date [-u] [+format]
 /usr/bin/date [-a [-]sss.fff]
 /usr/bin/date [-u] [[mdd] HHMM | mddHHMM [cc] yy] [.SS]
 /usr/xpg4/bin/date [-u] [+format]
 /usr/xpg4/bin/date [-a [-]sss.fff]
 /usr/xpg4/bin/date [-u]
 [[mdd] HHMM | mddHHMM [cc] yy] [.SS]

Description The date utility writes the date and time to standard output or attempts to set the system date and time. By default, the current date and time is written.

Specifications of native language translations of month and weekday names are supported. The month and weekday names used for a language are based on the locale specified by the environment variable LC_TIME. See [environ\(5\)](#).

The following is the default form for the "C" locale:

```
%a %b %e %T %Z %Y
```

For example,

```
Fri Dec 23 10:10:42 EST 1988
```

Options The following options are supported:

- a [-] sss.fff Slowly adjust the time by sss.fff seconds (fff represents fractions of a second). This adjustment can be positive or negative. The system's clock is sped up or slowed down until it has drifted by the number of seconds specified. Only the super-user may adjust the time.
- u Display (or set) the date in Greenwich Mean Time (GMT—universal time), bypassing the normal conversion to (or from) local time.

Operands The following operands are supported:

- +format If the argument begins with +, the output of date is the result of passing *format* and the current time to `strftime()`. date uses the conversion specifications listed on the [strftime\(3C\)](#) manual page, with the conversion specification for %C determined by whether /usr/bin/date or /usr/xpg4/bin/date is used:

/usr/bin/date	Locale's date and time representation. This is the default output for date.
/usr/xpg4/bin/date	Century (a year divided by 100 and truncated to an integer) as a decimal number [00-99].

The string is always terminated with a NEWLINE. An argument containing blanks must be quoted; see the EXAMPLES section.

<i>mm</i>	Month number
<i>dd</i>	Day number in the month
<i>HH</i>	Hour number (24 hour system)
<i>MM</i>	Minute number
<i>SS</i>	Second number
<i>cc</i>	Century (a year divided by 100 and truncated to an integer) as a decimal number [00-99]. For example, <i>cc</i> is 19 for the year 1988 and 20 for the year 2007.
<i>yy</i>	Last two digits of the year number. If century (<i>cc</i>) is not specified, then values in the range 69–99 shall refer to years 1969 to 1999 inclusive, and values in the range 00–68 shall refer to years 2000 to 2068, inclusive.

The month, day, year number, and century may be omitted; the current values are applied as defaults. For example, the following entry:

```
example% date 10080045
```

sets the date to Oct 8, 12:45 a.m. The current year is the default because no year is supplied. The system operates in GMT. `date` takes care of the conversion to and from local standard and daylight time. Only the super-user may change the date. After successfully setting the date and time, `date` displays the new date according to the default format. The `date` command uses TZ to determine the correct time zone information; see [environ\(5\)](#).

Examples EXAMPLE 1 Generating Output

The following command:

```
example% date '+DATE: %m/%d/%y%nTIME:%H:%M:%S'
```

generates as output

```
DATE: 08/01/76
```

```
TIME: 14:45:05
```

EXAMPLE 2 Setting the Current Time

The following command sets the current time to 12:34:56:

```
example# date 1234.56
```

EXAMPLE 3 Setting Another Time and Date in Greenwich Mean Time
The following command sets the date to January 1st, 12:30 am, 2000:

```
example# date -u 010100302000
```

This is displayed as:
Thu Jan 01 00:30:00 GMT 2000

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of date: LANG, LC_ALL, LC_CTYPE, LC_TIME, LC_MESSAGES, and NLSPATH.

TZ Determine the timezone in which the time and date are written, unless the -u option is specified. If the TZ variable is not set and the -u is not specified, the system default timezone is used.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/date	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcsu
	CSI	enabled

/usr/xpg4/bin/date	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	CSI	enabled
	Interface Stability	Standard

See Also [strftime\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Diagnostics no permission You are not the super-user and you tried to change the date.
bad conversion The date set is syntactically incorrect.

Notes If you attempt to set the current date to one of the dates that the standard and alternate time zones change (for example, the date that daylight time is starting or ending), and you attempt to set the time to a time in the interval between the end of standard time and the beginning of the alternate time (or the end of the alternate time and the beginning of standard time), the results are unpredictable.

Using the `date` command from within windowing environments to change the date can lead to unpredictable results and is unsafe. It can also be unsafe in the multi-user mode, that is, outside of a windowing system, if the date is changed rapidly back and forth. The recommended method of changing the date is '`date -a`'.

Setting the system time or allowing the system time to progress beyond 03:14:07 UTC Jan 19, 2038 is not supported on Solaris.

Name dc – desk calculator

Synopsis /usr/bin/dc [*filename*]
 /usr/xpg6/bin/dc [*filename*]

Description dc is an arbitrary precision arithmetic package. Ordinarily it operates on decimal integers, but one may specify an input base, output base, and a number of fractional digits to be maintained. The overall structure of dc is a stacking (reverse Polish) calculator. If an argument is given, input is taken from that file until its end, then from the standard input.

bc is a preprocessor for dc that provides infix notation and a C-like syntax that implements functions. bc also provides reasonable control structures for programs. See [bc\(1\)](#).

Usage

/usr/bin/dc, /usr/xpg6/bin/dc	The following constructions are recognized under both /usr/bin/dc and /usr/xpg6/bin/dc:
<i>number</i>	The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (<code>_</code>) to input a negative number. Numbers may contain decimal points.
<i>s</i> <i>x</i>	The top of the stack is popped and stored into a register named <i>x</i> , where <i>x</i> may be any character. If the <i>s</i> is capitalized, <i>x</i> is treated as a stack and the value is pushed on it.
<i>l</i> <i>x</i>	The value in register <i>x</i> is pushed on the stack. The register <i>x</i> is not altered. All registers start with zero value. If the <i>l</i> is capitalized, register <i>x</i> is treated as a stack and its top value is popped onto the main stack.
<i>d</i>	The top value on the stack is duplicated.
<i>p</i>	The top value on the stack is printed. The top value remains unchanged.
<i>P</i>	Interprets the top of the stack as an ASCII string, removes it, and prints it.
<i>f</i>	All values on the stack are printed.
<i>q</i>	Exits the program. If executing a string, the recursion level is popped by two.
<i>Q</i>	Exits the program. The top value on the stack is popped and the string execution level is popped by that value.
<i>x</i>	Treats the top element of the stack as a character string and executes it as a string of dc commands.
<i>X</i>	Replaces the number on the top of the stack with its scale factor.
[...]	Puts the bracketed ASCII string onto the top of the stack.
<i><x></i> <i>x</i> = <i>x</i>	The top two elements of the stack are popped and compared. Register <i>x</i> is evaluated if they obey the stated relation.

v	Replaces the top element on the stack by its square root. Any existing fractional part of the argument is taken into account, but otherwise the scale factor is ignored.
!	Interprets the rest of the line as a shell command.
c	All values on the stack are popped.
i	The top value on the stack is popped and used as the number radix for further input.
I	Pushes the input base on the top of the stack.
o	The top value on the stack is popped and used as the number radix for further output.
O	Pushes the output base on the top of the stack.
k	The top of the stack is popped, and that value is used as a non-negative scale factor: the appropriate number of places are printed on output, and maintained during multiplication, division, and exponentiation. The interaction of scale factor, input base, and output base will be reasonable if all are changed together.
K	Pushes the current scale factor on the top of the stack.
z	The stack level is pushed onto the stack.
Z	Replaces the number on the top of the stack with its length.
?	A line of input is taken from the input source (usually the terminal) and executed.
Y	Displays dc debugging information.
; :	Used by bc(1) for array operations.

`/usr/bin/dc` The following construction is recognized under `/usr/bin/dc`, using the scale of whatever the result is.

`+ - / * % ^` The top two values on the stack are added (+), subtracted (-), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.

`/usr/xpg6/bin/dc` The following construction is recognized under `/usr/xpg6/bin/dc`. The results of division are forced to be a scale of 20.

`+ - / * % ^` The top two values on the stack are added (+), subtracted (-), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack. The result is pushed on the stack in their place. Any fractional part of an exponent is ignored.

Ensures that the scale set prior to division is the scale of the result.

Examples **EXAMPLE 1** Printing the first ten values of n!
This example prints the first ten values of n!:

```
[!a1+dsa*pla10>y]sy
0sa1
lyx
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also [bc\(1\)](#), [attributes\(5\)](#)

Diagnostics	<i>x</i> is unimplemented	<i>x</i> is an octal number.
	out of space	The free list is exhausted (too many digits).
	out of stack space	Too many pushes onto the stack (stack overflow).
	empty stack	Too many pops from the stack (stack underflow).
	nesting depth	Too many levels of nested execution.
	divide by 0	Division by zero.
	sqrt of neg number	Square root of a negative number is not defined (no imaginary numbers).
	exp not an integer	dc only processes integer exponentiation.
	exp too big	The largest exponent allowed is 999.
	input base is too large	The input base <i>x</i> : 2<= <i>x</i> <= 16.
	input base is too small	The input base <i>x</i> : 2<= <i>x</i> <= 16.
	output base is too large	The output base must be no larger than BC_BASE_MAX.
	invalid scale factor	Scale factor cannot be less than 1.
	scale factor is too large	A scale factor cannot be larger than BC_SCALE_MAX.
	symbol table overflow	Too many variables have been specified.
	invalid index	Index cannot be less than 1.
	index is too large	An index cannot be larger than BC_DIM_MAX.

Name deallocate – device deallocation

Synopsis deallocate [-s] [-w] [-F] [-z *zonename*]
 [-c *dev-class* | -g *dev-type* | *device*]
 deallocate [-s] [-w] [-F] [-z *zonename*] -I

Description The deallocate command frees an allocated device. It resets the ownership and permissions on all device special files associated with the device, disabling access to that device. deallocate runs the device cleaning program for that device as specified in [device_allocate\(4\)](#).

The default deallocate operation deallocates devices allocated to the user.

Options The following options are supported:

- c *dev-class* Deallocates all devices of the specified device class.
- F *device* Forces deallocation of the device associated with the file specified by *device*. Only a user with the `solaris.device.revoke` authorization is permitted to use this option.
- I Forces deallocation of all allocatable devices. Only a user with the `solaris.device.revoke` authorization is permitted to use this option. This option should only be used at system initialization.
- s Silent. Suppresses any diagnostic output.

The following options are supported when the system is configured with Trusted Extensions:

- g *dev-type* Deallocates a device of device type matching *dev-type*.
- w Runs the device cleaning program in a windowing environment. If a windowing version of the program exists, it is used. Otherwise, the standard version is run in a terminal window.
- z *zonename* Deallocates device from the zone specified by *zonename*.

Operands The following operands are supported:

- device* Deallocates the specified *device*.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 20 No entry for the specified device.
- other value* An error occurred.

Files /etc/security/device_allocate

/etc/security/device_maps

/etc/security/dev/*

/etc/security/lib/*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also [allocate\(1\)](#), [list_devices\(1\)](#), [bsmconv\(1M\)](#), [dminfo\(1M\)](#), [mkdevalloc\(1M\)](#), [mkdevmaps\(1M\)](#), [device_allocate\(4\)](#), [device_maps\(4\)](#), [attributes\(5\)](#)

Controlling Access to Devices

Notes The functionality described in this man page is available only if Solaris Auditing has been enabled. See [bsmconv\(1M\)](#) for more information.

On systems configured with Trusted Extensions, the functionality is enabled by default.

/etc/security/dev, [mkdevalloc\(1M\)](#), and [mkdevmaps\(1M\)](#) might not be supported in a future release of the Solaris Operating Environment.

Name deroff – remove nroff/troff, tbl, and eqn constructs

Synopsis deroff [-m [m | s | l]] [-w] [-i] [filename...]

Description deroff reads each of the *filenames* in sequence and removes all [troff\(1\)](#) requests, macro calls, backslash constructs, [eqn\(1\)](#) constructs (between .EQ and .EN lines, and between delimiters), and [tbl\(1\)](#) descriptions, perhaps replacing them with white space (blanks and blank lines), and writes the remainder of the file on the standard output. deroff follows chains of included files (.so and .nx troff commands); if a file has already been included, a .so naming that file is ignored and a .nx naming that file terminates execution. If no input file is given, deroff reads the standard input.

Options

- m The -m option may be followed by an m, s, or l. The -mm option causes the macros to be interpreted so that only running text is output (that is, no text from macro lines.) The -ml option forces the -mm option and also causes deletion of lists associated with the mm macros.
- w If the -w option is given, the output is a word list, one “word” per line, with all other characters deleted. Otherwise, the output follows the original, with the deletions mentioned above. In text, a “word” is any string that *contains* at least two letters and is composed of letters, digits, ampersands (&), and apostrophes ('); in a macro call, however, a “word” is a string that *begins* with at least two letters and contains a total of at least three letters. Delimiters are any characters other than letters, digits, apostrophes, and ampersands. Trailing apostrophes and ampersands are removed from “words.”
- i The -i option causes deroff to ignore .so and .nx commands.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

See Also [eqn\(1\)](#), [nroff\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#)

Notes deroff is not a complete troff interpreter, so it can be confused by subtle constructs. Most such errors result in too much rather than too little output.

The -ml option does not handle nested lists correctly.

Name df – display status of disk space on file systems

Synopsis /usr/ucb/df [-a] [-i] [-t *type*] [*filesystem...*]
[*filename...*]

Description The df utility displays the amount of disk space occupied by currently mounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used.

If arguments to df are path names, df produces a report on the file system containing the named file. Thus 'df .' shows the amount of space on the file system containing the current directory.

Options The following options are supported:

- a Report on all filesystems including the uninteresting ones which have zero total blocks (that is, auto-mounter).
- i Report the number of used and free inodes. Print '*' if no information is available.
- t *type* Report on filesystems of a given type (for example, nfs or ufs).

Examples **EXAMPLE 1** Using df

A sample of output for df looks like:

```
example% df
Filesystem  kbytes  used  avail  capacity  Mounted on
sparky:/      7445  4714  1986    70%      /
sparky:/usr  42277 35291  2758    93%     /usr
```

Note that used+avail is less than the amount of space in the file system (kbytes); this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this can be adjusted using tuneufs (see [tuneufs\(1M\)](#)). When all the space on a file system except for this reserve is in use, only the super-user can allocate new files and data blocks to existing files. When a file system is overallocated in this way, df can report that the file system is more than 100% utilized.

- Files** /etc/mnttab List of file systems currently mounted
/etc/vfstab List of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

See Also [du\(1\)](#), [quot\(1M\)](#), [tunefs\(1M\)](#), [mnttab\(4\)](#), [attributes\(5\)](#)

Name dhcpcinfo – display values of parameters received through DHCP

Synopsis dhcpcinfo [-c] [-i *interface*] [-n *limit*] [-v 4|6] *code*
dhcpcinfo [-c] [-i *interface*] [-n *limit*] [-v 4|6] *identifier*

Description The dhcpcinfo utility prints the DHCP-supplied value(s) of the parameter requested on the command line. The parameter can be identified either by its numeric code in the DHCP specification, or by its mnemonic identifier, as listed in [dhcp_inittab\(4\)](#). This command is intended to be used in command substitutions in the shell scripts invoked by [init\(1M\)](#) at system boot. It first contacts the DHCP client daemon at system boot or in event scripts as described in [dhcpcagent\(1M\)](#). It first contacts the DHCP client daemon [dhcpcagent\(1M\)](#) to verify that DHCP has successfully completed on the requested interface. If DHCP has successfully completed on the requested interface, dhcpcinfo retrieves the values for the requested parameter. Parameter values echoed by dhcpcinfo should not be used without checking its exit status. See [exit\(1\)](#).

See [dhcp_inittab\(4\)](#) for the list of mnemonic identifier codes for all DHCP parameters. See *RFC 2132, DHCP Options and BOOTP Vendor Extensions* for more details on DHCPv4 parameters, and RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6), for more details on DHCPv6 parameters.

Output Format The output from dhcpcinfo consists of one or more lines of ASCII text; the format of the output depends upon the requested parameter. The number of values returned per line and the total number of lines output for a given parameter are determined by the parameter's *granularity* and *maximum* values, respectively, as defined by [dhcp_inittab\(4\)](#).

The format of each individual value is determined by the data type of the option, as determined by [dhcp_inittab\(4\)](#). The possible data types and their formats are listed below:

Data Type	Format	dhcp_inittab(4) type
Unsigned Number	One or more decimal digits	UNUMBER8, UNUMBER16, UNUMBER32, UNUMBER64
Signed Number	One or more decimal digits, optionally preceded by a minus sign	SNUMBER8, SNUMBER16, SNUMBER32, SNUMBER64
IP Address	Dotted-decimal notation	IP
IPv6 Address	Colon-separated notation	IPv6
Octet	The string 0x followed by a two-digit hexadecimal value	OCTET
String	Zero or more ASCII characters	ASCII
DUID	DHCP Unique Identifier text	DUID

Data Type	Format	dhcp_inittab(4) type
Domain Name	Standard dot-separated domain name, RFC 1035 format	DOMAIN

Options The following options are supported:

- c Displays the output in a canonical format. This format is identical to the OCTET format with a granularity of 1.
- i *interface* Specifies the interface to retrieve values for DHCP parameters from. If this option is not specified, the primary interface is used.

For DHCPv6, the interface name used should be the name of the physical interface, not one of the logical interfaces created by dhcagent.
- n *limit* Limits the list of values displayed to *limit* lines.
- v4 | 6 Specifies the DHCP version to query. Use -v4 for DHCPv4 and -v6 for DHCPv6.

Operands The following operands are supported:

- code* Numeric code for the requested DHCP parameter, as defined by the DHCP specification. Vendor options are specified by adding 256 to the actual vendor code for DHCPv4, and 65536 for DHCPv6.
- identifier* Mnemonic symbol for the requested DHCP parameter, as listed in [dhcp_inittab\(4\)](#).

Exit Status The following exit values are returned:

- 0 Successful operation.
- 2 The operation was not successful. The DHCP client daemon might not be running, the interface might have failed to configure, or no satisfactory DHCP responses were received.
- 3 Bad arguments.
- 4 The operation timed out.
- 6 System error (should never occur).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr
Interface Stability	Committed

Name diff – compare two files

Synopsis diff [-bitw] [-c | -e | -f | -h | -n | -u] *file1 file2*
 diff [-bitw] [-C *number* | -U *number*] *file1 file2*
 diff [-bitw] [-D *string*] *file1 file2*
 diff [-bitw] [-c | -e | -f | -h | -n | -u] [-l] [-r] [-s]
 [-S *name*] *directory1 directory2*

Description The `diff` utility will compare the contents of *file1* and *file2* and write to standard output a list of changes necessary to convert *file1* into *file2*. This list should be minimal. Except in rare circumstances, `diff` finds a smallest sufficient set of file differences. No output will be produced if the files are identical.

The normal output contains lines of these forms:

```
n1 a n3,n4
n1,n2 d n3
n1,n2 c n3,n4
```

where *n1* and *n2* represent lines *file1* and *n3* and *n4* represent lines in *file2*. These lines resemble `ed(1)` commands to convert *file1* to *file2*. By exchanging a for d and reading backward, *file2* can be converted to *file1*. As in `ed`, identical pairs, where *n1*=*n2* or *n3*=*n4*, are abbreviated as a single number.

Following each of these lines come all the lines that are affected in the first file flagged by '<', then all the lines that are affected in the second file flagged by '>'.

Options The following options are supported:

- b Ignores trailing blanks (spaces and tabs) and treats other strings of blanks as equivalent.
- i Ignores the case of letters. For example, 'A' will compare equal to 'a'.
- t Expands TAB characters in output lines. Normal or -c output adds character(s) to the front of each line that may adversely affect the indentation of the original source lines and make the output lines difficult to interpret. This option will preserve the original source's indentation.
- w Ignores all blanks (SPACE and TAB characters) and treats all other strings of blanks as equivalent. For example, 'if (a = b)' will compare equal to 'if(a= b)'.

The following options are mutually exclusive:

- c Produces a listing of differences with three lines of context. With this option, output format is modified slightly. That is, output begins with identification of the files involved and their creation dates, then each change is separated by a

line with a dozen *'s. The lines removed from *file1* are marked with '-'. The lines added to *file2* are marked '+'. Lines that are changed from one file to the other are marked in both files with '!'.

- C *number* Produces a listing of differences identical to that produced by -c with *number* lines of context.
- D *string* Creates a merged version of *file1* and *file2* with C preprocessor controls included so that a compilation of the result without defining *string* is equivalent to compiling *file1*, while defining *string* will yield *file2*.
- e Produces a script of only a, c, and d commands for the editor ed, which will recreate *file2* from *file1*. In connection with the -e option, the following shell program may help maintain multiple versions of a file. Only an ancestral file (\$1) and a chain of version-to-version ed scripts (\$2,\$3,...) made by diff need be on hand. A "latest version" appears on the standard output.

```
(shift; cat $*; echo ' 1,$p') | ed - $1
```
- f Produces a similar script, not useful with ed, in the opposite order.
- h Does a fast, half-hearted job. It works only when changed stretches are short and well separated, but does work on files of unlimited length. Options -c, -C, -D, -e, -f, and -n are unavailable with -h. diff does not descend into directories with this option.
- n Produces a script similar to -e, but in the opposite order and with a count of changed lines on each insert or delete command.
- u Produces a listing of differences with three lines of context. The output is similar to that of the -c option, except that the context is "unified". Removed and changed lines in *file1* are marked by a '-' while lines added or changed in *file2* are marked by a '+'. Both versions of changed lines appear in the output, while added, removed, and context lines appear only once. The identification of *file1* and *file2* is different, with "—" and "+++" being printed where "***" and "—" would appear with the -c option. Each change is separated by a line of the form

```
@@ -n1,n2 +n3,n4 @@
```
- U *number* Produces a listing of differences identical to that produced by -u with *number* lines of context.

The following options are used for comparing directories:

- l Produces output in long format. Before the diff, each text file is piped through [pr\(1\)](#) to paginate it. Other differences are remembered and summarized after all text file differences are reported.
- r Applies diff recursively to common subdirectories encountered.

- s Reports files that are identical. These identical files would not otherwise be mentioned.
- S *name* Starts a directory `diff` in the middle, beginning with the file *name*.

Operands The following operands are supported:

file1
file2 A path name of a file or directory to be compared. If either *file1* or *file2* is `-`, the standard input will be used in its place.

directory1
directory2 A path name of a directory to be compared.

If only one of *file1* and *file2* is a directory, `diff` will be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.

Usage See [largefile\(5\)](#) for the description of the behavior of `diff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Typical output of the `diff` command

In the following command, `dir1` is a directory containing a directory named `x`, `dir2` is a directory containing a directory named `x`, `dir1/x` and `dir2/x` both contain files named `date.out`, and `dir2/x` contains a file named `y`:

```
example% diff -r dir1 dir2
Common subdirectories: dir1/x and dir2/x
```

```
Only in dir2/x: y
```

```
diff -r dir1/x/date.out dir2/x/date.out
```

```
1c1
```

```

> Tue Jun 19 21:41:39 PDT 1990
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `diff`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

TZ Determines the locale for affecting the timezone used for calculating file timestamps written with the `-C` and `-c` options.

Exit Status The following exit values are returned:

- 0 No differences were found.
- 1 Differences were found.
- >1 An error occurred.

Files /tmp/d????? temporary file used for comparison
/usr/lib/diffh executable file for -h option

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled
Interface Stability	Standard

See Also [bdiff\(1\)](#), [cmp\(1\)](#), [comm\(1\)](#), [dircmp\(1\)](#), [ed\(1\)](#), [pr\(1\)](#), [sdiff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Notes Editing scripts produced under the -e or -f options are naive about creating lines consisting of a single period (.).

Missing NEWLINE at end of file indicates that the last line of the file in question did not have a NEWLINE. If the lines are different, they will be flagged and output, although the output will seem to indicate they are the same.

Name diff3 – 3-way differential file comparison

Synopsis diff3 [-exEX3] *filename1 filename2 filename3*

Description diff3 compares three versions of a file. It publishes disagreeing ranges of text flagged with the following codes:

```
====      all three files differ
====1     filename1 is different
====2     filename2 is different
====3     filename3 is different
```

The type of change suffered in converting a given range of a given file to some other is indicated in one of the following ways:

```
f : n1 a      Text is to be appended after line number n1 in file f, where f = 1, 2, or 3.
f : n1 , n2 c  Text is to be changed in the range line n1 to line n2. If n1 = n2, the range
                  can be abbreviated to n1.
```

The original contents of the range follows immediately after a c indication. When the contents of two files are identical, the contents of the lower-numbered file is suppressed.

The following command applies the resulting script to *filename1*.

```
(cat script; echo '1,$'p) | ed - filename1
```

Options The following options are supported:

-e Produce a script for the [ed\(1\)](#) editor that incorporates into *filename1* all changes between *filename2* and *filename3* (that is, the changes that normally would be flagged ==== and ====3).

Text lines that consist of a single dot (.) defeat the -e option.

-E Produce a script that incorporates all changes between *filename2* and *filename3*, but treat overlapping changes (that is, changes that would be flagged with ==== in the normal listing) differently. The overlapping lines from both files are inserted by the edit script, bracketed by <<<<<< and >>>>>> lines.

-x Produce a script to incorporate only changes flagged ==.

-X Produce a script that incorporates only changes flagged ==., but treat these changes in the manner of the -E option.

-3 Produce a script to incorporate only changes flagged ==3.

Usage See [largefile\(5\)](#) for the description of the behavior of `diff3` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/tmp/d3*`
`/usr/lib/diff3prog`

Exit Status The following exit values are returned:

- `0` Successful completion.
- `1` An error occurred. A difference was found or there was a fatal error.
- `>1` A fatal error occurred.

Return values do not work the same as [diff\(1\)](#) or other vendor's versions of `diff3`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesc
CSI	Enabled

See Also [diff\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Notes Files longer than 64 Kbytes do not work.

Name diffmk – mark differences between versions of a troff input file

Synopsis diffmk *oldfile newfile markedfile*

Description diffmk compares two versions of a file and creates a third version that includes “change mark” (.mc) commands for [nroff\(1\)](#) and [troff\(1\)](#). *oldfile* and *newfile* are the old and new versions of the file. diffmk generates *markedfile*, which, contains the text from *newfile* with [troff\(1\)](#) “change mark” requests (.mc) inserted where *newfile* differs from *oldfile*. When *markedfile* is formatted, changed or inserted text is shown by | at the right margin of each line. The position of deleted text is shown by a single *.

Usage See [largefile\(5\)](#) for the description of the behavior of diffmk when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** An example of the diffmk command.

diffmk can also be used in conjunction with the proper troff requests to produce program listings with marked changes. In the following command line:

```
example% diffmk old.c new.c marked.c ; nroff reqs marked.c | pr
```

the file reqs contains the following troff requests:

```
.pl 1
.ll 77
.nf
.eo
.nh
```

which eliminate page breaks, adjust the line length, set no-fill mode, ignore escape characters, and turn off hyphenation, respectively.

If the characters | and * are inappropriate, you might run *markedfile* through [sed\(1\)](#) to globally change them.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

See Also [diff\(1\)](#), [nroff\(1\)](#), [sed\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Bugs Aesthetic considerations may dictate manual adjustment of some output. File differences involving only formatting requests may produce undesirable output, that is, replacing .sp by .sp 2 will produce a “change mark” on the preceding or following line of output.

Name digest – calculate a message digest

Synopsis /usr/bin/digest -l | [-v] -a *algorithm* [*file*]....

Description The digest utility calculates the message digest of the given files or stdin using the algorithm specified. If more than one file is given, each line of output is the digest of a single file.

Options The following options are supported:

- a *algorithm* Specifies the name of the algorithm to use during the encryption or decryption process. See USAGE, Algorithms, for details.
- l Displays list of algorithms available on the system. This list can change depending on the configuration of the cryptographic framework.
- v Verbose output. Includes the algorithm name and filename in the output.

Usage

Algorithms These algorithms are provided by the Cryptographic Framework. Each algorithm supported by the command is an alias of the PKCS #11 mechanism for easier access. For example, sha1 is an alias to CKM_SHA_1.

These aliases are used with the -a option and are case-sensitive.

Examples

EXAMPLE 1 Simulating Output

The following example simulates output of the common md5sum program:

```
example$ digest -v -a md5 /usr/bin/vi
md5 (/usr/bin/vi) = e4e3588c5212903847c66d36b1a828a5
```

EXAMPLE 2 Digesting a File

The following example generates the sha1 digest of the file /etc/motd:

```
example$ digest -a sha1 /etc/motd
9498a4f5303d056ad3ecae826b59f41448d63790
```

EXAMPLE 3 Generating a Directory Manifest

The following example generates a directory manifest with sha1:

```
example$ digest -v -a sha1 /usr/lib/inet/*
sha1 (/usr/lib/inet/certdb) = f6d43e6e395d50db24d34e4af4828598c8918b16
sha1 (/usr/lib/inet/certlocal) = 7f74ba4a019b809c7023212b4bda10d9485e071d
sha1 (/usr/lib/inet/certrldb) = 1f845d30b8d02066647de04311e74549049852ed
sha1 (/usr/lib/inet/dhcp) = e3db5e4ff40a69d13f2497254526c2015d2c37b3
sha1 (/usr/lib/inet/dsvclockd) = b61aad7ed6a0f82145c3c26aedc613ab4a1f032e
sha1 (/usr/lib/inet/in.dhcpd) = 382210180c826fbb2e747236c489062bac8cc30b
sha1 (/usr/lib/inet/in.iked) = be6061fad725d37256e773dc85f8bd5248649463
sha1 (/usr/lib/inet/in.mpathd) = 5bd6bf0340fd5c4cc0c53f2df158302a0e85f9d0
```

EXAMPLE 3 Generating a Directory Manifest (Continued)

```

sha1 (/usr/lib/inet/in.ndpd) = fdb768aebe7e5eb4465e1c1bb5e679b496f5c5c6
sha1 (/usr/lib/inet/in.ripngd) = 4f56a0df2d4a252f581a73c2e84143b920d0b66b
sha1 (/usr/lib/inet/mipagent) = 3c45e95231959d738625b9fcb84735148393ce47
sha1 (/usr/lib/inet/ncaconfd) = 7219542b5585a8d1104d7ce4a2ced07d8a260ea3
sha1 (/usr/lib/inet/ppp) = c96ee458549871a6ffdf2674a888b01d0c9e9740
sha1 (/usr/lib/inet/pppoec) = 5f022498d79dacacd947cddadc64f171822e3dee
sha1 (/usr/lib/inet/pppoed) = 252bd2f0863dbc1b05fffae72821a2a95609b8ad
sha1 (/usr/lib/inet/slpd) = dfa24cc0f0b05f790546d4f0948a9094f7089027
sha1 (/usr/lib/inet/wanboot) = a8b8c51c389c774d0be2ae43cb85d1b1439484ae
sha1 (/usr/lib/inet/xntpd) = 5b4aff102372cea801e7d08acde9655fec81f07c

```

EXAMPLE 4 Displaying a List of Available Algorithms

The following example displays a list of available algorithms to digest:

```

example$ digest -l
sha1
md5
sha256
sha385
sha512

```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed

See Also [cksum\(1\)](#), [encrypt\(1\)](#), [mac\(1\)](#), [bart\(1M\)](#), [cryptoadm\(1M\)](#), [libpkcs11\(3LIB\)](#), [attributes\(5\)](#), [pkcs11_softtoken\(5\)](#)

Name dircmp – directory comparison

Synopsis dircmp [-ds] [-w *n*] *dir1 dir2*

Description The `dircmp` command examines *dir1* and *dir2* and generates various tabulated information about the contents of the directories. Listings of files that are unique to each directory are generated for all the options. If no option is entered, a list is output indicating whether the file names common to both directories have the same contents.

Options The following options are supported:

- d Compares the contents of files with the same name in both directories and output a list telling what must be changed in the two files to bring them into agreement. The list format is described in [diff\(1\)](#).
- s Suppresses messages about identical files.
- w *n* Changes the width of the output line to *n* characters. The default width is 72.

Operands The following operands are supported:

dir1
dir2 A path name of a directory to be compared.

Usage See [largefile\(5\)](#) for the description of the behavior of `dircmp` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `dircmp`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred. (Differences in directory contents are not considered errors.)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also [cmp\(1\)](#), [diff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#)

Name dis – object code disassembler

Synopsis dis [-onqCLV] [-d *sec*] [-D *sec*] [-F *function*]
[-l *string*] [-t *sec*] *file*...

Description The `dis` command produces an assembly language listing of *file*, which can be an object file or an archive of object files. The listing includes assembly statements and an octal or hexadecimal representation of the binary that produced those statements.

Options Options are interpreted by the disassembler and can be specified in any order.

The following options are supported:

- C Displays demangled C++ symbol names in the disassembly.
- d *sec* Disassembles the named section as data, printing the offset of the data from the beginning of the section.
- D *sec* Disassembles the named section as data, printing the actual address of the data.
- F *function* Disassembles only the named function in each object file specified on the command line. The -F option can be specified multiple times on the command line.
- l *string* Disassembles the archive file specified by *string*. For example, one would issue the command `dis -l x -l z` to disassemble `libx.a` and `libz.a`, which are assumed to be in `LIBDIR`.
- This option is obsolete and might be removed in a future release of Solaris.
- L Invokes a lookup of C-language source labels in the symbol table for subsequent writing to standard output.
- This option is obsolete and might be removed in a future release of Solaris.
- n Displays all addresses numerically. Addresses are displayed using symbolic names by default.
- o Prints numbers in octal. The default is hexadecimal.
- q Quiet mode. Does not print any headers or function entry labels.
- t *sec* Disassembles the named section as text.
- V Prints, on standard error, the version number of the disassembler being executed.
- This option is obsolete and might be removed in a future release of Solaris.

If the -d, -D, or -t options are specified, only those named sections from each user-supplied file is disassembled. Otherwise, all sections containing text is disassembled.

On output, a number enclosed in brackets at the beginning of a line, such as [5], indicates that the break-pointable line number starts with the following instruction. These line numbers is printed only if the file was compiled with additional debugging information, for example, the -g option of [cc\(1B\)](#). An expression such as <40> in the operand field or in the symbolic disassembly, following a relative displacement for control transfer instructions, is the computed address within the section to which control is transferred. A function name appears in the first column, followed by () if the object file contains a symbol table.

Operands The following operand is supported:

file A path name of an object file or an archive (see [ar\(1\)](#)) of object files.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of dis: LC_CTYPE, LC_MESSAGES, and NLSPATH.

LIBDIR If this environment variable contains a value, use this as the path to search for the library. If the variable contains a null value, or is not set, it defaults to searching for the library under /usr/lib.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /usr/lib default LIBDIR

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	See below.

The human readable output is Unstable. The command line options are Evolving.

See Also [ar\(1\)](#), [as\(1\)](#), [cc\(1B\)](#), [ld\(1\)](#), [a.out\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Diagnostics The self-explanatory diagnostics indicate errors in the command line or problems encountered with the specified files.

Name dispgid – displays a list of all valid group names

Synopsis dispgid

Description dispgid displays a list of all group names on the system (one group per line).

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 Cannot read the group file.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Name dispuid – displays a list of all valid user names

Synopsis dispuid

Description dispuid displays a list of all user names on the system (one line per name).

Exit Status The following exit values are returned:

- 0 Successful execution.
- 1 Cannot read the password file.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [attributes\(5\)](#)

Name dos2unix – convert text file from DOS format to ISO format

Synopsis dos2unix [-ascii] [-iso] [-7]
 [-437 | -850 | -860 | -863 | -865] *originalfile convertedfile*

Description The dos2unix utility converts characters in the DOS extended character set to the corresponding ISO standard characters.

This command can be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.

If the original file and the converted file are the same, dos2unix will rewrite the original file after converting it.

Options The following options are supported:

- ascii Removes extra carriage returns and converts end of file characters in DOS format text files to conform to SunOS requirements.
- iso This is the default. It converts characters in the DOS extended character set to the corresponding ISO standard characters.
- 7 Converts 8 bit DOS graphics characters to 7 bit space characters so that SunOS can read the file.

On non-i386 systems, dos2unix will attempt to obtain the keyboard type to determine which code page to use. Otherwise, the default is US. The user may override the code page with one of the following options:

- 437 Use US code page
- 850 Use multilingual code page
- 860 Use Portuguese code page
- 863 Use French Canadian code page
- 865 Use Danish code page

Operands The following operands are required:

- originalfile* The original file in DOS format that is being converted to ISO format.
- convertedfile* The new file in ISO format that has been converted from the original DOS file format.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also [unix2dos\(1\)](#), [ls\(1\)](#), [attributes\(5\)](#)

Diagnostics File *filename* not found, or no read permission
The input file you specified does not exist, or you do not have read permission. Check with the SunOS command, `ls -l` (see [ls\(1\)](#)).

Bad output filename *filename*, or no write permission
The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.

Error while writing to temporary file
An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Notice that when this error occurs, the original file remains intact.

Translated temporary file name = *filename*.
Could not rename temporary file to *filename*.
The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.

Name download – host resident PostScript font downloader

Synopsis download [-f] [-p *printer*] [-m *name*] [-H *directory*]
[*file*]...

/usr/lib/lp/postscript/download

Description download prepends host resident fonts to *files* and writes the results on the standard output. If no *files* are specified, or if – is one of the input *files*, the standard input is read. download assumes the input *files* make up a single PostScript job and that requested fonts can be included at the start of each input file.

Requested fonts are named in a comment (marked with %%DocumentFonts:) in the input *files*. Available fonts are the ones listed in the map table selected using the -m option.

The map table consists of fontname–file pairs. The fontname is the full name of the PostScript font, exactly as it would appear in a %%DocumentFonts: comment. The file is the pathname of the host resident font. A file that begins with a / is used as is. Otherwise the pathname is relative to the host font directory. Comments are introduced by % (as in PostScript) and extend to the end of the line.

The only candidates for downloading are fonts listed in the map table that point download to readable files. A font is downloaded once, at most. Requests for unlisted fonts or inaccessible files are ignored. All requests are ignored if the map table can not be read.

Options

- f Force a complete scan of each input file. In the absence of an explicit comment pointing download to the end of the file, the default scan stops immediately after the PostScript header comments.
- p *printer* Check the list of printer-resident fonts in /etc/lp/printers/*printer*/residentfonts before downloading.
- m *name* Use *name* as the font map table. A *name* that begins with / is the full pathname of the map table and is used as is. Otherwise *name* is appended to the pathname of the host font directory.
- H *directory* Use *dir* as the host font directory. The default is /usr/lib/lp/postscript.

Examples EXAMPLE 1 Examples of the download command.

The following map table could be used to control the downloading of the Bookman font family:

```
%
% The first string is the full PostScript font name. The second string
% is the file name - relative to the host font directory unless it begins
% with a /.
%
```

Bookman-Light

bookman/light

EXAMPLE 1 Examples of the download command. *(Continued)*

```
Bookman-LightItalic      bookman/lightitalic
Bookman-Demi             bookman/demi
Bookman-DemiItalic       bookman/demiitalic
```

Using the file `myprinter/map` (in the default host font directory) as the map table, you could download fonts by issuing the following command:

```
example% download -m myprinter/map file
```

Exit Status The following exit values are returned:

- `0` Successful completion.
- `non-zero` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

See Also [dpost\(1\)](#), [postdaisy\(1\)](#), [postdmd\(1\)](#), [postio\(1\)](#), [postmd\(1\)](#), [postprint\(1\)](#), [posttek\(1\)](#), [attributes\(5\)](#)

Notes The download program should be part of a more general program.

`download` does not look for `%%PageFonts`: comments and there is no way to force multiple downloads of a particular font.

Using full pathnames in either map tables or the names of map tables is not recommended.

Name dpost – troff postprocessor for PostScript printers

Synopsis dpost [-c *num*] [-e *num*] [-m *num*] [-n *num*] [-o *list*]
 [-w *num*] [-x *num*] [-y *num*] [-F *dir*] [-H *dir*]
 [-L *file*] [-O] [-T *name*] [*file*]...

/usr/lib/lp/postscript/dpost

Description dpost translates *files* created by [troff\(1\)](#) into PostScript and writes the results on the standard output. If no *files* are specified, or if `–` is one of the input *files*, the standard input is read.

The *files* should be prepared by `troff`. The default font files in `/usr/lib/font/devpost` produce the best and most efficient output. They assume a resolution of 720 dpi, and can be used to format files by adding the `-Tpost` option to the `troff` call. Older versions of the `eqn` and `pic` preprocessors need to know the resolution that `troff` will be using to format the *files*. If those are the versions installed on your system, use the `-r720` option with `eqn` and `-T720` with `pic`.

dpost makes no assumptions about resolutions. The first `x res` command sets the resolution used to translate the input *files*, the `DESC.out` file, usually `/usr/lib/font/devpost/DESC.out`, defines the resolution used in the binary font files, and the PostScript prologue is responsible for setting up an appropriate user coordinate system.

- Options**
- `-c num` Print *num* copies of each page. By default only one copy is printed.
 - `-e num` Sets the text encoding level to *num*. The recognized choices are 0, 1, and 2. The size of the output file and print time should decrease as *num* increases. Level 2 encoding will typically be about 20 percent faster than level 0, which is the default and produces output essentially identical to previous versions of dpost.
 - `-m num` Magnify each logical page by the factor *num*. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.
 - `-n num` Print *num* logical pages on each piece of paper, where *num* can be any positive integer. By default, *num* is set to 1.
 - `-o list` Print those pages for which numbers are given in the comma-separated *list*. The list contains single numbers *N* and ranges *N1–N2*. A missing *N1* means the lowest numbered page, a missing *N2* means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then *only* page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.
 - `-p mode` Print *files* in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.

- w *num* Set the line width used to implement `troff` graphics commands to *num* points, where a point is approximately 1/72 of an inch. By default, *num* is set to 0.3 points.
- x *num* Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves everything right. The default offset is 0 inches.
- y *num* Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is 0.
- F *dir* Use *dir* as the font directory. The default *dir* is `/usr/lib/font`, and `dpost` reads binary font files from directory `/usr/lib/font/devpost`.
- H *dir* Use *dir* as the host resident font directory. Files in this directory should be complete PostScript font descriptions, and must be assigned a name that corresponds to the appropriate two-character `troff` font name. Each font file is copied to the output file only when needed and at most once during each job. There is no default directory.
- L *file* Use *file* as the PostScript prologue which, by default, is `/usr/lib/lp/postscript/dpost.ps`.
- O Disables PostScript picture inclusion. A recommended option when `dpost` is run by a spooler in a networked environment.
- T *name* Use font files for device *name* as the best description of available PostScript fonts. By default, *name* is set to `post` and `dpost` reads binary files from `/usr/lib/font/devpost`.

Examples EXAMPLE 1 Examples of the `dpost` command.

If the old versions of `eqn` and `pic` are installed on your system, you can obtain the best possible looking output by issuing a command line such as the following:

```
example% pic -T720 file | tbl | eqn -r720 | troff -mm -Tpost | dpost
```

Otherwise,

```
example% pic file | tbl | eqn | troff -mm -Tpost | dpost
```

should give the best results.

Exit Status The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

Files /usr/lib/font/devpost/*.out
/usr/lib/font/devpost/charlib/*
/usr/lib/lp/postscript/color.ps
/usr/lib/lp/postscript/draw.ps
/usr/lib/lp/postscript/forms.ps
/usr/lib/lp/postscript/ps.requests

Availability	SUNWpsf

See Also [download\(1\)](#), [postdaisy\(1\)](#), [postdmd\(1\)](#), [postio\(1\)](#), [postmd\(1\)](#), [postprint\(1\)](#), [postreverse\(1\)](#), [posttek\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#)

Notes Output files often do not conform to Adobe's file structuring conventions. Piping the output of dpost through [postreverse\(1\)](#) should produce a minimally conforming PostScript file.

Although dpost can handle files formatted for any device, emulation is expensive and can easily double the print time and the size of the output file. No attempt has been made to implement the character sets or fonts available on all devices supported by troff. Missing characters will be replaced by white space, and unrecognized fonts will usually default to one of the Times fonts (that is, R, I, B, or BI).

An x res command must precede the first x init command, and all the input *files* should have been prepared for the same output device.

Use of the -T option is not encouraged. Its only purpose is to enable the use of other PostScript font and device description files, that perhaps use different resolutions, character sets, or fonts.

Although level 0 encoding is the only scheme that has been thoroughly tested, level 2 is fast and may be worth a try.

Name dtappsession – start a new Application Manager session

Synopsis /usr/dt/bin/dtappsession [*hostname*]

Description dtappsession is a specialized version of the Xsession shell script. It is an alternative to using the CDE remote login that allows you to access a remote host without logging out of your current CDE session. dtappsession starts a new instance of the CDE Application Manager in its own ToolTalk session. It can be used to remotely display the Application Manager back to your local display after logging in to a remote host with the [rlogin\(1\)](#) command.

A new, independent instance of ttsession(1) starts a simple session management window. This window displays the title

remote_hostname: Remote Administration

where *remote_hostname* is the system that is being accessed. The window also displays an Exit button. Clicking Exit terminates the ToolTalk session and all windows that are part of the session.

The Application Manager that is displayed can be used to start remote CDE actions to run in this session. Exiting the Application Manager does not terminate the session, and it is not recommended. Clicking Exit is the recommended way to end the session. To avoid confusing the remote CDE applications with local ones, it is recommended that a new CDE workspace be created for clients in the remote session.

The *hostname* is not needed when the DISPLAY environment variable is set to the local hostname on the remote host.

On a system that is configured with Trusted Extensions, dtappsession can be used for remote administration by administrative roles that have the ability to log in to the remote host.

dtappsession does not require any privilege, and it does not need to run on a system that is configured with Trusted Extensions. When installed in /usr/dt/bin on a Solaris system, along with the startApp.ds file, dtappsession can be used to administer the remote Solaris system from a local system that is configured with Trusted Extensions. However, in this case, the CDE workspace that is used for remote display must be a normal workspace, rather than a role workspace.

Examples **EXAMPLE 1** Remote Login and dtappsession

After creating a new CDE workspace, type the following in a terminal window:

```
# rlogin remote_hostname
password: /*type the remote password*/

# dtappsession local_hostname /* on the remote host */
```

Files /usr/dt/bin/startApp.ds dt Korn shell script for session manager window

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdttssu
Interface Stability	Committed

Bugs X11/CDE applications that do not register with the ToolTalk session manager will not exit automatically when the session is terminated. Such applications must be explicitly terminated.

See Also [dtfile\(1\)](#), [rlogin\(1\)](#), [ttsession\(1\)](#), [attributes\(5\)](#)

Chapter 8, “Remote Administration in Trusted Extensions (Tasks),” in *Oracle Solaris Trusted Extensions Administrator's Procedures*

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name du – summarize disk usage

Synopsis /usr/bin/du [-adr] [-k | -h] [-H | -L] [-o | -s] [*file* ...]
 /usr/xpg4/bin/du [-a | -s] [-k | -h] [-H | -L] [-rx]
 [*file* ...]

Description The du utility writes to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. The size of the file space allocated to a file of type directory is defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself. This sum will include the space allocated to any extended attributes encountered.

Files with multiple links will be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes are written in 512-byte units, rounded up to the next 512-byte unit.

/usr/xpg4/bin/du When du cannot obtain file attributes or read directories (see [stat\(2\)](#)), it will report an error condition and the final exit status will be affected.

Options The following options are supported for /usr/bin/du and /usr/xpg4/bin/du:

- a In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the -a option, non-directories given as *file* operands will always be listed.
- h All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.
- H If a symbolic link to a directory is specified on the command line, process the symbolic link by using the directory which the symbolic link references, rather than the link itself.
- k Write the files sizes in units of 1024 bytes, rather than the default 512-byte units.
- L Process symbolic links by using the file or directory which the symbolic link references, rather than the link itself.
- s Instead of the default output, report only the total sum for each of the specified files.

Specifying more than one of the options in the mutually exclusive pair, -H and -L, is not considered an error. The last option specified determines the output format.

/usr/bin/du The following options are supported for /usr/bin/du only:

- d Do not cross filesystem boundaries. For example, du -d / reports usage only on the root partition.

- o Do not add child directories' usage to a parent's total. Without this option, the usage listed for a particular directory is the space taken by the files in that directory, as well as the files in all directories beneath it. This option does nothing if -s is used.
- r Generate messages about directories that cannot be read, files that cannot be opened, and so forth, rather than being silent (the default).

/usr/xpg4/bin/du The following options are supported for /usr/xpg4/bin/du only:

- r By default, generate messages about directories that cannot be read, files that cannot be opened, and so forth.
- x When evaluating file sizes, evaluate only those files that have the same device as the file specified by the *file* operand.

Operands The following operand is supported:

file The path name of a file whose size is to be written. If no *file* is specified, the current directory is used.

Output The output from du consists of the amount of the space allocated to a file and the name of the file.

Usage See [largefile\(5\)](#) for the description of the behavior of du when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of du: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/du	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcsu
	CSI	Enabled
	Interface Stability	Stable

/usr/xpg4/bin/du	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	CSI	Enabled
	Interface Stability	Standard

See Also [ls\(1\)](#), [stat\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

System Administration Guide: Basic Administration

Notes A file with two or more links is counted only once. If, however, there are links between files in different directories where the directories are on separate branches of the file system hierarchy, du will count the excess files more than once.

Files containing holes will result in an incorrect block count.

Name du – display the number of disk blocks used per directory or file

Synopsis /usr/ucb/du [-adkLr] [-o | -s] [*filename*]

Description The du utility gives the number of kilobytes contained in all files and, recursively, directories within each specified directory or file *filename*. If *filename* is missing, '.' (the current directory) is used.

A file that has multiple links to it is only counted once.

Options The following options are supported:

- a Generates an entry for each file.
- d Does not cross file system boundaries. For example, du -d / reports usage only on the root partition.
- k Writes the files sizes in units of 1024 bytes, rather than the default 512-byte units.
- L Processes symbolic links by using the file or directory that the symbolic link references, rather than the link itself.
- o Does not add child directories' usage to a parent's total. Without this option, the usage listed for a particular directory is the space taken by the files in that directory, as well as the files in all directories beneath it. This option does nothing if the -s option is used.
- r Generates messages about directories that cannot be read, files that cannot be opened, and so forth, rather than being silent (the default).
- s Only displays the grand total for each of the specified *filenames*.

Entries are generated only for each directory in the absence of options.

Examples **EXAMPLE 1** Showing usage of all subdirectories in a directory

This example uses du in a directory. The `pwd(1)` command was used to identify the directory, then du was used to show the usage of all the subdirectories in that directory. The grand total for the directory is the last entry in the display:

```
example% pwd
/usr/ralph/misc
example% du
5      ./jokes
33     ./squash
44     ./tech.papers/lpr.document
217    ./tech.papers/new.manager
401    ./tech.papers
144    ./memos
80     ./letters
388    ./window
93     ./messages
```

EXAMPLE 1 Showing usage of all subdirectories in a directory (Continued)

```
15      ./useful.news
1211    .
```

Environment Variables If any of the LC_* variables, that is, LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY (see [environ\(5\)](#)), are not set in the environment, the operational behavior of du for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how du behaves.

LC_CTYPE Determines how du handles characters. When LC_CTYPE is set to a valid value, du can display and handle text and filenames containing valid characters for that locale. du can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. du can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

See Also [pwd\(1\)](#), [df\(1M\)](#), [du\(1\)](#), [quot\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Notes Filename arguments that are not directory names are ignored, unless you use -a.
If there are too many distinct linked files, du will count the excess files more than once.

Name dump – dump selected parts of an object file

Synopsis dump [-aCcghLorstV [-p]] [-T *index* [, *indexn*]] *filename*...
 dump [-afhorstL [-p] [v]] *filename*...
 dump [-hsr [-p] [-d *number* [, *numbern*]]] *filename*...
 dump [-hsrt [-p] [-n *name*]] *filename*...

Description The dump utility dumps selected parts of each of its object *file* arguments.

The dump utility is best suited for use in shell scripts, whereas the `elfdump(1)` command is recommended for more human-readable output.

Options This utility will accept both object files and archives of object files. It processes each file argument according to one or more of the following options:

- a Dumps the archive header of each member of an archive.
- c Dumps the string table(s).
- C Dumps decoded C++ symbol table names.
- f Dumps each file header.
- g Dumps the global symbols in the symbol table of an archive.
- h Dumps the section headers.
- L Dumps dynamic linking information and static shared library information, if available.
- o Dumps each program execution header.
- r Dumps relocation information.
- s Dumps section contents in hexadecimal.
- t Dumps symbol table entries.
- T *index*
- T *index1,index2* Dumps only the indexed symbol table entry defined by *index* or a range of entries defined by *index1*, *index2*.
- V Prints version information.

The following modifiers are used in conjunction with the options listed above to modify their capabilities.

- d *number*
- d *number1,number2* Dumps the section number indicated by *number* or the range of sections starting at *number1* and ending at *number2*. This modifier can be used with -h, -s, and -r. When -d is used with -h or -s, the

argument is treated as the number of a section or range of sections. When `-d` is used with `-r`, the argument is treated as the number of the section or range of sections to which the relocation applies. For example, to print out all relocation entries associated with the `.text` section, specify the number of the section as the argument to `-d`. If `.text` is section number 2 in the file, `dump -r -d 2` will print all associated entries. To print out a specific relocation section, use `dump -s -n name` for raw data output, or `dump -sv -n name` for interpreted output.

`-n name` Dumps information pertaining only to the named entity. This modifier can be used with `-h`, `-s`, `-r`, and `-t`. When `-n` is used with `-h` or `-s`, the argument will be treated as the name of a section. When `-n` is used with `-t` or `-r`, the argument will be treated as the name of a symbol. For example, `dump -t -n .text` will dump the symbol table entry associated with the symbol whose name is `.text`, where `dump -h -n .text` will dump the section header information for the `.text` section.

`-p` Suppresses printing of the headings.

`-v` Dumps information in symbolic representation rather than numeric. This modifier can be used with

- `-a` (date, user id, group id)
- `-f` (class, data, type, machine, version, flags)
- `-h` (type, flags)
- `-L` (value)
- `-o` (type, flags)
- `-r` (name, type)
- `-s` (interpret section contents wherever possible)
- `-t` (type, bind)

When `-v` is used with `-s`, all sections that can be interpreted, such as the string table or symbol table, will be interpreted. For example, `dump -sv -n .symtab filename. . .` will produce the same formatted output as `dump -tv filename. . .`, but `dump -s -n .symtab filename. . .` will print raw data in hexadecimal. Without additional modifiers, `dump -sv filename...` will dump all sections in the files, interpreting all those that it can and dumping the rest (such as `.text` or `.data`) as raw data.

The dump utility attempts to format the information it dumps in a meaningful way, printing certain information in character, hexadecimal, octal, or decimal representation as appropriate.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

See Also [elfdump\(1\)](#), [nm\(1\)](#), [ar.h\(3HEAD\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

Name dumpcs – show codeset table for the current locale

Synopsis dumpcs [-0123vw]

Description dumpcs shows a list of printable characters for the user's current locale, along with their hexadecimal code values. The display device is assumed to be capable of displaying characters for a given locale. With no option, dumpcs displays the entire list of printable characters for the current locale.

With one or more numeric options specified, it shows EUC codeset(s) for the current locale according to the numbers specified, and in order of codeset number. Each non-printable character is represented by an asterisk “*” and enough ASCII space character(s) to fill that codeset's column width.

- Options**
- 0 Show ASCII (or EUC primary) codeset.
 - 1 Show EUC codeset 1, if used for the current locale.
 - 2 Show EUC codeset 2, if used for the current locale.
 - 3 Show EUC codeset 3, if used for the current locale.
 - v “Verbose”. Normally, ranges of non-printable characters are collapsed into a single line. This option produces one line for each non-printable character.
 - w Replace code values with corresponding wide character values (process codes).

Environment Variables The environment variables LC_CTYPE and LANG control the character classification throughout dumpcs. On entry to dumpcs, these environment variables are checked in that order. This implies that a new setting for LANG does not override the setting of LC_CTYPE. When none of the values is valid, the character classification defaults to the POSIX.1 “C” locale.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [localedef\(1\)](#), [attributes\(5\)](#)

Notes dumpcs can only handle EUC locales.

Name echo – echo arguments

Synopsis /usr/bin/echo [*string*]...

Description The echo utility writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output. If there are no arguments, only the NEWLINE character is written.

echo is useful for producing diagnostics in command files, for sending known data into a pipe, and for displaying the contents of environment variables.

The C shell, the Korn shell, and the Bourne shell all have echo built-in commands, which, by default, is invoked if the user calls echo without a full pathname. See [shell_builtins\(1\)](#). sh's echo, ksh's echo, and /usr/bin/echo understand the back-slashed escape characters, except that sh's echo does not understand \a as the alert character. In addition, ksh's echo does not have an -n option. sh's echo and /usr/bin/echo have an -n option if the SYSV3 environment variable is set (see ENVIRONMENT VARIABLES below). csh's echo and /usr/ucb/echo, on the other hand, have an -n option, but do not understand the back-slashed escape characters. sh and ksh determine whether /usr/ucb/echo is found first in the PATH and, if so, they adapt the behavior of the echo builtin to match /usr/ucb/echo.

Operands The following operand is supported:

<i>string</i>	A string to be written to standard output. If any operand is “-n”, it is treated as a string, not an option. The following character sequences is recognized within any of the arguments:
\a	Alert character.
\b	Backspace.
\c	Print line without new-line. All characters following the \c in the argument are ignored.
\f	Form-feed.
\n	New-line.
\r	Carriage return.
\t	Tab.
\v	Vertical tab.
\\	Backslash.
\0 <i>n</i>	Where <i>n</i> is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.

Usage Portable applications should not use -n (as the first argument) or escape sequences.

The [printf\(1\)](#) utility can be used portably to emulate any of the traditional behaviors of the echo utility as follows:

- The Solaris 2.6 operating environment or compatible version's `/usr/bin/echo` is equivalent to:

```
printf "%b\n" "$*
```

- The `/usr/ucb/echo` is equivalent to:

```
if [ "X$1" = "X-n" ]  
  
then  
  
    shift  
  
    printf "%s" "$*  
  
else  
  
    printf "%s\n" "$*  
  
fi
```

New applications are encouraged to use `printf` instead of `echo`.

Examples **EXAMPLE 1** Finding how far below root your current directory is located

You can use `echo` to determine how many subdirectories below the root directory (`/`) is your current directory, as follows:

- Echo your current-working-directory's full pathname.
- Pipe the output through `tr` to translate the path's embedded slash-characters into space-characters.
- Pipe that output through `wc -w` for a count of the names in your path.

```
example% /usr/bin/echo $PWD | tr '/' ' ' | wc -w
```

See [tr\(1\)](#) and [wc\(1\)](#) for their functionality.

Below are the different flavors for echoing a string without a NEWLINE:

EXAMPLE 2 `/usr/bin/echo`

```
example% /usr/bin/echo "$USER's current directory is $PWD\c"
```

EXAMPLE 3 `sh/ksh shells`

```
example$ echo "$USER's current directory is $PWD\c"
```

EXAMPLE 4 `csh shell`

```
example% echo -n "$USER's current directory is $PWD"
```

```
EXAMPLE5 /usr/ucb/echo
example% /usr/ucb/echo -n "$USER's current directory is $PWD"
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of echo: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

SYSV3 This environment variable is used to provide compatibility with INTERACTIVE UNIX System and SCO UNIX installation scripts. It is intended for compatibility only and should not be used in new scripts. This variable is applicable only for Solaris x86 platforms, not Solaris SPARC systems.

Exit Status The following error values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

See Also [echo\(1B\)](#), [printf\(1\)](#), [shell_builtins\(1\)](#), [tr\(1\)](#), [wc\(1\)](#), [ascii\(5\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes When representing an 8-bit character by using the escape convention `\0n`, the *n* must *always* be preceded by the digit zero (0).

For example, typing: `echo 'WARNING:\ 07'` prints the phrase WARNING: and sounds the “bell” on your terminal. The use of single (or double) quotes (or two backslashes) is required to protect the “\” that precedes the “07”.

Following the `\0`, up to three digits are used in constructing the octal output character. If, following the `\0n`, you want to echo additional digits that are not part of the octal representation, you must use the full 3-digit *n*. For example, if you want to echo “ESC 7” you must use the three digits “033” rather than just the two digits “33” after the `\ 0`.

```
2 digits      Incorrect:    echo "\0337" | od -xc
                produces:    df0a                                (hex)
                337                                (ascii)

3 digits      Correct:      echo "\00337" | od -xc
                produces:    lb37 0a00                            (hex)
                033 7                                (ascii)
```

For the octal equivalents of each character, see [ascii\(5\)](#).

Name echo – echo arguments to standard output

Synopsis /usr/ucb/echo [-n] [*argument*]

Description echo writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output.

echo is useful for producing diagnostics in command files and for sending known data into a pipe, and for displaying the contents of environment variables.

For example, you can use echo to determine how many subdirectories below the root directory (/) is your current directory, as follows:

- echo your current-working-directory's full pathname
- pipe the output through tr to translate the path's embedded slash-characters into space-characters
- pipe that output through wc -w for a count of the names in your path.

example% /usr/bin/echo "echo \$PWD | tr '/' ' ' | wc -w"

See [tr\(1\)](#) and [wc\(1\)](#) for their functionality.

The shells [csh\(1\)](#), [ksh\(1\)](#), and [sh\(1\)](#), each have an echo built-in command, which, by default, will have precedence, and will be invoked if the user calls echo without a full pathname. /usr/ucb/echo and csh's echo() have an -n option, but do not understand back-slashed escape characters. sh's echo(), ksh's echo(), and /usr/bin/echo, on the other hand, understand the black-slashed escape characters, and ksh's echo() also understands \a as the audible bell character; however, these commands do not have an -n option.

Options -n Do not add the NEWLINE to the output.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

See Also [csh\(1\)](#), [echo\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [tr\(1\)](#), [wc\(1\)](#), [attributes\(5\)](#)

Notes The -n option is a transition aid for BSD applications, and may not be supported in future releases.

Name echo – put string on virtual output

Synopsis echo [*string*] . . .

Description The echo function directs each string it is passed to the standard output. If no argument is given, echo looks to the standard input for input. It is often used in conditional execution or for passing a string to another command.

Examples **EXAMPLE 1** Using the echo command.
Set the done descriptor to help if a test fails:

```
done='if [ -s $F1 ];
      then echo close;
      else echo help;
      fi'
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [echo\(1\)](#), [attributes\(5\)](#)

Name ed, red – text editor

Synopsis /usr/bin/ed [-s | -] [-p *string*] [-x] [-C] [*file*]
 /usr/xpg4/bin/ed [-s | -] [-p *string*] [-x] [-C] [*file*]
 /usr/xpg6/bin/ed [-s | -] [-p *string*] [-x] [-C] [*file*]
 /usr/bin/red [-s | -] [-p *string*] [-x] [-C] [*file*]

Description The ed utility is the standard text editor. If *file* is specified, ed simulates an e command (see below) on the named file. That is, the file is read into ed's buffer so that it can be edited.

The ed utility operates on a copy of the file it is editing. Changes made to the copy have no effect on the file until a w (write) command is given. The copy of the text being edited resides in a temporary file called the *buffer*. There is only one buffer.

The red utility is a restricted version of ed. It will only allow editing of files in the current directory. red prohibits executing shell commands via *!shell command*. Attempts to bypass these restrictions result in an error message (*restricted shell*).

Both ed and red support the [fspec\(4\)](#) formatting capability. The default terminal mode is either stty - tabs or stty tab3, where tab stops are set at eight columns (see [stty\(1\)](#)). If, however, the first line of *file* contains a format specification, that specification will override the default mode. For example, tab stops would be set at 5, 10, and 15, and a maximum line length of 72 would be imposed if the first line of *file* contains

```
<: t5,10,15 s72:>
```

Commands to ed have a simple and regular structure: zero, one, or two *addresses* followed by a single-character *command*, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses can very often be omitted.

In general, only one command may appear on a line. Certain commands allow the input of text. This text is placed in the appropriate place in the buffer. While ed is accepting text, it is said to be in *input mode*. In this mode, *no* commands are recognized; all input is merely collected. Leave input mode by typing a period (.) at the beginning of a line, followed immediately by a carriage return.

/usr/bin/ed If ed executes commands with arguments, it uses the default shell /usr/bin/sh (see [sh\(1\)](#)).

/usr/xpg4/bin/ed and /usr/xpg6/bin/ed If ed executes commands with arguments, it uses /usr/xpg4/bin/sh (see [ksh\(1\)](#)).

Regular Expressions The ed utility supports a limited form of *regular expression* notation. Regular expressions are used in addresses to specify lines and in some commands (for example, s) to specify portions of a line that are to be substituted. To understand addressing in ed, it is necessary to know that at any time there is a *current line*. Generally speaking, the current line is the last line affected by a command. The exact effect on the current line is discussed under the description of each command.

Internationalized Basic Regular Expressions are used for all system-supplied locales. See [regex\(5\)](#).

ed Commands Commands may require zero, one, or two addresses. Commands that require no addresses regard the presence of an address as an error. Commands that accept one or two addresses assume default addresses when an insufficient number of addresses is given; if more addresses are given than such a command requires, the last one(s) are used.

Typically, addresses are separated from each other by a comma (,). They may also be separated by a semicolon (;). In the latter case, the first address is calculated, the current line (.) is set to that value, and then the second address is calculated. This feature can be used to determine the starting line for forward and backward searches (see Rules 5 and 6, above). The second address of any two-address sequence must correspond to a line in the buffer that follows the line corresponding to the first address.

For `/usr/xpg6/bin/ed`, the address can be omitted on either side of the comma or semicolon separator, in which case the resulting address pairs are as follows:

Specified	Resulting
,	1,\$
, addr	1, addr
addr ,	addr, addr
;	1;\$
; addr	1; addr
addr ;	addr; addr

Any *<blank>*s included between addresses, address separators, or address offsets are ignored.

In the following list of `ed` commands, the parentheses shown prior to the command are *not* part of the address. Rather, the parentheses show the default address(es) for the command.

Each address component can be preceded by zero or more blank characters. The command letter can be preceded by zero or more blank characters. If a suffix letter (l, n, or p) is given, it must immediately follow the command.

The `e`, `E`, `f`, `r`, and `w` commands take an optional *file* parameter, separated from the command letter by one or more blank characters.

If changes have been made in the buffer since the last `w` command that wrote the entire buffer, `ed` warns the user if an attempt is made to destroy the editor buffer via the `e` or `q` commands. The `ed` utility writes the string:

"?\n"

(followed by an explanatory message if *help mode* has been enabled via the H command) to standard output and continues in command mode with the current line number unchanged. If the e or q command is repeated with no intervening command, ed takes effect.

If an end-of-file is detected on standard input when a command is expected, the ed utility acts as if a q command had been entered.

It is generally illegal for more than one command to appear on a line. However, any command (except e, f, r, or w) may be suffixed by l, n, or p in which case the current line is either listed, numbered or written, respectively, as discussed below under the l, n, and p commands.

(.)a

<text>

.

The append command accepts zero or more lines of text and appends it after the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. Address 0 is legal for this command: it causes the “appended” text to be placed at the beginning of the buffer. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

(.,.)c

<text>

.

The change command deletes the addressed lines from the buffer, then accepts zero or more lines of text that replaces these lines in the buffer. The current line (.) is left at the last line input, or, if there were none, at the first line that was not deleted. If the lines deleted were originally at the end of the buffer, the current line number will be set to the address of the new last line. If no lines remain in the buffer, the current line number will be set to 0.

/usr/xpg4/bin/ed Address 0 is not legal for this command.

/usr/xpg6/bin/ed Address 0 is valid for this command. It is interpreted as if the address 1 were specified.

C Same as the X command, described later, except that ed assumes all text read in for the e and r commands is encrypted unless a null key is typed in.

(.,.)d

The delete command deletes the addressed lines from the buffer. The line after the last line deleted becomes the current line. If the lines deleted were originally at the end of the buffer, the new last line becomes the current line. If no lines remain in the buffer, the current line number will be set to 0.

e *file*

The edit command deletes the entire contents of the buffer and then reads the contents of *file* into the buffer. The current line (.) is set to the last line of the buffer. If *file* is not given, the currently remembered file name, if any, is used (see the f command). The number of bytes read will be written to standard output, unless the -s option was specified, in the following format:

`"%d\n" <number of bytes read>`

file is remembered for possible use as a default file name in subsequent `e`, `E`, `r`, and `w` commands. If *file* is replaced by `!`, the rest of the line is taken to be a shell (`sh(1)`) command whose output is to be read. Such a shell command is *not* remembered as the current file name. See also DIAGNOSTICS below. All marks are discarded upon the completion of a successful `e` command. If the buffer has changed since the last time the entire buffer was written, the user is warned, as described previously.

`E file` The Edit command is like `e`, except that the editor does not check to see if any changes have been made to the buffer since the last `w` command.

`f file` If *file* is given, the `f` command changes the currently remembered path name to *file*. Whether the name is changed or not, the `f` command then writes the (possibly new) currently remembered path name to the standard output in the following format:

`"%s\n"pathname`

The current line number is unchanged.

`(1,$)g/RE/command list` In the global command, the first step is to mark every line that matches the given *RE*. Then, for every such line, the given *command list* is executed with the current line (`.`) initially set to that line. When the `g` command completes, the current line number has the value assigned by the last command in the *command list*. If there were no matching lines, the current line number is not changed. A single command or the first of a list of commands appears on the same line as the global command. All lines of a multi-line list except the last line must be ended with a backslash (`\`); `a`, `i`, and `c` commands and associated input are permitted. The `.` terminating input mode may be omitted if it would be the last line of the *command list*. An empty *command list* is equivalent to the `p` command. The `g`, `G`, `v`, `V`, and `!` commands are *not* permitted in the *command list*. See also the NOTES and the last paragraph before FILES below. Any character other than space or newline can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

`(1,$)G/RE/` In the interactive Global command, the first step is to mark every line that matches the given *RE*. Then, for every such line, that line is written to standard output, the current line (`.`) is changed to that line, and any *one* command (other than one of

the a, c, i, g, G, v, and V commands) may be input and is executed. After the execution of that command, the next marked line is written, and so on. A new-line acts as a null command. An & causes the re-execution of the most recent non-null command executed within the current invocation of G. *Note:* The commands input as part of the execution of the G command may address and affect *any* lines in the buffer. The final value of the current line number is the value set by the last command successfully executed. (Notice that the last command successfully executed is the G command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number is not changed. The G command can be terminated by a SIGINT signal. The G command can be terminated by an interrupt signal (ASCII DEL or BREAK). Any character other than space or newline can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

h The help command gives a short error message that explains the reason for the most recent ? diagnostic. The current line number is unchanged.

H The Help command causes ed to enter a mode in which error messages are written for all subsequent ? diagnostics. It also explains the previous ? if there was one. The H command alternately turns this mode on and off; it is initially off. The current line number is unchanged.

(. . .)i
<text>
.

The insert command accepts zero or more lines of text and inserts it before the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. This command differs from the a command only in the placement of the input text. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

/usr/xpg4/bin/ed Address 0 is not legal for this command.

/usr/xpg6/bin/ed Address 0 is valid for this command. It is interpreted as if the address 1 were specified.

(.,.+1)j	The join command joins contiguous lines by removing the appropriate new-line characters. If exactly one address is given, this command does nothing. If lines are joined, the current line number is set to the address of the joined line. Otherwise, the current line number is unchanged.
(.)kx	The mark command marks the addressed line with name <i>x</i> , which must be an ASCII lower-case letter (a-z). The address <i>x</i> then addresses this line. The current line (.) is unchanged.
(.,.)l	The <i>l</i> command writes to standard output the addressed lines in a visually unambiguous form. The characters (\\, \a, \b, \f, \r, \t, \v) are written as the corresponding escape sequence. The \n in that table is not applicable. Non-printable characters not in the table are written as one three-digit octal number (with a preceding backslash character) for each byte in the character, with the most significant byte first. Long lines are folded, with the point of folding indicated by writing backslash/newline character. The length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line is marked with a \$. When using the /usr/xpg6/bin/ed command, the end of each line is marked with a \$ due to folding, and \$ characters within the text are written with a preceding backslash. An <i>l</i> command can be appended to any other command other than e, E, f, q, Q, r, w, or !. The current line number is set to the address of the last line written.
(.,.)ma	The move command repositions the addressed line(s) after the line addressed by <i>a</i> . Address 0 is legal for <i>a</i> and causes the addressed line(s) to be moved to the beginning of the file. It is an error if address <i>a</i> falls within the range of moved lines. The current line (.) is left at the last line moved.
(.,.)n	The number command writes the addressed lines, preceding each line by its line number and a tab character. The current line (.) is left at the last line written. The <i>n</i> command may be appended to any command other than e, E, f, q, Q, r, w, or !.
(.,.)p	The print command writes the addressed lines to standard output. The current line (.) is left at the last line written. The <i>p</i> command may be appended to any command other than e, E, f, q, Q, r, w, or !. For example, <i>dp</i> deletes the current line and writes the new current line.

P	The P command causes ed to prompt with an asterisk (*) (or <i>string</i> , if -p is specified) for all subsequent commands. The P command alternatively turns this mode on and off; it is initially on if the -p option is specified, otherwise off. The current line is unchanged.
q	The quit command causes ed to exit. If the buffer has changed since the last time the entire buffer was written, the user is warned. See DIAGNOSTICS.
Q	The editor exits without checking if changes have been made in the buffer since the last w command.
(<i>\$</i>) r <i>file</i>	<p>The read command reads the contents of <i>file</i> into the buffer. If <i>file</i> is not given, the currently remembered file name, if any, is used (see the e and f commands). The currently remembered file name is <i>not</i> changed unless <i>file</i> is the very first file name mentioned since ed was invoked. Address 0 is legal for r and causes the file to be read in at the beginning of the buffer. If the read is successful and the -s option was not specified, the number of characters read is written to standard output in the following format:</p> <pre>%d\n, <number of bytes read></pre> <p>The current line (.) is set to the last line read. If <i>file</i> is replaced by !, the rest of the line is taken to be a shell command (see sh(1)) whose output is to be read. For example, \$r !ls appends the current directory to the end of the file being edited. Such a shell command is <i>not</i> remembered as the current file name.</p>
(. . .) s/RE/replacement/	<p>The substitute command searches each addressed line for an occurrence of the specified RE. Zero or more substitution commands can be specified. In each line in which a match is found, all (non-overlapped) matched strings are replaced by the <i>replacement</i> if the global replacement indicator g appears after the command. If the global indicator does not appear, only the first occurrence of the matched string is</p>
(. . .) s/RE/replacement/count, count=[1-2047]	
(. . .) s/RE/replacement/g	
(. . .) s/RE/replacement/\	
(. . .) s/RE/replacement/n	
(. . .) s/RE/replacement/p	

replaced. If a number *count* appears after the command, only the *count*-th occurrence of the matched string on each addressed line is replaced. It is an error if the substitution fails on *all* addressed lines. Any character other than space or new-line may be used instead of the slash (/) to delimit the *RE* and the *replacement*. The current line (.) is left at the last line on which a substitution occurred. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash. See also the last paragraph before FILES below.

An ampersand (&) appearing in the *replacement* is replaced by the string matching the *RE* on the current line. The special meaning of & in this context may be suppressed by preceding it by \. As a more general feature, the characters \n, where *n* is a digit, are replaced by the text matched by the *n*-th regular subexpression of the specified *RE* enclosed between \(and \). When nested parenthesized subexpressions are present, *n* is determined by counting occurrences of \(starting from the left. When the character % is the only character in the *replacement*, the *replacement* used in the most recent substitute command is used as the *replacement* in the current substitute command. If there was no previous substitute command, the use of % in this manner is an error. The % loses its special meaning when it is in a replacement string of more than one character or is preceded by a \. For each backslash (\) encountered in scanning *replacement* from beginning to end, the following character loses its special meaning (if any). It is unspecified what special

meaning is given to any character other than `&`, `\`, `%`, or digits.

A line may be split by substituting a new-line character into it. The new-line in the *replacement* must be escaped by preceding it by `\`. Such substitution cannot be done as part of a `g` or `v` command list. The current line number is set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number is unchanged. If a line is split, a substitution is considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.

The substitute command supports the following indicators:

- | | |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i> | Substitute for the <i>count</i> th occurrence only of the <i>RE</i> found on each addressed line. <i>count</i> must be between 1-2047. |
| <i>g</i> | Globally substitute for all non-overlapping instances of the <i>RE</i> rather than just the first one. If both <i>g</i> and <i>count</i> are specified, the results are unspecified. |
| <i>l</i> | Write to standard output the final line in which a substitution was made. The line is written in the format specified for the <i>l</i> command. |
| <i>n</i> | Write to standard output the final line in which a substitution was made. The |

	line is written in the format specified for the <code>n</code> command.
<code>p</code>	Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the <code>p</code> command.
<code>(.,.)ta</code>	This command acts just like the <code>m</code> command, except that a <i>copy</i> of the addressed lines is placed after address <code>a</code> (which may be 0). The current line <code>(.)</code> is left at the last line copied.
<code>u</code>	The undo command nullifies the effect of the most recent command that modified anything in the buffer, namely the most recent <code>a</code> , <code>c</code> , <code>d</code> , <code>g</code> , <code>i</code> , <code>j</code> , <code>m</code> , <code>r</code> , <code>s</code> , <code>t</code> , <code>u</code> , <code>v</code> , <code>G</code> , or <code>V</code> command. All changes made to the buffer by a <code>g</code> , <code>v</code> , or <code>V</code> global command is undone as a single change. If no changes were made by the global command (such as with <code>g/RE/p</code>), the <code>u</code> command has no effect. The current line number is set to the value it had immediately before the command being undone started.
<code>(1,\$)v/RE/command list</code>	This command is the same as the global command <code>g</code> , except that the lines marked during the first step are those that do <i>not</i> match the <i>RE</i> .
<code>(1,\$)V/RE/</code>	This command is the same as the interactive global command <code>G</code> , except that the lines that are marked during the first step are those that do <i>not</i> match the <i>RE</i> .
<code>(1,\$)w file</code>	The write command writes the addressed lines into <i>file</i> . If <i>file</i> does not exist, it is created with mode 666 (readable and writable by everyone), unless your file creation mask dictates otherwise. See the

description of the `umask` special command on [sh\(1\)](#). The currently remembered file name is *not* changed unless *file* is the very first file name mentioned since `ed` was invoked. If no file name is given, the currently remembered file name, if any, is used (see the `e` and `f` commands). The current line (`.`) is unchanged. If the command is successful, the number of characters written is printed, unless the `-s` option is specified in the following format:

`"%d\n", <number of bytes written>`

If *file* is replaced by `!`, the rest of the line is taken to be a shell (see [sh\(1\)](#)) command whose standard input is the addressed lines. Such a shell command is *not* remembered as the current path name. This usage of the write command with `!` is to be considered as a "last w command that wrote the entire buffer".

`(1, $)W file`

This command is the same as the `w` command above, except that it appends the addressed lines to the end of *file* if it exists. If *file* does not exist, it is created as described above for the `w` command.

`X`

An educated guess is made to determine whether text read for the `e` and `r` commands is encrypted. A null key turns off encryption. Subsequent `e`, `r`, and `w` commands will use this key to encrypt or decrypt the text. An explicitly empty key turns off encryption. Also, see the `-x` option of `ed`.

`($) =`

The line number of the addressed line is written to standard output in the following format:

`"%d\n" <line number>`

The current line number is unchanged by this command.

`!shell command`

The remainder of the line after the `!` is sent to the UNIX system shell (see [sh\(1\)](#)) to be interpreted as a command. Within the text of that command, the unescaped character `%` is replaced with the remembered file name. If a `!` appears as the first character of the shell command, it is replaced with the text of the previous shell command. Thus, `!!` repeats the last shell command. If any replacements of `%` or `!` are performed, the

modified line is written to the standard output before *command* is executed. The `!` command will write:

```
"!\n"
```

to standard output upon completion, unless the `-s` option is specified. The current line number is unchanged.

(`.+1`)<new-line> An address alone on a line causes the addressed line to be written. A new-line alone is equivalent to `.+1p`. It is useful for stepping forward through the buffer. The current line number will be set to the address of the written line.

If an interrupt signal (ASCII DEL or BREAK) is sent, ed writes a `"?\n"` and returns to *its* command level.

The ed utility takes the standard action for all signals with the following exceptions:

SIGINT	The ed utility interrupts its current activity, writes the string <code>"?\n"</code> to standard output, and returns to command mode.
SIGHUP	If the buffer is not empty and has changed since the last write, the ed utility attempts to write a copy of the buffer in a file. First, the file named <code>ed.hup</code> in the current directory is used. If that fails, the file named <code>ed.hup</code> in the directory named by the <code>HOME</code> environment variable is used. In any case, the ed utility exits without returning to command mode.

Some size limitations are in effect: 512 characters in a line, 256 characters in a global command list, and 255 characters in the path name of a file (counting slashes). The limit on the number of lines depends on the amount of user memory. Each line takes 1 word.

When reading a file, ed discards ASCII and NUL characters.

If a file is not terminated by a new-line character, ed adds one and puts out a message explaining what it did.

If the closing delimiter of an RE or of a replacement string (for example, `/`) would be the last character before a new-line, that delimiter may be omitted, in which case the addressed line is written. The following pairs of commands are equivalent:

<code>s/s1/s2</code>	<code>s/s1/s2/p</code>
<code>g/s1</code>	<code>g/s1/p</code>
<code>?s1</code>	<code>?s1?</code>

If an invalid command is entered, ed writes the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled by the H command) to standard output and continues in command mode with the current line number unchanged.

- Options**
- C Encryption option. The same as the -x option, except that ed simulates a C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.
 - pstring Allows the user to specify a prompt string. By default, there is no prompt string.
 - s | - ; Suppresses the writing of character counts by e, r, and w commands, of diagnostics from e and q commands, and of the ! prompt after a *!shell command*.
 - x Encryption option. When -x is used, ed simulates an X command and prompts the user for a key. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the -x option. See NOTES.

Operands The following operand is supported:

file If *file* is specified, ed simulates an e command on the file named by the path name *file* before accepting commands from the standard input.

Usage See [largefile\(5\)](#) for the description of the behavior of ed and red when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ed: HOME, LANG, LC_ALL, LC_CTYPE, LC_COLLATE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 Successful completion without any file or command errors.
- >0 An error occurred.

Files

- \$TMPDIR If this environment variable is not NULL, its value is used in place of /var/tmp as the directory name for the temporary work file.
- /var/tmp If /var/tmp exists, it is used as the directory name for the temporary work file.
- /tmp If the environment variable TMPDIR does not exist or is NULL, and if /var/tmp does not exist, then /tmp is used as the directory name for the temporary work file.
- ed.hup Work is saved here if the terminal is hung up.

Diagnostics [?](#) for command errors.
[?file](#) for an inaccessible file. Use the help and Help commands for detailed explanations.

If changes have been made in the buffer since the last `w` command that wrote the entire buffer, `ed` warns the user if an attempt is made to destroy `ed`'s buffer via the `e` or `q` commands. It writes `?` and allows one to continue editing. A second `e` or `q` command at this point will take effect. The `-s` command-line option inhibits this feature.

Notes The `-` option, although it continues to be supported, has been replaced in the documentation by the `-s` option that follows the Command Syntax Standard (see [Intro\(1\)](#)).

A `!` command cannot be subject to a `g` or a `v` command.

The `!` command and the `!` escape from the `e`, `r`, and `w` commands cannot be used if the editor is invoked from a restricted shell (see [sh\(1\)](#)).

The sequence `\n` in an RE does not match a new-line character.

If the editor input is coming from a command file (for example, `ed file < ed_cmd_file`), the editor exits at the first failure.

Loading an alternate `malloc()` library using the environment variable `LD_PRELOAD` can cause problems for `/usr/bin/ed`.

Name edit – text editor (variant of ex for casual users)

Synopsis /usr/bin/edit [-] [-s] [-l] [-L] [-R] [-r *filename*]
 [-t *tag*] [-v] [-V] [-x] [-wn] [-C]
 [+*command* | -c *command*] *filename*...

/usr/xpg4/bin/edit [-] [-s] [-l] [-L] [-R] [-r *filename*]
 [-t *tag*] [-v] [-V] [-x] [-wn] [-C]
 [+*command* | -c *command*] *filename*...

/usr/xpg6/bin/edit [-] [-s] [-l] [-L] [-R] [-r *filename*]
 [-t *tag*] [-v] [-V] [-x] [-wn] [-C]
 [+*command* | -c *command*] *filename*...

Description The `edit` utility is a variant of the text editor `ex` recommended for new or casual users who wish to use a command-oriented editor. It operates precisely as `ex` with the following options automatically set:

novice	ON
report	ON
showmode	ON
magic	OFF

The following brief introduction should help you get started with `edit`. If you are using a CRT terminal you might want to learn about the display editor `vi`.

To edit the contents of an existing file you begin with the command `edit name` to the shell. `edit` makes a copy of the file that you can then edit, and tells you how many lines and characters are in the file. To create a new file, you also begin with the command `edit` with a filename: `edit name`; the editor tells you it is a [New File].

The `edit` command prompt is the colon (:), which you should see after starting the editor. If you are editing an existing file, then you have some lines in `edit`'s buffer (its name for the copy of the file you are editing). When you start editing, `edit` makes the last line of the file the current line. Most commands to `edit` use the current line if you do not tell them which line to use. Thus if you say `print` (which can be abbreviated `p`) and type carriage return (as you should after all `edit` commands), the current line is printed. If you `delete` (`d`) the current line, `edit` prints the new current line, which is usually the next line in the file. If you `delete` the last line, then the new last line becomes the current one.

If you start with an empty file or wish to add some new lines, then the `append` (`a`) command can be used. After you execute this command (typing a carriage return after the word `append`), `edit` reads lines from your terminal until you type a line consisting of just a dot (.); it places these lines after the current line. The last line you type then becomes the current line. The `insert` (`i`) command is like `append`, but places the lines you type before, rather than after, the current line.

The `edit` utility numbers the lines in the buffer, with the first line having number 1. If you execute the command `1`, then `edit` types the first line of the buffer. If you then execute the command `d`, `edit` deletes the first line, line 2 becomes line 1, and `edit` prints the current line (the new line 1) so you can see where you are. In general, the current line is always the last line affected by a command.

You can make a change to some text within the current line by using the `substitute (s)` command: `s/old /new/` where *old* is the string of characters you want to replace and *new* is the string of characters you want to replace *old* with.

The `filename (f)` command tells you how many lines there are in the buffer you are editing and says [Modified] if you have changed the buffer. After modifying a file, you can save the contents of the file by executing a `write (w)` command. You can leave the editor by issuing a `quit (q)` command. If you run `edit` on a file, but do not change it, it is not necessary (but does no harm) to write the file back. If you try to quit from `edit` after modifying the buffer without writing it out, you receive the message `No write since last change (:quit! overrides)`, and `edit` waits for another command. If you do not want to write the buffer out, issue the `quit` command followed by an exclamation point (`q!`). The buffer is then irretrievably discarded and you return to the shell.

By using the `d` and `a` commands and giving line numbers to see lines in the file, you can make any changes you want. You should learn at least a few more things, however, if you use `edit` more than a few times.

The `change (c)` command changes the current line to a sequence of lines you supply (as in `append`, you type lines up to a line consisting of only a dot `.`). You can tell `change` to change more than one line by giving the line numbers of the lines you want to change, that is, `3,5c`. You can print lines this way too: `1,23p` prints the first 23 lines of the file.

The `undo (u)` command reverses the effect of the last command you executed that changed the buffer. Thus if you execute a `substitute` command that does not do what you want, type `u` and the old contents of the line are restored. You can also undo an `undo` command. `edit` gives you a warning message when a command affects more than one line of the buffer. Note that commands such as `write` and `quit` cannot be undone.

To look at the next line in the buffer, type carriage return. To look at a number of lines, type `^D` (while holding down the control key, press `d`) rather than carriage return. This shows you a half-screen of lines on a CRT or 12 lines on a hardcopy terminal. You can look at nearby text by executing the `z` command. The current line appears in the middle of the text displayed, and the last line displayed becomes the current line; you can get back to the line where you were before you executed the `z` command by typing `''`. The `z` command has other options: `z-` prints a screen of text (or 24 lines) ending where you are; `z+` prints the next screenful. If you want less than a screenful of lines, type `z.n` to display five lines before and five lines after the current line. (Typing `z.n`, when *n* is an odd number, displays a total of *n* lines, centered about the current line; when *n* is an even number, it displays *n* - 1 lines, so that the lines displayed are

centered around the current line.) You can give counts after other commands; for example, you can delete 5 lines starting with the current line with the command `d5`.

To find things in the file, you can use line numbers if you happen to know them; since the line numbers change when you insert and delete lines this is somewhat unreliable. You can search backwards and forwards in the file for strings by giving commands of the form `/text/` to search forward for *text* or `?text?` to search backward for *text*. If a search reaches the end of the file without finding *text*, it wraps around and continues to search back to the line where you are. A useful feature here is a search of the form `/^text/` which searches for *text* at the beginning of a line. Similarly `/text$/` searches for *text* at the end of a line. You can leave off the trailing `/` or `?` in these commands.

The current line has the symbolic name `dot (.)`; this is most useful in a range of lines as in `., $p` which prints the current line plus the rest of the lines in the file. To move to the last line in the file, you can refer to it by its symbolic name `$`. Thus the command `$d` deletes the last line in the file, no matter what the current line is. Arithmetic with line references is also possible. Thus the line `$-5` is the fifth before the last and `.+20` is 20 lines after the current line.

You can find out the current line by typing `.' = '`. This is useful if you wish to move or copy a section of text within a file or between files. Find the first and last line numbers you wish to copy or move. To move lines 10 through 20, type `10, 20d a` to delete these lines from the file and place them in a buffer named `a`. `edit` has 26 such buffers named `a` through `z`. To put the contents of buffer `a` after the current line, type `put a`. If you want to move or copy these lines to another file, execute an `edit (e)` command after copying the lines; following the `e` command with the name of the other file you wish to edit, that is, `edit chapter2`. To copy lines without deleting them, use `yank (y)` in place of `d`. If the text you wish to move or copy is all within one file, it is not necessary to use named buffers. For example, to move lines 10 through 20 to the end of the file, type `10, 20m $`.

Options These options can be turned on or off using the `set` command in [ex\(1\)](#).

- | | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -C | Encryption option; same as the <code>-x</code> option, except that <code>vi</code> simulates the <code>C</code> command of <code>ex</code> . The <code>C</code> command is like the <code>X</code> command of <code>ex</code> , except that all text read in is assumed to have been encrypted. |
| -l | Set up for editing LISP programs. |
| -L | List the name of all files saved as the result of an editor or system crash. |
| -R | Readonly mode; the <code>readonly</code> flag is set, preventing accidental overwriting of the file. |
| -r <i>filename</i> | Edit <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.) |

- t tag

Edit the file containing the *tag* and position the editor at its definition.
- v

Start up in display editing state using vi. You can achieve the same effect by simply typing the vi command itself.
- V

Verbose. When ex commands are read by means of standard input, the input is echoed to standard error. This can be useful when processing ex commands within shell scripts.
- x

Encryption option; when used, edit simulates the X command of ex and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the -x option.
- wn

Set the default window size to *n*. This is useful when using the editor over a slow speed line.
- +command | -c command

Begin editing by executing the specified editor command (usually a search or positioning command).
- | -s

Suppress all interactive user feedback. This is useful when processing editor scripts.

The *filename* argument indicates one or more files to be edited.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Notes The encryption options are provided with the Security Administration Utilities package, which is available only in the United States.

Name egrep – search a file for a pattern using full regular expressions

Synopsis `/usr/bin/egrep [-bchilnsv] -e pattern_list [file...]`
`/usr/bin/egrep [-bchilnsv] -f file [file...]`
`/usr/bin/egrep [-bchilnsv] pattern [file...]`
`/usr/xpg4/bin/egrep [-bchilnqsvx] -e pattern_list [-f file]`
`[file...]`
`/usr/xpg4/bin/egrep [-bchilnqsvx] [-e pattern_list] -f file`
`[file...]`
`/usr/xpg4/bin/egrep [-bchilnqsvx] pattern [file...]`

Description The egrep (*expression grep*) utility searches files for a pattern of characters and prints all lines that contain that pattern. egrep uses full regular expressions (expressions that have string values that use the full set of alphanumeric and special characters) to match the patterns. It uses a fast deterministic algorithm that sometimes needs exponential space.

If no files are specified, egrep assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.

`/usr/bin/egrep` The `/usr/bin/egrep` utility accepts full regular expressions as described on the [regex\(5\)](#) manual page, except for `\(` and `\)`, `\(` and `\)`, `\{` and `\}`, `\<` and `\>`, and `\n`, and with the addition of:

1. A full regular expression followed by `+` that matches one or more occurrences of the full regular expression.
2. A full regular expression followed by `?` that matches 0 or 1 occurrences of the full regular expression.
3. Full regular expressions separated by `|` or by a NEWLINE that match strings that are matched by any of the expressions.
4. A full regular expression that can be enclosed in parentheses `()` for grouping.

Be careful using the characters `$`, `*`, `[`, `^`, `|`, `(`, `)`, and `\` in *full regular expression*, because they are also meaningful to the shell. It is safest to enclose the entire *full regular expression* in single quotes (`' '`).

The order of precedence of operators is `[]`, then `*` `?` `+`, then concatenation, then `|` and NEWLINE.

`/usr/xpg4/bin/egrep` The `/usr/xpg4/bin/egrep` utility uses the regular expressions described in the EXTENDED REGULAR EXPRESSIONS section of the [regex\(5\)](#) manual page.

Options The following options are supported for both `/usr/bin/egrep` and `/usr/xpg4/bin/egrep`:

- b Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
- c Print only a count of the lines that contain the pattern.
- e *pattern_list* Search for a *pattern_list* (*full regular expression* that begins with a `—`).
- f *file* Take the list of *full regular expressions* from *file*.
- h Suppress printing of filenames when searching multiple files.
- i Ignore upper/lower case distinction during comparisons.
- l Print the names of files with matching lines once, separated by NEWLINES. Does not repeat the names of files when the pattern is found more than once.
- n Precede each line by its line number in the file (first line is 1).
- s Work silently, that is, display nothing except error messages. This is useful for checking the error status.
- v Print all lines except those that contain the pattern.

`/usr/xpg4/bin/egrep` The following options are supported for `/usr/xpg4/bin/egrep` only:

- q Quiet. Does not write anything to the standard output, regardless of matching lines. Exits with zero status if an input line is selected.
- x Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

Operands The following operands are supported:

file A path name of a file to be searched for the patterns. If no *file* operands are specified, the standard input is used.

`/usr/bin/egrep` *pattern* Specify a pattern to be used during the search for input.

`/usr/xpg4/bin/egrep` *pattern* Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as `-epattern_list..`

Usage See [largefile\(5\)](#) for the description of the behavior of `egrep` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `egrep`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 If any matches are found.

- 1 If no matches are found.
- 2 For syntax errors or inaccessible files (even if matches were found).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/egrep	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcsu
	CSI	Not Enabled

/usr/xpg4/bin/egrep	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	CSI	Enabled

See Also [fgrep\(1\)](#), [grep\(1\)](#), [sed\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [regexp\(5\)](#), [XPG4\(5\)](#)

Notes Ideally there should be only one `grep` command, but there is not a single algorithm that spans a wide enough range of space-time tradeoffs.

Lines are limited only by the size of the available virtual memory.

/usr/xpg4/bin/egrep The `/usr/xpg4/bin/egrep` utility is identical to `/usr/xpg4/bin/grep -E` (see [grep\(1\)](#)). Portable applications should use `/usr/xpg4/bin/grep -E`.

Name eject – eject media such as CD-ROM and floppy from drive

Synopsis eject [-dfnpq] [*device* | *nickname*]

Description The eject utility is used for those removable media devices that do not have a manual eject button, or for those that do, but are managed by Volume Management (see [vold\(1M\)](#)). The device may be specified by its name or by a nickname; if Volume Management is running and no device is specified, the default device is used.

Only devices that support eject under program control respond to this command. eject responds differently, depending on whether or not Volume Management is running.

With Volume Management When eject is used on media that can only be ejected manually, it will do everything except remove the media, including unmounting the file system if it is mounted. In this case, eject displays a message that the media can now be manually ejected. If a window system is running, the message is displayed as a pop-up window, unless the -p option is supplied. If no window system is running or the -p option is supplied, a message is displayed both to stderr and to the system console that the media can now be physically removed.

Volume Management has the concept of a default device, which eject uses if no pathname or nickname is specified. Use the -d option to check what default device will be used.

Without Volume Management When Volume Management is not running and a pathname is specified, eject sends the eject command to that pathname. If a nickname is supplied instead of a pathname, eject will recognize the following list:

Nickname	Path
fd	/dev/rdiskette
fd0	/dev/rdiskette
fd1	/dev/rdiskette1
diskette	/dev/rdiskette
diskette0	/dev/rdiskette0
diskette1	/dev/rdiskette1
rdiskette	/dev/rdiskette
rdiskette0	/dev/rdiskette0
rdiskette1	/dev/rdiskette1
floppy	/dev/rdiskette
floppy0	/dev/rdiskette0
floppy1	/dev/rdiskette1

The list above can be reproduced with the `-n` option.

Do not physically eject media from a device which contains mounted file systems. `eject` automatically searches for any mounted file systems which reside on the device and attempts to unmount them prior to ejecting the media (see `mount(1M)`). If the unmount operation fails, `eject` prints a warning message and exits. The `-f` option may be used to specify an eject even if the device contains mounted partitions; this option works only if Volume Management is not running.

`eject` can also display its default device and a list of nicknames.

If you have inserted a floppy diskette, you must use `volcheck(1)` before ejecting the media to inform Volume Management of the floppy's presence.

Options The following options are supported:

- `-d` Displays the name of the default device to be ejected.
- `-f` Forces the device to eject even if it is busy, if Volume Management is *not* running.
- `-n` Displays the nickname to device name translation table.
- `-p` Does not try to call the `eject_popup` program.
- `-q` Queries to see if the media is present.

Operands The following operands are supported:

- device* Specifies which device to eject, by the name it appears in the directory `/dev`.
- nickname* Specifies which device to eject, by its nickname as known to this command.

Examples **EXAMPLE 1** Ejecting a CD while Volume Management is running

To eject a CD from its drive, while Volume Management is running (assuming only one CD-ROM drive):

```
example> eject cdrom0
```

EXAMPLE 2 Ejecting a CD-ROM without running Volume Management

To eject a CD-ROM drive with pathname `/dev/dsk/c0t3d0s2`, without Volume Management running:

```
example> eject /dev/dsk/c0t3d0s2
```

EXAMPLE 3 Ejecting a floppy disk

To eject a floppy disk (whether or not Volume Management is running):

```
example> eject floppy0
```

- Exit Status** The following exit codes are returned:
- 0 The operation was successful or, with the -q option, the media *is* in the drive.
 - 1 The operation was unsuccessful or, with the -q option, the media is *not* in the drive.
 - 2 Invalid options were specified.
 - 3 An `ioctl()` request failed.
 - 4 Manually ejectable media is now okay to remove.

Files

<code>/dev/diskette0</code>	default diskette file
<code>/dev/sr0</code>	default CD-ROM file (deprecated)
<code>/dev/dsk/c0t6d0s2</code>	default CD-ROM file
<code>/usr/lib/vold/eject_popup</code>	popup used for manually ejected media

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also [volcancel\(1\)](#), [volcheck\(1\)](#), [volmissing\(1\)](#), [mount\(1M\)](#), [rmmount\(1M\)](#), [vold\(1M\)](#), [ioctl\(2\)](#), [rmmount.conf\(4\)](#), [vold.conf\(4\)](#), [attributes\(5\)](#), [volfs\(7FS\)](#)

Diagnostics A short help message is printed if an unknown option is specified. A diagnostic is printed if the device name cannot be opened or does not support `eject`.

Device Busy An attempt was made to eject a device that has a mounted file system. A warning message is printed when doing a forced eject of a mounted device.

Bugs There should be a way to change the default on a per-user basis.

If Volume Management is not running, it is possible to eject a volume that is currently mounted (see [mount\(1M\)](#)). For example, if you have a CD-ROM drive at `/dev/dsk/c0t3d0s2` mounted on `/mnt`, the following command (without Volume Management running) will work:

example> `eject /dev/dsk/c0t3d0s0`

since both slices `s0` and `s2` reference the whole CD-ROM drive.

Name elfdump – dumps selected parts of an object file

Synopsis elfdump [-cCdegGhHiklmnprrsuvy] [-N *name*] [-w *file*] *filename...*

Description The `elfdump` utility symbolically dumps selected parts of the specified object file(s). The options allow specific portions of the file to be displayed.

The `elfdump` utility is similar in function to the [dump\(1\)](#) utility. The `dump` utility offers an older and less user-friendly interface than `elfdump`, although `dump` might be more appropriate for certain uses such as in shell scripts.

Archive files, produced by [ar\(1\)](#), can also be inspected with `elfdump`. In this case, each object within the archive is processed using the options supplied.

For a complete description of the displayed information, refer to the [Linker and Libraries Guide](#).

Options The following options are supported:

- c Dumps section header information.
- C Demangles C++ symbol names.
- d Dumps the contents of the `.dynamic` section.
- e Dumps the ELF header.
- g Dumps the contents of the `.group` section.
- G Dumps the contents of the `.got` section.
- h Dumps the contents of the `.hash` section.
- H Dumps the contents of the `.SUNW_cap` hardware and software capabilities section.
- i Dumps the contents of the `.interp` section.
- k Calculates the ELF checksum. See [gelf_checksum\(3ELF\)](#).
- l Displays long section names without truncation.
- m Dumps the contents of the `.SUNW_move` section.
- n Dumps the contents of the `.note` section.
- N *name* Qualifies an option with a specific name. For example, in a file that contains more than one symbol table, the `.dynsym` table can be displayed using:

example% `elfdump -s -N .dynsym filename`
- p Dumps the program headers.
- r Dumps the contents of the `.rel[a]` relocation sections.

- s Dumps the contents of the .dysym and .symtab symbol table sections. For archives, the archive symbol table is also dumped. Individual sections can be specified with the -N option. An archive symbol table can be specified using the special section name -N ARSYM.

In the case of core files, the shndx field will have the value “unknown” since the field does not contain the valid values.

In addition to the standard symbol table information, the version definition index of the symbol is also provided under the *ver* heading.
- u Dumps the contents of a frame unwind.
- v Dumps the contents of the .SUNW_version version sections.
- w *file* Writes the contents of a section that is specified with the -N option, to the named file. For example, extracting the .text section of a file can be carried out with:

example% **elfdump -w text.out -N .text filename**
- y Dumps the contents of the .SUNW_syminfo section.

Operands The following operand is supported:

filename The name of the specified object file.

Files liblddbg.so linker debugging library

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Linker and Libraries Guide

Name elfsign – sign binaries

Synopsis /usr/bin/elfsign sign [-a] [-v] -k *private_key* -c *certificate_file*
 -e *elf_object* [-F *format*] [*file*]...

/usr/bin/elfsign sign [-a] [-v] -c *certificate_file*
 -e *elf_object* -T *token_label* [-P *pin_file*] [-F *format*] [*file*]...

/usr/bin/elfsign verify [-c *certificate_file*]
 [-v] -e *elf_object* [*file*]...

/usr/bin/elfsign request -r *certificate_request_file*
 {-k *private_key* | -T *token_label*}

/usr/bin/elfsign list -f *field* -c *certificate_file*

/usr/bin/elfsign list -f *field* -e *elf_object*

Description

list Lists on standard output information from a single certificate file or signed elf object. The selected field appears on a single line. If the field specified does not apply to the named file, the command terminates with no standard output. This output of this subcommand is intended for use in scripts and by other commands.

request Generates a private key and a PKCS#10 certificate request. The PKCS#10 certificate request for use with the Solaris Cryptographic Framework. If the private key is to be created in a token device, elfsign prompts for the PIN required to update the token device. The PKCS#10 certificate request should be sent to the email address *solaris-crypto-req@sun.com* to obtain a Certificate.

Users of elfsign must first generate a certificate request and obtain a certificate before signing binaries for use with the Solaris Cryptographic Framework.

sign Signs the elf object, using the given private key and certificate file.

verify Verifies an existing signed object. Uses the certificate given or searches for an appropriate certificate in /etc/crypto/certs if -c is not given.

Options The following options are supported:

-a Generates a signed ELF Sign Activation (.esa) file. This option is used when a cryptographic provider has nonretail export approval for unrestricted use and desires retail approval by restricting which export sensitive callers (for example, IPsec) can use the provider. This option assumes that the provider binary has previously been signed with a restricted certificate.

-c *certificate_file* Specifies the path to an X.509 certificate in PEM/PKCS#7 or ASN.1 BER format.

-e *elf_object* Specifies the path to the object to be signed or verified.

- The `-e` option can be specified multiple times for signing or verifying multiple objects.
- F *format*** For the `sign` subcommand, specifies the format of the signature. The valid format options are
- | | |
|---------------------------|------------------------------------------------------------------------------------------|
| <code>rsa_md5_sha1</code> | Default format Solaris 10 and updates, The <code>rsa_md5_sha1</code> format is Obsolete. |
| <code>rsa_sha1</code> | Default format for this release. |
- Formats other than `rsa_md5_sha1` include an informational timestamp with the signature indicating when the signature was applied. This timestamp is not cryptographically secure, nor is it used as part of verification.
- f *field*** For the `list` subcommand, specifies what field should appear in the output.
- The valid field specifiers for a certificate file are:
- | | |
|----------------------|---------------------------------|
| <code>subject</code> | Subject DN (Distinguished Name) |
| <code>issuer</code> | Issuer DN |
- The valid field specifiers for an elf object are:
- | | |
|---------------------|----------------------------------------------------------------|
| <code>format</code> | Format of the signature |
| <code>signer</code> | Subject DN of the certificate used to sign the object |
| <code>time</code> | Time the signature was applied, in the locale's default format |
- k *private_key*** Specifies the location of the private key file when not using a PKCS#11 token. This file is an RSA Private key file in a Solaris specific format. When used with the `request` subcommand, this is the output file for the newly generated key.
- It is an error to specify both the `-k` and `-T` options.
- P *pin_file*** Specifies the file which holds the PIN for accessing the token device. If the PIN is not provided in a *pin_file*, `elfsign` prompts for the PIN.
- It is an error to specify the `-P` option without the `-T` option.
- r *certificate_request_file*** Specifies the path to the certificate request file, which is in PKCS#10 format.

-T *token_label* Specifies the label of the PKCS#11 token device, as provided by `pktool`, which holds the private key.

It is an error to specify both the `-T` and `-k` options.

-v Requests more detailed information. The additional output includes the signer and, if the signature format contains it, the time the object was signed. This is not stable parseable output.

Operands The following operand is supported:

file One or more elf objects to be signed or verified. At least one elf object must be specified either via the `-e` option or after all other options.

Examples **EXAMPLE 1** Signing an ELF Object Using a Key/Certificate in a File

```
example$ elfsign sign -k myprivatekey -c mycert -e lib/libmylib.so.1
```

EXAMPLE 2 Verifying an elf Object's Signature

```
example$ elfsign verify -c mycert -e lib/libmylib.so.1
elfsign: verification of lib/libmylib.so.1 passed
```

EXAMPLE 3 Generating a Certificate Request

```
example$ elfsign request -k mykey -r req.pkcs10
Enter Company Name / Stock Symbol or some other globally
unique identifier.
This will be the prefix of the Certificate DN: SUNW
```

The government of the United States of America restricts the export of "open cryptographic interfaces", also known as "crypto-with-a-hole". Due to this restriction, all providers for the Solaris cryptographic framework must be signed, regardless of the country of origin.

The terms "retail" and "non-retail" refer to export classifications for products manufactured in the USA. These terms define the portion of the world where the product may be shipped.) Roughly speaking, "retail" is worldwide (minus certain excluded nations) and "non-retail" is domestic only (plus some highly favored nations).

If your provider is subject to USA export control, then you must obtain an export approval (classification) from the government of the USA before exporting your provider. It is critical that you specify the obtained (or expected, when used during development) classification to the following questions so that your provider will be appropriately signed.

Do you have retail export approval for use without restrictions based on the caller (for example, IPsec)? [Yes/No] **No**

EXAMPLE 3 Generating a Certificate Request *(Continued)*

If you have non-retail export approval for unrestricted use of your provider by callers, are you also planning to receive retail approval by restricting which export sensitive callers (for example, IPsec) may use your provider? [Yes/No] **No**

[...]

EXAMPLE 4 Determining Information About an Object

```
example$ elfsign list -f format -e lib/libmylib.so.1
rsa_md5_sha1

example$ elfsign list -f signer -e lib/libmylib.so.1
CN=VENDOR, OU=Software Development, O=Vendor Inc.
```

Exit Status The following exit values are returned:

VALUE	MEANING	SUB-COMMAND
0	Operation successful	sign/verify/request
1	Invalid arguments	
2	Failed to verify ELF object	verify
3	Unable to open ELF object	sign/verify
4	Unable to load or invalid certificate	sign/verify
5	Unable to load private key, private key is invalid, or token label is invalid	sign
6	Failed to add signature	sign
7	Attempt to verify unsigned object or object not an ELF file	verify

Files /etc/crypto/certs Directory searched for the `verify` subcommand if the `-c` flag is not used

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtoo
Interface Stability	See below.

The `elfsign` command and subcommands are Committed. While applications should not depend on the output format of `elfsign`, the output format of the `list` subcommand is Committed.

See Also [date\(1\)](#), [pktool\(1\)](#), [cryptoadm\(1M\)](#), [libpkcs11\(3LIB\)](#), [attributes\(5\)](#)

Name enable, disable – enable/disable LP printers

Synopsis `/usr/bin/enable printer...`
`/usr/bin/disable [-c | -W] [-r [reason]] printer...`

Description The `enable` command activates printers, enabling them to print requests submitted by the `lp` command. `enable` must be run on the printer server.

The `disable` command deactivates printers, disabling them from printing requests submitted by the `lp` command. By default, any requests that are currently printing on *printer* are reprinted in their entirety either on *printer* or another member of the same class of printers. The `disable` command must be run on the print server.

Use `lpstat -p` to check the status of printers.

Generally, `enable` and `disable` are run on the print server to control local print queues. Under some configurations, they can also be run on client systems when IPP is being used to communicate between client and server.

Options The following options are supported for use with `disable`:

- `-c` Cancels any requests that are currently printing on *printer*. This option cannot be used with the `-W` option. If the printer is remote, the `-c` option is silently ignored.
- `-W` Waits until the request currently being printed is finished before disabling *printer*. This option cannot be used with the `-c` option. If the printer is remote, the `-W` option is silently ignored.
- `-r [reason]` Assigns a *reason* for the disabling of the printer(s). This *reason* applies to all printers specified. This *reason* is reported by `lpstat -p`. Enclose *reason* in quotes if it contains blanks. The default reason is unknown reason for the existing printer, and "new printer" for a printer added to the system but not yet enabled.

Operands The following operand is supported for both `enable` and `disable`:

printer The name of the printer to be enabled or disabled. Specify *printer* using atomic or URI-style (*scheme*://*endpoint*) names. See [printers.conf\(4\)](#) regarding the naming conventions for destinations.

Exit Status The following exit values are returned:

- `0` Successful completion.
- non-zero An error occurred.

Files `/etc/printers.conf` System printer configuration database
`$HOME/.printers` User-configurable printer database
`ou=printers` LDAP version of `/etc/printers.conf`
`printers.conf.byname` NIS version of `/etc/printers.conf`
`printers.org_dir` NIS+ version of `/etc/printers.conf`

Notes When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

Name encrypt, decrypt – encrypt or decrypt files

Synopsis `/usr/bin/encrypt -l | -a algorithm [-v] [-k key_file]
 [-i input_file] [-o output_file]`
`/usr/bin/decrypt -l | -a algorithm [-v] [-k key_file]
 [-i input_file] [-o output_file]`

Description This utility encrypts or decrypts the given file or stdin using the algorithm specified. If no output file is specified, output is to standard out. If input and output are the same file, the encrypted output is written to a temporary work file in the same filesystem and then used to replace the original file.

On decryption, if the input and output are the same file, the cleartext replaces the ciphertext file.

The output file of `encrypt` and the input file for `decrypt` contains the following information:

- Output format version number, 4 bytes in network byte order. The current version is 1.
- Iterations used in key generation function, 4 bytes in network byte order.
- IV (`ivlen` bytes)[1]. iv data is generated by random bytes equal to one block size.
- Salt data used in key generation (16 bytes).
- Cipher text data.

Options The following options are supported:

- `-a algorithm` Specify the name of the algorithm to use during the encryption or decryption process. See `USAGE, Algorithms` for details.
- `-i input_file` Specify the input file. Default is stdin if *input_file* is not specified.
- `-k key_file` Specify the file containing the key value for the encryption algorithm. Each algorithm has specific key material requirements, as stated in the PKCS#11 specification. If `-k` is not specified, `encrypt` prompts for key material using [getpassphrase\(3C\)](#).

For information on generating a key file, see [dd\(1M\)](#) or [System Administration Guide: Security Services](#).

- `-l` Display the list of algorithms available on the system. This list can change depending on the configuration of the cryptographic framework. The key sizes are displayed in bits.
- `-o output_file` Specify output file. Default is stdout if *output_file* is not specified. If stdout is used without redirecting to a file, the terminal window can appear to hang because the raw encrypted or decrypted data has disrupted the terminal emulation, much like viewing a binary file can do at times.
- `-v` Display verbose information. See `Verbose`.

Usage

Algorithms The supported algorithms are displayed with their minimum and maximum key sizes in the `-l` option. These algorithms are provided by the cryptographic framework. Each supported algorithm is an alias of the PKCS #11 mechanism that is the most commonly used and least restricted version of a particular algorithm type. For example: `des` is an alias to `CKM_DES_CBC_PAD` and `arcfour` is an alias to `CKM_RC4`. Algorithm variants with no padding or ECB are not supported.

These aliases are used with the `-a` option and are case-sensitive.

Passphrase When the `-k` option is not used during encryption and decryption tasks, the user is prompted for a passphrase. The passphrase is manipulated into a more secure key using the PBKDF2 algorithm specified in PKCS #5.

When a passphrase is used with `encrypt` and `decrypt`, the user entered passphrase is turned into an encryption key using the PBKDF2 algorithm as defined defined in <http://www.rsasecurity.com>, PKCS #5 v2.0.

Verbose If an input file is provided to the command, a progress bar spans the screen. The progress bar denotes every 25% completed with a pipe sign (`|`). If the input is from standard input, a period (`.`) is displayed each time 40KB is read. Upon completion of both input methods, Done is printed.

Examples

EXAMPLE 1 Listing Available Algorithms

The following example lists available algorithms:

```
example$ encrypt -l
Algorithm      Keysize:  Min   Max
-----
aes             128    128
arcfour         8      128
des             64     64
3des            192    192
```

EXAMPLE 2 Encrypting Using AES

The following example encrypts using AES and prompts for the encryption key:

```
example$ encrypt -a aes -i myfile.txt -o secretstuff
```

EXAMPLE 3 Using an In Pipe to Provide Encrypted Tape Backup

The following example uses an in pipe to provide encrypted tape backup:

```
example$ ufsdump 0f - /var | encrypt -a arcfour \
-k /etc/mykeys/backup.k | dd of=/dev/rmt/0
```

EXAMPLE 4 Using an In Pipe to Restore Tape Backup

The following example uses an in pipe to restore a tape backup:

```
example$ decrypt -a arcfour -k /etc/mykeys/backup.k \  
         -i /dev/rmt/0 | ufsrestore xvf -
```

EXAMPLE 5 Encrypting an Input File Using the 3DES Algorithm

The following example encrypts the input file file with the 192-bit key stored in the des3key file:

```
example$ encrypt -a 3des -k des3key -i inputfile -o outputfile
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

RSA PKCS#5 v2.0: <http://www.rsasecurity.com>

Name enhance – enhanced command-line editing facilities

Synopsis enhance *command* [*argument*]. . .

Description The enhance program provides enhanced command-line editing facilities to users of third party applications, to which one doesn't have any source code. It does this by placing a pseudo-terminal between the application and the real terminal. It uses the `tecla` command-line editing library to read input from the real terminal, then forwards each just completed input line to the application via the pseudo-terminal. All output from the application is forwarded back unchanged to the real terminal.

Whenever the application stops generating output for more than a tenth of a second, the enhance program treats the latest incomplete output line as the prompt, and re-displays any incompleted input line that the user has typed after it. The small delay, which is imperceptible to the user, isn't necessary for correct operation of the program. It is just an optimization, designed to stop the input line from being re-displayed so often that it slows down output.

The user-level command-line editing facilities provided by the Tecla library are documented in the [tecla\(5\)](#) man page

DEFICIENCIES The one major problem that hasn't been solved yet, is how to deal with applications that change whether typed input is echo'd by their controlling terminal. For example, programs that ask for a password, such as `ftp` and `telnet`, temporarily tell their controlling terminal not to echo what the user types. Since this request goes to the application side of the pseudo terminal, the enhance program has no way of knowing that this has happened, and continues to echo typed input to its controlling terminal, while the user types their password.

Furthermore, before executing the host application, the enhance program initially sets the pseudo terminal to `noecho` mode, so that everything that it sends to the program doesn't get redundantly echoed. If a program that switches to `noecho` mode explicitly restores echoing afterwards, rather than restoring the terminal modes that were previously in force, then subsequently, every time that you enter a new input line, a duplicate copy will be displayed on the next line.

Files `/usr/lib/libtecla.so` `tecla` library
`~/.teclarc` `tecla` personal customization file.

-
- Name** env – set environment for command invocation
- Synopsis** /usr/bin/env [-i | -] [*name=value*]... [*utility* [*arg*...]]
 /usr/xpg4/bin/env [-i | -] [*name=value*]...
 [*utility* [*arg*...]]
- Description** The env utility obtains the current environment, modifies it according to its arguments, then invokes the utility named by the *utility* operand with the modified environment.
- Optional arguments are passed to *utility*. If no *utility* operand is specified, the resulting environment is written to the standard output, with one *name=value* pair per line.
- /usr/bin If env executes commands with arguments, it uses the default shell /usr/bin/sh (see [sh\(1\)](#)).
- /usr/xpg4/bin If env executes commands with arguments, it uses /usr/xpg4/bin/sh (see [ksh\(1\)](#)).
- Options** The following options are supported:
- i | – Ignores the environment that would otherwise be inherited from the current shell.
 - Restricts the environment for *utility* to that specified by the arguments.
- Operands** The following operands are supported:
- name=value* Arguments of the form *name=value* modify the execution environment, and are placed into the inherited environment before *utility* is invoked.
 - utility* The name of the utility to be invoked. If *utility* names any of the special shell built-in utilities, the results are undefined.
 - arg* A string to pass as an argument for the invoked utility.
- Examples** **EXAMPLE 1** Invoking utilities with new PATH values
- The following utility:
- ```
example% env -i PATH=/mybin mygrep xyz myfile
```
- invokes the utility mygrep with a new PATH value as the only entry in its environment. In this case, PATH is used to locate mygrep, which then must reside in /mybin.
- Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of env: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.
- PATH Determine the location of the *utility*. If PATH is specified as a *name=value* operand to env, the value given shall be used in the search for *utility*.
- Exit Status** If *utility* is invoked, the exit status of env is the exit status of *utility*. Otherwise, the env utility returns one of the following exit values:
- 0 Successful completion.
  - 1-125 An error occurred.

- 126        *utility* was found but could not be invoked.
- 127        *utility* could not be found.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** eqn, neqn, checkeq – typeset mathematics test

**Synopsis** eqn [-d *xy*] [-f *n*] [-p *n*] [-s *n*] [*file*]...  
 neqn [*file*]...  
 checkeq [*file*]...

**Description** eqn and neqn are language processors to assist in describing equations. eqn is a preprocessor for `troff(1)` and is intended for devices that can print `troff`'s output. neqn is a preprocessor for `nroff(1)` and is intended for use with terminals. Usage is almost always:

```
example% eqn file ... | troff
example% neqn file ... | nroff
```

If no *files* are specified, eqn and neqn read from the standard input. A line beginning with `.EQ` marks the start of an equation. The end of an equation is marked by a line beginning with `.EN`. Neither of these lines is altered, so they may be defined in macro packages to get centering, numbering, and so on. It is also possible to set two characters as “delimiters”; subsequent text between delimiters is also treated as eqn input.

checkeq reports missing or unbalanced delimiters and `.EQ/.EN` pairs.

**Options** The following options are supported:

- dxy Sets equation delimiters set to characters *x* and *y* with the command-line argument. The more common way to do this is with `delim xy` between `.EQ` and `.EN`. The left and right delimiters may be identical. Delimiters are turned off by `delim off` appearing in the text. All text that is neither between delimiters nor between `.EQ` and `.EN` is passed through untouched.
- fn Changes font to *n* globally in the document. The font can also be changed globally in the body of the document by using the `gfont n` directive, where *n* is the font specification.
- pn Reduces subscripts and superscripts by *n* point sizes from the previous size. In the absence of the `-p` option, subscripts and superscripts are reduced by 3 point sizes from the previous size.
- sn Changes point size to *n* globally in the document. The point size can also be changed globally in the body of the document by using the `gsize n` directive, where *n* is the point size.

**Operands** The following operands are supported:

*file* The `nroff` or `troff` file processed by eqn or neqn.

**Eqn Language** The `nroff` version of this description depicts the output of neqn to the terminal screen exactly as neqn is able to display it. To see an accurate depiction of the output, view the printed version of this page.

Subscripts and superscripts:

$$x_{sub\ i}$$
 $a \text{ sub } i \text{ sup } 2$ 
$$e^{\sup \{x^2 + y^2\}}$$

Fractions:

$$a \text{ over } b$$

### Square Roots:

$$\frac{1}{\sqrt{ax^2+bx+c}}$$

Limits:

$$\lim_{n \rightarrow \infty} \sum_{i=0}^n x_i$$

### Brackets and Braces:

$$\left[ \frac{x^2 + y^2}{\alpha} \right] \approx 1$$

The right clause is optional. Legal characters after `left` and `right` are braces, brackets, bars, `c` and `f` for ceiling and floor, and `"` for nothing at all (useful for a right-side-only

bracket).

Vertical piles:

Vertical piles of things are made with `pile`, `lpile`, `cpile`, and `rpile`.

`pile {a above b above c}`

$\begin{array}{c} a \\ b \\ \text{produces } c \end{array}$

There can be an arbitrary number of elements in a pile. `lpile` left-justifies, `pile` and `cpile` center, with different vertical spacing, and `rpile` right justifies.

Matrices:

Matrices are made with `matrix`.

`matrix { lcol { x sub i above y sub 2 } ccol { 1 above 2 } }`

$x_i \quad 1$

produces  $y_2 \quad 2$

In addition, there is `rcol` for a right-justified column.

Diacritical marks:

Diacritical marks are made with `dot`, `dotdot`, `hat`, `tilde`, `bar`, `vec`, `dyad`, and `under`.

`x dot = f(t) bar`

is  $\dot{x} = \overline{f(t)}$

`y dotdot bar ~~~ n under`

is  $\ddot{y} = \underline{n}$

`x vec ~~~ y dyad`

is  $\vec{x} = \overleftrightarrow{y}$

Sizes and Fonts:

Sizes and font can be changed with `size n` or `size ±n`, `roman`, `italic`, `bold`, and `font n`.

Size and fonts can be changed globally in a document by `gsize n` and `gfont n`, or by the command-line arguments `-sn` and `-fn`.

Successive display arguments:

Successive display arguments can be lined up. Place `mark` before the desired lineup point in the first equation; place `lineup` at the place that is to line up vertically in subsequent equations.

Shorthands:

Shorthands may be defined or existing keywords redefined with `define`:

`define thing%replacement%` Defines a new token called *thing* which will be replaced by *replacement* whenever it appears thereafter. The % may be any character that does not occur in *replacement*.

**Keywords and Shorthands:**  
Keywords like `sum` `int` `inf` and shorthands like `>=` `→` and `!=` are recognized.

**Greek letters:**  
Greek letters are spelled out in the desired case, as in `alpha` or `GAMMA`.

**Mathematical words:**  
Mathematical words like `sin`, `cos`, and `log` are made Roman automatically.

`troff(1)` four-character escapes like `\\(bu (•)` can be used anywhere. Strings enclosed in double quotes `"..."` are passed through untouched; this permits keywords to be entered as text, and can be used to communicate with `troff` when all else fails.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**See Also** `nroff(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `ms(5)`

**Bugs** To embolden characters such as digits and parentheses, it is necessary to quote them, as in `'bold "12.3"`.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Synopsis</b>    | error [-n] [-q] [-s] [-v] [-t <i>suffixlist</i> ] [-I <i>ignorefile</i> ]<br>[ <i>filename</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>error analyzes error messages produced by a number of compilers and language processors. It replaces the painful, traditional methods of scribbling abbreviations of errors on paper, and permits error messages and source code to be viewed simultaneously.</p> <p>error looks at error messages, either from the specified file <i>filename</i> or from the standard input, and:</p> <ul style="list-style-type: none"> <li>▪ Determines which language processor produced each error message.</li> <li>▪ Determines the file name and line number of the erroneous line.</li> <li>▪ Inserts the error message into the source file immediately preceding the erroneous line.</li> </ul> <p>Error messages that can't be categorized by language processor or content are not inserted into any file, but are sent to the standard output. error touches source files only after all input has been read.</p> <p>error is intended to be run with its standard input connected with a pipe to the error message source. Some language processors put error messages on their standard error file; others put their messages on the standard output. Hence, both error sources should be piped together into error. For example, when using the <i>csh</i> syntax, the following command analyzes all the error messages produced by whatever programs <a href="#">make(1S)</a> runs when making <i>lint</i>:</p> <pre>example% make -s lint   &amp; error -q -v</pre> <p>error knows about the error messages produced by: <a href="#">as(1)</a>, <a href="#">cpp(1)</a>, <a href="#">ld(1)</a>, <a href="#">cc(1B)</a>, <a href="#">make(1S)</a> and other compilers. For all languages except Pascal, error messages are restricted to one line. Some error messages refer to more than one line in more than one file, in which case error duplicates the error message and inserts it in all the appropriate places.</p> |
| <b>Options</b>     | <p>-n Do <i>not</i> touch any files; all error messages are sent to the standard output.</p> <p>-q error asks whether the file should be touched. A 'y' or 'n' to the question is necessary to continue. Absence of the -q option implies that all referenced files (except those referring to discarded error messages) are to be touched.</p> <p>-s Print out statistics regarding the error categorization.</p> <p>-v After all files have been touched, overlay the visual editor <i>vi</i> with it set up to edit all files touched, and positioned in the first touched file at the first error. If <a href="#">vi(1)</a> can't be found, try <a href="#">ex(1)</a> or <a href="#">ed(1)</a> from standard places.</p> <p>-t <i>suffixlist</i> Take the following argument as a suffix list. Files whose suffices do not appear in the suffix list are not touched. The suffix list is dot separated, and '*' wildcards work. Thus the suffix list:</p> <pre>.c.y.f*.h</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

allows error to touch files ending with `‘.c’`, `‘.y’`, `‘.f*’` and `‘.h’`.

error catches interrupt and terminate signals, and terminates in an orderly fashion.

**Examples** EXAMPLE 1 Examples of the error command.

In the following C shell (`/usr/bin/csh`) example, error takes its input from the FORTRAN compiler:

```
example% f77 -c any.f |& error options
```

Here is the same example using the Korn shell (`/usr/bin/ksh`):

```
example% f77 -c any.f 2>&1 | error options
```

**Usage** error does one of six things with error messages.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| synchronize       | Some language processors produce short errors describing which file they are processing. error uses these to determine the file name for languages that do not include the file name in each error message. These synchronization messages are consumed entirely by error.                                                                                                                                                                                                                                                                                                           |
| discard           | Error messages from <code>lint</code> that refer to one of the two <code>lint</code> libraries, <code>/usr/lib/lint/llib-lc</code> and <code>/usr/lib/lint/llib-port</code> are discarded, to prevent accidentally touching these libraries. Again, these error messages are consumed entirely by error.                                                                                                                                                                                                                                                                             |
| nullify           | Error messages from <code>lint</code> can be nullified if they refer to a specific function, which is known to generate diagnostics which are not interesting. Nullified error messages are not inserted into the source file, but are written to the standard output. The names of functions to ignore are taken from either the file named <code>.errorc</code> in the user's home directory, or from the file named by the <code>-I</code> option. If the file does not exist, no error messages are nullified. If the file does exist, there must be one function name per line. |
| not file specific | Error messages that can't be intuited are grouped together, and written to the standard output before any files are touched. They are not inserted into any source file.                                                                                                                                                                                                                                                                                                                                                                                                             |
| file specific     | Error messages that refer to a specific file but to no specific line are written to the standard output when that file is touched.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| true errors       | Error messages that can be intuited are candidates for insertion into the file to which they refer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Only true error messages are inserted into source files. Other error messages are consumed entirely by error or are written to the standard output. error inserts the error messages into the source file on the line preceding the line number in the error message. Each error message

is turned into a one line comment for the language, and is internally flagged with the string `###` at the beginning of the error, and `%%%` at the end of the error. This makes pattern searching for errors easier with an editor, and allows the messages to be easily removed. In addition, each error message contains the source line number for the line the message refers to. A reasonably formatted source program can be recompiled with the error messages still in it, without having the error messages themselves cause future errors. For poorly formatted source programs in free format languages, such as C or Pascal, it is possible to insert a comment into another comment, which can wreak havoc with a future compilation. To avoid this, format the source program so there are no language statements on the same line as the end of a comment.

**Files** `~/ .errorrc` function names to ignore for `lint` error messages  
`/dev/tty` user's teletype

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**See Also** [as\(1\)](#), [cc\(1B\)](#), [cpp\(1\)](#), [csh\(1\)](#), [ed\(1\)](#), [ex\(1\)](#), [make\(1S\)](#), [ld\(1\)](#), [vi\(1\)](#), [attributes\(5\)](#)

**Bugs** Opens the `tty`-device directly for user input.

Source files with links make a new copy of the file with only one link to it.

Changing a language processor's error message format may cause `error` to not understand the error message.

`error`, since it is purely mechanical, will not filter out subsequent errors caused by “floodgating” initiated by one syntactically trivial error. Humans are still much better at discarding these related errors.

Pascal error messages belong after the lines affected, `error` puts them before. The alignment of the ‘|’ marking the point of error is also disturbed by `error`.

`error` was designed for work on CRT's at reasonably high speed. It is less pleasant on slow speed terminals, and was not designed for use on hardcopy terminals.

**Name** ex – text editor

**Synopsis** /usr/bin/ex [-| -s] [-l] [-L] [-R] [-r *file*] [-t *tag*]  
          [-v] [-V] [-x] [-wn] [-C] [+*command* | -c *command*] *file*...

/usr/xpg4/bin/ex [-| -s] [-l] [-L] [-R] [-r *file*]  
          [-t *tag*] [-v] [-V] [-x] [-wn] [-C]  
          [+*command* | -c *command*] *file*...

/usr/xpg6/bin/ex [-| -s] [-l] [-L] [-R] [-r *file*]  
          [-t *tag*] [-v] [-V] [-x] [-wn] [-C]  
          [+*command* | -c *command*] *file*...

**Description** The ex utility is the root of a family of editors: ex and vi. ex is a superset of [ed\(1\)](#), with the most notable extension being a display editing facility. Display based editing is the focus of vi.

If you have a CRT terminal, you can wish to use a display based editor; in this case see [vi\(1\)](#), which is a command which focuses on the display-editing portion of ex.

If you have used ed you find that, in addition to having all of the ed commands available, ex has a number of additional features useful on CRT terminals. Intelligent terminals and high speed terminals are very pleasant to use with vi. Generally, the ex editor uses far more of the capabilities of terminals than ed does, and uses the terminal capability data base (see [terminfo\(4\)](#)) and the type of the terminal you are using from the environment variable TERM to determine how to drive your terminal efficiently. The editor makes use of features such as insert and delete character and line in its `visual` command (which can be abbreviated `vi`) and which is the central mode of editing when using the `vi` command.

The ex utility contains a number of features for easily viewing the text of the file. The `z` command gives easy access to windows of text. Typing `^D` (CTRL-D) causes the editor to scroll a half-window of text and is more useful for quickly stepping through a file than just typing return. Of course, the screen-oriented `visual` mode gives constant access to editing context.

The ex utility gives you help when you make mistakes. The `undo` (`u`) command allows you to reverse any single change which goes astray. ex gives you a lot of feedback, normally printing changed lines, and indicates when more than a few lines are affected by a command so that it is easy to detect when a command has affected more lines than it should have.

The editor also normally prevents overwriting existing files, unless you edited them, so that you do not accidentally overwrite a file other than the one you are editing. If the system (or editor) crashes, or you accidentally hang up the telephone, you can use the editor `recover` command (or `-r file` option) to retrieve your work. This gets you back to within a few lines of where you left off.

The ex utility has several features for dealing with more than one file at a time. You can give it a list of files on the command line and use the `next` (`n`) command to deal with each in turn. The `next` command can also be given a list of file names, or a pattern as used by the shell to

specify a new set of files to be dealt with. In general, file names in the editor can be formed with full shell metasyntax. The metacharacter '%' is also available in forming file names and is replaced by the name of the current file.

The editor has a group of buffers whose names are the ASCII lower-case letters (a-z). You can place text in these named buffers where it is available to be inserted elsewhere in the file. The contents of these buffers remain available when you begin editing a new file using the `edit` (e) command.

There is a command `&` in `ex` which repeats the last `substitute` command. In addition, there is a confirmed substitute command. You give a range of substitutions to be done and the editor interactively asks whether each substitution is desired.

It is possible to ignore the case of letters in searches and substitutions. `ex` also allows regular expressions which match words to be constructed. This is convenient, for example, in searching for the word "edit" if your document also contains the word "editor."

`ex` has a set of options which you can set to tailor it to your liking. One option which is very useful is the `autoindent` option that allows the editor to supply leading white space to align text automatically. You can then use `^D` as a backtab and space or tab to move forward to align new code easily.

Miscellaneous useful features include an intelligent `join` (j) command that supplies white space between joined lines automatically, commands `<` and `>` which shift groups of lines, and the ability to filter portions of the buffer through commands such as `sort`.

**Options** The following options are supported:

|                      |                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-  -s</code>   | Suppresses all interactive user feedback. This is useful when processing editor scripts.                                                             |
| <code>-l</code>      | Sets up for editing LISP programs.                                                                                                                   |
| <code>-L</code>      | Lists the name of all files saved as the result of an editor or system crash.                                                                        |
| <code>-R</code>      | Readonly mode. The <code>readonly</code> flag is set, preventing accidental overwriting of the file.                                                 |
| <code>-r file</code> | Edits <i>file</i> after an editor or system crash. (Recovers the version of <i>file</i> that was in the buffer when the crash occurred.)             |
| <code>-t tag</code>  | Edits the file containing the <i>tag</i> and positions the editor at its definition. It is an error to specify more than one <code>-t</code> option. |
| <code>-v</code>      | Starts up in display editing state, using <code>vi</code> . You can achieve the same effect by typing the <code>vi</code> command itself.            |

- V

Verbose. When ex commands are read by means of standard input, the input is echoed to standard error. This can be useful when processing ex commands within shell scripts.
- x

Encryption option. Simulates the X command and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the -x option.
- wn

Sets the default window size to *n*. This is useful when using the editor over a slow speed line.
- C

Encryption option. Same as the -x option, except that -C simulates the C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.
- +command | -c command

Begins editing by executing the specified editor *command* (usually a search or positioning command).
- /usr/xpg4/bin/ex, /usr/xpg6/bin/ex

If both the -t *tag* and the -c *command* options are given, the -t *tag* is processed first. That is, the file containing the tag is selected by -t and then the command is executed.

**Operands** The following operand is supported:

*file* A path name of a file to be edited.

**Usage** This section defines the ex states, commands, initializing options, and scanning pattern formations.

- ex States

Command

Normal and initial state. Input prompted for by “:”. The line kill character cancels a partial command.
- Insert

Entered by a, i, or c. Arbitrary text can be entered. Insert state normally is terminated by a line having only “.” on it, or, abnormally, with an interrupt.
- Visual

Entered by typing vi. Terminated by typing Q or ^\ (Control-\\).

| ex Command Names and Abbreviations | Command Name | Abbrevi-<br>ation | Command Name | Abbrevi-<br>ation | Command Name | Abbrevi-<br>ation |
|------------------------------------|--------------|-------------------|--------------|-------------------|--------------|-------------------|
|                                    | abbrev       | ab                | map          |                   | set          | se                |
|                                    | append       | a                 | mark         | ma                | shell        | sh                |

|        |    |          |     |            |      |

Join Command Arguments   Join    [range] j[oin][!] [count] [flags]

If count is specified:

/usr/bin/ex, /usr/xpg6/bin/ex

If no address is specified, the join command behaves as if *2addr* were the current line and the current line plus *count* (.,. + *count*). If one address is specified, the join command behaves as if *2addr* were the specified address and the specified address plus *count* (*addr*, *addr* + *count*).

/usr/xpg4/bin/ex

If no address is specified, the join command behaves as if *2addr* were the current line and the current line plus *count* - 1 (.,. + *count* - 1). If one address is specified, the join command behaves as if *2addr* were the specified address and the specified address plus *count* - 1 (*addr*, *addr* + *count* - 1).

/usr/bin/ex, /usr/xpg4/bin/ex, /usr/xpg6/bin/ex

If two or more addresses are specified, the join command behaves as if an additional address, equal to the last address plus *count* - 1 (*addr1*, ..., *lastaddr*, *lastaddr* + *count* - 1), was specified. If this results in a second address greater than the last line of the edit buffer, it is corrected to be equal to the last line of the edit buffer.

If no count is specified:

/usr/bin/ex, /usr/xpg4/bin/ex, /usr/xpg6/bin/ex

If no address is specified, the join command behaves as if *2addr* were the current line and the next line (.,. + 1). If one address is specified, the join command behaves as if *2addr* were the specified address and the next line (*addr*, *addr* + 1).

|                                 |                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Additional ex Command Arguments | <code>/usr/bin/ex, /usr/xpg6/bin/ex</code>                                         | For the following ex commands, if <i>count</i> is specified, it is equivalent to specifying an additional address to the command. The additional address is equal to the last address specified to the command (either explicitly or by default) plus <i>count</i> - 1. If this results in an address greater than the last line of the edit buffer, it is corrected to equal the last line of the edit buffer. |
|                                 | <code>/usr/xpg4/bin/ex</code>                                                      | For the following ex commands, if both a count and a range are specified for a command that uses them, the number of lines affected is taken from the count value rather than the range. The starting line for the command is taken to be the first line addressed by the range.                                                                                                                                |
| Abbreviate                      | <code>ab[brev] word rhs</code>                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                 |

/usr/bin/ex, /usr/xpg4/bin/ex, /usr/xpg6/bin/ex

For the following ex commands, if *count* is specified, it is equivalent to specifying an additional address to the command. The additional address is equal to the last address specified to the command (either explicitly or by default) plus *count* - 1. If this results in an address greater than the last line of the edit buffer, it is corrected to equal the last line of the edit buffer.

*Solaris Advanced User's Guide*

**Author** The vi and ex utilities are based on software developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

**Notes** Several options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see [Intro\(1\)](#)). The `–` option has been replaced by `-s`, a `-r` option that is not followed with an option-argument has been replaced by `-L`, and `+command` has been replaced by `-c command`.

The message file too large to recover with `-r` option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the `-r` option is not possible.

The `z` command prints the number of logical rather than physical lines. More than a screen full of output can result if long lines are present.

File input/output errors do not print a name if the command line `-s` option is used.

The editing environment defaults to certain configuration options. When an editing session is initiated, `ex` attempts to read the `EXINIT` environment variable. If it exists, the editor uses the values defined in `EXINIT`, otherwise the values set in `$HOME/.exrc` are used. If `$HOME/.exrc` does not exist, the default values are used.

To use a copy of `.exrc` located in the current directory other than `$HOME`, set the `exrc` option in `EXINIT` or `$HOME/.exrc`. Options set in `EXINIT` can be turned off in a local `.exrc` only if `exrc` is set in `EXINIT` or `$HOME/.exrc`. In order to be used, `.exrc` in `$HOME` or the current directory must fulfill these conditions:

- It must exist.
- It must be owned by the same userid as the real userid of the process, or the process has appropriate privileges.
- It is not writable by anyone other than the owner.

There is no easy way to do a single scan ignoring case.

The editor does not warn if text is placed in named buffers and not used before exiting the editor.

Null characters are discarded in input files and cannot appear in resultant files.

**Name** `exec`, `eval`, `source` – shell built-in functions to execute other commands

## Synopsis

```
sh exec [argument]...
 eval [argument]...

csh exec command
 eval argument...
 source [-h] name

ksh *exec [arg]...
 *eval [arg]...
```

## Description

- sh The `exec` command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.
- The *arguments* to the `eval` built-in are read as input to the shell and the resulting command(s) executed.
- csh `exec` executes *command* in place of the current shell, which terminates.
- `eval` reads its *arguments* as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution.
- `source` reads commands from *name*. `source` commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested `source` commands.
- h Place commands from the file *name* on the history list without executing them.
- ksh With the `exec` built-in, if *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.
- The arguments to `eval` are read as input to the shell and the resulting command(s) executed.
- On this man page, [ksh\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.

- 2. I/O redirections are processed after variable assignments.
- 3. Errors cause a script that contains them to abort.
- 4. Words, following a command preceded by **\*\*** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**Exit Status** For ksh:

If *command* is not found, the exit status is 127. If *command* is found, but is not an executable utility, the exit status is 126. If a redirection error occurs, the shell exits with a value in the range 1-125. Otherwise, exec returns a zero exit status.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [csh\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#)

**Name** exit, return, goto – shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps

## Synopsis

```
sh exit [n]
 return [n]
csh exit [(expr)]
 goto label
ksh *exit [n]
 *return [n]
```

## Description

sh `exit` will cause the calling shell or shell script to exit with the exit status specified by *n*. If *n* is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

`return` causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

csh `exit` will cause the calling shell or shell script to exit, either with the value of the status variable or with the value specified by the expression *expr*.

The `goto` built-in uses a specified *label* as a search string amongst commands. The shell rewinds its input as much as possible and searches for a line of the form *label*: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a `while` or `for` built-in command and its corresponding `end`.

ksh `exit` will cause the calling shell or shell script to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When `exit` occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An end-of-file will also cause the shell to exit except for a shell which has the `ignoreeof` option (See `set` below) turned on.

`return` causes a shell function or `'.'` script to return to the invoking script with the return status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the return status is that of the last command executed. If `return` is invoked while not in a function or a `'.'` script, then it is the same as an `exit`.

On this man page, [ksh\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.

- 2. I/O redirections are processed after variable assignments.
- 3. Errors cause a script that contains them to abort.
- 4. Words, following a command preceded by **\*\*** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [break\(1\)](#), [csh\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#)

- Name** expand, unexpand – expand TAB characters to SPACE characters, and vice versa
- Synopsis** expand [-t *tablist*] [*file*]...  
 expand [-tabstop] [-tab1, tab2, . . ., tabn] [*file*]...  
 unexpand [-a] [-t *tablist*] [*file*]...
- Description** The expand utility copies *files* (or the standard input) to the standard output, with TAB characters expanded to SPACE characters. BACKSPACE characters are preserved into the output and decrement the column count for TAB calculations. expand is useful for pre-processing character files (before sorting, looking at specific columns, and so forth) that contain TAB characters.
- unexpand copies *files* (or the standard input) to the standard output, putting TAB characters back into the data. By default, only leading SPACE and TAB characters are converted to strings of tabs, but this can be overridden by the -a option (see the OPTIONS section below).
- Options** The following options are supported for expand:
- t *tablist* Specifies the tab stops. The argument *tablist* must consist of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set *tablist* column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions.
  - Each tab-stop position *N* must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* causes the next character output to be in the (*N*+1)th column position on that line.
  - In the event of expand having to process a tab character at a position beyond the last of those specified in a multiple tab-stop list, the tab character is replaced by a single space character in the output.
  - tabstop Specifies as a single argument, sets TAB characters *tabstop* SPACE characters apart instead of the default 8.
  - tab1, tab2,...,tabn Sets TAB characters at the columns specified by -tab1,tab2,..., tabn

The following options are supported for unexpand:

- a Inserts TAB characters when replacing a run of two or more SPACE characters would produce a smaller output file.
- t *tablist* Specifies the tab stops. The option-argument *tablist* must be a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a

single number is given, tabs will be set *tablist* column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions. Each tab-stop position *N* must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* will cause the next character output to be in the (*N*+1)th column position on that line. When the -t option is not specified, the default is the equivalent of specifying -t 8 (except for the interaction with -a, described below).

No space-to-tab character conversions occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When -t is specified, the presence or absence of the -a option is ignored; conversion will not be limited to the processing of leading blank characters.

**Operands** The following ooperand is supported for expand and unexpand:

*file* The path name of a text file to be used as input.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of expand and unexpand: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**See Also** [tabs\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

- Name** exportfs – translates exportfs options to share/unshare commands
- Synopsis** /usr/sbin/exportfs [-aiuv] [-o *options*] [*pathname*]
- Description**

exportfs translates SunOS 4.x exportfs options to the corresponding share/unshare options and invokes share/unshare with the translated options.

With no options or arguments, exportfs invokes share to print out the list of all currently shared NFS filesystems.

exportfs is the BSD/Compatibility Package command of [share\(1M\)](#) and [unshare\(1M\)](#). Use [share\(1M\)](#)/[unshare\(1M\)](#) whenever possible.
- Options**

-a

Invokes [shareall\(1M\)](#), or if -u is specified, invokes [unshareall\(1M\)](#).

-i

Ignore options in /etc/dfs/dfstab.

-u

Invokes [unshare\(1M\)](#) on *pathname*.

-v

Verbose.

-o *options*

Specify a comma-separated list of optional characteristics for the filesystems being exported. exportfs translates *options* to share-equivalent options. (see [share\(1M\)](#) for information about individual options).
- Attributes**

See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** `expr` – evaluate arguments as an expression

**Synopsis** `/usr/bin/expr argument...`  
`/usr/xpg4/bin/expr argument...`  
`/usr/xpg6/bin/expr argument...`

## Description

`/usr/bin/expr`,  
`/usr/xpg4/bin/expr` The `expr` utility evaluates the expression and writes the result to standard output. The character `0` is written to indicate a zero value and nothing is written to indicate a null string.

`/usr/xpg6/bin/expr` The `expr` utility evaluates the expression and writes the result to standard output followed by a NEWLINE. If there is no result from `expr` processing, a NEWLINE is written to standard output.

**Operands** The *argument* operand is evaluated as an expression. Terms of the expression must be separated by blanks. Characters special to the shell must be escaped (see [sh\(1\)](#)). Strings containing blanks or other special characters should be quoted. The length of the expression is limited to `LINE_MAX` (2048 characters).

The operators and keywords are listed below. The list is in order of increasing precedence, with equal precedence operators grouped within `{ }` symbols. All of the operators are left-associative.

`expr \ | expr` Returns the evaluation of the first *expr* if it is neither NULL nor `0`; otherwise, returns the evaluation of the second *expr* if it is not NULL; otherwise, `0`.

`expr \& expr` Returns the first *expr* if neither *expr* is NULL or `0`, otherwise returns `0`.

`expr{ =, >, >=, <, <=, != } expr` Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a string comparison using the locale-specific coalition sequence. The result of each comparison will be 1 if the specified relationship is TRUE, `0` if the relationship is FALSE.

`expr { +, - } expr` Addition or subtraction of integer-valued arguments.

`expr { \*, /, % } expr` Multiplication, division, or remainder of the integer-valued arguments.

`expr : expr` The matching operator `:` (colon) compares the first argument with the second argument, which must be an internationalized basic regular expression (BRE), except that all patterns are anchored to the beginning of the string. That is, only sequences starting at the first

character of a string are matched by the regular expression. See [regex\(5\)](#) and NOTES. Normally, the `/usr/bin/expr` matching operator returns the number of bytes matched and the `/usr/xpg4/bin/expr` matching operator returns the number of characters matched (0 on failure). If the second argument contains at least one BRE sub-expression `[\(...\)]`, the matching operator returns the string corresponding to `\1`.

*integer* An argument consisting only of an (optional) unary minus followed by digits.

*string* A string argument that cannot be identified as an *integer* argument or as one of the expression operator symbols.

Compatibility Operators (x86 only) The following operators are included for compatibility with INTERACTIVE UNIX System only and are not intended to be used by non- INTERACTIVE UNIX System scripts:

`index string character-list` Report the first position in which any one of the bytes in *character-list* matches a byte in *string*.

`length string` Return the length (that is, the number of bytes) of *string*.

`substr string integer-1 integer-2` Extract the substring of *string* starting at position *integer-1* and of length *integer-2* bytes. If *integer-1* has a value greater than the number of bytes in *string*, `expr` returns a null string. If you try to extract more bytes than there are in *string*, `expr` returns all the remaining bytes from *string*. Results are unspecified if either *integer-1* or *integer-2* is a negative value.

**Examples** **EXAMPLE 1** Adding an integer to a shell variable

Add 1 to the shell variable `a`:

```
example$ a='expr $a + 1'
```

**EXAMPLE 2** Returning a path name segment

The following example emulates [basename\(1\)](#), returning the last segment of the path name `$a`. For `$a` equal to either `/usr/abc/file` or just `file`, the example returns `file`. (Watch out for `/` alone as an argument: `expr` takes it as the division operator. See NOTES below.)

```
example$ expr $a : '.*\/(.*\)' \| $a
```

**EXAMPLE 3** Using `//` characters to simplify the expression

Here is a better version of the previous example. The addition of the `//` characters eliminates any ambiguity about the division operator and simplifies the whole expression.

**EXAMPLE 3** Using // characters to simplify the expression (Continued)

```
example$ expr // $a : '.*\/(.*\).'
```

/usr/bin/expr **EXAMPLE 4** Returning the number of bytes in a variable

```
example$ expr "$VAR" : '.*'
```

/usr/xpg4/bin/expr **EXAMPLE 5** Returning the number of characters in a variable

```
example$ expr "$VAR" : '.*'
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of expr: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** As a side effect of expression evaluation, expr returns the following exit values:

- 0 If the expression is neither NULL nor 0.
- 1 If the expression is either NULL or 0.
- 2 For invalid expressions.
- >2 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWcsu        |
| CSI                 | enabled        |
| Interface Stability | Standard       |

**See Also** [basename\(1\)](#), [ed\(1\)](#), [sh\(1\)](#), [Intro\(3\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [standards\(5\)](#)

**Diagnostics** syntax error Operator and operand errors.  
non-numeric argument Arithmetic is attempted on such a string.

**Notes** After argument processing by the shell, expr cannot tell the difference between an operator and an operand except by the value. If \$a is an =, the command:

```
example$ expr $a = '='
```

looks like:

```
example$ expr = = =
```

as the arguments are passed to expr (and they are all taken as the = operator). The following works:

```
example$ expr X$a = X=
```

Regular Expressions Unlike some previous versions, `expr` uses Internationalized Basic Regular Expressions for all system-provided locales. Internationalized Regular Expressions are explained on the [regex\(5\)](#) manual page.

**Name** `expr` – evaluate arguments as a logical, arithmetic, or string expression

**Synopsis** `/usr/ucb/expr argument...`

**Description** The `expr` utility evaluates expressions as specified by its arguments. After evaluation, the result is written on the standard output. Each token of the expression is a separate argument, so terms of the expression must be separated by blanks. Characters special to the shell must be escaped. Note: `0` is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, two's-complement numbers.

The operators and keywords are listed below. Characters that need to be escaped are preceded by `'\'`. The list is in order of increasing precedence, with equal precedence operators grouped within `{ }` symbols.

`expr \| expr` Returns the evaluation of the first *expr* if it is neither NULL nor `0`; otherwise, returns the evaluation of the second *expr* if it is not NULL; otherwise, `0`.

`expr \& expr` Returns the first *expr* if neither *expr* is NULL or `0`, otherwise returns `0`.

`expr { =, \, \, \<, \<=, != } expr` Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.

`expr { +, - } expr` Addition or subtraction of integer-valued arguments.

`expr { \, /, % } expr` Multiplication, division, or remainder of the integer-valued arguments.

*string* : *regular-expression*  
`match string regular-expression`

The two forms of the matching operator above are synonymous. The matching operators `:` and `match` compare the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of [regexp\(5\)](#), except that all patterns are “anchored” (treated as if they begin with `^`) and therefore `^` is not a special character, in that context. Normally, the matching operator returns the number of characters matched (`0` on failure). Alternatively, the `\ . . . \` pattern symbols can be used to return a portion of the first argument.

`substr string integer-1 integer-2` Extracts the substring of *string* starting at position *integer-1* and of length *integer-2* characters. If *integer-1* has a value greater than the length of *string*, `expr` returns

a null string. If you try to extract more characters than there are in *string*, *expr* returns all the remaining characters from *string*. Beware of using negative values for either *integer-1* or *integer-2* as *expr* tends to run forever in these cases.

|                                          |                                                                                                                                                |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>index string character-list</code> | Reports the first position in <i>string</i> at which any one of the characters in <i>character-list</i> matches a character in <i>string</i> . |
| <code>length string</code>               | Returns the length (that is, the number of characters) of <i>string</i> .                                                                      |
| <code>( expr )</code>                    | Parentheses may be used for grouping.                                                                                                          |

### Examples **EXAMPLE 1** Adding an integer to a shell variable

Add 1 to the shell variable *a*.

```
a='expr $a + 1'
```

### **EXAMPLE 2** Returning a path name segment

Return the last segment of a path name (that is, the filename part). Watch out for / alone as an argument: *expr* will take it as the division operator (see **BUGS** below).

```
'For $a equal to either "/usr/abc/file" or just "file"
expr $a : '.*\/ \ $a
```

### **EXAMPLE 3** Using // characters to simplify the expression

The addition of the // characters eliminates any ambiguity about the division operator and simplifies the whole expression.

```
A better representation of example 2.
expr // $a : '.*\/
```

### **EXAMPLE 4** Returning the value of a variable

Returns the number of characters in \$VAR.

```
expr $VAR : '.*'
```

### **Exit Status** *expr* returns the following exit codes:

- 0 If the expression is neither NULL nor 0.
- 1 If the expression is NULL or 0.
- 2 For invalid expressions.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [sh\(1\)](#), [test\(1\)](#), [attributes\(5\)](#), [regex\(5\)](#)

**Diagnostics**    syntax error                    for operator/operand errors  
                  non-numeric argument        if arithmetic is attempted on such a string  
                  division by zero            if an attempt to divide by zero is made

**Bugs** After argument processing by the shell, `expr` cannot tell the difference between an operator and an operand except by the value. If `$a` is an `=`, the command:

```
expr $a = '='
```

looks like:

```
expr = = =
```

as the arguments are passed to `expr` (and they will all be taken as the `=` operator). The following works:

```
expr X$a = X=
```

Note: the `match`, `substr`, `length`, and `index` operators cannot themselves be used as ordinary strings. That is, the expression:

```
example% expr index expurgatorious length
syntax error
example%
```

generates the 'syntax error' message as shown instead of the value 1 as you might expect.

**Name** exstr – extract strings from source files

**Synopsis** exstr *filename...*  
 exstr -e *filename...*  
 exstr -r [-d] *filename...*

**Description** The `exstr` utility is used to extract strings from C-language source files and replace them by calls to the message retrieval function (see [gettext\(3C\)](#)). This utility will extract all character strings surrounded by double quotes, not just strings used as arguments to the `printf` command or the `printf` routine. In the first form, `exstr` finds all strings in the source files and writes them on the standard output. Each string is preceded by the source file name and a colon (:).

The first step is to use `exstr -e` to extract a list of strings and save it in a file. Next, examine this list and determine which strings can be translated and subsequently retrieved by the message retrieval function. Then, modify this file by deleting lines that can't be translated and, for lines that can be translated, by adding the message file names and the message numbers as the fourth (*msgfile*) and fifth (*msgnum*) entries on a line. The message files named must have been created by [mkmsgs\(1\)](#) and exist in `/usr/lib/locale/locale/LC_MESSAGES`. (The directory `locale` corresponds to the language in which the text strings are written; see [setlocale\(3C\)](#)). The message numbers used must correspond to the sequence numbers of strings in the message files.

Now use this modified file as input to `exstr -r` to produce a new version of the original C-language source file in which the strings have been replaced by calls to the message retrieval function `gettext()`. The *msgfile* and *msgnum* fields are used to construct the first argument to `gettext()`. The second argument to `gettext()` is printed if the message retrieval fails at run-time. This argument is the null string, unless the `-d` option is used.

This utility cannot replace strings in all instances. For example, a static initialized character string cannot be replaced by a function call. A second example is that a string could be in a form of an escape sequence which could not be translated. In order not to break existing code, the files created by invoking `exstr -e` must be examined and lines containing strings not replaceable by function calls must be deleted. In some cases the code may require modifications so that strings can be extracted and replaced by calls to the message retrieval function.

**Options** The following options are supported:

-e Extract a list of strings from the named C-language source files, with positional information. This list is produced on standard output in the following format:

*file:line:position:msgfile:msgnum:string*

The fields are defined as follows:

|                 |                                      |
|-----------------|--------------------------------------|
| <i>file</i>     | the name of a C-language source file |
| <i>line</i>     | line number in the file              |
| <i>position</i> | character position in the line       |
| <i>msgfile</i>  | null                                 |
| <i>msgnum</i>   | null                                 |
| <i>string</i>   | the extracted text string            |

Normally you would redirect this output into a file. Then you would edit this file to add the values you want to use for *msgfile* and *msgnum*:

*msgfile* the file that contains the text strings that will replace *string*. A file with this name must be created and installed in the appropriate place by the [mkmsgs\(1\)](#) utility.

*msgnum* the sequence number of the string in *msgfile*.

The next step is to use `exstr -r` to replace *strings* in *file*.

- r Replace strings in a C-language source file with function calls to the message retrieval function `gettext()`.
- d This option is used together with the `-r` option. If the message retrieval fails when `gettext()` is invoked at run-time, then the extracted string is printed. You would use the capability provided by `exstr` on an application program that needs to run in an international environment and have messages print in more than one language. `exstr` replaces text strings with function calls that point at strings in a message data base. The data base used depends on the run-time value of the `LC_MESSAGES` environment variable (see [environ\(5\)](#)).

### Examples EXAMPLE 1 Usind the `exstr` Command

Assume that the file `example.c` contains two strings:

```
main()
{
 printf("This is an example\n");
 printf("Hello world!\n");
}
```

The `exstr` utility, invoked with the argument `example.c` extracts strings from the named file and prints them on the standard output.

**EXAMPLE 1** Using the `exstr` Command (Continued)

```
example% exstr example.c
```

produces the following output:

```
example.c:This is an example\n
example.c:Hello world!\n
```

The `exstr` utility, invoked with the `-e` option and the argument `example.c`, and redirecting output to the file `example.stringsout`

```
example% exstr -e example.c > example.stringsout
```

produces the following output in the file `example.stringsout`

```
example.c:3:8::This is an example\n
example.c:4:8::Hello world!\n
```

You must edit `example.stringsout` to add the values you want to use for the *msgfile* and *msgnum* fields before these strings can be replaced by calls to the retrieval function. If `UX` is the name of the message file, and the numbers 1 and 2 represent the sequence number of the strings in the file, here is what `example.stringsout` looks like after you add this information:

```
example.c:3:8:UX:1:This is an example\n
example.c:4:8:UX:2:Hello world!\n
```

The `exstr` utility can now be invoked with the `-r` option to replace the strings in the source file by calls to the message retrieval function `gettext()`.

```
example% exstr -r example.c <example.stringsout >intlexample.c
```

produces the following output:

```
extern char *gettext();

main()

{

 printf(gettext("UX:1", ""));

 printf(gettext("UX:2", ""));

}
```

The following example:

```
example% exstr -rd example.c <example.stringsout >intlexample.c
```

uses the extracted strings as a second argument to `gettext()`:

**EXAMPLE 1** Using the `exstr` Command (Continued)

```
extern char *gettext();

main()
{
 printf(gettext("UX:1", "This is an example\n"));
 printf(gettext("UX:2", "Hello world!\n"));
}
```

**Files** `/usr/lib/locale/locale/LC_MESSAGES/*` files created by [mkmsgs\(1\)](#)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

**See Also** [gettext\(1\)](#), [mkmsgs\(1\)](#), [printf\(1\)](#), [srchtxt\(1\)](#), [gettext\(3C\)](#), [printf\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Diagnostics** The error messages produced by `exstr` are intended to be self-explanatory. They indicate errors in the command line or format errors encountered within the input file.

**Name** face – executable for the Framed Access Command Environment Interface

**Synopsis** face [-i *init\_file*] [-c *command\_file*] [-a *alias\_file*]  
[*filename*]...

**Description** The Framed Access Command Environment Interface (FACE) presents your files and file folders on the screen through a system of menus and forms if you are properly set up as a FACE user.

*filename* must follow the naming convention Menu.*xxx* for a menu, Form.*xxx* for a form, and Text.*xxx* for a text file, where *xxx* is any string that conforms to the UNIX system file naming conventions. The Form and Menu Language Interpreter (FMLI) descriptor lifetime will be ignored for all frames opened by argument to face. These frames have a lifetime of immortal by default. If *filename* is not specified on the command line, the FACE Menu will be opened along with those objects specified by the LOGINWIN environment variables. These variables are found in the user's .environ file.

**Options** The following options are supported:

|                        |              |
|------------------------|--------------|
| -a <i>alias_file</i>   | Alias file   |
| -c <i>command_file</i> | Command file |
| -i <i>init_file</i>    | Initial file |

**Operands** The following operand is supported:

|                 |                                                                             |
|-----------------|-----------------------------------------------------------------------------|
| <i>filename</i> | The full pathname of the file describing the object to be opened initially. |
|-----------------|-----------------------------------------------------------------------------|

**Exit Status** The face command will return a non-zero exit value if the user is not properly set up as a FACE user.

**Files** \$HOME/pref/.environ

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWfac         |
| Stability      | Obsolete        |

**See Also** [env\(1\)](#), [attributes\(5\)](#)

**Notes** The Framed Access Command Environment Interface (FACE) is obsolete and might be removed in a future release.

**Name** factor – obtain the prime factors of a number

**Synopsis** factor [*integer*]

**Description** factor writes to standard input all prime factors for any positive integer less than or equal to  $10^{14}$ . The prime factors are written the proper number of times.

If factor is used *without* an argument, it waits for an integer to be entered. After entry of the integer, it factors it, writes its prime factors the proper number of times, and then waits for another integer. factor exits if a 0 or any non-numeric character is entered.

If factor is invoked *with* an argument (*integer*), it writes the integer, factors it and writes all the prime factors as described above, and then exits. If the argument is 0 or non-numeric, factor writes a 0 and then exits.

The maximum time to factor an integer is proportional to  $\sqrt{n}$ , where  $n$  is the integer which is entered. factor will take this time when  $n$  is prime or the square of a prime.

**Operands** *integer* Any positive integer less than or equal to  $10^{14}$ .

**Exit Status** 0 Successful completion.  
1 An error occurred.

**Diagnostics** factor prints the error message Ouch! for input out of range or for garbage input.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** fastboot, fasthalt – reboot/halt the system without checking the disks

**Synopsis** /usr/ucb/fastboot [*boot-options*]

/usr/ucb/fasthalt [*halt-options*]

**Description** fastboot and fasthalt are shell scripts that invoke reboot and halt with the proper arguments.

These commands are provided for compatibility only.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**Name** fdformat – format floppy diskette or PCMCIA memory card

**Synopsis** fdformat [-dDeFhLmMUqvX] [-b *label*] [-B *filename*]  
[-t *dostype*] [*devname*]

**Description** The fdformat utility has been superseded by [rmformat\(1\)](#), which provides most but not all of fdformat's functionality.

fdformat is used to format diskettes and PCMCIA memory cards. All new blank diskettes or PCMCIA memory cards must be formatted before they can be used.

fdformat formats and verifies the media and indicates whether any bad sectors were encountered. All existing data on the diskette or PCMCIA memory card, if any, is destroyed by formatting. If no device name is given, fdformat uses the diskette as a default.

By default, fdformat uses the configured capacity of the drive to format the diskette. A 3.5 inch high-density drive uses diskettes with a formatted capacity of 1.44MB. A 5.25 inch high-density drive uses diskettes with a formatted capacity of 1.2MB. In either case, a density option does not have to be specified to fdformat. However, a density option must be specified when using a diskette with a lower capacity than the drive's default. Use the -H option to format high-density diskettes (1.44MB capacity) in an extra-high-density (ED) drive. Use the -D option, the -l option, or the -L option to format double-density (or low-density) diskettes (720KB capacity) in an HD or ED drive. To format medium-density diskettes (1.2MB capacity), use the -M option with -t nec (this is the same as using the -m option with -t nec).

Extended density uses double-sided, extended-density or extra-high-density (DS/ED) diskettes. Medium and high densities use the same media: double-sided, high-density (DS/HD) diskettes. Double (low) density uses double-sided, double-density (DS/DD

D) diskettes. Substituting diskettes of one density for diskettes of either a higher or lower density generally does not work. Data integrity cannot be assured whenever a diskette is formatted to a capacity not matching its density.

A PCMCIA memory card with densities from 512KB to 64MB may be formatted.

fdformat writes new identification and data fields for each sector on all tracks unless the -x option is specified. For diskettes, each sector is verified if the -v option is specified.

After formatting and verifying, fdformat writes an operating-system label on block 0. Use the -t dos option (same as the -d option) to put an MS-DOS file system on the diskette or PCMCIA memory card after the format is done. Use the -t nec option with the -M option (same as the -m option) to put an NEC-DOS file system on a diskette. Otherwise, fdformat writes a SunOS label in block 0.

**Options** The following options are supported:

-b *label* Labels the media with volume label. A SunOS volume label is restricted to 8 characters. A DOS volume label is restricted to 11 upper-case characters.

- B *filename*      Installs special boot loader in *filename* on an MS-DOS diskette. This option is only meaningful when the -d option (or -t dos) is also specified.
- D                  Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as the -l or -L options). This is the default for double-density type drives. It is needed if the drive is a high- or extended-density type.
- e                  Ejects the diskette when done. This feature is not available on all systems.
- E                  Formats a 2.88MB (3.5 inch) extended-density diskette. This is the default for extended-density type drives.
- f                  Forces formatting, that is, this option does not ask for confirmation before starting format.
- H                  Formats a 1.44MB (3.5 inch) or 1.2MB (5.25 inch) high-density diskette. This is the default for high-density type drives; it is needed if the drive is the extended-density type.
- M                  Writes a 1.2MB (3.5 inch) medium-density format on a high-density diskette (use only with the -t nec option). This is the same as using -m.  
  
This feature is not available on all systems.
- q                  Quiet; does not print status messages.
- t dos              Installs an MS-DOS file system and boot sector formatting. This is equivalent to the DOS format command or the -d option.
- t nec              Installs an NEC-DOS file system and boot sector on the disk after formatting. This should be used only with the -M option. This feature is not available on all systems.
- U                  Performs umount on any file systems and then formats. See [mount\(1M\)](#).
- v                  Verifies each block of the diskette after the format.
- x                  Skips the format and only writes a SunOS label or an MS-DOS file system.

**Operands**    The following operands are supported:

- devname*        Replaces *devname* with `rdiskette0` (systems without Volume Management) or `floppy0` (systems with Volume Management) to use the first drive or `rdiskette1` (systems without Volume Management) or `floppy1` (systems with Volume Management) to use the second drive. If *devname* is omitted, the first drive, if one exists, is used. For PCMCIA memory cards, replace *devname* with the device name for the PCMCIA memory card which resides in `/dev/rdisk/cNtNdNsN` or `/dev/dsk/cNtNdNsN`. If *devname* is omitted, the default diskette drive, if one exists, is used.

If devname is omitted, the default diskette drive, if one exists, will be used. *N* represents a decimal number and can be specified as follows:

- cN*     Controller *N*
- tN*     Technology type *N*:
  - 0x1     ROM
  - 0x2     OTPROM
  - 0x3     EPROM
  - 0x4     EEPROM
  - 0x5     FLASH
  - 0x6     SRAM
  - 0x7     DRAM
- dN*     Technology region in type *N*.
- sN*     Slice *N*.

The following options are provided for compatibility with previous versions of `fdformat`. Their use is discouraged.

- d**     Formats an MS-DOS floppy diskette or PCMCIA memory card (same as **-t dos**). This is equivalent to the MS-DOS `FORMAT` command.
- l**     Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as **-D** or **-L**). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type.
- L**     Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as **-l** or **-D**). This is the default for double-density type drives.
- m**     Writes a 1.2 MB (3.5 inch) medium- density format on a high-density diskette (use only with the **-t nec** option). This is the same as using **-M**. This feature is not available on all systems.

|              |                                 |                                                                                                                  |

| <code>/dev/dsk/cNtNdNsN</code>       | Directory providing block device access for the PCMCIA memory card. See OPERANDS for a description of <i>N</i> .                      |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE |
|---------------|-----------------|
| Availability  | SUNWcsu         |

**See Also** [cpio\(1\)](#), [eject\(1\)](#), [rmformat\(1\)](#), [tar\(1\)](#), [volcancel\(1\)](#), [volcheck\(1\)](#), [volmissing\(1\)](#), [volrmmount\(1\)](#), [mount\(1M\)](#), [newfs\(1M\)](#), [prtvtoc\(1M\)](#), [vold\(1M\)](#), [rmmount.conf\(4\)](#), [vold.conf\(4\)](#), [attributes\(5\)](#), [pcfs\(7FS\)](#), [volfs\(7FS\)](#)

x86 Only [fd\(7D\)](#)

**Notes** A diskette or PCMCIA memory card containing a ufs file system created on a SPARC based system (by using `fdformat` and [newfs\(1M\)](#)), is not identical to a diskette or PCMCIA memory card containing a ufs file system created on an x86 based system. Do not interchange ufs diskettes or memory cards between these platforms. Use [cpio\(1\)](#) or [tar\(1\)](#) to transfer files on diskettes or memory cards between them. A diskette or PCMCIA memory card formatted using the `-t dos` option (or `-d`) for MS-DOS does not have the necessary system files, and is therefore not bootable. Trying to boot from it on a PC produces the following message:

```
Non-System disk or disk error.
Replace and strike any key when ready
```

**Bugs** Currently, bad sector mapping is not supported on floppy diskettes or PCMCIA memory cards. Therefore, a diskette or memory card is unusable if `fdformat` finds an error (bad sector).

**Name** fgrep – search a file for a fixed-character string

**Synopsis** /usr/bin/fgrep [-bchilnsvx] -e *pattern\_list* [*file...*]  
/usr/bin/fgrep [-bchilnsvx] -f *file* [*file...*]  
/usr/bin/fgrep [-bchilnsvx] *pattern* [*file...*]  
/usr/xpg4/bin/fgrep [-bchilnqsvx] -e *pattern\_list* [-f *file*]  
[*file...*]  
/usr/xpg4/bin/fgrep [-bchilnqsvx] [-e *pattern\_list*] -f *file*  
[*file...*]  
/usr/xpg4/bin/fgrep [-bchilnqsvx] *pattern* [*file...*]

**Description** The fgrep (fixed grep) utility searches files for a character string and prints all lines that contain that string. fgrep is different from [grep\(1\)](#) and from [egrep\(1\)](#) because it searches for a string, instead of searching for a pattern that matches an expression.

The characters \$, \*, [, ^, |, (, ), and \ are interpreted literally by fgrep, that is, fgrep does not recognize full regular expressions as does egrep. These characters have special meaning to the shell. Therefore, to be safe, enclose the entire *string* within single quotes ( ' ).

If no files are specified, fgrep assumes standard input. Normally, each line that is found is copied to the standard output. The file name is printed before each line that is found if there is more than one input file.

**Options** The following options are supported for both /usr/bin/fgrep and /usr/xpg4/bin/fgrep:

- b               Precedes each line by the block number on which the line was found. This can be useful in locating block numbers by context. The first block is 0.
- c               Prints only a count of the lines that contain the pattern.
- e *pattern\_list*   Searches for a *string* in *pattern-list*. This is useful when the *string* begins with a –.
- f *pattern-file*   Takes the list of patterns from *pattern-file*.
- h               Suppresses printing of files when searching multiple files.
- i               Ignores upper/lower case distinction during comparisons.
- l               Prints the names of files with matching lines once, separated by new-lines. Does not repeat the names of files when the pattern is found more than once.
- n               Precedes each line by its line number in the file. The first line is 1.
- s               Works silently, that is, displays nothing except error messages. This is useful for checking the error status.
- v               Prints all lines except those that contain the pattern.

-x Prints only lines that are matched entirely.

/usr/xpg4/bin/fgrep The following options are supported for /usr/xpg4/bin/fgrep only:

-q Quiet. Does not write anything to the standard output, regardless of matching lines. Exits with zero status if an input line is selected.

**Operands** The following operands are supported:

*file* Specifies a path name of a file to be searched for the patterns. If no *file* operands are specified, the standard input will be used.

/usr/bin/fgrep *pattern* Specifies a pattern to be used during the search for input.

/usr/xpg4/bin/fgrep *pattern* Specifies one or more patterns to be used during the search for input. This operand is treated as if it were specified as -e *pattern\_list*.

**Usage** See [largefile\(5\)](#) for the description of the behavior of fgrep when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of fgrep: LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 If any matches are found
- 1 If no matches are found
- 2 For syntax errors or inaccessible files, even if matches were found.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| /usr/bin/fgrep | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------|-----------------|
|                | Availability   | SUNWcs          |

| /usr/xpg4/bin/fgrep | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------|-----------------|
|                     | Availability   | SUNWxcu4        |
|                     | CSI            | Enabled         |

**See Also** [ed\(1\)](#), [egrep\(1\)](#), [grep\(1\)](#), [sed\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [XPG4\(5\)](#)

**Notes** Ideally, there should be only one grep command, but there is not a single algorithm that spans a wide enough range of space-time tradeoffs.

Lines are limited only by the size of the available virtual memory.

`/usr/xpg4/bin/fgrep` The `/usr/xpg4/bin/fgrep` utility is identical to `/usr/xpg4/bin/grep -F` (see [grep\(1\)](#)). Portable applications should use `/usr/xpg4/bin/grep -F`.

**Name** file – determine file type

**Synopsis** /usr/bin/file [-dh] [-m *mfile*] [-M *Mfile*] [-f *ffile*]  
*file*...  
 /usr/bin/file [-dh] [-m *mfile*] [-M *Mfile*] -f *ffile*  
 /usr/bin/file -i [-h] [-f *ffile*] *file*...  
 /usr/bin/file -i [-h] -f *ffile*  
 /usr/bin/file -c [-d] [-m *mfile*] [-M *Mfile*]  
 /usr/xpg4/bin/file [-dh] [-m *mfile*] [-M *Mfile*] [-f *ffile*]  
*file*...  
 /usr/xpg4/bin/file [-dh] [-m *mfile*] [-M *Mfile*] -f *ffile*  
 /usr/xpg4/bin/file -i [-h] [-f *ffile*] *file*...  
 /usr/xpg4/bin/file -i [-h] -f *ffile*  
 /usr/xpg4/bin/file -c [-d] [-m *mfile*] [-M *Mfile*]

**Description** The *file* utility performs a series of tests on each file supplied by *file* and, optionally, on each file listed in *ffile* in an attempt to classify it. If the file is not a regular file, its file type is identified. The file types directory, FIFO, block special, and character special are identified as such. If the file is a regular file and the file is zero-length, it is identified as an empty file.

If *file* appears to be a text file, *file* examines the first 512 bytes and tries to determine its programming language. If *file* is a symbolic link, by default the link is followed and *file* tests the file to which the symbolic link refers.

If *file* is a relocatable object, executable, or shared object, *file* prints out information regarding the file's execution requirements. This information includes the machine class, byte-ordering, static or dynamic linkage, and any software or hardware capability requirements.

By default, *file* will try to use the localized magic file /usr/lib/locale/locale/LC\_MESSAGES/magic, if it exists, to identify files that have a magic number. For example, in the Japanese locale, *file* will try to use /usr/lib/locale/ja/LC\_MESSAGES/magic. If a localized magic file does not exist, *file* will utilize /etc/magic. A magic number is a numeric or string constant that indicates the file type. See [magic\(4\)](#) for an explanation of the format of /etc/magic.

If *file* does not exist, cannot be read, or its file status could not be determined, it is not considered an error that affects the exit status. The output will indicate that the file was processed, but that its type could not be determined.

**Options** The following options are supported:

- c Checks the magic file for format errors. For reasons of efficiency, this validation is normally not carried out.
- d Applies any position-sensitive and context-sensitive default system tests to the file.
- f *ffile* *ffile* contains a list of the files to be examined.
- h When a symbolic link is encountered, this option identifies the file as a symbolic link. If -h is not specified and *file* is a symbolic link that refers to a non-existent file, the `file` utility identifies the file as a symbolic link, as if -h had been specified.
- i If a file is a regular file, this option does not attempt to classify the type of file further, but identifies the file as a “regular file”.
- m *mfile*  
  
    /usr/bin/file  
    Uses *mfile* as an alternate magic file, instead of /etc/magic.  
  
    /usr/xpg4/bin/file  
    Specifies the name of a file containing position-sensitive tests that are applied to a file in order to classify it (see [magic\(4\)](#)). If the -m option is specified without specifying the -d option or the -M option, position-sensitive default system tests are applied after the position-sensitive tests specified by the -m option.
- M *Mfile* Specifies the name of a file containing position-sensitive tests that are applied to a file in order to classify it (see [magic\(4\)](#)). No position-sensitive default system tests nor context-sensitive default system tests are applied unless the -d option is also specified.

If the -M option is specified with the -d option, the -m option, or both, or if the -m option is specified with the -d option, the concatenation of the position-sensitive tests specified by these options is applied in the order specified by the appearance of these options.

**Operands** The following operands are supported:

*file* A path name of a file to be tested.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `file` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Binary executable files

Determine if an argument is a binary executable file:

EXAMPLE 1 Binary executable files (Continued)

```
file "$1" | grep -Fq executable &&
printf "%s is executable.\n" "$1"
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of file: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files** /etc/magic file's magic number file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWcsu        |
| CSI                 | enabled        |
| Interface Stability | Standard       |

**See Also** [elfdump\(1\)](#), [ls\(1\)](#), [magic\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** file – determine the type of a file by examining its contents

**Synopsis** /usr/ucb/file [-f *ffile*] [-cL] [-m *mfile*] *filename*...

**Description** file performs a series of tests on each *filename* in an attempt to determine what it contains. If the contents of a file appear to be ASCII text, file examines the first 512 bytes and tries to guess its language.

file uses the file /etc/magic to identify files that have some sort of *magic number*, that is, any file containing a numeric or string constant that indicates its type.

**Options**

- c Check for format errors in the magic number file. For reasons of efficiency, this validation is not normally carried out. No file type-checking is done under -c.
- f *ffile* Get a list of filenames to identify from *ffile*.
- L If a file is a symbolic link, test the file the link references rather than the link itself.
- m *mfile* Use *mfile* as the name of an alternate magic number file.

**Examples** **EXAMPLE 1** Using file on all the files in a specific user's directory.

This example illustrates the use of file on all the files in a specific user's directory:

```
example% pwd
/usr/blort/misc

example% /usr/ucb/file *

code: mc68020 demand paged executable
code.c: c program text
counts: ascii text
doc: roff,nroff, or eqn input text
empty.file: empty
libz: archive random library
memos: directory
project: symboliclink to /usr/project
script: executable shell script
titles: ascii text
s5.stuff: cpio archive

example%
```

**Environment Variables** The environment variables LC\_CTYPE, LANG, and LC\_default control the character classification throughout file. On entry to file, these environment variables are checked in the following order: LC\_CTYPE, LANG, and LC\_default. When a valid value is found, remaining environment variables for character classification are ignored. For example, a new setting for LANG does not override the current valid character classification rules of LC\_CTYPE. When none of the values is valid, the shell character classification defaults to the POSIX.1 “C” locale.

**Files** /etc/magic

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [magic\(4\)](#), [attributes\(5\)](#)

**Bugs** file often makes mistakes. In particular, it often suggests that command files are C programs.  
file does not recognize Pascal or LISP.

**Name** filesync – synchronize ordinary, directory or special files

**Synopsis** filesync [-aehmnqvy] [-o src | dst]  
          [-f src | dst | old | new] [-r *directory*]...  
filesync [-aehmnqvy] -s *source-dir* -d *dest-dir* *filename*...

**Description** The filesync utility *synchronizes* files between multiple computer systems, typically a server and a portable computer. filesync synchronizes ordinary, directory or special files. Although intended for use on nomadic systems, filesync is useful for backup and file replication on more permanently connected systems.

If files are synchronized between systems, the corresponding files on each of the systems are *identical*. Changing a file on one or both of the systems causes the files to become different (not synchronized). In order to make the files identical again, the differences between the files must be *reconciled*. See Reconciling and Synchronizing Files for specific details about how filesync reconciles and synchronizes files.

There are two forms of the filesync command. The first form of filesync is invoked without file arguments. This form of filesync reconciles differences between the files and systems specified in the \$HOME/.packingrules file. \$HOME/.packingrules is a packing rules list for filesync and cachefspack, and contains a list of files to be kept synchronized. See [packingrules\(4\)](#) and [cachefspack\(1M\)](#).

The second form of filesync copies specific files from a directory on the source system to a directory on the destination system. In addition, this form of filesync adds the file or files specified as arguments (*filename*) to \$HOME/.packingrules. See -s and -d for information about specifying directories on source and destination systems. See OPERANDS for details about specifying file (*filename*) arguments.

Multiple filesync commands are cumulative (that is, the specified files are added to the already existing packing rules file list). See Multiple filesync Commands.

Reconciling and  
Synchronizing Files filesync synchronizes files between computer systems by performing the following two tasks:

1. filesync examines the directories and files specified in the packing rules file on both systems, and determines whether or not they are identical. Any file that differs requires reconciliation.

filesync also maintains a baseline summary in the \$HOME/.filesync-base file for all of the files that are being monitored. This file lists the names, types, and sizes of all files as of the last reconciliation.

2. Based on the information contained in the baseline file and the specified options (see Resolving filesync Conflicts), filesync determines which of the various copies is the correct one, and makes the corresponding changes to the other system. Once this has been done, the two copies are, again, identical (synchronized).

If a source file has changed and the destination file has not, the changes on the source system are propagated to the destination system. If a destination file has changed and the corresponding source file has not, the changes on the destination file are propagated to the source system. If both systems have changed (and the files are not still identical) a warning message will be printed out, asking the user to resolve the conflict manually. See [Resolving filesync Conflicts](#).

**Resolving filesync Conflicts** In cases where files on both sides have changed, `filesync` attempts to determine which version should be chosen. If `filesync` cannot automatically determine which version should be selected, it prints out a warning message and leaves the two incompatible versions of the file unreconciled.

In these cases, you must either resolve the differences manually, or tell `filesync` how to choose which file should win. Use the `-o` and `-f` options to tell `filesync` how to resolve conflicts (see [OPTIONS](#)).

Alternatively, for each conflicting file, you can examine the two versions, determine which one should be kept, and manually bring the two versions into agreement (by copying, deleting, or changing the ownership or protection to be correct). You can then re-run `filesync` to see whether or not any other conflicts remain.

**Packing Rules File** The packing rules file `$HOME/.packingrules` contains a list of files to be kept synchronized. The syntax of this file is described in [packingrules\(4\)](#).

The `$HOME/.packingrules` file is automatically created if users invoke `filesync` with filename arguments. By using `filesync` options, users can augment the packing rules in `$HOME/.packingrules`.

Many users choose to create the packing rules file manually and edit it by hand. Users can edit `$HOME/.packingrules` (using any editor) to permanently change the `$HOME/.packingrules` file, or to gain access to more powerful options that are not available from the command line (such as `IGNORE` commands). It is much easier to enter complex wildcard expressions by editing the `$HOME/.packingrules` file.

**Baseline File** `$HOME/.filesync-base` is the `filesync` baseline summary file. `filesync` uses the information in `$HOME/.filesync-base` to identify the differences between files during the reconciliation and synchronization process. Users do not create or edit the baseline file. It is created automatically by `filesync` and records the last known state of agreement between all of the files being maintained.

**Multiple filesync Commands** Over a period of time, the set of files you want to keep synchronized can change. It is common, for instance, to want to keep files pertaining to only a few active projects on your notebook. If you continue to keep files associated with every project you have ever worked on synchronized, your notebook's disk will fill up with old files. Each `filesync` command will waste a lot of time updating files you no longer care about.

If you delete the files from your notebook, `filesync` will want to perform the corresponding deletes on the server, which would not be what you wanted. Rather, you would like a way to tell `filesync` to stop synchronizing some of the files. There are two ways to do this:

1. Edit `$HOME/.packingrules`. Delete the rules for the files that you want to delete.
2. Delete `$HOME/.packingrules`. Use the `filesync` command to specify the files that you want synchronized.

Either way works, and you can choose the one that seems easiest to you. For minor changes, it is probably easier to just edit `$HOME/.packingrules`. For major changes it is probably easier to start from scratch.

Once `filesync` is no longer synchronizing a set of files, you can delete them from your notebook without having any effect on the server.

**Nomadic Machines** When using `filesync` to keep files synchronized between nomadic machines and a server, store the packing rules and baseline files on the nomadic machines, not the server. If, when logged into your notebook, the `HOME` environment variable does not normally point to a directory on your notebook, you can use the `FILESYNC` environment variable to specify an alternate location for the packing rules and baseline files.

Each nomadic machine should carry its own packing rules and baseline file. Incorrect file synchronization can result if a server carries a baseline file and multiple nomadic machines attempt to reconcile against the server's baseline file. In this case, a nomadic machine could be using a baseline file that does not accurately describe the state of its files. This might result in incorrect reconciliations.

To safeguard against the dangers associated with a single baseline file being shared by more than two machines, `filesync` adds a default rule to each new packing rules file. This default rule prevents the packing rules and baseline files from being copied.

**Options** The following options are supported:

- a Force the checking of Access Control Lists (ACLs) and attempt to make them agree for all new and changed files. If it is not possible to set the ACL for a particular file, `filesync` stops ACL synchronization for that file.  
  
Some file systems do not support ACLs. It is not possible to synchronize ACLs between file systems that support ACLs and those that do not; attempting to do so will result in numerous error messages.
- d *dest-dir* Specify the directory on the destination system into which *filename* is to be copied. Use with the -s *source-dir* option and the *filename* operand. See -s and OPERANDS.

- 
- e** Flag all differences. It may not be possible to resolve all conflicts involving modes and ownership (unless `filesync` is being run with root privileges). If you cannot change the ownership or protections on a file, `filesync` will normally ignore conflicts in ownership and protection. If you specify the `-e` (everything must agree) flag, however, `filesync` will flag these differences.
- f src | dst | old | new** The `-f` option tells `filesync` how to resolve conflicting changes. If a file has been changed on both systems, and an `-f` option has been specified, `filesync` will retain the changes made on the favored system and discard the changes made on the unfavored system.
- Specify `-f src` to favor the source-system file. Specify `-f dst` to favor the destination-system file. Specify `-f old` to favor the older version of the file. Specify `-f new` to favor the newer version of the file.
- It is possible to specify the `-f` and `-o` options in combination if they both specify the same preference (`src` and `dst`). If `-f` and `-o` conflict, the `-f` option is ignored. See the `-o` option description.
- h** Halt on error. Normally, if `filesync` encounters a read or write error while copying files, it notes the error and the program continues, in an attempt to reconcile other files. If the `-h` option is specified, `filesync` will immediately halt when one of these errors occurs and will not try to process any more files.
- m** Ensure that both copies of the file have the same modification time. The modification time for newly copied files is set to the time of reconciliation by default. File changes are ordered by increasing modification times so that the propagated files have the same relative modification time ordering as the original changes. Users should be warned that there is usually some time skew between any two systems, and transferring modification times from one system to another can occasionally produce strange results.
- There are instances in which using `filesync` to update some (but not all) files in a directory will confuse the make program. If, for instance, `filesync` is keeping `.c` files synchronized, but ignoring `.o` files, a changed `.c` file may show up with a modification time prior to a `.o` file that was built from a prior version of the `.c` file.
- n** Do not really make the changes. If the `-n` option is specified, `filesync` determines what changes have been made to files, and

what reconciliations are required and displays this information on the standard output. No changes are made to files, including the packing rules file.

Specifying both the `-n` and `-o` options causes `filesync` to analyze the prevailing system and report the changes that have been made on that system. Using `-n` and `-o` in combination is useful if your machine is disconnected (and you cannot access the server) but you want to know what changes have been made on the local machine. See the `-o` option description.

`-o src | dst`

The `-o` option forces a one-way reconciliation, favoring either the source system (`src`) or destination system (`dst`).

Specify `-o src` to propagate changes only from the source system to the destination system. Changes made on the destination system are ignored. `filesync` aborts if it cannot access a source or destination directory.

Specify `-o dst` to propagate changes only from the destination system to the source system. Changes made on the source system are ignored. `filesync` aborts if it cannot access a source or destination directory.

Specifying `-n` with the `-o` option causes `filesync` to analyze the prevailing system and reports on what changes have been made on that system. Using `-n` and `-o` in combination is useful if a machine is disconnected (and there is no access to the server), but you want to know what changes have been made on the local machine. See the `-n` option description.

It is possible to specify the `-o` and `-f` options in combination if they both specify the same preference (`src` or `dst`). If `-o` and `-f` options conflict, the `-f` option will be ignored. See the `-f` option description.

`-q`

Suppress the standard `filesync` messages that describe each reconciliation action as it is performed.

The standard `filesync` message describes each reconciliation action in the form of a UNIX shell command (for example, `mv`, `ln`, `cp`, `rm`, `chmod`, `chown`, `chgrp`, `setfacl`, and so forth).

`-r directory`

Limit the reconciliation to *directory*. Specify multiple directories with multiple `-r` specifications.

---

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-s</b> <i>source-dir</i> | Specify the directory on the source system from which the <i>filename</i> to be copied is located. Use with the <b>-d</b> <i>dest-dir</i> option and the <i>filename</i> operand. See the <b>-d</b> option description and OPERANDS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>-v</b>                   | Display additional information about each file comparison as it is made on the standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>-y</b>                   | Bypass safety check prompts. Nomadic machines occasionally move between domains, and many of the files on which <code>filesync</code> operates are expected to be accessed by NFS. There is a danger that someday <code>filesync</code> will be asked to reconcile local changes against the wrong file system or server. This could result in a large number of inappropriate copies and deletions. To prevent such a mishap, <code>filesync</code> performs a few safety checks prior to reconciliation. If large numbers of files are likely to be deleted, or if high level directories have changed their I-node numbers, <code>filesync</code> prompts for a confirmation before reconciliation. If you know that this is likely, and do not want to be prompted, use the <b>-y</b> (yes) option to automatically confirm these prompts. |

**Operands** The following operands are supported:

*filename* The name of the ordinary file, directory, symbolic link, or special file in the specified source directory (*source-dir*) to be synchronized. Specify multiple files by separating each filename by spaces. Use the *filename* operand with the **-s** and **-d** options. See OPTIONS.

If *filename* is an ordinary file, that ordinary file will be replicated (with the same *filename*) in the specified destination directory (*dest-dir*).

If *filename* is a directory, that directory and all of the files and subdirectories under it will be replicated (recursively) in the specified destination directory (*dest-dir*).

If *filename* is a symbolic link, a copy of that symbolic link will be replicated in the specified destination directory (*dest-dir*).

If *filename* is a special file, a special file with the same major or minor device numbers will be replicated in the specified destination directory. (*dest-dir*). Only super-users can use `filesync` to create special files.

Files created in the destination directory (*dest-dir*) will have the same owner, group and other permissions as the files in the source directory.

If *filename* contains escaped shell wildcard characters, the wildcard characters are stored in `$HOME/.packingrules` and evaluated each time `filesync` is run.

For example, the following would make sure that the two specified files, currently in \$RHOME, were replicated in \$HOME:

```
filesync -s $RHOME -d $HOME a.c b.c
```

The following example would ensure that all of the \*.c files in \$RHOME were replicated in \$HOME, even if those files were not created until later.

```
filesync -s $RHOME -d $HOME '*.c'
```

If any of the destination files already exist, filesync ensures that they are identical and issues warnings if they are not.

Once files have been copied, the distinction between the source and destination is a relatively arbitrary one (except for its use in the -o and -f switches).

|                       |                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                           |

**Name** find – find files

**Synopsis** /usr/bin/find [-H | -L] *path...* *expression*  
/usr/xpg4/bin/find [-H | -L] *path...* *expression*

**Description** The `find` utility recursively descends the directory hierarchy for each *path* seeking files that match a Boolean *expression* written in the primaries given below.

`find` is able to descend to arbitrary depths in a file hierarchy and does not fail due to path length limitations (unless a *path* operand specified by the application exceeds `PATH_MAX` requirements).

**Options** The following options are supported:

- H Causes the file information and file type evaluated for each symbolic link encountered on the command line to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type is for the link itself. File information for all symbolic links not on the command line is that of the link itself.
- L Causes the file information and file type evaluated for each symbolic link to be those of the file referenced by the link, and not the link itself. See NOTES.

Specifying more than one of the mutually-exclusive options `-H` and `-L` is not considered an error. The last option specified determines the behavior of the utility.

**Operands** The following operands are supported:

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                    |                |                  |                 |                    |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|----------------|------------------|-----------------|--------------------|
| <i>path</i>       | A pathname of a starting point in the directory hierarchy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                    |                |                  |                 |                    |
| <i>expression</i> | The first argument that starts with a <code>–</code> , or is a <code>!</code> or a <code>(</code> , and all subsequent arguments are interpreted as an <i>expression</i> made up of the following primaries and operators. In the descriptions, wherever <i>n</i> is used as a primary argument, it is interpreted as a decimal integer optionally preceded by a plus (+) or minus (–) sign, as follows:<br><br><table><tbody><tr><td><code>+n</code></td><td>more than <i>n</i></td></tr><tr><td><code>n</code></td><td>exactly <i>n</i></td></tr><tr><td><code>-n</code></td><td>less than <i>n</i></td></tr></tbody></table> | <code>+n</code> | more than <i>n</i> | <code>n</code> | exactly <i>n</i> | <code>-n</code> | less than <i>n</i> |
| <code>+n</code>   | more than <i>n</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                    |                |                  |                 |                    |
| <code>n</code>    | exactly <i>n</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                    |                |                  |                 |                    |
| <code>-n</code>   | less than <i>n</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                    |                |                  |                 |                    |

**Expressions** Valid expressions are:

- `-acl` True if the file have additional ACLs defined.
- `-atimen` True if the file was accessed *n* days ago. The access time of directories in *path* is changed by `find` itself.
- `-cpio device` Always true. Writes the current file on *device* in `cpio` format (5120-byte records).

---

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-ctime <i>n</i></code>      | True if the file's status was changed <i>n</i> days ago.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-depth</code>               | Always true. Causes descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. This can be useful when <code>find</code> is used with <a href="#">cpio(1)</a> to transfer files that are contained in directories without write permission.                                                                                                                                                                                                                                                                                  |
| <code>-exec <i>command</i></code> | True if the executed command returns a zero value as exit status. The end of command must be punctuated by an escaped semicolon ( <code>;</code> ). A command argument <code>{}</code> is replaced by the current pathname. If the last argument to <code>-exec</code> is <code>{}</code> and you specify <code>+</code> rather than the semicolon ( <code>;</code> ), the command is invoked fewer times, with <code>{}</code> replaced by groups of pathnames. If any invocation of the command returns a non-zero value as exit status, <code>find</code> returns a non-zero exit status. |
| <code>-follow</code>              | Always true. Causes symbolic links to be followed. When following symbolic links, <code>find</code> keeps track of the directories visited so that it can detect infinite loops. For example, such a loop would occur if a symbolic link pointed to an ancestor. This expression should not be used with the <code>find -type l</code> expression. See NOTES.                                                                                                                                                                                                                                |
| <code>-fstype <i>type</i></code>  | True if the filesystem to which the file belongs is of type <i>type</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-group <i>gname</i></code>  | True if the file belongs to the group <i>gname</i> . If <i>gname</i> is numeric and does not appear in the <code>/etc/group</code> file, or in the NIS/NIS+ tables, it is taken as a group ID.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-inum <i>n</i></code>       | True if the file has inode number <i>n</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-links <i>n</i></code>      | True if the file has <i>n</i> links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-local</code>               | True if the file system type is not a remote file system type as defined in the <code>/etc/dfs/fstypes</code> file. <code>nfs</code> is used as the default remote filesystem type if the <code>/etc/dfs/fstypes</code> file is not present. The <code>-local</code> option descends the hierarchy of non-local directories. See EXAMPLES for an example of how to search for local files without descending.                                                                                                                                                                                |
| <code>-ls</code>                  | <p>Always true. Prints current pathname together with its associated statistics. These include (respectively):</p> <ul style="list-style-type: none"> <li>■ inode number</li> <li>■ size in kilobytes (1024 bytes)</li> <li>■ protection mode</li> <li>■ number of hard links</li> <li>■ user</li> <li>■ group</li> <li>■ size in bytes</li> <li>■ modification time.</li> </ul>                                                                                                                                                                                                             |

If the file is a special file, the size field instead contains the major and minor device numbers.

If the file is a symbolic link, the pathname of the linked-to file is printed preceded by '→'. The format is identical to that of `ls -glds` (see [ls\(1B\)](#)).

Formatting is done internally, without executing the `ls` program.

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |   |                                               |   |                            |

| <code>-mount</code>               | Always true. Restricts the search to the file system containing the directory specified. Does not list mount points to other file systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |                                               |   |                            |
| <code>-mtime <i>n</i></code>      | True if the file's data was modified <i>n</i> days ago.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |                                               |   |                            |
| <code>-name <i>pattern</i></code> | <p>True if <i>pattern</i> matches the basename of the current file name. Normal shell file name generation characters (see <a href="#">sh(1)</a>) can be used. A backslash ( \ ) is used as an escape character within the pattern. The pattern should be escaped or quoted when <code>find</code> is invoked from the shell.</p> <p>Unless the character '.' is explicitly specified in the beginning of <i>pattern</i>, a current file name beginning with '.' does not match <i>pattern</i> when using <code>/usr/bin/find</code>. <code>/usr/xpg4/bin/find</code> does not make this distinction; wildcard file name generation characters can match file names beginning with '.'.</p> |   |                                               |   |                            |
| <code>-ncpio <i>device</i></code> | Always true. Writes the current file on <i>device</i> in <code>cpio -c</code> format (5120 byte records).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |                                               |   |                            |
| <code>-newer <i>file</i></code>   | True if the current file has been modified more recently than the argument <i>file</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |                                               |   |                            |
| <code>-nogroup</code>             | True if the file belongs to a group not in the <code>/etc/group</code> file, or in the NIS/NIS+ tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |                                               |   |                            |
| <code>-nouser</code>              | True if the file belongs to a user not in the <code>/etc/passwd</code> file, or in the NIS/NIS+ tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |                                               |   |                            |
| <code>-ok <i>command</i></code>   | Like <code>-exec</code> , except that the generated command line is printed with a question mark first, and is executed only if the response on standard input is affirmative.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |                                               |   |                            |
| <code>-perm [-]<i>mode</i></code> | <p>The <i>mode</i> argument is used to represent file mode bits. It is identical in format to the symbolic mode operand, <i>symbolic_mode_list</i>, described in <a href="#">chmod(1)</a>, and is interpreted as follows. To start, a template is assumed with all file mode bits cleared. An <i>op</i> symbol of:</p> <table><tr><td>+</td><td>Set the appropriate mode bits in the template</td></tr><tr><td>—</td><td>Clear the appropriate bits</td></tr></table>                                                                                                                                                                                                                       | + | Set the appropriate mode bits in the template | — | Clear the appropriate bits |
| +                                 | Set the appropriate mode bits in the template                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |                                               |   |                            |
| —                                 | Clear the appropriate bits                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |                                               |   |                            |

= Set the appropriate mode bits, without regard to the contents of the file mode creation mask of the process

The *op* symbol of – cannot be the first character of *mode*, to avoid ambiguity with the optional leading hyphen. Since the initial mode is all bits off, there are no symbolic modes that need to use – as the first character.

If the hyphen is omitted, the primary evaluates as true when the file permission bits exactly match the value of the resulting template.

Otherwise, if *mode* is prefixed by a hyphen, the primary evaluates as true if at least all the bits in the resulting template are set in the file permission bits.

|                             |                                                                                                                                                                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -perm [-] <i>onum</i>       | True if the file permission flags exactly match the octal number <i>onum</i> (see <a href="#">chmod(1)</a> ). If <i>onum</i> is prefixed by a minus sign (–), only the bits that are set in <i>onum</i> are compared with the file permission flags, and the expression evaluates true if they match. |
| -print                      | Always true. Causes the current pathname to be printed.                                                                                                                                                                                                                                               |
| -prune                      | Always yields true. Does not examine any directories or files in the directory structure below the <i>pattern</i> just matched. (See EXAMPLES). If -depth is specified, -prune has no effect.                                                                                                         |
| -size <i>n</i> [ <i>c</i> ] | True if the file is <i>n</i> blocks long (512 bytes per block). If <i>n</i> is followed by a <i>c</i> , the size is in bytes.                                                                                                                                                                         |
| -type <i>c</i>              | True if the type of the file is <i>c</i> , where <i>c</i> is b, c, d, f, l, p, or s for block special file, character special file, directory, door, plain file, symbolic link, fifo (named pipe), or socket, respectively.                                                                           |
| -user <i>uname</i>          | True if the file belongs to the user <i>uname</i> . If <i>uname</i> is numeric and does not appear as a login name in the <code>/etc/passwd</code> file, or in the NIS/NIS+ tables, it is taken as a user ID.                                                                                         |
| -xdev                       | Same as the -mount primary.                                                                                                                                                                                                                                                                           |
| -xattr                      | True if the file has extended attributes.                                                                                                                                                                                                                                                             |

Complex Expressions The primaries can be combined using the following operators (in order of decreasing precedence):

|                          |                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------|
| 1) ( <i>expression</i> ) | True if the parenthesized expression is true (parentheses are special to the shell and must be escaped). |
|--------------------------|----------------------------------------------------------------------------------------------------------|

- |                                      |                                                                                                         |
|--------------------------------------|---------------------------------------------------------------------------------------------------------|
| 2) <i>! expression</i>               | The negation of a primary (! is the unary <i>not</i> operator).                                         |
| 3) <i>expression [-a] expression</i> | Concatenation of primaries (the <i>and</i> operation is implied by the juxtaposition of two primaries). |
| 4) <i>expression -o expression</i>   | Alternation of primaries (-o is the <i>or</i> operator).                                                |

When you use `find` in conjunction with `cpio`, if you use the `-L` option with `cpio` then you must use the `-follow` expression with `find` and vice versa. Otherwise there are undesirable results.

If no *expression* is present, `-print` is used as the expression. Otherwise, if the given expression does not contain any of the primaries `-exec`, `-ls`, `-ok`, or `-print`, the given expression is effectively replaced by:

`( given_expression ) -print`

The `-user`, `-group`, and `-newer` primaries each evaluate their respective arguments only once. Invocation of *command* specified by `-exec` or `-ok` does not affect subsequent primaries on the same file.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `find` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Writing Out the Hierarchy Directory

The following commands are equivalent:

```
example% find .
example% find . -print
```

They both write out the entire directory hierarchy from the current directory.

**EXAMPLE 2** Removing Files

The following command removes all files in your home directory named `a.out` or `*.o` that have not been accessed for a week:

```
example% find $HOME \(-name a.out -o -name '*.o' \) \
-atime +7 -exec rm {} \;
```

**EXAMPLE 3** Printing All File Names But Skipping SCCS Directories

The following command recursively print all file names in the current directory and below, but skipping SCCS directories:

```
example% find . -name SCCS -prune -o -print
```

**EXAMPLE 4** Printing all file names and the SCCS directory name

Recursively print all file names in the current directory and below, skipping the contents of SCCS directories, but printing out the SCCS directory name:

```
example% find . -print -name SCCS -prune
```

**EXAMPLE 5** Testing for the Newer File

The following command is basically equivalent to the `-nt` extension to `test(1)`:

```
example$ if [-n "$(find
file1 -prune -newer file2)"]; then

printf %s\\n "file1 is newer than file2"
```

**EXAMPLE 6** Selecting a File Using 24-hour Mode

The descriptions of `-atime`, `-ctime`, and `-mtime` use the terminology *n* “24-hour periods”. For example, a file accessed at 23:59 is selected by:

```
example% find . -atime -1 -print
```

at 00:01 the next day (less than 24 hours later, not more than one day ago). The midnight boundary between days has no effect on the 24-hour calculation.

**EXAMPLE 7** Printing Files Matching a User's Permission Mode

The following command recursively print all file names whose permission mode exactly matches read, write, and execute access for user, and read and execute access for group and other:

```
example% find . -perm u=rwx,g=rx,o=rx
```

The above could alternatively be specified as follows:

```
example% find . -perm a=rwx,g-w,o-w
```

**EXAMPLE 8** Printing Files with Write Access for other

The following command recursively print all file names whose permission includes, but is not limited to, write access for other:

```
example% find . -perm -o+w
```

**EXAMPLE 9** Printing Local Files without Descending Non-local Directories

```
example% find . ! -local -prune -o -print
```

**EXAMPLE 10** Printing the Files in the Name Space Possessing Extended Attributes

```
example% find . -xattr
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of find: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

PATH Determine the location of the *utility\_name* for the -exec and -ok primaries.

**Exit Status** The following exit values are returned:

- 0 All *path* operands were traversed successfully.
- >0 An error occurred.

**Files**

|                  |                                                      |
|------------------|------------------------------------------------------|
| /etc/passwd      | Password file                                        |
| /etc/group       | Group file                                           |
| /etc/dfs/fstypes | File that registers distributed file system packages |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| Availability        | SUNWcsu                            |
| CSI                 | Enabled                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [chmod\(1\)](#), [cpio\(1\)](#), [ls\(1B\)](#), [sh\(1\)](#), [test\(1\)](#), [acl\(2\)](#), [stat\(2\)](#), [umask\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Warnings** The following options are obsolete and will not be supported in future releases:

- cpio *device* Always true. Writes the current file on *device* in cpio format (5120-byte records).
- ncpio *device* Always true. Writes the current file on *device* in cpio -c format (5120-byte records).

**Notes** When using find to determine files modified within a range of time, use the -mtime argument *before* the -print argument. Otherwise, find gives all files.

Some files that might be under the Solaris root file system are actually mount points for virtual file systems, such as mntfs or namefs. When comparing against a ufs file system, such files are not selected if -mount or -xdev is specified in the find expression.

Using the -L or -follow option is not recommended when descending a file-system hierarchy that is under the control of other users. In particular, when using -exec, symbolic links can lead the find command out of the hierarchy in which it started. Using -type is not sufficient

to restrict the type of files on which the `-exec` command operates, because there is an inherent race condition between the type-check performed by the `find` command and the time the executed command operates on the file argument.

**Name** finger – display information about local and remote users

**Synopsis** finger [-bfhilmqsw] [*username*]...

```
finger [-l]
 [username@hostname 1 [@hostname 2 .. @hostname n]...]
finger [-l] [@hostname 1 [@hostname 2 .. @hostname n]...]
```

**Description** By default, the `finger` command displays in multi-column format the following information about each logged-in user:

- user name
- user's full name
- terminal name (preceded with a '\*' (asterisk) if write-permission is denied)
- idle time
- login time
- host name, if logged in remotely

Idle time is in minutes if it is a single integer, in hours and minutes if a ':' (colon) is present, or in days and hours if a 'd' is present.

When one or more *username* arguments are given, more detailed information is given for each *username* specified, whether they are logged in or not. *username* must be that of a local user, and may be a first or last name, or an account name. Information is presented in multi-line format as follows:

- the user name and the user's full name
- the user's home directory and login shell
- time the user logged in if currently logged in, or the time the user last logged in; and the terminal or host from which the user logged in
- last time the user received mail, and the last time the user read mail
- the first line of the `$HOME/.project` file, if it exists
- the contents of the `$HOME/.plan` file, if it exists

Note: when the comment (GECOS) field in `/etc/passwd` includes a comma, `finger` does not display the information following the comma.

If the arguments `username@hostname1[@hostname2 .. @hostnamen]` or `@hostname1[@hostname2 .. @hostnamen]` are used, the request is sent first to `hostnamen` and forwarded through each `hostnamen-1` to `hostname1`. The program uses the `finger` user information protocol (see RFC 1288) to query that remote host for information about the named user (if *username* is specified), or about each logged-in user. The information displayed is server dependent.

As required by RFC 1288, `finger` passes only printable, 7-bit ASCII data. This behavior may be modified by a system administrator by using the `PASS` option in `/etc/default/finger`. Specifying `PASS=low` allows all characters less than decimal 32 ASCII. Specifying `PASS=high` allows all characters greater than decimal 126 ASCII. `PASS=low,high` or `PASS=high,low` allows both characters less than 32 and greater than 126 to pass through.

**Options** The following options are supported, except that the *username@hostname* form supports only the `-l` option:

- `-b` Suppresses printing the user's home directory and shell in a long format printout.
- `-f` Suppresses printing the header that is normally printed in a non-long format printout.
- `-h` Suppresses printing of the `.project` file in a long format printout.
- `-i` Forces “idle” output format, which is similar to short format except that only the login name, terminal, login time, and idle time are printed.
- `-l` Forces long output format.
- `-m` Matches arguments only on user name (not first or last name).
- `-p` Suppresses printing of the `.plan` file in a long format printout.
- `-q` Forces quick output format, which is similar to short format except that only the login name, terminal, and login time are printed.
- `-s` Forces short output format.
- `-w` Suppresses printing the full name in a short format printout.

**Files**

|                                  |                     |
|----------------------------------|---------------------|
| <code>\$HOME/.plan</code>        | user's plan         |
| <code>\$HOME/.project</code>     | user's projects     |
| <code>/etc/default/finger</code> | finger options file |
| <code>/etc/passwd</code>         | password file       |
| <code>/var/adm/lastlog</code>    | time of last login  |
| <code>/var/adm/utmpx</code>      | accounting          |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmds       |

**See Also** [passwd\(1\)](#), [who\(1\)](#), [whois\(1\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

Zimmerman, D., *The Finger User Information Protocol*, RFC 1288, Center for Discrete Mathematics and Theoretical Computer Science (DIMACS), Rutgers University, December 1991.

**Notes** The finger user information protocol limits the options that may be used with the remote form of this command.

**Name** fmlcut – cut out selected fields of each line of a file

**Synopsis** fmlcut -clist [*filename*]. . .  
fmlcut -flist [-d*char*] [-s] [*filename*]. . .

**Description** The fmlcut function cuts out columns from a table or fields from each line in *filename*; in database parlance, it implements the projection of a relation. fmlcut can be used as a filter; if *filename* is not specified or is –, the standard input is read. *list* specifies the fields to be selected. Fields can be fixed length (character positions) or variable length (separated by a field delimiter character), depending on whether -c or -f is specified.

Note: Either the -c or the -f option must be specified.

**Options** *list* A comma-separated list of integer field numbers (in increasing order), with optional – to indicate ranges. For example: 1,4,7; 1–3,8; –5,10 (short for 1–5,10); or 3– (short for third through last field).

-clist If -c is specified, *list* specifies character positions (for instance, –c1–72 would pass the first 72 characters of each line). Note: No space intervenes between -c and *list*.

-flist If -f is specified, *list* is a list of fields assumed to be separated in the file by the default delimiter character, TAB, or by *char* if the -d option is specified. For example, –f1,7 copies the first and seventh field only. Lines with no delimiter characters are passed through intact (useful for table subheadings), unless -s is specified. Note: No space intervenes between -f and *list*. The following options can be used if you have specified -f.

-d*char* If -d is specified, *char* is the field delimiter. Space or other characters with special meaning to FMLI must be quoted. Note: No space intervenes between -d and *char*. The default field delimiter is TAB.

-s Suppresses lines with no delimiter characters. If -s is not specified, lines with no delimiters will be passed through untouched.

**Examples** EXAMPLE 1 Getting login IDs and names

The following example gets the login IDs and names.

```
example% fmlcut -d: -f1,5 /etc/passwd
```

EXAMPLE 2 Getting the current login name

The next example gets the current login name.

```
example% 'who am i | fmlcut -f1 -d" "'
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [fmlgrep\(1F\)](#), [attributes\(5\)](#)

**Diagnostics** fmlcut returns the following exit values:

- 0 when the selected field is successfully cut out
- 2 on syntax errors

The following error messages may be displayed on the FMLI message line:

- ERROR: line too long A line has more than 1023 characters or fields, or there is no new-line character.
- ERROR: bad list for c / f option Missing -c or -f option or incorrectly specified *list*. No error occurs if a line has fewer fields than the *list* calls for.
- ERROR: no fields The *list* is empty.
- ERROR: no delimiter Missing *char* on -d option.

**Notes** fmlcut cannot correctly process lines longer than 1023 characters, or lines with no newline character.

**Name** fmlexpr – evaluate arguments as an expression

**Synopsis** fmlexpr *arguments*

**Description** The fmlexpr function evaluates its arguments as an expression. After evaluation, the result is written on the standard output. Terms of the expression must be separated by blanks. Characters special to FMLI must be escaped. Note that 30 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, 2s complement numbers.

The operators and keywords are listed below. Characters that need to be escaped are preceded by \. The list is in order of increasing precedence, with equal precedence operators grouped within { } symbols.

### Usage

|             |                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Expressions | <i>expr</i> \  <i>expr</i>                          | Returns the first <i>expr</i> if it is neither NULL nor 0, otherwise returns the second <i>expr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | <i>expr</i> \& <i>expr</i>                          | Returns the first <i>expr</i> if neither <i>expr</i> is NULL or 0, otherwise returns 0.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>expr</i> { =, \>, \>=, \<, \<=, != } <i>expr</i> | Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <i>expr</i> { +, - } <i>expr</i>                    | Addition or subtraction of integer-valued arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | <i>expr</i> { *, /, % } <i>expr</i>                 | Multiplication, division, or remainder of the integer-valued arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>expr</i> : <i>expr</i>                           | The matching operator : (colon) compares the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of <a href="#">ed(1)</a> , except that all patterns are "anchored" (that is, begin with ^) and, therefore, ^ is not a special character, in that context. Normally, the matching operator returns the number of bytes matched (0 on failure). Alternatively, the ( . . . ) pattern symbols can be used to return a portion of the first argument. |

**Examples** EXAMPLE 1 Incrementing a variable

Add 1 to the variable a:

```
example% fmlexpr $a + 1 | set -l a
```

**EXAMPLE 2** Setting a variable equal to a filename

For \$a equal to either /usr/abc/file or just file:

```
example% fmlexpr $a : .*\/(.*\)\ \| $a
```

returns the last segment of a path name (that is, file). Watch out for / alone as an argument: fmlexpr will take it as the division operator (see NOTES below).

**EXAMPLE 3** A better representation of Example 2

```
example% fmlexpr //$a : .*\/(.*\)
```

The addition of the // characters eliminates any ambiguity about the division operator (because it makes it impossible for the left-hand expression to be interpreted as the division operator), and simplifies the whole expression.

**EXAMPLE 4** Counting characters in a variable

Return the number of characters in \$VAR:

```
example% fmlexpr $VAR : .*
```

**Exit Status** As a side effect of expression evaluation, fmlexpr returns the following exit values:

- 0 if the expression is neither NULL nor 0 (that is, TRUE)
- 1 if the expression is NULL or 0 (that is, FALSE)
- 2 for invalid expressions (that is, FALSE).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [ed\(1\)](#), [expr\(1\)](#), [set\(1F\)](#), [sh\(1\)](#), [attributes\(5\)](#)

**Diagnostics** syntax error for operator/operand errors  
non-numeric argument if arithmetic is attempted on such a string

In the case of syntax errors and non-numeric arguments, an error message will be printed at the current cursor position. Use refresh to redraw the screen.

**Notes** After argument processing by FMLI, fmlexpr cannot tell the difference between an operator and an operand except by the value. If \$a is an =, the command:

```
example% fmlexpr $a = =
```

looks like:

```
example% fmlexpr = = =
```

as the arguments are passed to `fmlexpr` (and they will all be taken as the `=` operator). The following works, and returns TRUE:

```
example% fmlexpr X$a = X=
```

**Name** fmlgrep – search a file for a pattern

**Synopsis** fmlgrep [-b] [-c] [-i] [-l] [-n] [-s] [-v]  
          *limited\_regular\_expression* [filename]...

**Description** fmlgrep searches *filename* for a pattern and prints all lines that contain that pattern. fmlgrep uses limited regular expressions (expressions that have string values that use a subset of the possible alphanumeric and special characters) like those described on the [regexp\(5\)](#) manual page to match the patterns. It uses a compact non-deterministic algorithm.

Be careful when using FMLI special characters (for instance, \$, ‘, ’, ") in *limited\_regular\_expression*. It is safest to enclose the entire *limited\_regular\_expression* in single quotes ' ... '.

If *filename* is not specified, fmlgrep assumes standard input. Normally, each line matched is copied to standard output. The file name is printed before each line matched if there is more than one input file.

**Options** The following options are supported:

- b    Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
- c    Print only a count of the lines that contain the pattern.
- i    Ignore upper/lower case distinction during comparisons.
- l    Print only the names of files with matching lines, separated by new-lines. Does not repeat the names of files when the pattern is found more than once.
- n    Precede each line by its line number in the file (first line is 1).
- s    Suppress error messages about nonexistent or unreadable files.
- v    Print all lines except those that contain the pattern.

**Exit Status** The following exit values are returned:

- 0    if the pattern is found (that is, TRUE)
- 1    if the pattern is not found (that is, FALSE)
- 2    if an invalid expression was used or *filename* is inaccessible

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [egrep\(1\)](#), [fgrep\(1\)](#), [fmlcut\(1F\)](#), [grep\(1\)](#), [attributes\(5\)](#), [regex\(5\)](#)

**Notes** Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in `/usr/include/stdio.h`.

If there is a line with embedded nulls, `fmlgrep` will only match up to the first null; if it matches, it will print the entire line.

**Name** fmli – invoke FMLI

**Synopsis** fmli [-a *alias\_file*] [-c *command\_file*]  
          [-i *initialization\_file*] *filename...*

**Description** The fmli command invokes the Form and Menu Language Interpreter and opens the frame(s) specified by the *filename* argument. The *filename* argument is the pathname of the initial frame definition file(s), and must follow the naming convention Menu.xxx, Form.xxx, or Text.xxx for a menu, form or text frame respectively, where xxx is any string that conforms to UNIX system file naming conventions. The FMLI descriptor *lifetime* will be ignored for all frames opened by argument to fmli. These frames have a lifetime of *immortal* by default.

**Options** The following options are supported:

- |                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a <i>alias_file</i>          | If -a is specified, <i>alias_file</i> is the name of a file which contains lines of the form <i>alias=pathname</i> . Thereafter, \$ <i>alias</i> can be used in definition files to simplify references to objects or devices with lengthy pathnames, or to define a search path (similar to \$PATH in the UNIX system shell).                                                                                                                                                     |
| -c <i>command_file</i>        | If -c is specified, <i>command_file</i> is the name of a file in which default FMLI commands can be disabled, and new application-specific commands can be defined. The contents of <i>command_file</i> are reflected in the FMLI Command Menu.                                                                                                                                                                                                                                    |
| -i <i>initialization_file</i> | If -i is specified, <i>initialization_file</i> is the name of a file in which the following characteristics of the application as a whole can be specified: <ul style="list-style-type: none"><li>– A transient introductory frame displaying product information</li><li>– A banner, its position, and other elements of the banner line</li><li>– Color attributes for all elements of the screen</li><li>– Screen Labeled Keys (SLKs) and their layout on the screen.</li></ul> |

**Examples** EXAMPLE 1 Examples of the fmli command.

To invoke fmli:

```
example% fmli Menu.start
```

where Menu.start is an example of *filename* named according to the file name conventions for menu definition files explained above.

To invoke fmli and name an initialization file:

```
example% fmli -i init.myapp Menu.start
```

where init.myapp is an example of *initialization\_file*.

## Environment Variables

|           |         |                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Variables | LOADPFK | Leaving this environment variable unset tells FMLI, for certain terminals like the AT&T 5620 and 630, to download its equivalent character sequences for using function keys into the terminal's programmable function keys, wiping out any settings the user may already have set in the function keys. Setting LOADPFK=NO in the environment will prevent this downloading. |
|           | COLUMNS | Can be used to override the width of the logical screen defined for the terminal set in TERM. For terminals with a 132-column mode, for example, invoking FMLI with the line<br><br>COLUMNS=132 <i>fml frame-file</i><br><br>will allow this wider screen width to be used.                                                                                                   |
|           | LINES   | Can be used to override the length of the logical screen defined for the terminal set in TERM.                                                                                                                                                                                                                                                                                |

**Files** /usr/bin/fml

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [vsig\(1F\)](#), [attributes\(5\)](#)

**Diagnostics** If *filename* is not supplied to the *fml* command, *fml* returns the message:

Initial object must be specified.

If *filename* does not exist or is not readable, *fml* returns an error message and exits. The example command line above returns the following message and exits:

Can't open object "Menu.start"

If *filename* exists, but does not start with one of the three correct object names (Menu., Form., or Text.) or if it is named correctly but does not contain the proper data, *fml* starts to build the screen by putting out the screen labels for function keys, after which it flashes the message:

I do not recognize that kind of object  
  
and then exits.

**Name**    `fmt` – simple text formatters

**Synopsis**    `fmt [-cs] [-w width | -width] [inputfile]...`

**Description**    `fmt` is a simple text formatter that fills and joins lines to produce output lines of (up to) the number of characters specified in the `-w width` option. The default *width* is 72. `fmt` concatenates the *inputfiles* listed as arguments. If none are given, `fmt` formats text from the standard input.

Blank lines are preserved in the output, as is the spacing between words. `fmt` does not fill nor split lines beginning with a ‘.’ (dot), for compatibility with [nroff\(1\)](#). Nor does it fill or split a set of contiguous non-blank lines which is determined to be a mail header, the first line of which must begin with “From”.

Indentation is preserved in the output, and input lines with differing indentation are not joined (unless `-c` is used).

`fmt` can also be used as an in-line text filter for [vi\(1\)](#). The `vi` command:

```
!}fmt
```

reformats the text between the cursor location and the end of the paragraph.

- Options**
- `-c`                      Crown margin mode. Preserve the indentation of the first two lines within a paragraph, and align the left margin of each subsequent line with that of the second line. This is useful for tagged paragraphs.
  - `-s`                      Split lines only. Do not join short lines to form longer ones. This prevents sample lines of code, and other such formatted text, from being unduly combined.
  - `-w width | -width`      Fill output lines to up to *width* columns.

**Operands**    *inputfile*      Input file.

**Environment Variables**    See [environ\(5\)](#) for a description of the `LC_CTYPE` environment variable that affects the execution of `fmt`.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also**    [nroff\(1\)](#), [vi\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes**    The `-width` option is acceptable for BSD compatibility, but it may go away in future releases.

**Name** `fmtmsg` – display a message on `stderr` or system console

**Synopsis** `fmtmsg [-c class] [-u subclass] [-l label] [-s severity]  
[-t tag] [-a action] text`

**Description** Based on a message's classification component, the `fmtmsg` utility either writes a formatted message to `stderr` or writes a formatted message to the console.

A formatted message consists of up to five standard components (see environment variable `MSGVERB` in the ENVIRONMENT VARIABLES section of this page). The classification and subclass components are not displayed as part of the standard message, but rather define the source of the message and direct the display of the formatted message.

**Options** The following options are supported:

- `-c class` Describes the source of the message. Valid keywords are:
  - `hard` The source of the condition is hardware.
  - `soft` The source of the condition is software.
  - `firm` The source of the condition is firmware.
- `-u subclass` A list of keywords (separated by commas) that further defines the message and directs the display of the message. Valid keywords are:
  - `appl` The condition originated in an application. This keyword should not be used in combination with either `util` or `opsys`.
  - `util` The condition originated in a utility. This keyword should not be used in combination with either `appl` or `opsys`.
  - `opsys` The message originated in the kernel. This keyword should not be used in combination with either `appl` or `util`.
  - `recov` The application will recover from the condition. This keyword should not be used in combination with `nrecov`.
  - `nrecov` The application will not recover from the condition. This keyword should not be used in combination with `recov`.
  - `print` Print the message to the standard error stream `stderr`.
  - `console` Write the message to the system console. `print`, `console`, or both may be used.
- `-l label` Identifies the source of the message.
- `-s severity` Indicates the seriousness of the error. The keywords and definitions of the standard levels of *severity* are:
  - `halt` The application has encountered a severe fault and is halting.

|                  |       |                                                                                                                                                                                                                                                                         |
|------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | error | The application has detected a fault.                                                                                                                                                                                                                                   |
|                  | warn  | The application has detected a condition that is out of the ordinary and might be a problem.                                                                                                                                                                            |
|                  | info  | The application is providing information about a condition that is not in error.                                                                                                                                                                                        |
| -t <i>tag</i>    |       | The string containing an identifier for the message.                                                                                                                                                                                                                    |
| -a <i>action</i> |       | A text string describing the first step in the error recovery process. This string must be written so that the entire <i>action</i> argument is interpreted as a single argument. <code>fmtmsg</code> precedes each action string with the <code>TO FIX:</code> prefix. |
| <i>text</i>      |       | A text string describing the condition. Must be written so that the entire <i>text</i> argument is interpreted as a single argument.                                                                                                                                    |

### Examples **EXAMPLE 1** Standard message format

The following example of `fmtmsg` produces a complete message in the standard message format and displays it to the standard error stream.

```
example% fmtmsg -c soft -u recov,print,appl -l UX:cat \
 -s error -t UX:cat:001 -a "refer to manual" "invalid syntax"
```

produces:

```
UX:cat: ERROR: invalid syntax
TO FIX: refer to manual UX:cat:138
```

### **EXAMPLE 2** Using MSGVERB

When the environment variable `MSGVERB` is set as follows:

```
MSGVERB=severity:text:action
```

and Example 1 is used, `fmtmsg` produces:

```
ERROR: invalid syntax
TO FIX: refer to manual
```

### **EXAMPLE 3** Using SEV\_LEVEL

When the environment variable `SEV_LEVEL` is set as follows:

```
SEV_LEVEL=note,5,NOTE
```

the following `fmtmsg` command:

```
example% fmtmsg -c soft -u print -l UX:cat -s note \
 -a "refer to manual" "invalid syntax"
```

produces:

**EXAMPLE 3** Using SEV\_LEVEL (Continued)

NOTE: invalid syntax  
 TO FIX: refer to manual

and displays the message on `stderr`.

**Environment Variables**

The environment variables `MSGVERB` and `SEV_LEVEL` control the behavior of `fmtmsg`. `MSGVERB` is set by the administrator in the `/etc/profile` for the system. Users can override the value of `MSGVERB` set by the system by resetting `MSGVERB` in their own `.profile` files or by changing the value in their current shell session. `SEV_LEVEL` can be used in shell scripts.

`MSGVERB` tells `fmtmsg` which message components to select when writing messages to `stderr`. The value of `MSGVERB` is a colon-separated list of optional keywords. `MSGVERB` can be set as follows:

```
MSGVERB=[keyword[:keyword[:...]]]

export MSGVERB
```

Valid *keywords* are: `label`, `severity`, `text`, `action`, and `tag`. If `MSGVERB` contains a keyword for a component and the component's value is not the component's null value, `fmtmsg` includes that component in the message when writing the message to `stderr`. If `MSGVERB` does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If `MSGVERB` is not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, `fmtmsg` selects all components.

`MSGVERB` affects only which message components are selected for display. All message components are included in console messages.

`SEV_LEVEL` defines severity levels and associates print strings with them for use by `fmtmsg`. The standard severity levels shown below cannot be modified. Additional severity levels can be defined, redefined, and removed.

- 0 (no severity is used)
- 1 HALT
- 2 ERROR
- 3 WARNING
- 4 INFO

`SEV_LEVEL` is set as follows:

*description* is a comma-separated list containing three fields:

```
SEV_LEVEL= [description[:description[...]]]
export SEV_LEVEL
```

*description*=severity\_keyword, level, printstring

*severity\_keyword* is a character string used as the keyword with the -s severity option to `fmtmsg`.

*level* is a character string that evaluates to a positive integer (other than 0, 1, 2, 3, or 4, which are reserved for the standard severity levels). If the keyword *severity\_keyword* is used, *level* is the severity value passed on to `fmtmsg(3C)`.

*printstring* is the character string used by `fmtmsg` in the standard message format whenever the severity value *level* is used.

If `SEV_LEVEL` is not defined, or if its value is null, no severity levels other than the defaults are available. If a *description* in the colon separated list is not a comma separated list containing three fields, or if the second field of a comma separated list does not evaluate to a positive integer, that *description* in the colon separated list is ignored.

**Exit Status** The following exit values are returned:

- 0 All the requested functions were executed successfully.
- 1 The command contains a syntax error, an invalid option, or an invalid argument to an option.
- 2 The function executed with partial success, however the message was not displayed on `stderr`.
- 4 The function executed with partial success; however, the message was not displayed on the system console.
- 32 No requested functions were executed successfully.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** `addseverity(3C)`, `fmtmsg(3C)`, `attributes(5)`

**Name** fold – filter for folding lines

**Synopsis** fold [-bs] [-w *width* | -width] [*file*]...

**Description** The `fold` utility is a filter that will fold lines from its input files, breaking the lines to have a maximum of *width* column positions (or bytes, if the `-b` option is specified). Lines will be broken by the insertion of a NEWLINE character such that each output line (referred to later in this section as a segment) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line will not be broken in the middle of a character. The behavior is undefined if *width* is less than the number of columns any single character in the input would occupy.

If the CARRIAGE-RETURN, BACKSPACE, or TAB characters are encountered in the input, and the `-b` option is not specified, they will be treated specially:

|                 |                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BACKSPACE       | The current count of line width will be decremented by one, although the count never will become negative. <code>fold</code> will not insert a NEWLINE character immediately before or after any BACKSPACE character. |
| CARRIAGE-RETURN | The current count of line width will be set to 0. <code>fold</code> will not insert a NEWLINE character immediately before or after any CARRIAGE-RETURN character.                                                    |
| TAB             | Each TAB character encountered will advance the column position pointer to the next tab stop. Tab stops will be at each column position <i>n</i> such that <i>n</i> modulo 8 equals 1.                                |

**Options** The following options are supported:

|                                       |                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-b</code>                       | Counts <i>width</i> in bytes rather than column positions.                                                                                                                                                                                                                                                                                         |
| <code>-s</code>                       | If a segment of a line contains a blank character within the first <i>width</i> column positions (or bytes), breaks the line after the last such blank character meeting the width constraints. If there is no blank character meeting the requirements, the <code>-s</code> option will have no effect for that output segment of the input line. |
| <code>-w <i>width</i>   -width</code> | Specifies the maximum line length, in column positions (or bytes if <code>-b</code> is specified). If <i>width</i> is not a positive decimal number, an error is returned. The default value is 80.                                                                                                                                                |

**Operands** The following operand is supported:

|             |                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| <i>file</i> | A path name of a text file to be folded. If no <i>file</i> operands are specified, the standard input will be used. |
|-------------|---------------------------------------------------------------------------------------------------------------------|

**Examples**    **EXAMPLE 1**    Submitting a file of possibly long lines to the line printer

An example invocation that submits a file of possibly long lines to the line printer (under the assumption that the user knows the line width of the printer to be assigned by `lp(1)`):

```
example% fold -w 132 bigfile | lp
```

**Environment Variables**    See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `fold`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status**    The following exit values are returned:

- `0`        All input files were processed successfully.
- `>0`      An error occurred.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | enabled         |
| Interface Stability | Standard        |

**See Also**    [cut\(1\)](#), [pr\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes**    `fold` and [cut\(1\)](#) can be used to create text files out of files with arbitrary line lengths. `fold` should be used when the contents of long lines need to be kept contiguous. `cut` should be used when the number of lines (or records) needs to remain constant.

`fold` is frequently used to send text files to line printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

`fold` may not work correctly if underlining is present.

**Name** from – display the sender and date of newly-arrived mail messages

**Synopsis** /usr/ucb/from [-s *sender*] [*username*]

**Description** The `from` utility prints out the mail header lines in your mailbox file to show you who your mail is from. If *username* is specified, *username*'s mailbox is examined instead of your own.

**Options** The following option is supported:

-s *sender* Only display headers for mail sent by *sender*.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `from` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Files** /var/mail/\*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [biff\(1B\)](#), [mail\(1B\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** ftp – file transfer program

**Synopsis** ftp [-adfginpstv] [-m *GSS Mech*] [-T *timeout*]  
[*hostname* [*port*]]

**Description** The ftp command is the user interface to the Internet standard File Transfer Protocol (FTP). ftp transfers files to and from a remote network site.

The host and optional port with which ftp is to communicate can be specified on the command line. If this is done, ftp immediately attempts to establish a connection to an FTP server on that host. Otherwise, ftp enters its command interpreter and awaits instructions from the user. When ftp is awaiting commands from the user, it displays the prompt ftp>.

**Options** The following options can be specified at the command line, or to the command interpreter:

- a Uses GSSAPI authentication *only*. If the authentication fails, this option closes the connection.
- d Enables debugging.
- f Forwards local security credentials to the remote server.
- g Disables filename “globbing”.
- i Turns off interactive prompting during multiple file transfers.
- m Specifies the GSS-API mechanism to use. The default is to use the kerberos\_v5 mechanism. Supported alternatives are defined in /etc/gss/mech (see [mech\(4\)](#)).
- n Does not attempt “auto-login” upon initial connection. If auto-login is not disabled, ftp checks the .netrc file in the user's home directory for an entry describing an account on the remote machine. If no entry exists, ftp prompts for the login name of the account on the remote machine (the default is the login name on the local machine), and, if necessary, prompts for a password and an account with which to login.
- p Enables passive mode for data transfers. This command is useful when connecting to a remote host from behind a connection filtering firewall.
- s Skips the SYST command that is sent by default to all remote servers upon connection. The system command is what enables the automatic use of binary mode rather than the protocol default ascii mode.  
  
As some older servers cannot handle the ftp command, this directive is provided to allow inter-operability with these servers.
- t Enables packet tracing (unimplemented).
- T *timeout* Enables global connection timer, specified in seconds (decimal). There is a timer for the control connection that is reset when anything is sent to the

server and disabled while the client is prompting for user input. Another independent timer is used to monitor incoming or outgoing data connections.

- v Shows all responses from the remote server, as well as report on data transfer statistics. This is turned on by default if `ftp` is running interactively with its input coming from the user's terminal.
- x Attempts to use GSSAPI for authentication and encryption. Data and Command channel protection is set to "private".

The following commands can be specified to the command interpreter:

|                                                 |                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| !                                               | [ <i>command</i> ] Runs <i>command</i> as a shell command on the local machine. If no <i>command</i> is given, invokes an interactive shell.                                                                                                                                                                          |
| \$ <i>macro-name</i> [ <i>args</i> ]            | Executes the macro <i>macro-name</i> that was defined with the <code>macdef</code> command. Arguments are passed to the macro unglobbed.                                                                                                                                                                              |
| account [ <i>passwd</i> ]                       | Supplies a supplemental password required by a remote system for access to resources once a login has been successfully completed. If no argument is included, the user is prompted for an account password in a non-echoing input mode.                                                                              |
| append <i>local-file</i> [ <i>remote-file</i> ] | Appends a local file to a file on the remote machine. If <i>remote-file</i> is not specified, the local file name is used, subject to alteration by any <code>nt rans</code> or <code>nmap</code> settings. File transfer uses the current settings for "representation type", "file structure", and "transfer mode". |
| ascii                                           | Sets the "representation type" to "network ASCII". This is the default type.                                                                                                                                                                                                                                          |
| bell                                            | Sounds a bell after each file transfer command is completed.                                                                                                                                                                                                                                                          |
| binary                                          | Sets the "representation type" to "image".                                                                                                                                                                                                                                                                            |
| bye                                             | Terminates the FTP session with the remote server and exit <code>ftp</code> . An EOF also terminates the session and exit.                                                                                                                                                                                            |
| case                                            | Toggles remote computer file name case mapping during <code>mget</code> commands. When <code>case</code> is on (default is off), remote computer file names with all letters in upper case are written in the local directory with the letters mapped to lower case.                                                  |

|                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cd <i>remote-directory</i></code>                           | Changes the working directory on the remote machine to <i>remote-directory</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>cdup</code>                                                 | Changes the remote machine working directory to the parent of the current remote machine working directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>clear</code>                                                | Sets the protection level on data transfers to “clear”. If no ADAT command succeeded, then this is the default protection level.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>close</code>                                                | Terminates the FTP session with the remote server, and return to the command interpreter. Any defined macros are erased.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>cr</code>                                                   | Toggles RETURN stripping during “network ASCII” type file retrieval. Records are denoted by a RETURN/LINEFEED sequence during “network ASCII” type file transfer. When <code>cr</code> is on (the default), RETURN characters are stripped from this sequence to conform with the UNIX system single LINEFEED record delimiter. Records on non-UNIX-system remote hosts can contain single LINEFEED characters; when an “network ASCII” type transfer is made, these LINEFEED characters can be distinguished from a record delimiter only when <code>cr</code> is off. |
| <code>delete <i>remote-file</i></code>                            | Deletes the file <i>remote-file</i> on the remote machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>debug</code>                                                | Toggles debugging mode. When debugging is on, <code>ftp</code> prints each command sent to the remote machine, preceded by the string <code>-&gt;</code> .                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>dir [ <i>remote-directory</i> [ <i>local-file</i> ]]</code> | Prints a listing of the directory contents in the directory, <i>remote-directory</i> , and, optionally, placing the output in <i>local-file</i> . If no directory is specified, the current working directory on the remote machine is used. If no local file is specified, or <i>local-file</i> is <code>-</code> , output is sent to the terminal.                                                                                                                                                                                                                    |
| <code>disconnect</code>                                           | A synonym for <code>close</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>form [ <i>format-name</i> ]</code>                          | Sets the carriage control format subtype of the “representation type” to <i>format-name</i> . The only valid <i>format-name</i> is <code>non-print</code> , which corresponds to the default “non-print” subtype.                                                                                                                                                                                                                                                                                                                                                       |

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>get remote-file [ local-file ]</code>               | Retrieves the <i>remote-file</i> and store it on the local machine. If the local file name is not specified, it is given the same name it has on the remote machine, subject to alteration by the current case, ntrans, and nmap settings. The current settings for “representation type”, “file structure”, and “transfer mode” are used while transferring the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>glob</code>                                         | <p>Toggles filename expansion, or “globbing”, for <code>delete</code>, <code>mget</code> and <code>mput</code>. If globbing is turned off, filenames are taken literally.</p> <p>Globbing for <code>mput</code> is done as in <a href="#">sh(1)</a>. For <code>delete</code> and <code>mget</code>, each remote file name is expanded separately on the remote machine, and the lists are not merged.</p> <p>Expansion of a directory name is likely to be radically different from expansion of the name of an ordinary file: the exact result depends on the remote operating system and FTP server, and can be previewed with the command, <code>mls remote-files -</code>.</p> <p><code>mget</code> and <code>mput</code> are not meant to transfer entire directory subtrees of files. You can do this by transferring a <a href="#">tar(1)</a> archive of the subtree (using a “representation type” of “image” as set by the binary command).</p> |
| <code>hash</code>                                         | Toggles hash-sign (#) printing for each data block transferred. The size of a data block is 8192 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>help [ command ]</code>                             | Prints an informative message about the meaning of <i>command</i> . If no argument is given, <code>ftp</code> prints a list of the known commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>lcd [ directory ]</code>                            | Changes the working directory on the local machine. If no <i>directory</i> is specified, the user's home directory is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>ls [ -al   remote-directory [ local-file ] ]</code> | By default, prints an abbreviated listing of the contents of a directory on the remote machine. This default behavior can be changed to make <code>ls</code> a synonym of the <code>dir</code> command. This change can be achieved by setting <code>FTP_LS_SENDS_NLST</code> to 'no' in <code>/etc/default/ftp</code> or in the environment. See <a href="#">ftp(4)</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The `-a` option lists all entries, including those that begin with a dot (`.`), which are normally not listed. The `-l` option lists files in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file. If the file is a special file, the size field instead contains the major and minor device numbers rather than a size. If the file is a symbolic link, the filename is printed followed by “`→`” and the pathname of the referenced file.

If *remote-directory* is left unspecified, the current working directory is used.

If no local file is specified, or if *local-file* is `-`, the output is sent to the terminal.

`macdef macro-name`

Defines a macro. Subsequent lines are stored as the macro *macro-name*. A null line (consecutive NEWLINE characters in a file or RETURN characters from the terminal) terminates macro input mode. There is a limit of 16 macros and 4096 total characters in all defined macros. Macros remain defined until a `close` command is executed.

The macro processor interprets `$` and `\` as special characters. A `$` followed by a number (or numbers) is replaced by the corresponding argument on the macro invocation command line. A `$` followed by an `i` signals that macro processor that the executing macro is to be looped. On the first pass, `$i` is replaced by the first argument on the macro invocation command line; on the second pass, it is replaced by the second argument, and so on. A `\` followed by any character is replaced by that character. Use the `\` to prevent special treatment of the `$`.

`mdelete remote-files`

Deletes the *remote-files* on the remote machine.

`mdir remote-files local-file`

Like `dir`, except multiple remote files can be specified. If interactive prompting is on, `ftp` prompts the user to verify that the last argument is indeed the target local file for receiving `mdir` output.

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mget remote-files</code>                                            | Expands the <i>remote-files</i> on the remote machine and do a <code>get</code> for each file name thus produced. See <code>glob</code> for details on the filename expansion. Resulting file names are processed according to <code>case</code> , <code>nt rans</code> , and <code>nmap</code> settings. Files are transferred into the local working directory, which can be changed with <code>lcd directory</code> . New local directories can be created with <code>! mkdir directory</code> .                                                                                           |
| <code>mkdir directory-name</code>                                         | Makes a directory on the remote machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>mls remote-files local-file</code>                                  | Like <code>ls(1)</code> , except multiple remote files can be specified. If interactive prompting is on, <code>ftp</code> prompts the user to verify that the last argument is indeed the target local file for receiving <code>mls</code> output.                                                                                                                                                                                                                                                                                                                                            |
| <code>mode [ mode-name ]</code>                                           | Sets the “transfer mode” to <i>mode-name</i> . The only valid <i>mode-name</i> is <code>stream</code> , which corresponds to the default “stream” mode. This implementation only supports <code>stream</code> , and requires that it be specified.                                                                                                                                                                                                                                                                                                                                            |
| <code>mput local-files</code>                                             | Expands wild cards in the list of local files given as arguments and do a <code>put</code> for each file in the resulting list. See <code>glob</code> for details of filename expansion. Resulting file names are processed according to <code>nt rans</code> and <code>nmap</code> settings.                                                                                                                                                                                                                                                                                                 |
| <code>nlist [ -a<code>l</code>   remote-directory [ local-file ] ]</code> | Prints an abbreviated listing of the contents of a directory on the remote machine, listing only those files that can be retrieved by the <code>get</code> command, unless the <code>-a</code> or <code>-l</code> option is used. If <i>remote-directory</i> is left unspecified, the current working directory is used.<br><br>The <code>-a</code> option lists all entries, including those that begin with a dot ( <code>.</code> ), which are normally not listed. The <code>-l</code> option lists files in long format the same way it does when used with the <code>ls</code> command. |
| <code>nmap [ inpattern outpattern ]</code>                                | Sets or unsets the filename mapping mechanism. If no arguments are specified, the filename mapping mechanism is unset. If arguments are specified, remote filenames are                                                                                                                                                                                                                                                                                                                                                                                                                       |

mapped during `mput` commands and `put` commands issued without a specified remote target filename. If arguments are specified, local filenames are mapped during `mget` commands and `get` commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. The mapping follows the pattern set by *inpattern* and *outpattern*. *inpattern* is a template for incoming filenames (which can have already been processed according to the `nt rans` and case settings). Variable templating is accomplished by including the sequences `$1`, `$2`, . . . , `$9` in *inpattern*. Use `\` to prevent this special treatment of the `$` character. All other characters are treated literally, and are used to determine the `nmap inpattern` variable values.

For example, given *inpattern* `$1.$2` and the remote file name `mydata.data`, `$1` would have the value `mydata`, and `$2` would have the value `data`.

The *outpattern* determines the resulting mapped filename. The sequences `$1`, `$2`, . . . , `$9` are replaced by any value resulting from the *inpattern* template. The sequence `$0` is replaced by the original filename. Additionally, the sequence `[ seq1 , seq2 ]` is replaced by `seq1` if `seq1` is not a null string; otherwise it is replaced by `seq2`.

For example, the command `nmap $1.$2.$3 [ $1,$2 ] . [ $2, file ]` would yield the output filename `myfile.data` for input filenames `myfile.data` and `myfile.data.old`, `myfile.file` for the input filename `myfile`, and `myfile.myfile` for the input filename `.myfile`. SPACE characters can be included in *outpattern*, as in the example `nmap $1 | sed`

`nt rans [ inchars [ outchars ] ]`

"s/ \*\$//>" > \$1. Use the \ character to prevent special treatment of the \$, [, ], and ,, characters.

Sets or unsets the filename character translation mechanism. If no arguments are specified, the filename character translation mechanism is unset. If arguments are specified, characters in remote filenames are translated during `mput` commands and `put` commands issued without a specified remote target filename, and characters in local filenames are translated during `mget` commands and `get` commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. Characters in a filename matching a character in *inchars* are replaced with the corresponding character in *outchars*. If the character's position in *inchars* is longer than the length of *outchars*, the character is deleted from the file name.

Only 16 characters can be translated when using the `nt rans` command under `ftp`. Use case (described above) if needing to convert the entire alphabet.

`open host [ port ]`

Establishes a connection to the specified *host* FTP server. An optional port number can be supplied, in which case, `ftp` attempts to contact an FTP server at that port. If the *auto-login* option is on (default setting), `ftp` also attempts to automatically log the user in to the FTP server.

`passive`

Toggles passive mode. When passive mode is turned on, the `ftp` client sends the `PASV` command requesting that the FTP server open a port for the data connection and return the address of that port. The remote server listens on that port and the client connects to it. When passive mode is turned off, the `ftp` client sends

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | <p>the PORT command to the server specifying an address for the remote server to connect back to. Passive mode is useful when the connections to the ftp client are controlled, for example, when behind a firewall. When connecting to an IPv6-enabled FTP server, EPSV can be used in place of PASV and EPRT in place of PORT.</p>                                                                                                                                                                                            |
| <code>private</code>                         | <p>Sets the protection level on data transfers to “private”. Data transmissions are confidentiality— and integrity—protected by encryption. If no ADAT command succeeded, then the only possible level is “clear”.</p>                                                                                                                                                                                                                                                                                                          |
| <code>prompt</code>                          | <p>Toggles interactive prompting. Interactive prompting occurs during multiple file transfers to allow the user to selectively retrieve or store files. By default, prompting is turned on. If prompting is turned off, any <code>mget</code> or <code>mput</code> transfers all files, and any <code>mdelete</code> deletes all files.</p>                                                                                                                                                                                     |
| <code>protect</code> <i>protection-level</i> | <p>Sets the protection level on data transfers to <i>protection-level</i>. The valid protection levels are “clear” for unprotected data transmissions, “safe” for data transmissions that are integrity-protected by cryptographic checksum, and “private” for data transmissions that are confidentiality— and integrity— protected by encryption. If no ADAT command succeeded, then the only possible level is “clear”. If no level is specified, the current level is printed. The default protection level is “clear”.</p> |
| <code>proxy</code> <i>ftp-command</i>        | <p>Executes an FTP command on a secondary control connection. This command allows simultaneous connection to two remote FTP servers for transferring files between the two servers. The first proxy command should be an open, to establish the secondary control connection. Enter the command <code>proxy ?</code> to see other FTP commands executable on the secondary connection.</p>                                                                                                                                      |

The following commands behave differently when prefaced by `proxy`: `open` does not define new macros during the auto-login process, `close` does not erase existing macro definitions, `get` and `mget` transfer files from the host on the primary control connection to the host on the secondary control connection, and `put`, `mput`, and `append` transfer files from the host on the secondary control connection to the host on the primary control connection.

Third party file transfers depend upon support of the `PASV` command by the server on the secondary control connection.

`put local-file [ remote-file ]`

Stores a local file on the remote machine. If *remote-file* is left unspecified, the local file name is used after processing according to any `nttrans` or `nmap` settings in naming the remote file. File transfer uses the current settings for “representation type”, “file structure”, and “transfer mode”.

`pwd`

Prints the name of the current working directory on the remote machine.

`quit`

A synonym for `bye`.

`quote arg1 arg2 ...`

Sends the arguments specified, verbatim, to the remote FTP server. A single FTP reply code is expected in return. (The `remotehelp` command displays a list of valid arguments.)

`quote` should be used only by experienced users who are familiar with the FTP protocol.

`recv remote-file [ local-file ]`

A synonym for `get`.

`reget remote-file [ local-file ]`

The `reget` command acts like `get`, except that if *local-file* exists and is smaller than *remote-file*, *local-file* is presumed to be a partially transferred copy of *remote-file* and the transfer is continued from the apparent point of failure. This command is useful when transferring large files over networks that are prone to dropping connections.

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>remotehelp [ <i>command-name</i> ]</code>            | Requests help from the remote FTP server. If a <i>command-name</i> is specified it is supplied to the server as well.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>rename <i>from to</i></code>                         | Renames the file <i>from</i> on the remote machine to have the name <i>to</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>reset</code>                                         | Clears reply queue. This command re-synchronizes command/reply sequencing with the remote FTP server. Resynchronization can be necessary following a violation of the FTP protocol by the remote server.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>restart [ <i>marker</i> ]</code>                     | Restarts the immediately following get or put at the indicated marker. On UNIX systems, <i>marker</i> is usually a byte offset into the file. When followed by an <code>mget</code> , the <code>restart</code> applies to the first get performed. Specifying a <i>marker</i> of 0 clears the restart marker. If no argument is specified, the current restart status is displayed.                                                                                                                                                                                                                                 |
| <code>rmdir <i>directory-name</i></code>                   | Deletes a directory on the remote machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>runique</code>                                       | Toggles storing of files on the local system with unique filenames. If a file already exists with a name equal to the target local filename for a get or <code>mget</code> command, a <code>.1</code> is appended to the name. If the resulting name matches another existing file, a <code>.2</code> is appended to the original name. If this process continues up to <code>.99</code> , an error message is printed, and the transfer does not take place. The generated unique filename is reported. <code>runique</code> does not affect local files generated from a shell command. The default value is off. |
| <code>safe</code>                                          | Sets the protection level on data transfers to “safe”. Data transmissions are integrity-protected by cryptographic checksum. If no ADAT command succeeded, then the only possible level is “clear”.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>send <i>local-file</i> [ <i>remote-file</i> ]</code> | A synonym for <code>put</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

---

|                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sendport</code>                           | Toggles the use of <code>PORT</code> commands. By default, <code>ftp</code> attempts to use a <code>PORT</code> command when establishing a connection for each data transfer. The use of <code>PORT</code> commands can prevent delays when performing multiple file transfers. If the <code>PORT</code> command fails, <code>ftp</code> uses the default data port. When the use of <code>PORT</code> commands is disabled, no attempt is made to use <code>PORT</code> commands for each data transfer. This is useful when connected to certain FTP implementations that ignore <code>PORT</code> commands but incorrectly indicate they have been accepted. |
| <code>site <i>arg1</i> [<i>arg2</i>] ...</code> | Sends the arguments specified, verbatim, to the remote FTP server as a <code>SITE</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>status</code>                             | Show the current status of <code>ftp</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>struct [<i>struct-name</i>]</code>        | Sets the file structure to <i>struct-name</i> . The only valid <i>struct-name</i> is <code>file</code> , which corresponds to the default “file” structure. The implementation only supports <code>file</code> , and requires that it be specified.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>sunique</code>                            | Toggles storing of files on remote machine under unique file names. The remote FTP server must support the <code>STOU</code> command for successful completion. The remote server reports the unique name. Default value is off.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>tcpwindow [<i>size</i>]</code>            | Sets the TCP window size to be used for data connections. Specifying a size of 0 stops the explicit setting of the TCP window size on data connections. If no argument is specified, the current setting is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>tenex</code>                              | Sets the “representation type” to that needed to talk to TENEX machines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>trace</code>                              | Toggles packet tracing (unimplemented).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>type [<i>type-name</i>]</code>            | Sets the “representation type” to <i>type-name</i> . The valid <i>type-names</i> are <code>ascii</code> for “network ASCII”, <code>binary</code> or <code>image</code> for “image”, and <code>tenex</code> for “local byte size” with a byte size of 8 (used to talk to TENEX machines). If no type is                                                                                                                                                                                                                                                                                                                                                           |

`user user-name [ password [ account ] ]`

specified, the current type is printed. The default type is “network ASCII”.

Identify yourself to the remote FTP server. If the password is not specified and the server requires it, `ftp` prompts the user for it (after disabling local echo). If an account field is not specified, and the FTP server requires it, the user is prompted for it. If an account field is specified, an account command is relayed to the remote server after the login sequence is completed if the remote server did not require it for logging in. Unless `ftp` is invoked with “auto-login” disabled, this process is done automatically on initial connection to the FTP server.

`verbose`

Toggles verbose mode. In verbose mode, all responses from the FTP server are displayed to the user. In addition, if verbose mode is on, when a file transfer completes, statistics regarding the efficiency of the transfer are reported. By default, verbose mode is on if `ftp`'s commands are coming from a terminal, and off otherwise.

`? [ command ]`

A synonym for `help`.

Command arguments which have embedded spaces can be quoted with quote (") marks.

If any command argument which is not indicated as being optional is not specified, `ftp` prompts for that argument.

### **Aborting A File Transfer**

To abort a file transfer, use the terminal interrupt key. Sending transfers is immediately halted. Receiving transfers are halted by sending an FTP protocol ABOR command to the remote server, and discarding any further data received. The speed at which this is accomplished depends upon the remote server's support for ABOR processing. If the remote server does not support the ABOR command, an `ftp>` prompt does not appear until the remote server has completed sending the requested file.

The terminal interrupt key sequence is ignored when `ftp` has completed any local processing and is awaiting a reply from the remote server. A long delay in this mode can result from the ABOR processing described above, or from unexpected behavior by the remote server, including violations of the `ftp` protocol. If the delay results from unexpected remote server behavior, the local `ftp` program must be killed by hand.

- 
- File Naming Conventions** Local files specified as arguments to `ftp` commands are processed according to the following rules.
- 1) If the file name `-` is specified, the standard input (for reading) or standard output (for writing) is used.
  - 2) If the first character of the file name is `|`, the remainder of the argument is interpreted as a shell command. `ftp` then forks a shell, using [popen\(3C\)](#) with the argument supplied, and reads (writes) from the standard output (standard input) of that shell. If the shell command includes SPACE characters, the argument must be quoted; for example `"| ls -lt"`. A particularly useful example of this mechanism is: `"dir | more"`.
  - 3) Failing the above checks, if globbing is enabled, local file names are expanded according to the rules used in the [sh\(1\)](#); see the `glob` command. If the `ftp` command expects a single local file (for example, `put`), only the first filename generated by the globbing operation is used.
  - 4) For `mget` commands and `get` commands with unspecified local file names, the local filename is the remote filename, which can be altered by a `case`, `nt rans`, or `nmap` setting. The resulting filename can then be altered if `runique` is on.
  - 5) For `mput` commands and `put` commands with unspecified remote file names, the remote filename is the local filename, which can be altered by a `nt rans` or `nmap` setting. The resulting filename can then be altered by the remote server if `sunique` is on.
- File Transfer Parameters** The FTP specification specifies many parameters which can affect a file transfer.
- The “representation type” can be one of “network ASCII”, “EBCDIC”, “image”, or “local byte size” with a specified byte size (for PDP-10’s and PDP-20’s mostly). The “network ASCII” and “EBCDIC” types have a further subtype which specifies whether vertical format control (NEWLINE characters, form feeds, and so on) are to be passed through (“non-print”), provided in TELNET format (“TELNET format controls”), or provided in ASA (FORTRAN) (“carriage control (ASA)”) format. `ftp` supports the “network ASCII” (subtype “non-print” only) and “image” types, plus “local byte size” with a byte size of 8 for communicating with TENEX machines.
- The “file structure” can be one of `file` (no record structure), `record`, or `page`. `ftp` supports only the default value, which is `file`.
- The “transfer mode” can be one of `stream`, `block`, or `compressed`. `ftp` supports only the default value, which is `stream`.
- Usage** See [largefile\(5\)](#) for the description of the behavior of `ftp` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).
- The `ftp` command is IPv6-enabled. See [ip6\(7P\)](#).

**Files** ~/.netrc

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbip         |
| CSI            | enabled         |

**Notes** Failure to log in can arise from an explicit denial by the remote FTP server because the account is listed in /etc/ftpusers. See [in.ftpd\(1M\)](#) and [ftpusers\(4\)](#).

Correct execution of many commands depends upon proper behavior by the remote server.

An error in the treatment of carriage returns in the 4.2 BSD code handling transfers with a “representation type” of “network ASCII” has been corrected. This correction can result in incorrect transfers of binary files to and from 4.2 BSD servers using a “representation type” of “network ASCII”. Avoid this problem by using the “image” type.

**Name** ftpcount – show current number of users in each FTP Server class

**Synopsis** ftpcount [-v] [-V]

**Description** Use the ftpcount command to show the current number of users logged in and the login limit for each FTP Server class defined in the [ftppaccess\(4\)](#) file.

**Options** The ftpcount command supports the following options:

- v Display the user counts for FTP Server classes defined in virtual host [ftppaccess\(4\)](#) files.
- V Display program copyright and version information, then terminate.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files** /var/run/ftp.pids-*classnames*

/etc/ftpd/ftppaccess

/etc/ftpd/ftpservers

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWftpu        |
| Interface Stability | Standard        |

**See Also** [ftpwho\(1\)](#), [in.ftpd\(1M\)](#), [ftppaccess\(4\)](#), [ftpservers\(4\)](#), [attributes\(5\)](#)

**Notes** For separate class counts to be kept, class names defined in complete virtual host ftpaccess files must be unique.

**Name**   ftppwho – show current process information for each FTP Server user

**Synopsis**   ftppwho [-v] [-V]

**Description**   Use the `ftppwho` command to show the current process information for each user logged in to the FTP Server. This information is in addition to information displayed by the `ftpcount(1)` command.

- Options**   The `ftppwho` command supports the following options:
- v    Display the current process information and user counts for FTP Server classes defined in virtual host `ftppaccess(4)` files.
  - V    Display the program copyright and version information, then terminate.

**Exit Status**   The following exit values are returned:

- 0     Successful completion.
- >0    An error occurred.

**Files**    `/etc/ftpd/ftppaccess`  
  
          `/var/run/ftp.pids-classname`  
  
          `/etc/ftpd/ftpservers`

**Attributes**   See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWftpu       |
| Interface Stability | External       |

**See Also**   `ftpcount(1)`, `ps(1)`, `in.ftpd(1M)`, `ftppaccess(4)`, `ftpservers(4)`, `attributes(5)`

**Notes**    For separate class counts to be kept, class names defined in complete virtual host `ftppaccess` files must be unique.

- Name** gcore – get core images of running processes
- Synopsis** gcore [-pgF] [-o *filename*] [-c *content*] *process-id*...
- Description** The gcore utility creates a core image of each specified process. By default, the name of the core image file for the process whose process ID is *process-id* is *core.process-id*.
- Options** The following options are supported:
- c *content* Produces core image files with the specified content. The content description uses the same tokens as in [coreadm\(1M\)](#). The -c option does not apply to cores produced due to the -p or -g flags.
  - F Force. Grabs the target process even if another process has control.
  - g Produces core image files in the global core file repository with the global content as configured by [coreadm\(1M\)](#). The command fails if the user does not have permissions to the global core file repository.
  - o *filename* Substitutes *filename* in place of core as the first part of the name of the core image files. *filename* can contain the same tokens to be expanded as the paths in [coreadm\(1M\)](#).
  - p Produces a core image file in the process-specific location with the process-specific content for each process as configured by [coreadm\(1M\)](#). The command fails if the user does not have permissions to the per-process core file repository.
- Operands** The following operand is supported:
- process-id* process ID
- Usage** Caution should be exercised when using the -F flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.
- Exit Status** The following exit values are returned:
- 0 On success.
  - non-zero On failure, such as non-existent process ID.
- Files** *core.process-id* core images
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | See below.      |

The command syntax is Evolving. The Output Formats are Unstable.

**See Also** [kill\(1\)](#), [coreadm\(1M\)](#), [setrlimit\(2\)](#), [core\(4\)](#), [proc\(4\)](#), [attributes\(5\)](#)

**Notes** gcore is unaffected by the [setrlimit\(2\)](#) system call using the RLIMIT\_CORE value.

| <b>Synopsis</b>                    | gencat <i>catfile</i> <i>msgfile</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |
| <b>Description</b>                 | <p>The gencat command merges the message text source file(s) <i>msgfile</i> into a formatted message database <i>catfile</i>. The database <i>catfile</i> is created if it does not already exist. If <i>catfile</i> does exist, its messages are included in the new <i>catfile</i>. If set and message numbers collide, the new message-text defined in <i>msgfile</i> replaces the old message text currently contained in <i>catfile</i>. The message text source file (or set of files) input to gencat can contain either set and message numbers or simply message numbers, in which case the set NL_SETD (see <a href="#">nl_types.h(3HEAD)</a>) is assumed.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |
| Message Text Source<br>File Format | <p>The format of a message text source file is defined as follows. Note that the fields of a message text source line are separated by a single ASCII space or tab character. Any other ASCII spaces or tabs are considered as part of the subsequent field.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |
|                                    | <code>\$set <i>n</i> <i>comment</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Where <i>n</i> specifies the set identifier of the following messages until the next \$set, \$delset, or end-of-file appears. <i>n</i> must be a number in the range (1–{NL_SETMAX}). Set identifiers within a single source file need not be contiguous. Any string following the set identifier is treated as a comment. If no \$set directive is specified in a message text source file, all messages are located in the default message set NL_SETD.                                                                                                                                                                                                                                               |  |

|                                    | <code><i>m</i> <i>message-text</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | The <i>m</i> denotes the message identifier, a number in the range (1–{NL_MSGMAX}). The <i>message-text</i> is stored in the message catalog with the set identifier specified by the last \$set directive, and with message identifier <i>m</i> . If the <i>message-text</i> is empty, and an ASCII space or tab field separator is present, an empty string is stored in the message catalog. If a message source line has a message number, but neither a field separator nor <i>message-text</i> , the existing message with that number (if any) is deleted from the catalog. Message identifiers need not be contiguous. The length of <i>message-text</i> must be in the range (0–{NL_TEXTMAX}). |  |
|                                    | <code>\$quote <i>c</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | This line specifies an optional quote character <i>c</i> , which can be used to surround <i>message-text</i> so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty \$quote directive is supplied, no quoting of <i>message-text</i> will be recognized.                                                                                                                                                                                                                                                                                                                                                                                     |  |

Empty lines in a message text source file are ignored.

Text strings can contain the special characters and escape sequences defined in the following table:

| Description     | Symbol | Sequence |
|-----------------|--------|----------|
| newline         | NL(LF) | \n       |
| horizontal tab  | HT     | \t       |
| vertical tab    | VT     | \v       |
| backspace       | BS     | \b       |
| carriage return | CR     | \r       |
| form feed       | FF     | \f       |
| backslash       | \      | \\       |
| bit pattern     | ddd    | \ddd     |

The escape sequence `\ddd` consists of backslash followed by 1, 2 or 3 octal digits, which are taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash is ignored.

Backslash followed by an ASCII newline character is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which is equivalent to:

```
1 This line continues to the next line
```

**Operands** The following operands are supported:

- catfile* A path name of the formatted message catalog. If `-` is specified, standard output is used.
- msgfile* A path name of a message text source file. If `-` is specified for an instance of *msgfile*, standard input is used. The format of message text source files is defined in Message Text Source File Format.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of gencat: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWloc         |
| CSI                 | enabled         |
| Interface Stability | Standard        |

**Name** geniconvtbl – generate iconv code conversion tables

**Synopsis** geniconvtbl [-fnq] [-p *preprocessor*] [-W *arg*] [-D*name*]  
[-D*name=def*] [-Idirectory] [-U*name*] [*infile*]...

**Description** The geniconvtbl utility accepts code conversion rules defined in flat text file(s) and writes code conversion binary table file(s) that can be used to support user-defined iconv code conversions (see [iconv\(1\)](#) and [iconv\(3C\)](#) for more detail on the iconv code conversion).

**Options** The following options are supported:

- f Overwrites output file if the output file exists.
- n Does not generate an output file. This is useful to check the contents of the input file.
- p *preprocessor* Uses specified *preprocessor* instead of the default preprocessor, /usr/lib/cpp.
- q Quiet option. It suppresses warning and error messages.
- W *arg* Passes the argument *arg* to the preprocessor. If this option is specified more than once, all arguments are passed to the preprocessor.
- D*name*
- D*name=def*
- Idirectory
- U*name* geniconvtbl recognizes these options and passes them and their arguments to the preprocessor.

**Operands** The following operand is supported:

*infile* A path name of an input file. If no input file is specified, geniconvtbl reads from the standard input stream. The user can specify more than one input file if necessary.

**Output** If input is from the standard input stream, geniconvtbl writes output to the standard output stream. If one or more input files are specified, geniconvtbl reads from each input file and writes to a corresponding output file. Each of the output file names will be the same as the corresponding input file with .bt appended.

The generated output files must be moved to the following directory prior to using the code conversions at [iconv\(1\)](#) and [iconv\(3C\)](#):

/usr/lib/iconv/geniconvtbl/binarytables/

The output file name should start with one or more printable ASCII characters as the 'fromcode' name followed by a percentage character (%), followed by one or more printable ASCII characters as the 'to code' name, followed by the suffix '.bt'. The 'fromcode' and 'to code' names are used to identify the iconv code conversion at [iconv\(1\)](#) and

`iconv_open(3C)`). The properly named output file should be placed in the directory, `/usr/lib/iconv/geniconvtbl/binarytables/`.

### Examples **EXAMPLE 1** Generating an iconv code conversion binary table

The following example generates a code conversion binary table with output file name `convertA2B.bt`:

```
example% geniconvtbl convertA2B
```

### **EXAMPLE 2** Generating multiple iconv code conversion binary tables

The following example generates two code conversion binary tables with output files `test1.bt` and `test2.bt`:

```
example% geniconvtbl test1 test2
```

### **EXAMPLE 3** Using another preprocessor

The following example generates a code conversion binary table once the specified preprocessor has processed the input file:

```
example% geniconvtbl -p /opt/SUNWspro/bin/cc -W -E convertB2A
```

### **EXAMPLE 4** Placing a binary table

To use the binary table created in the first example above as the engine of the conversion 'fromcode' ABC to 'tocode' DEF, become super-user and then rename it and place it like this:

```
example# mv convertA2B.bt \

 /usr/lib/iconv/geniconvtbl/binarytables/ABC%DEF.bt
```

### **EXAMPLE 5** Providing modified ISO8859-1 to UTF-8 code conversion

Write a `geniconvtbl` source file that defines the code conversion. For instance, you can copy over `/usr/lib/iconv/geniconvtbl/srcs/ISO8859-1_to_UTF-8.src` into your directory and make necessary changes at the source file. Once the modifications are done, generate the binary table:

```
example% geniconvtbl ISO8859-1_to_UTF-8.src
```

As super-user, place the generated binary table with a unique name at the system directory where `iconv_open(3C)` can find the binary table:

```
example su

Password:

example% cp ISO8859-1_to_UTF-8.bt \

 /usr/lib/iconv/geniconvtbl/binarytables/my-iso-8859-1%utf-8.bt
```

After that, you can do the `iconv` code conversion. For instance:

```
example% iconv -f my-iso-8859-1 -t utf-8 testfile.txt
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of geniconvtbl: LANG and LC\_CTYPE.

- Exit Status** The following exit values are returned:
- 0 No errors occurred and the output files were successfully created.
  - 1 Command line options are not correctly used or an unknown command line option was specified.
  - 2 Invalid input or output file was specified.
  - 3 Conversion rules in input files are not correctly defined.
  - 4 Conversion rule limit of input files has been reached. See NOTES section of [geniconvtbl\(4\)](#).
  - 5 No more system resource error.
  - 6 Internal error.

**Files** /usr/lib/iconv/geniconvtbl/binarytables/\*.bt  
conversion binary tables

/usr/lib/iconv/geniconvtbl/srcs/\*  
conversion source files for user reference

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [cpp\(1\)](#), [iconv\(1\)](#), [iconv\(3C\)](#), [iconv\\_close\(3C\)](#), [iconv\\_open\(3C\)](#), [geniconvtbl\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [iconv\(5\)](#)

*Solaris Internationalization Guide for Developers*

**Notes** The generated and correctly placed output files, /usr/lib/iconv/geniconvtbl/binarytables/\*.bt, are used in both 32-bit and 64-bit environments.

| <b>Synopsis</b>                  | genlayouttbl [-o <i>outfile</i> ] [ <i>infile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |                                                                                                                                                           |
| <b>Description</b>               | The genlayouttbl utility accepts a locale's layout definition in a flat text file and writes a binary layout table file that can be used in the complex text layout of the locale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |                                                                                                                                                           |
| <b>Options</b>                   | <p>The following option is supported:</p> <p>-o <i>outfile</i>      Writes output binary layout table to the <i>outfile</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |      |                                                                                                                                                           |
| <b>Operands</b>                  | <p>The following operand is supported:</p> <p><i>infile</i>      A path name of an input file. If no input file is specified, genlayouttbl reads from the standard input stream.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |                                                                                                                                                           |
| <b>Output And Symbolic Links</b> | <p>If no <i>outfile</i> is specified, genlayouttbl writes output to the standard output stream.</p> <p>The generated output file must be moved to the following directory prior to the use at the system and the file name should be layout.dat:</p> <p>/usr/lib/locale/locale/LO_LTYPE/layout.dat</p> <p>The locale should also have a symbolic link,<br/>/usr/lib/locale/locale/LO_LTYPE/locale.layout.so.1, to the 32-bit Universal Multiscript Layout Engine (UMLE), /usr/lib/locale/common/LO_LTYPE/umle.layout.so.1.</p> <p>For proper 64-bit platform operations, the locale should also have a symbolic link, as for instance, in 64-bit SPARC platform,<br/>/usr/lib/locale/locale/LO_LTYPE/sparcv9/locale.layout.so.1, to the 64-bit UMLE,<br/>/usr/lib/locale/common/LO_LTYPE/sparcv9/umle.layout.so.1.</p> <p>The <i>locale</i> is the locale that you want to provide and to use the layout functionality you defined.</p> |      |                                                                                                                                                           |
| <b>Input File Format</b>         | <p>A layout definition file to genlayouttbl contains three different sections of definitions:</p> <ul style="list-style-type: none"> <li>■ Layout attribute definition</li> <li>■ Bidirectional data and character type data definition</li> <li>■ Shaping data definition</li> </ul> <p>For appropriate complex text layout support, all three sections need to be defined in the layout definition file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |      |                                                                                                                                                           |
| <b>The Lexical Conventions</b>   | <p>The following lexical conventions are used in the layout definition:</p> <table> <tr> <td>NAME</td><td>A string of characters that consists of printable ASCII characters. It includes DECIMAL and HEXADECIMAL also.<br/><i>Examples:</i> test, a1_src, b32, 123.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | NAME | A string of characters that consists of printable ASCII characters. It includes DECIMAL and HEXADECIMAL also.<br><i>Examples:</i> test, a1_src, b32, 123. |
| NAME                             | A string of characters that consists of printable ASCII characters. It includes DECIMAL and HEXADECIMAL also.<br><i>Examples:</i> test, a1_src, b32, 123.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |                                                                                                                                                           |

|                  |                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HEXADECIMAL_BYTE | Two-digit hexadecimal number. The number starts with a hexadecimal digit followed by another hexadecimal digit.<br><i>Examples:</i> e0, E1, a7, fe.                                                             |
| HEXADECIMAL      | A hexadecimal number. The hexadecimal representation consists of an escape character, '\0' followed by the constant 'x' or 'X' and one or more hexadecimal digits. <i>Examples:</i> 0x0, 0x1, 0x1a, 0xA, 0x1b3. |
| DECIMAL          | A decimal number, represented by one or more decimal digits.<br><i>Examples:</i> 0, 123, 2165.                                                                                                                  |

Each comment must start with '#'. The comment ends at the end of the line.

The following keywords are reserved:

```
active_directional, active_shape_editing, AL,

```

Layout Attribute Definition    The layout attribute definition section defines the layout attributes and their associated values.

The definition starts with a keyword, LAYOUT\_ATTRIBUTES, and ends with END LAYOUT\_ATTRIBUTES:

```
LAYOUT_ATTRIBUTES
```

```
Layout attributes here.
:
:
```

```
END LAYOUT_ATTRIBUTES
```

There are a total of eight layout attribute value trios that can be defined in this section:

- orientation
- context
- type\_of\_text
- implicit\_algorithm
- swapping
- numerals
- text\_shaping
- shape\_context\_size

Additionally, there are five layout attribute value pairs that also can be defined in this section:

- active\_directional
- active\_shape\_editing
- shape\_charset
- shape\_charset\_size
- check\_mode

Each attribute value trio will have an attribute name, an attribute value for the input buffer, and an attribute value for the output buffer, as in the following example:

```
Orientation layout attribute value trio. The input and output
attribute values are separated by a colon and the left one
is the input attribute value:
orientation ORIENTATION_LTR:ORIENTATION_LTR
```

Each attribute value pair will have an attribute name and an associated attribute value, as in the following example:

```
Shape charset attribute value pair:
shape_charset ISO8859-6
```

The orientation value trio defines the global directional text orientation. The possible values are:

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| ORIENTATION_LTR    | Left-to-right horizontal rows that progress from top to bottom.  |
| ORIENTATION_RTL    | Right-to-left horizontal rows that progress from top to bottom.  |
| ORIENTATION_TTBRL  | Top-to-bottom vertical columns that progress from right to left. |
| ORIENTATION_TTBRLR | Top-to-bottom vertical columns that progress from left to right. |

**ORIENTATION\_CONTEXTUAL**     The global orientation is set according to the direction of the first significant (strong) character. If there are no strong characters in the text and the attribute is set to this value, the global orientation of the text is set according to the value of the attribute context. This value is meaningful only for bidirectional text.

If no value or value trio is defined, the default is **ORIENTATION\_LTR**.

The context value trio is meaningful only if the attribute orientation is set to **ORIENTATION\_CONTEXTUAL**. It defines what orientation is assumed when no strong character appears in the text. The possible values are:

- CONTEXT\_LTR**     In the absence of characters with strong directionality in the text, orientation is assumed to be left-to-right rows progressing from top to bottom.
- CONTEXT\_RTL**     In the absence of characters with strong directionality in the text, orientation is assumed to be right-to-left rows progressing from top to bottom.

If no value or value trio is specified, the default is **CONTEXT\_LTR**.

The **type\_of\_text** value trio specifies the ordering of the directional text. The possible values are:

- TEXT\_VISUAL**     Code elements are provided in visually ordered segments, which can be rendered without any segment inversion.
- TEXT\_IMPLICIT**     Code elements are provided in logically ordered segments. Logically ordered means that the order in which the characters are provided is the same as the order in which the characters are pronounced when reading the presented text or the order in which characters would be entered from a keyboard.
- TEXT\_EXPLICIT**     Code elements are provided in logically ordered segments with a set of embedded controls. Some examples of such embedded controls from ISO/IEC 10646-1 are:
  - LEFT-TO-RIGHT EMBEDDING (LRE)
  - RIGHT-TO-LEFT EMBEDDING (RLE)
  - RIGHT-TO-LEFT OVERRIDE (RLO)
  - LEFT-TO-RIGHT OVERRIDE (LRO)
  - POP DIRECTIONAL FORMAT (PDF)

If no value or value trio is specified, the default is **TEXT\_IMPLICIT**.

The **implicit\_algorithm** value trio specifies the type of bidirectional implicit algorithm used in reordering and shaping of directional or context-dependent text. The possible values are:

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| ALGORITHM_IMPLICIT | Directional code elements will be reordered using an implementation-defined implicit algorithm.               |
| ALGORITHM_BASIC    | Directional code elements will be reordered using a basic implicit algorithm defined in the Unicode standard. |

Even though we allow two different values for the `implicit_algorithm`, since the Solaris implementation-defined implicit algorithm is based on the Unicode standard, there is no difference in behavior whether you choose `ALGORITHM_IMPLICIT` or `ALGORITHM_BASIC` for this attribute.

The default value is `ALGORITHM_IMPLICIT`.

The `swapping` value trio specifies whether symmetric swapping is applied to the text. The possible values are:

|              |                                                  |
|--------------|--------------------------------------------------|
| SWAPPING_YES | The text conforms to symmetric swapping.         |
| SWAPPING_NO  | The text does not conform to symmetric swapping. |

If no value or value trio is specified, the default is `SWAPPING_NO`.

The `numerals` value trio specifies the shaping of numerals. The possible values are:

|                     |                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| NUMERALS_NOMINAL    | Nominal shaping of numerals using the Arabic numbers of the portable character set (in Solaris, ASCII digits).                                         |
| NUMERALS_NATIONAL   | National shaping of numerals based on the script of the locale. For instance, Thai digits in the Thai locale.                                          |
| NUMERALS_CONTEXTUAL | Contextual shaping of numerals depending on the context script of surrounding text, such as Hindi numbers in Arabic text and Arabic numbers otherwise. |

If no value or value trio is specified, the default is `NUMERALS_NOMINAL`.

The `text_shaping` value trio specifies the shaping; that is, choosing (or composing) the correct shape of the input or output text. The possible values are:

|              |                                        |
|--------------|----------------------------------------|
| TEXT_SHAPED  | The text has presentation form shapes. |
| TEXT_NOMINAL | The text is in basic form.             |

If no value or value trio is specified, the default is `TEXT_NOMINAL` for input and `TEXT_SHAPED` for output.

The `shape_context_size` value trio specifies the size of the context (surrounding code elements) that must be accounted for when performing active shape editing. If not defined, the default value 0 is used for the number of surrounding code elements at both front and rear:

```
The shape_context_size for both front and rear surrounding code
elements are all zero:
shape_context_size 0:0
```

The front and rear attribute values are separated by a colon, with the front value to the left of the colon.

The `active_directional` value pair specifies whether the current locale requires (bi-)directional processing. The possible values are:

TRUE      Requires (bi-)directional processing.  
FALSE     Does not require (bi-)directional processing.

The `active_shape_editing` value pair specifies whether the current locale requires context-dependent shaping for presentation. The possible values are:

TRUE      Requires context-dependent shaping.  
FALSE     Does not require context-dependent shaping.

The `shape_charset` value pair specifies the current locale's shape charset on which the complex text layout is based. There are two different kinds of shape charset values that can be specified:

- A single shape charset
- Multiple shape charsets

For a single shape charset, it can be defined by using `NAME` as defined in the `Lexical Convention` section above. For multiple shape charsets, however, it should follow the syntax given below in extended BNF form:

```
multiple_shape_charset
 : charset_list
 ;

charset_list : charset
 | charset_list ';' charset
 ;

charset : charset_name '=' charset_id
 ;

charset_name : NAME
 ;

charset_id : HEXADECIMAL_BYTE
 ;
```

For instance, the following is a valid multiple shape charsets value for the `shape_charset` attribute:

```
Multi-shape charsets:
shape_charset tis620.2533=e4;iso8859-8=e5;iso8859-6=e6
```

The `shape_charset` must be specified.

The `shape_charset_size` value pair specifies the encoding size of the current `shape_charset`. The valid value is a positive integer from 1 to 4. If the multiple shape charsets value is defined for the `shape_charset` attribute, the `shape_charset_size` must be 4.

The `shape_charset_size` must be specified.

The `check_mode` value pair specifies the level of checking of the elements in the input buffer for shaping and reordering purposes. The possible values are:

|                          |                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------|
| <code>MODE_STREAM</code> | The string in the input buffer is expected to have valid combinations of characters or character elements. |
| <code>MODE_EDIT</code>   | The shaping of input text may vary depending on locale-specific validation or assumption.                  |

When no value or value pair is not specified, the default value is `MODE_STREAM`.

#### Bidirectional Data And Character Type Data Definition

This section defines the bidirectional and other character types that will be used in the Unicode Bidirectional Algorithm and the shaping algorithm part of the UMLE.

The definition starts with a keyword `LAYOUT_BIDI_CHAR_TYPE_DATA` and ends with `END LAYOUT_BIDI_CHAR_TYPE_DATA`:

```
LAYOUT_BIDI_CHAR_TYPE_DATA

 # Layout bidi definitions here.
 :
 :

END LAYOUT_BIDI_CHAR_TYPE_DATA
```

The bidirectional data and character type data definition should be defined for the two different kinds of text shape forms, `TEXT_SHAPED` and `TEXT_NOMINAL`, depending on the `text_shaping` attribute value and also for the two different kinds of text representations, file code representation and process code representation (that is, wide character representation):

```
LAYOUT_BIDI_CHAR_TYPE_DATA

 FILE_CODE_REPRESENTATION
 TEXT_SHAPED
```

```
 # TEXT_SHAPED bidi and character type data
 # definition in file code representation here.
 :
 :

 END TEXT_SHAPED

 TEXT_NOMINAL

 # TEXT_NOMINAL bidi and character type data
 # definition in file code representation here.
 :
 :

 END TEXT_NOMINAL

 TEXT_NOMINAL

 # TEXT_NOMINAL bidi and character type data
 # definition in process code representation here.
 :
 :

 END TEXT_NOMINAL
END PROCESS_CODE_REPRESENTATION

END LAYOUT_BIDI_CHAR_TYPE_DATA
```

Each bidi and character type data definition can have the following definitions:

- Bidirectional data type definition
- `swapping_pairs` character type definition
- `national_numerals` character type definition

There are nineteen different bidirectional data types that can be defined, as in the following table:

| Keyword | Category  | Description                |
|---------|-----------|----------------------------|
| L       | Strong    | Left-to-right              |
| LRE     | Strong    | Left-to-right embedding    |
| LRO     | Strong    | Left-to-right override     |
| R       | Strong    | Right-to-left              |
| AL      | Strong    | Right-to-left              |
| RLE     | Strong    | Right-to-left embedding    |
| RLO     | Strong    | Right-to-left override     |
| PDF     | Weak      | Pop directional format     |
| EN      | Weak      | European number            |
| ES      | Weak      | European number separator  |
| ET      | Weak      | European number terminator |
| AN      | Weak      | Arabic number              |
| CS      | Weak      | Common number separator    |
| PS      | Separator | Paragraph separator        |
| S       | Separator | Segment separator          |
| WS      | Neutral   | White space                |
| ON      | Neutral   | Other neutrals             |
| NSM     | Weak      | Non-spacing mark           |
| BN      | Weak      | Boundary neutral           |

If not defined in this section, the characters belong to the other neutrals type, ON.

Each keyword list above will be accompanied by one or more HEXADECIMAL ranges of characters that belong to the bidirectional character type. The syntax is as follows:

```

bidi_char_type : bidi_keyword ':' range_list
 ;

bidi_keyword : 'L'
 | 'LRE'
 | 'LRO'
 | 'R'
 | 'AL'
 | 'RLE'
 | 'RLO'

```

```
 | 'PDF'
 | 'EN'
 | 'ES'
 | 'ET'
 | 'AN'
 | 'CS'
 | 'PS'
 | 'S'
 | 'WS'
 | 'ON'
 | 'NSM'
 | 'BN'
 ;

range_list : range
 | range_list ',' range
 ;

range : HEXADECIMAL
 | HEXADECIMAL '...' HEXADECIMAL
 ;
```

For example:

```
Bidi character type definitions:
L: 0x26, 0x41...0x5a, 0xc380...0xc396, 0xe285a0...0xe28682
WS: 0x20, 0xc2a0, 0xe28080...0xe28086
```

The `swapping_pairs` specifies the list of swappable characters if `SWAPPING_YES` is specified as a value at the swapping value trio. The syntax of the `swapping_pairs` is as follows:

```
swapping_pair_list : swapping_keyword ':' swap_pair_list
 ;
swapping_keyword : 'swapping_pairs'
 ;

swap_pair_list : swap_pair
 | swap_pair_list ',' swap_pair
 ;

swap_pair : '(' HEXADECIMAL ',' HEXADECIMAL ')'
```

For example:

```
Swapping pair definitions:
swapping_pairs: (0x28, 0x29), (0x7b, 0x7d)
```

The `national_numerals` specifies the list of national digits that can be converted as the numerals value trio specifies. The syntax of the `national_numerals` is as follows:

```

numerals_list : numerals_keyword ':'
 numerals_list ';' contextual_range_list
 ;

numerals_keyword : 'national_numerals'
 ;

numerals_list : '(' zero ',' one ',' two ',' three ','
 four ',' five ',' six ',' seven ','
 eight ',' nine ')'

zero : HEXADECIMAL
 ;

one : HEXADECIMAL
 ;

two : HEXADECIMAL
 ;

three : HEXADECIMAL
 ;

four : HEXADECIMAL
 ;

five : HEXADECIMAL
 ;

six : HEXADECIMAL
 ;

seven : HEXADECIMAL
 ;

eight : HEXADECIMAL
 ;

nine : HEXADECIMAL
 ;

contextual_range_list
: contextual_range
| contextual_range_list ',' contextual_range
;

contextual_range : HEXADECIMAL
 | HEXADECIMAL '...' HEXADECIMAL
 ;

```

For instance:

```
National numerals definition. The national number that will
replace Arabic number 0 to 9 is 0, 0x41, 0x42, and so on.
The contextual surrounding characters are 0x20 to 0x40 and
0x50 to 0x7f:
national_numerals:
 (0x0, 0x41, 0x42, 0x43, 0x44, 0x45, 0x46, 0x47, 0x48, 0x49)
 ; 0x20...0x40, 0x50...0x7f
```

Unless NUMERALS\_CONTEXTUAL is the value of the numerals attribute, the contextual range list definition is meaningless.

**Shaping Data Definition** The shaping data definition section defines the context-dependent shaping rules that will be used in the shaping algorithm of the UMLE.

The definition starts with a keyword, LAYOUT\_SHAPE\_DATA, and ends with END LAYOUT\_SHAPE\_DATA:

```
LAYOUT_SHAPE_DATA

 # Layout shaping data definitions here.
 :
 :

END LAYOUT_SHAPE_DATA
```

The shaping data definition should be defined for the two different kinds of text shape forms, TEXT\_SHAPED and TEXT\_NOMINAL, depending on the text\_shaping attribute value and also for the two different kinds of text representations, file code representation and process code representation (that is, wide character representation:

```
LAYOUT_SHAPE_DATA

 FILE_CODE_REPRESENTATION
 TEXT_SHAPED

 # TEXT_SHAPED shaping data definition in file code
 # representation here.
 :
 :

 END TEXT_SHAPED

 TEXT_NOMINAL

 # TEXT_NOMINAL shaping data definition in file code
 # representation here.
 :
```

```

:

END TEXT_NOMINAL
END FILE_CODE_REPRESENTATION

PROCESS_CODE_REPRESENTATION
TEXT_SHAPED

 # TEXT_SHAPED shaping data definition in process code
 # representation here.
 :
 :

END TEXT_SHAPED

TEXT_NOMINAL

 # TEXT_NOMINAL shaping data definition in process
 # code representation here.
 :
 :

END TEXT_NOMINAL
END PROCESS_CODE_REPRESENTATION

END LAYOUT_SHAPE_DATA

```

Each shaping data definition consists of one or more of the shaping sequence definitions. Each shaping sequence definition is a representation of a series of state transitions triggered by an input character and the current state at each transition.

The syntax of the shaping sequence definition is as follows:

```

shaping_sequence : initial_state '+' input '->' next_state_list
 ;

initial_state : '(' ')'
 ;

input : HEXADECIMAL
 ;

next_state_list : next_state
 | next_state_list '+' input '->' next_state
 | '(' next_state_list '+' input ')' 'repeat+'
 | '(' next_state_list '+' input ')' 'repeat*'
 ;

next_state : '(' out_buffer ',' in2out ',' out2in ','

```

```

 property ')'
 ;

out_buffer : '[' out_char_list ']'
 ;

out_char_list : HEXADECIMAL
 | '(' HEXADECIMAL ')' 'repeat+'
 | out_char_list ';' HEXADECIMAL
 ;

in2out : '[' i2o_list ']'
 ;

i2o_list : DECIMAL
 | '(' DECIMAL ')' 'repeat+'
 | i2o_list ';' DECIMAL
 ;

out2in : '[' o2i_list ']'
 ;

o2i_list : DECIMAL
 | '(' DECIMAL ')' 'repeat+'
 | o2i_list ';' DECIMAL
 ;

property : '[' prop_list ']'
 ;

prop_list : HEXADECIMAL
 | '(' HEXADECIMAL ')' 'repeat+'
 | prop_list ';' HEXADECIMAL
 ;

```

For example, the following shaping sequences can be defined:

```

A simple shaping sequence:
() + 0x21 ->
([0x0021], [0], [0;0], [0x80]) + 0x22 ->
([0x0021;0x0022], [0;1], [0;0;1;1], [0x80;0x80]) + 0xc2a0 ->
([0x0021;0x0022;0xe030], [0;1;2], [0;0;1;1;2;2],
 [0x80;0x80;0x80])

A repeating shaping sequence:
() + 0x21 ->
(
 ([0x0021], [0], [0;0], [0x80]) + 0x22 ->

```

```
([0x0021;0x0022], [0;1], [0;0;1;1], [0x80;0x80]) + 0xc2a2
) repeat+
```

The first example shows a shaping sequence such that if 0x21, 0x22, and 0xc2a0 are the input buffer contents, it will be converted into an output buffer containing 0x0021, 0x0022, and 0xe030; an input to the output buffer containing 0, 1, and 2; an output to the input buffer containing 0, 0, 1, 1, 2, and 2; and a property buffer containing 0x80, 0x80, and 0x80.

The second example shows a repeating shaping sequence where, if the first input code element is 0x21, then the second and third input code elements are 0x22 and 0xc2a2, respectively.

**Exit Status** The following exit values are returned:

- 0 No errors occurred and the output file was successfully created.
- 1 Command line options are not correctly used or unknown command line option specified.
- 2 Invalid input or output file specified.
- 3 The layout definitions not correctly defined.
- 4 No more system resource error.
- 6 Internal error.

- Files** /usr/lib/locale/common/LO\_LTYPE/umle.layout.so.1  
The Universal Multiscript Layout Engine for 32-bit platforms.
- /usr/lib/locale/common/LO\_LTYPE/sparcv9/umle.layout.so.1  
The Universal Multiscript Layout Engine for 64-bit SPARC platform.
- /usr/lib/locale/common/LO\_LTYPE/ia64/umle.layout.so.1  
The Universal Multiscript Layout Engine for 64-bit Intel platform.
- /usr/lib/locale/locale/LO\_LTYPE/layout.dat  
The binary layout table file for the *locale*.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWglt         |
| Interface Stability | Obsolete        |

**See Also** [m\\_create\\_layout\(3LAYOUT\)](#), [m\\_destroy\\_layout\(3LAYOUT\)](#), [m\\_getvalues\\_layout\(3LAYOUT\)](#), [m\\_setvalues\\_layout\(3LAYOUT\)](#), [m\\_transform\\_layout\(3LAYOUT\)](#), [m\\_wtransform\\_layout\(3LAYOUT\)](#), [attributes\(5\)](#), [environ\(5\)](#)

*International Language Environments Guide*

Unicode Technical Report #9: The Bidirectional Algorithm from  
<http://www.unicode.org/unicode/reports/>

**Notes** This utility might not be included in a future release.

- Name** genmsg – generate a message source file by extracting messages from source files
- Synopsis** genmsg [-abdfntx] [-c *message-tag*] [-g *project-file*]  
 [-l *project-file*] [-m *prefix*] [-M *suffix*]  
 [-o *message-file*] [-p *preprocessor*] [-s *set-tags*] *file...*
- Description** The genmsg utility extracts message strings with calls to [catgets\(3C\)](#) from source files and writes them in a format suitable for input to [gencat\(1\)](#).
- Invocation** genmsg reads one or more input files and, by default, generates a message source file whose name is composed of the first input file name with .msg. If the -o option is specified, genmsg uses the option argument for its output file.

| <i>Command</i>                   | <i>Output File</i> |
|----------------------------------|--------------------|
| genmsg prog.c                    | prog.c.msg         |
| gensmg main.c util.c tool.c      | main.c.msg         |
| genmsg -o prog.msg mail.c util.c | prog.msg           |

genmsg also allows you to invoke a preprocessor to solve the dependencies of macros and define statements for the [catgets\(3C\)](#) calls.

- Auto Message Numbering** genmsg replaces message numbers with the calculated numbers based upon the project file if the message numbers are -1, and it generates copies of the input files with the new message numbers and a copy of the project file with the new maximum message numbers.

A project file is a database that stores a list of set numbers with their maximum message numbers. Each line in a project file is composed of a set number and its maximum message number:

*Set\_number*      *Maximum\_message\_number*

In a project file, a line beginning with a number sign (#) or an ASCII space is considered as a comment and ignored.

genmsg also has the reverse operation to replace all message numbers with -1.

- Comment Extraction** genmsg allows you to comment about messages and set numbers to inform the translator how the messages should be translated. It extracts the comment, which is surrounded with the comment indicators and has the specified tag inside the comment, from the input file and writes it with a dollar (\$) prefix in the output file. genmsg supports the C and C++ comment indicators, '/\*', '\*/', and '//'.

**Testing** genmsg generates two kinds of messages for testing, prefixed messages and long messages. Prefixed messages allow you to check that your program is retrieving the messages from the message catalog. Long messages allow you to check the appearance of your window program's initial size and position.

**Options** The following options are supported:

- a Append the output into the message file *message-file* that is specified by the -o option. If two different messages that have the same set and message number are found, the message in the specified message file is kept and the other message in the input file is discarded.
- b Place the extracted comment after the corresponding message in the output file. This option changes the placement behavior of the -s or -c option.
- c *message-tag* Extract message comments having *message-tag* inside them from the input files and write them with a '\$' prefix as a comment in the output file.
- d Include an original text of a message as a comment to be preserved along with its translations. With this option, the translator can see the original messages even after they are replaced with their translations.
- f Overwrite the input files and the project file when used with the -l or -r option. With the -r option, genmsg overwrites only the input files.
- g *project-file* Generate *project-file* that has a list of set numbers and their maximum message numbers in the input files.
- l *project-file* Replace message numbers with the calculated numbers based upon *project-file* if the message numbers are -1 in the input files, and then generate copies of the input files with the new message numbers and a copy of *project-file* with the new maximum message numbers. If *project-file* is not found, genmsg uses the maximum message number in the input file as a base number and generates *project-file*.
- m *prefix* Fill in the message with *prefix*. This option is useful for testing.
- M *suffix* Fill in the message with *suffix*. This option is useful for testing.
- n Add comment lines to the output file indicating the file name and line number in the input files where each extracted string is encountered.
- o *message-file* Write the output to *message-file*.
- p *preprocessor* Invoke *preprocessor* to preprocess macros and define statements for the [catgets\(3C\)](#) calls. genmsg first invokes the option argument as a preprocessor and then starts the normal process against the output from the preprocessor. genmsg initiates this process for all the input files.

- r            Replace message numbers with -1. This is the reverse operation of the -l option.
- s *set-tag*    Extract set number comments having *set-tag* inside them from the input files and write them with a '\$' prefix as a comment in the output file. If multiple comments are specified for one set number, the first one is extracted and the rest of them are discarded.
- t            Generate a message that is three times as long as the original message. This option is useful for testing.
- x            Suppress warning messages about message and set number range checks and conflicts.

**Operands** *file*    An input source file.

**Examples** **EXAMPLE 1** Assigning Message Numbers and Generating New Files

Suppose that you have the following source and project files:

```
example% cat test.c
printf(catgets(catfd, 1, -1, "line too long\n"));
printf(catgets(catfd, 2, -1, "invalid code\n"));
```

```
example% cat proj
1 10
2 20
```

The command

```
example% genmsg -l proj test.c
```

would assign the calculated message numbers based upon *proj* and generate the following files:

*test.c.msg*    Message file

*proj.new*      Updated project file

*test.c.new*    New source file

```
example% cat test.c.msg
$quote "
$set 1
11 "line too long\n"
$set 2
21 "invalid code\n"
```

```
example% cat proj.new
1 11
2 21
```

**EXAMPLE 1** Assigning Message Numbers and Generating New Files *(Continued)*

```
example% cat test.c.new
printf(catgets(catfd, 1, 11, "line too long\n"));
printf(catgets(catfd, 2, 21, "invalid code\n"));
```

**EXAMPLE 2** Extracting Comments Into a File

The command

```
example% genmsg -s SET -c MSG test.c
example% cat test.c
/* SET: tar messages */
/* MSG: don't translate "tar". */
catgets(catfd, 1, 1, "tar: tape write error");
// MSG: don't translate "tar" and "-I".
catgets(catfd, 1, 2, "tar: missing argument for -I flag");
```

would extract the comments and write them in the following output file:

```
example% cat test.c.msg
$ /* SET: tar messages */
$set 1
$ /* MSG: don't translate "tar". */
1 "tar: tape write error"
$ // MSG: don't translate "tar" and "-I".
2 "tar: missing argument for -I flag"
```

**EXAMPLE 3** Generating Test Messages

The following command:

```
example% genmsg -m PRE: -M :FIX test.c
```

might generate the following messages for testing:

```
example% cat test.c.msg
1 "PRE:OK:FIX"
2 "PRE:Cancel:FIX"
```

**EXAMPLE 4** Parsing a Macro and Writing the Extracted Messages

Given the following input:

```
example% cat example.c
#include <nl_types.h>
#define MSG1 "message1"
#define MSG2 "message2"
#define MSG3 "message3"
#define MSG(n) catgets(catd, 1, n, MSG ## n)
```

**EXAMPLE 4** Parsing a Macro and Writing the Extracted Messages *(Continued)*

```

void
main(int argc, char **argv)
{
 nl_catd catd = catopen(argv[0], NL_CAT_LOCALE);
 (void) printf("%s0\n", MSG(1));
 (void) printf("%s0\n", MSG(2));
 (void) printf("%s0\n", MSG(3));
 (void) catclose(catd);
}

```

The following command:

```
example% genmsg -p "cc -E" -o example.msg example.c
```

would parse the MSG macros and write the extracted messages in `example.msg`.

**EXAMPLE 5** Assigning Calculated Message Numbers

Suppose that you have the following header, source, and project files:

```

example% cat ../inc/msg.h
#define WARN_SET 1
#define ERR_SET 2
#define WARN_MSG(id, msg) catgets(catd, WARN_SET, (id), (msg))
#define ERR_MSG(id, msg) catgets(catd, ERR_SET, (id), (msg))
example% example.c
#include "msg.h"
printf("%s, WARN_MSG(-1, "Warning error");
printf("%s, ERR_MSG(-1, "Fatal error");
example % proj
1 10
2 10

```

The command

```
example% genmsg -f -p "cc -E -I../inc" -l proj \
-o example.msg example.c
```

would assign each of the -1 message numbers a calculated number based upon `proj` and would overwrite the results to `example.c` and `proj`. Also, this command writes the extracted messages in `example.msg`.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `genmsg`: `LC_MESSAGES` and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

**See Also** [gencat\(1\)](#), [catgets\(3C\)](#), [catopen\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** genmsg does not handle pointers or variables in the [catgets\(3C\)](#) call. For example:

```
const int set_num = 1;
extern int msg_num(const char *);
const char *msg = "Hello";
catgets(catd, set_num, msg_num(msg), msg);
```

When the auto message numbering is turned on with a preprocessor, if there are multiple -1's in the [catgets\(3C\)](#) line, genmsg replaces all of the -1's in the line with a calculated number. For example, given the input:

```
#define MSG(id, msg) catgets(catd, 1, (id), (msg))
if (ret == -1) printf("%s, MSG(-1, "Failed");
```

the command

```
genmsg -l proj -p "cc -E"
```

would produce:

```
#define MSG(id, msg) catgets(catd, 1, (id), (msg))
if (ret == 1) printf("%s, MSG(1, "Failed");
```

The workaround would be to split it into two lines as follows:

```
if (ret == -1)
 printf("%s, MSG(-1, "Failed");
```

**Name** getconf – get configuration values

**Synopsis** /usr/bin/getconf [-v *specification*] *system\_var*  
 /usr/bin/getconf [-v *specification*] *path\_var* *pathname*  
 /usr/bin/getconf -a  
 /usr/xpg4/bin/getconf [-v *specification*] *system\_var*  
 /usr/xpg4/bin/getconf [-v *specification*] *path\_var* *pathname*  
 /usr/xpg4/bin/getconf -a  
 /usr/xpg6/bin/getconf [-v *specification*] *system\_var*  
 /usr/xpg6/bin/getconf [-v *specification*] *path\_var* *pathname*  
 /usr/xpg6/bin/getconf -a

**Description** In the first synopsis form, the getconf utility will write to the standard output the value of the variable specified by *system\_var*, in accordance with *specification* if the -v option is used.

In the second synopsis form, getconf will write to the standard output the value of the variable specified by *path\_var* for the path specified by *pathname*, in accordance with *specification* if the -v option is used.

In the third synopsis form, config will write to the standard output the names of the current system configuration variables.

The value of each configuration variable will be determined as if it were obtained by calling the function from which it is defined to be available. The value will reflect conditions in the current operating environment.

**Options** The following options are supported:

- a Writes the names of the current system configuration variables to the standard output.
- v *specification* Gives the specification which governs the selection of values for configuration variables.

**Operands** The following operands are supported:

*path\_var* A name of a configuration variable whose value is available from the [pathconf\(2\)](#) function. All of the values in the following table are supported:

|           |          |                         |
|-----------|----------|-------------------------|
| LINK_MAX  | NAME_MAX | _POSIX_CHOWN_RESTRICTED |
| MAX_CANON | PATH_MAX | _POSIX_NO_TRUNC         |
| MAX_INPUT | PIPE_BUF | _POSIX_VDISABLE         |

*pathname*      A path name for which the variable specified by *path\_var* is to be determined.

*system\_var*    A name of a configuration variable whose value is available from [confstr\(3C\)](#) or [sysconf\(3C\)](#). All of the values in the following table are supported:

|                         |                     |
|-------------------------|---------------------|
| ARG_MAX                 | BC_BASE_MAX         |
| BC_DIM_MAX              | BC_SCALE_MAX        |
| BC_STRING_MAX           | CHAR_BIT            |
| CHARCLASS_NAME_MAX      | CHAR_MAX            |
| CHAR_MIN                | CHILD_MAX           |
| CLK_TCK                 | COLL_WEIGHTS_MAX    |
| CS_PATH                 | EXPR_NEST_MAX       |
| HOST_NAME_MAX           | INT_MAX             |
| INT_MIN                 | LFS64_CFLAGS        |
| LFS64_LDFLAGS           | LFS64_LIBS          |
| LFS64_LINTFLAGS         | LFS_CFLAGS          |
| LFS_LDFLAGS             | LFS_LIBS            |
| LFS_LINTFLAGS           | LINE_MAX            |
| LONG_BIT                | LONG_MAX            |
| LONG_MIN                | MB_LEN_MAX          |
| NGROUPS_MAX             | NL_ARGMAX           |
| NL_LANGMAX              | NL_MSGMAX           |
| NL_NMAX                 | NL_SETMAX           |
| NL_TEXTMAX              | NZERO               |
| OPEN_MAX                | POSIX2_BC_BASE_MAX  |
| POSIX2_BC_DIM_MAX       | POSIX2_BC_SCALE_MAX |

| <code>_XOPEN_XPG3</code>        | <code>_XOPEN_XPG4</code>    |

The symbol `PATH` also is recognized, yielding the same value as the `confstr()` name value `CS_PATH`.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `getconf` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Writing the Value of a Variable

This example illustrates the value of `{NGROUPS_MAX}`:

```
example% getconf NGROUPS_MAX
```

**EXAMPLE 2** Writing the Value of a Variable for a Specific Directory

This example illustrates the value of `NAME_MAX` for a specific directory:

```
example% getconf NAME_MAX /usr
```

**EXAMPLE 3** Dealing with Unspecified Results

This example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
 if ["$value" = "undefined"]; then
 echo PATH_MAX in /usr is infinite.
 else
 echo PATH_MAX in /usr is $value.
 fi
else
 echo Error in getconf.
fi
```

Notice that

```
sysconf(_SC_POSIX_C_BIND);

and

system("getconf POSIX2_C_BIND");
```

in a C program could give different answers. The `sysconf` call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation. The `system` call to `getconf` always supplies a value corresponding to conditions when the program is executed.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `getconf`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- `0`      The specified variable is valid and information about its current state was written successfully.
- `>0`     An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also** [pathconf\(2\)](#), [confstr\(3C\)](#), [sysconf\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** getfacl – display discretionary file information

**Synopsis** getfacl [-ad] *file*...

**Description** For each argument that is a regular file, special file, or named pipe, the `getfacl` utility displays the owner, the group, and the Access Control List (ACL). For each directory argument, `getfacl` displays the owner, the group, and the ACL and/or the default ACL. Only directories contain default ACLs.

The `getfacl` utility may be executed on a file system that does not support ACLs. It reports the ACL based on the base permission bits.

With no options specified, `getfacl` displays the filename, the file owner, the file group owner, and both the ACL and the default ACL, if it exists.

**Options** The following options are supported:

- a Displays the filename, the file owner, the file group owner, and the ACL of the file.
- d Displays the filename, the file owner, the file group owner, and the default ACL of the file, if it exists.

**Operands** The following operands are supported:

*file* The path name of a regular file, special file, or named pipe.

**Output** The format for ACL output is as follows:

```
file: filename
owner: uid
group: gid
user::perm
user:uid:perm
group::perm
group:gid:perm
mask:perm
other:perm
default:user::perm
default:user:uid:perm
default:group::perm
default:group:gid:perm
default:mask:perm
default:other:perm
```

When multiple files are specified on the command line, a blank line separates the ACLs for each file.

The ACL entries are displayed in the order in which they are evaluated when an access check is performed. The default ACL entries that may exist on a directory have no effect on access checks.

The first three lines display the filename, the file owner, and the file group owner. Notice that when only the `-d` option is specified and the file has no default ACL, only these three lines are displayed.

The user entry without a user ID indicates the permissions that are granted to the file owner. One or more additional user entries indicate the permissions that are granted to the specified users.

The group entry without a group ID indicates the permissions that are granted to the file group owner. One or more additional group entries indicate the permissions that are granted to the specified groups.

The mask entry indicates the ACL mask permissions. These are the maximum permissions allowed to any user entries except the file owner, and to any group entries, including the file group owner. These permissions restrict the permissions specified in other entries.

The other entry indicates the permissions that are granted to others.

The default entries may exist only for directories. These entries indicate the default entries that are added to a file created within the directory.

The uid is a login name or a user ID if there is no entry for the uid in the system password file, `/etc/passwd`. The gid is a group name or a group ID if there is no entry for the gid in the system group file, `/etc/group`. The perm is a three character string composed of the letters representing the separate discretionary access rights: r (read), w (write), x (execute/search), or the place holder character `-`. The perm is displayed in the following order: rwx. If a permission is not granted by an ACL entry, the place holder character appears.

If you use the `chmod(1)` command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file.

In order to indicate that the ACL mask restricts an ACL entry, `getfacl` displays an additional tab character, pound sign (`#`), and the actual permissions granted, following the entry.

### Examples **EXAMPLE 1** Displaying file information

Given file `foo`, with an ACL six entries long, the command

```
host% getfacl foo
```

would print:

```
file: foo
owner: shea
group: staff
user::rwx
```

**EXAMPLE 1** Displaying file information      *(Continued)*

```
user:spy: -- --
user:mookie:r --
group::r --
mask::rw --
other:: -- --
```

**EXAMPLE 2** Displaying information after chmod command

Continue with the above example, after `chmod 700 foo` was issued:

```
host% getfacl foo
```

would print:

```
file: foo
owner: shea
group: staff
user::rwx
user:spy: -- --
user:mookie:r -- #effective: -- --
group:: -- --
mask:: -- --
other:: -- --
```

**EXAMPLE 3** Displaying information when ACL contains default entries

Given directory `doo`, with an ACL containing default entries, the command

```
host% getfacl -d doo
```

would print:

```
file: doo
owner: shea
group: staff
default:user::rwx
default:user:spy: -- --
default:user:mookie:r --
default:group::r --
default:mask:: -- --
default:other:: -- --
```

**Files**    `/etc/passwd`      system password file  
         `/etc/group`        group file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

**See Also** [chmod\(1\)](#), [ls\(1\)](#), [setfacl\(1\)](#), [acl\(2\)](#), [aclsort\(3SEC\)](#), [group\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

**Notes** The output from `getfacl` is in the correct format for input to the `setfacl -f` command. If the output from `getfacl` is redirected to a file, the file may be used as input to `setfacl`. In this way, a user may easily assign one file's ACL to another file.

**Name** getfrm – returns the current frameID number

**Synopsis** getfrm

**Description** getfrm returns the current frameID number. The frameID number is a number assigned to the frame by FMLI and displayed flush left in the frame's title bar. If a frame is closed its frameID number may be reused when a new frame is opened. getfrm takes no arguments.

**Examples** **EXAMPLE 1** A sample of the getfrm command.

If a menu whose frameID is 3 defines an item to have this action descriptor:

```
action=open text stdtext 'getfrm'
```

the text frame defined in the definition file stdtext would be passed the argument 3 when it is opened.

**Notes** It is not a good idea to use getfrm in a backquoted expression coded on a line by itself. Stand-alone backquoted expressions are evaluated before any descriptors are parsed, thus the frame is not yet fully current, and may not have been assigned a frameID number.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [attributes\(5\)](#)

**Name** getitems – returns a list of currently marked menu items

**Synopsis** getitems [*delimiter\_string*]

**Description** The getitems function returns the value of `lininfo` if defined, else it returns the value of the name descriptor, for all currently marked menu items. Each value in the list is delimited by *delimiter\_string*. The default value of *delimiter\_string* is newline.

**Examples** **EXAMPLE 1** A sample output of getitems command.

The done descriptor in the following menu definition file executes `getitems` when the user presses ENTER (note that the menu is multiselect):

```
Menu="Example"
multiselect=TRUE
done='getitems ":" | message'
name="Item 1"
action='message "You selected item 1"'
name="Item 2"
lininfo="This is item 2"
action='message "You selected item 2"'
name="Item 3"
action='message "You selected item 3"'
```

If a user marked all three items in this menu, pressing ENTER would cause the following string to be displayed on the message line:

```
Item 1:This is item 2:Item 3
```

**Notes** Because `lininfo` is defined for the second menu item, its value is displayed instead of the value of the name descriptor.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [attributes\(5\)](#)

**Name** getlabel – display the label of files

**Synopsis** /usr/bin/getlabel [-sS] *filename*...

**Description** getlabel displays the label that is associated with each *filename*. When options are not specified, the output format of the label is displayed in default format.

**Options** -s     Display the label that is associated with *filename* in short form.  
-S     Display the label that is associated with *filename* in long form.

**Exit Status** getlabel exits with one of the following values:

- 0     Successful completion.
- 1     Unsuccessful completion due to usage error.
- 2     Unable to translate label.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWtsu         |
| Interface Stability | See below.      |

The command line is Committed. The output is Not-an-Interface.

**See Also** [setlabel\(1\)](#), [label\\_encodings\(4\)](#), [attributes\(5\)](#)

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** getopt – parse command options

**Synopsis** set -- ‘ getopt *optstring* \$ \* ‘

**Description** The getopts command supersedes getopt. For more information, see NOTES below.

getopt is used to break up options in command lines for easy parsing by shell procedures and to check for legal options. *optstring* is a string of recognized option letters; see [getopt\(3C\)](#). If a letter is followed by a colon (:), the option is expected to have an argument which may or may not be separated from it by white space. The special option – is used to delimit the end of the options. If it is used explicitly, getopt recognizes it; otherwise, getopt generates it; in either case, getopt places it at the end of the options. The positional parameters (\$1 \$2 . . .) of the shell are reset so that each option is preceded by a – and is in its own positional parameter; each option argument is also parsed into its own positional parameter.

**Examples** **EXAMPLE 1** Processing the arguments for a command

The following code fragment shows how one might process the arguments for a command that can take the options -a or -b, as well as the option -o, which requires an argument:

```
set -- 'getopt abo: $*'
if [$? != 0]
then
 echo $USAGE
 exit 2
fi
for i in $*
do
 case $i in
 -a | -b) FLAG=$i; shift;;
 -o) OARG=$2; shift 2;;
 --) shift; break;;
 esac
done
```

This code accepts any of the following as equivalent:

```
cmd -aoarg filename1 filename2
cmd -a -o arg filename1 filename2
cmd -oarg -a filename1 filename2
cmd -a -oarg -- filename1 filename2
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| Availability   | SUNWcsu         |
| CSI            | enabled         |

**See Also** [Intro\(1\)](#), [getopts\(1\)](#), [getoptcvt\(1\)](#), [sh\(1\)](#), [shell\\_builtins\(1\)](#), [getopt\(3C\)](#), [attributes\(5\)](#)

**Diagnostics** `getopt` prints an error message on the standard error when it encounters an option letter not included in *optstring*.

**Notes** `getopt` will not be supported in the next major release. For this release a conversion tool has been provided, namely, `getoptcvt`. For more information, see [getopts\(1\)](#) and [getoptcvt\(1\)](#).

Reset `optind` to 1 when rescanning the options.

`getopt` does not support the part of Rule 8 of the command syntax standard (see [Intro\(1\)](#)) that permits groups of option-arguments following an option to be separated by white space and quoted. For example,

```
cmd -a -b -o "xxx z yy" filename
```

is not handled correctly. To correct this deficiency, use the `getopts` command in place of `getopt`.

If an option that takes an option-argument is followed by a value that is the same as one of the options listed in *optstring* (referring to the earlier EXAMPLES section, but using the following command line:

```
cmd -o -a filename
```

`getopt` always treats it as an option-argument to `-o`; it never recognizes `-a` as an option. For this case, the `for` loop in the example shifts past the *filename* argument.

**Name** getoptcv – convert to getopt to parse command options

**Synopsis** /usr/lib/getoptcv [-b] *filename*  
 /usr/lib/getoptcv

**Description** /usr/lib/getoptcv reads the shell script in *filename*, converts it to use `getopts` instead of `getopt`, and writes the results on the standard output.

`getopts` is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See [sh\(1\)](#). It supports all applicable rules of the command syntax standard (see Rules 3-10, [Intro\(1\)](#)). It should be used in place of the `getopt` command. (See the NOTES section below.) The syntax for the shell's built-in `getopts` command is:

```
getopts optstring name [argument . . .]
```

*optstring* must contain the option letters the command using `getopts` will recognize; if a letter is followed by a colon (:), the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, `getopts` places the next option in the shell variable *name* and the index of the next argument to be processed in the shell variable `OPTIND`. Whenever the shell or a shell script is invoked, `OPTIND` is initialized to 1.

When an option requires an option-argument, `getopts` places it in the shell variable `OPTARG`.

If an illegal option is encountered, ? will be placed in *name*.

When the end of options is encountered, `getopts` exits with a non-zero exit status. The special option `---` may be used to delimit the end of the options.

By default, `getopts` parses the positional parameters. If extra arguments (*argument* . . .) are given on the `getopts` command line, `getopts` parses them instead.

So that all new commands will adhere to the command syntax standard described in [Intro\(1\)](#), they should use `getopts` or `getopt` to parse positional parameters and check for options that are valid for that command (see the NOTES section below).

**Options** The following option is supported:

- b Makes the converted script portable to earlier releases of the UNIX system.  
 /usr/lib/getoptcv modifies the shell script in *filename* so that when the resulting shell script is executed, it determines at run time whether to invoke `getopts` or `getopt`.

**Examples** **EXAMPLE 1** Processing the arguments for a command

The following fragment of a shell program shows how one might process the arguments for a command that can take the options -a or -b, as well as the option -o, which requires an option-argument:

EXAMPLE 1 Processing the arguments for a command (Continued)

```
while getoptcs abo: c
do
 case $c in
 a | b) FLAG=$c;;
 o) OARG=$OPTARG;;
 \?) echo $USAGE
 exit 2;;
 esac
done
shift `expr $OPTIND - 1`
```

EXAMPLE 2 Equivalent code expressions

This code accepts any of the following as equivalent:

```
cmd -a -b -o "xxx z yy" filename
cmd -a -b -o "xxx z yy" -filename
cmd -ab -o xxx,z,yy filename
cmd -ab -o "xxx z yy" filename
cmd -o xxx,z,yy b a filename
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of getoptcs: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

- OPTIND** This variable is used by getoptcvt as the index of the next argument to be processed.
- OPTARG** This variable is used by getoptcvt to store the argument if an option is using arguments.

**Exit Status** The following exit values are returned:

- 0** An option, specified or unspecified by *optstring*, was found.
- >0** The end of options was encountered or an error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE |
|---------------|-----------------|
| Availability  | SUNWcsu         |
| CSI           | enabled         |

**See Also** [Intro\(1\)](#), [getopts\(1\)](#), [sh\(1\)](#), [shell\\_builtins\(1\)](#), [getopt\(3C\)](#), [attributes\(5\)](#)

**Diagnostics** `getopts` prints an error message on the standard error when it encounters an option letter not included in *optstring*.

**Notes** Although the following command syntax rule (see [Intro\(1\)](#)) relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the **EXAMPLES** section above, `-a` and `-b` are options, and the option `-o` requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd -abxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd -ab oxxx filename
```

Changing the value of the shell variable `OPTIND` or parsing different sets of arguments may lead to unexpected results.

**Name** getopts – parse utility options

**Synopsis** /usr/bin/getopts *optstring name* [*arg...*]

sh getopts *optstring name* [*argument*]...

ksh getopts *optstring name* [*arg*]...

## Description

/usr/bin/getopts The getopts utility can be used to retrieve options and option-arguments from a list of parameters.

Each time it is invoked, the getopts utility places the value of the next option in the shell variable specified by the *name* operand and the index of the next argument to be processed in the shell variable OPTIND. Whenever the shell is invoked, OPTIND is initialized to 1.

When the option requires an option-argument, the getopts utility places it in the shell variable OPTARG. If no option was found, or if the option that was found does not have an option-argument, OPTARG is unset.

If an option character not contained in the *optstring* operand is found where an option character is expected, the shell variable specified by *name* is set to the question-mark ( ? ) character. In this case, if the first character in *optstring* is a colon ( : , the shell variable OPTARG is set to the option character found, but no output is written to standard error; otherwise, the shell variable OPTARG is unset and a diagnostic message is written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in getopts processing.

If an option-argument is missing:

- If the first character of *optstring* is a colon, the shell variable specified by *name* is set to the colon character and the shell variable OPTARG is set to the option character found.
- Otherwise, the shell variable specified by *name* is set to the question-mark character ( ? ), the shell variable OPTARG is unset, and a diagnostic message is written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in getopts processing; a diagnostic message is written as stated, but the exit status is zero.

When the end of options is encountered, the getopts utility exits with a return value greater than zero; the shell variable OPTIND is set to the index of the first non-option-argument, where the first – argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value \$# + 1 if there are no non-option-arguments; the *name* variable is set to the question-mark character. Any of the following identifies the end of options: the special option –, finding an argument that does not begin with a –, or encountering an error.

The shell variables OPTIND and OPTARG are local to the caller of getopts and are not exported by default.

The shell variable specified by the *name* operand, OPTIND and OPTARG affect the current shell execution environment.

If the application sets OPTIND to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke `getopts` multiple times in a single shell execution environment with parameters (positional parameters or *arg* operands) that are not the same in all invocations, or with an OPTIND value modified to be a value other than 1, produces unspecified results.

`sh` `getopts` is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See [sh\(1\)](#). It supports all applicable rules of the command syntax standard (see Rules 3-10, [Intro\(1\)](#)). It should be used in place of the `getopt` command.

*optstring* must contain the option letters the command using `getopts` recognizes. If a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, `getopts` places the next option in the shell variable *name* and the index of the next argument to be processed in the shell variable OPTIND. Whenever the shell or a shell script is invoked, OPTIND is initialized to 1.

When an option requires an option-argument, `getopts` places it in the shell variable OPTARG.

If an illegal option is encountered, `?` is placed in *name*.

When the end of options is encountered, `getopts` exits with a non-zero exit status. The special option `-` can be used to delimit the end of the options.

By default, `getopts` parses the positional parameters. If extra arguments (*argument . . .*) are given on the `getopts` command line, `getopts` parses them instead.

`/usr/lib/getoptcvt` reads the shell script in *filename*, converts it to use `getopts` instead of `getopt`, and writes the results on the standard output.

So that all new commands adhere to the command syntax standard described in [Intro\(1\)](#), they should use `getopts` or `getopt` to parse positional parameters and check for options that are valid for that command.

`getopts` prints an error message on the standard error when it encounters an option letter not included in *optstring*.

Although the following command syntax rule (see [Intro\(1\)](#)) relaxations are permitted under the current implementation, they should not be used because they can not be supported in future releases of the system. As in the EXAMPLES section below, `-a` and `-b` are options, and the option `-o` requires an option-argument.

The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd -abxxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd -ab oxxx filename
```

Changing the value of the shell variable `OPTIND` or parsing different sets of arguments can lead to unexpected results.

- ksh Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument - ends the options. *optstring* contains the letters that `getopts` recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

`getopts` places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in `OPTIND`. The option argument, if any, gets stored in `OPTARG`.

A leading : in *optstring* causes `getopts` to store the letter of an invalid option in `OPTARG`, and to set *name* to ? for an unknown option and to : when a required option is missing. Otherwise, `getopts` prints an error message. The exit status is non-zero when there are no more options.

`getopts` supports both traditional single-character short options and long options defined by Sun's Command Line Interface Paradigm (CLIP).

Each long option is an alias for a short option and is specified in parentheses following its equivalent short option. For example, you can specify the long option `file` as an alias for the short option `f` using the following script line:

```
getopts "f(file)" opt
```

Precede long options on the command line with -- or ++. In the example above, --file on the command line would be the equivalent of -f, and ++file on the command line would be the equivalent of +f.

Each short option can have multiple long option equivalents, although this is in violation of the CLIP specification and should be used with caution. You must enclose each long option equivalent parentheses, as follows:

```
getopts "f:(file)(input-file)o:(output-file)"
```

In the above example, both --file and --input-file are the equivalent of -f, and --output-file is the equivalent of -o.

The variable name is always set to a short option. When a long option is specified on the command line, name is set to the short-option equivalent.

For a further discussion of the Korn shell's `getopts` built-in command, see the previous discussion in the Bourne shell (`sh`) section of this manpage.

**Operands** The following operands are supported:

- optstring* A string containing the option characters recognised by the utility invoking `getopts`. If a character is followed by a colon, the option is expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but `getopts` interprets the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognised if it is not supplied as a separate argument when `getopts` is invoked; see [getopt\(3C\)](#). The characters question-mark (?) and colon (:) must not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in `OPTARG` is stripped of the option character and the `-`. The first character in *optstring* determines how `getopts` behaves if an option character is not known or an option-argument is missing.
- name* The name of a shell variable that is set by the `getopts` utility to the option character that was found.

The `getopts` utility by default parses positional parameters passed to the invoking shell procedure. If *args* are given, they are parsed instead of the positional parameters.

**Usage** Since `getopts` affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(getopts abc value "$@")
nohup getopts ...
find . -exec getopts ... \;
```

it does not affect the shell variables in the caller's environment.

Notice that shell functions share `OPTIND` with the calling shell even though the positional parameters are changed. Functions that want to use `getopts` to parse their arguments usually want to save the value of `OPTIND` on entry and restore it before returning. However, there are cases when a function wants to change `OPTIND` for the calling shell.

**Examples** **EXAMPLE 1** Parsing and Displaying Arguments

The following example script parses and displays its arguments:

```
aflag=
bflag=
```

**EXAMPLE 1** Parsing and Displaying Arguments *(Continued)*

```

while getopts ab: name
do
 case $name in
 a) aflag=1;;
 b) bflag=1
 bval="$OPTARG";;
 ?) printf "Usage: %s: [-a] [-b value] args\n" $0
 exit 2;;
 esac
done
if [! -z "$aflag"]; then
 printf "Option -a specified\n"
fi
if [! -z "$bflag"]; then
 printf 'Option -b "%s" specified\n' "$bval"
fi
shift $(($OPTIND - 1))
printf "Remaining arguments are: %s\n" "$*"

```

**EXAMPLE 2** Processing Arguments for a Command with Options

The following fragment of a shell program processes the arguments for a command that can take the options -a or -b. It also processes the option -o, which requires an option-argument:

```

while getopts abo: c
do
 case $c in
 a | b) FLAG=$c;;
 o) OARG=$OPTARG;;
 \?) echo $USAGE
 exit 2;;
 esac
done
shift `expr $OPTIND - 1`

```

**EXAMPLE 3** Equivalent Code Expressions

This code example accepts any of the following as equivalent:

```

cmd -a -b -o "xxx z yy" filename
cmd -a -b -o "xxx z yy" -- filename
cmd -ab -o xxx,z,yy filename
cmd -ab -o "xxx z yy" filename
cmd -o xxx,z,yy -b -a filename

```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `getopts`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**OPTIND** This variable is used by `getopts` as the index of the next argument to be processed.

**OPTARG** This variable is used by `getopts` to store the argument if an option is using arguments.

**Exit Status** The following exit values are returned:

0 An option, specified or unspecified by *optstring*, was found.

>0 The end of options was encountered or an error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also** [Intro\(1\)](#), [getoptcvt\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [getopt\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Diagnostics** Whenever an error is detected and the first character in the *optstring* operand is not a colon (:), a diagnostic message is written to standard error with the following information in an unspecified format:

- The invoking program name is identified in the message. The invoking program name is the value of the shell special parameter `0` at the time the `getopts` utility is invoked. A name equivalent to *basename "\$0"* can be used.
- If an option is found that was not specified in *optstring*, this error is identified and the invalid option character is identified in the message.
- If an option requiring an option-argument is found, but an option-argument is not found, this error is identified and the invalid option character is identified in the message.

**Name** gettext – retrieve text string from message database

**Synopsis** gettext [-d *textdomain* | --domain=*textdomain*]  
          [*textdomain*] *msgid*  
  
          gettext -s [-e] [-n]  
          [-d *textdomain* | --domain=*textdomain*] *msgid*...

**Description** The gettext utility retrieves a translated text string corresponding to string *msgid* from a message object generated with [msgfmt\(1\)](#). The message object name is derived from the optional argument *textdomain* if present, otherwise from the TEXTDOMAIN environment. If no domain is specified, or if a corresponding string cannot be found, gettext prints *msgid*.

Ordinarily, gettext looks for its message object in `/usr/lib/locale/lang/LC_MESSAGES` where *lang* is the locale name. If present, the TEXTDOMAINDIR environment variable replaces the pathname component up to *lang*.

This command interprets C escape sequences such as `\t` for tab. Use `\\` to print a backslash. To produce a message on a line of its own, either enter `\n` at the end of *msgid*, or use this command in conjunction with [printf\(1\)](#).

When used with the `-s` option, gettext behaves like [echo\(1\)](#). But it does not simply copy its arguments to standard output. Instead, those messages found in the selected catalog are translated.

**Options** The following options are supported:

|                                         |                                                                                                                                                                                                                          |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d <i>textdomain</i></code>       |                                                                                                                                                                                                                          |
| <code>--domain=<i>textdomain</i></code> | Retrieves translated messages from the domain <i>textdomain</i> , if <i>textdomain</i> is not specified as an operand.                                                                                                   |
| <code>-e</code>                         | Enables expansion of some escape sequences if used with the <code>-s</code> option.                                                                                                                                      |
| <code>-n</code>                         | Suppresses trailing newline if used with the <code>-s</code> option.                                                                                                                                                     |
| <code>-s</code>                         | Behaves like <a href="#">echo(1)</a> (see DESCRIPTION above). If the <code>-s</code> option is specified, no expansion of C escape sequences is performed and a newline character is appended to the output, by default. |

**Operands** The following operands are supported:

|                   |                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>textdomain</i> | A domain name used to retrieve the messages. This overrides the specification by the <code>-d</code> or <code>--domain</code> options, if present. |
| <i>msgid</i>      | A key to retrieve the localized message.                                                                                                           |

|                              |             |                                                                         |
|------------------------------|-------------|-------------------------------------------------------------------------|
| <b>Environment Variables</b> | LANG        | Specifies locale name.                                                  |
|                              | LC_MESSAGES | Specifies messaging locale, and if present overrides LANG for messages. |

|               |                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------|
| TEXTDOMAIN    | Specifies the text domain name, which is identical to the message object filename without .mo suffix. |
| TEXTDOMAINDIR | Specifies the pathname to the message database. If present, replaces /usr/lib/locale.                 |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [echo\(1\)](#), [msgfmt\(1\)](#), [printf\(1\)](#), [gettext\(3C\)](#), [setlocale\(3C\)](#), [attributes\(5\)](#)

**Notes** This is the shell equivalent of the library routine [gettext\(3C\)](#).

**Name** gettxt – retrieve a text string from a message database

**Synopsis** gettxt *msgfile* : *msgnum* [*dflt\_msg*]

**Description** gettxt retrieves a text string from a message file in the directory `/usr/lib/locale/locale/LC_MESSAGES`. The directory name *locale* corresponds to the language in which the text strings are written; see [setlocale\(3C\)](#).

|                 |                                                                                                                                                                                                                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>msgfile</i>  | Name of the file in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code> to retrieve <i>msgnum</i> from. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon). |
| <i>msgnum</i>   | Sequence number of the string to retrieve from <i>msgfile</i> . The strings in <i>msgfile</i> are numbered sequentially from 1 to <i>n</i> , where <i>n</i> is the number of strings in the file.                                                                                                            |
| <i>dflt_msg</i> | Default string to be displayed if gettxt fails to retrieve <i>msgnum</i> from <i>msgfile</i> . Nongraphic characters must be represented as alphabetic escape sequences.                                                                                                                                     |

The text string to be retrieved is in the file *msgfile*, created by the [mkmsgs\(1\)](#) utility and installed under the directory `/usr/lib/locale/locale/LC_MESSAGES`. You control which directory is searched by setting the environment variable `LC_MESSAGES`. If `LC_MESSAGES` is not set, the environment variable `LANG` will be used. If `LANG` is not set, the files containing the strings are under the directory `/usr/lib/locale/C/LC_MESSAGES`.

If gettxt fails to retrieve a message in the requested language, it will try to retrieve the same message from `/usr/lib/locale/C/LC_MESSAGES/ msgfile`. If this also fails, and if *dflt\_msg* is present and non-null, then it will display the value of *dflt\_msg*; if *dflt\_msg* is not present or is null, then it will display the string `Message not found!!`.

**Examples** **EXAMPLE 1** The environment variables `LANG` and `LC_MESSAGES`.

If the environment variables `LANG` or `LC_MESSAGES` have not been set to other than their default values, the following example:

```
example% gettxt UX:10 "hello world\n"
```

will try to retrieve the 10th message from `/usr/lib/locale/C/UX/msgfile`. If the retrieval fails, the message "hello world," followed by a newline, will be displayed.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of gettxt: `LC_CTYPE` and `LC_MESSAGES`.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LC_CTYPE</code> | Determines how gettxt handles characters. When <code>LC_CTYPE</code> is set to a valid value, gettxt can display and handle text and filenames containing valid characters for that locale. gettxt can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. gettxt can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid. |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

LC\_MESSAGES      Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

**Files**    /usr/lib/locale/C/LC\_MESSAGES/\*      default message files created by [mkmsgs\(1\)](#)  
             /usr/lib/locale/locale/LC\_MESSAGES/\*      message files for different languages created by [mkmsgs\(1\)](#)

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** getzonepath – display root path of the zone corresponding to the specified label

**Synopsis** /usr/bin/getzonepath {sensitivity-label}

**Description** getzonepath displays the root pathname of the running labeled zone that corresponds to the specified sensitivity label. The returned pathname is relative to the caller's root pathname, and has the specified sensitivity label.

If the caller is in the global zone, the returned pathname is not traversable unless the caller's processes have the file\_dac\_search privilege.

If the caller is in a labeled zone, the caller's label must dominate the specified label. Access to files under the returned pathname is restricted to read-only operations.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtsu         |
| Stability      | Committed       |

**Diagnostics** getzonepath exits with one of the following values:

- 0 Success
- 1 Usage error
- 2 Failure; error message is the system error number from [getzonerootbylabel\(3TSOL\)](#)

**See Also** [getzonerootbylabel\(3TSOL\)](#), [attributes\(5\)](#)

“Acquiring a Sensitivity Label” in *Solaris Trusted Extensions Developer’s Guide*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** glob – shell built-in function to expand a word list

**Synopsis**

    csh glob *wordlist*

**Description**

    csh glob performs filename expansion on *wordlist*. Like [echo\(1\)](#), but no ‘\’ escapes are recognized. Words are delimited by null characters in the output.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** gprof – display call-graph profile data

**Synopsis** gprof [-abcDlsz] [-e *function-name*] [-E *function-name*]  
          [-f *function-name*] [-F *function-name*]  
          [*image-file* [*profile-file*...]]  
          [-n *number of functions*]

**Description** The gprof utility produces an execution profile of a program. The effect of called routines is incorporated in the profile of each caller. The profile data is taken from the call graph profile file that is created by programs compiled with the -xpg option of cc(1), or by the -pg option with other compilers, or by setting the LD\_PROFILE environment variable for shared objects. See [ld.so.1\(1\)](#). These compiler options also link in versions of the library routines which are compiled for profiling. The symbol table in the executable image file *image-file* (a.out by default) is read and correlated with the call graph profile file *profile-file* (gmon.out by default).

First, execution times for each routine are propagated along the edges of the call graph. Cycles are discovered, and calls into a cycle are made to share the time of the cycle. The first listing shows the functions sorted according to the time they represent, including the time of their call graph descendants. Below each function entry is shown its (direct) call-graph children and how their times are propagated to this function. A similar display above the function shows how this function's time and the time of its descendants are propagated to its (direct) call-graph parents.

Cycles are also shown, with an entry for the cycle as a whole and a listing of the members of the cycle and their contributions to the time and call counts of the cycle.

Next, a flat profile is given, similar to that provided by [prof\(1\)](#). This listing gives the total execution times and call counts for each of the functions in the program, sorted by decreasing time. Finally, an index is given, which shows the correspondence between function names and call-graph profile index numbers.

A single function may be split into subfunctions for profiling by means of the MARK macro. See [prof\(5\)](#).

Beware of quantization errors. The granularity of the sampling is shown, but remains statistical at best. It is assumed that the time for each execution of a function can be expressed by the total time for the function divided by the number of times the function is called. Thus the time propagated along the call-graph arcs to parents of that function is directly proportional to the number of times that arc is traversed.

The profiled program must call [exit\(2\)](#) or return normally for the profiling information to be saved in the gmon.out file.

**Options** The following options are supported:

|    |                                                                                                                                                                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a | Suppress printing statically declared functions. If this option is given, all relevant information about the static function (for instance, time samples, calls to other functions, calls from other functions) belongs to the function loaded just before the static function in the a.out file. |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- 
- b Brief. Suppress descriptions of each field in the profile.
  - c Discover the static call-graph of the program by a heuristic which examines the text space of the object file. Static-only parents or children are indicated with call counts of 0. Note that for dynamically linked executables, the linked shared objects' text segments are not examined.
  - C Demangle C++ symbol names before printing them out.
  - D Produce a profile file `gmon.sum` that represents the difference of the profile information in all specified profile files. This summary profile file may be given to subsequent executions of `gprof` (also with `-D`) to summarize profile data across several runs of an `a.out` file. See also the `-s` option.  
  
As an example, suppose function A calls function B  $n$  times in profile file `gmon.sum`, and  $m$  times in profile file `gmon.out`. With `-D`, a new `gmon.sum` file will be created showing the number of calls from A to B as  $n-m$ .
  - e *function-name* Suppress printing the graph profile entry for routine *function-name* and all its descendants (unless they have other ancestors that are not suppressed). More than one `-e` option may be given. Only one *function-name* may be given with each `-e` option.
  - E *function-name* Suppress printing the graph profile entry for routine *function-name* (and its descendants) as `-e`, below, and also exclude the time spent in *function-name* (and its descendants) from the total and percentage time computations. More than one `-E` option may be given. For example:  
  

```
'-E mcount -E mcleanup'
```

is the default.
  - f *function-name* Print the graph profile entry only for routine *function-name* and its descendants. More than one `-f` option may be given. Only one *function-name* may be given with each `-f` option.
  - F *function-name* Print the graph profile entry only for routine *function-name* and its descendants (as `-f`, below) and also use only the times of the printed routines in total time and percentage computations. More than one `-F` option may be given. Only one *function-name* may be given with each `-F` option. The `-F` option overrides the `-E` option.
  - l Suppress the reporting of graph profile entries for all local symbols. This option would be the equivalent of placing all of the local symbols for the specified executable image on the `-E` exclusion list.
  - n Limits the size of flat and graph profile listings to the top  $n$  offending functions.

- s

Produce a profile file `gmon.sum` which represents the sum of the profile information in all of the specified profile files. This summary profile file may be given to subsequent executions of `gprof` (also with `-s`) to accumulate profile data across several runs of an `a.out` file. See also the `-D` option.
- z

Display routines which have zero usage (as indicated by call counts and accumulated time). This is useful in conjunction with the `-c` option for discovering which routines were never called. Note that this has restricted use for dynamically linked executables, since shared object text space will not be examined by the `-c` option.

Environment Variables

PROFDIR

If this environment variable contains a value, place profiling output within that directory, in a file named `pid.programname`. `pid` is the process ID and `programname` is the name of the program being profiled, as determined by removing any path prefix from the `argv[0]` with which the program was called. If the variable contains a null value, no profiling output is produced. Otherwise, profiling output is placed in the file `gmon.out`.

- Files
- a.out

executable file containing namelist
- gmon.out

dynamic call-graph and profile
- gmon.sum

summarized dynamic call-graph and profile
- \$PROFDIR/pid.programname

*Linker and Libraries Guide*

Notes

If the executable image has been stripped and has no symbol table (`.symtab`), then `gprof` will read the dynamic symbol table (`.dyntab`), if present. If the dynamic symbol table is used, then only the information for the global symbols will be available, and the behavior will be identical to the `-a` option.

`LD_LIBRARY_PATH` must not contain `/usr/lib` as a component when compiling a program for profiling. If `LD_LIBRARY_PATH` contains `/usr/lib`, the program will not be linked correctly with the profiling versions of the system libraries in `/usr/lib/libp`.

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

Only programs that call `exit` or return from `main` are guaranteed to produce a profile file, unless a final call to `monitor` is explicitly coded.

Functions such as `mcount()`, `_mcount()`, `moncontrol()`, `_moncontrol()`, `monitor()`, and `_monitor()` may appear in the `gprof` report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

**64-bit profiling** 64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If name duplication occurs in the profile output, the module id prefix before the symbol name in the symbol index listing can be used to identify the appropriate module for the symbol.

When using the `-s` or `-D` option to sum multiple profile files, care must be taken not to mix 32-bit profile files with 64-bit profile files.

**32-bit profiling** 32-bit profiling may be used with dynamically linked executables, but care must be applied. In 32-bit profiling, shared objects cannot be profiled with `gprof`. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `gprof`. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes

10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, gprof will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

**Bugs** Parents which are not themselves profiled will have the time of their profiled children propagated to them, but they will appear to be spontaneously invoked in the call-graph listing, and will not have their time propagated further. Similarly, signal catchers, even though profiled, will appear to be spontaneous (although for more obscure reasons). Any profiled children of signal catchers should have their times propagated properly, unless the signal catcher was invoked during the execution of the profiling routine, in which case all is lost.

**Name** graph – draw a graph

**Synopsis** graph [-a *spacing* [*start*]] [-b] [-c *string*] [-g *gridstyle*]  
 [-l *label*] [-m *connectmode*] [-s]  
 [-x [*l*] *lower* [*upper* [*spacing*]]]  
 [-y [*l*] *lower* [*upper* [*spacing*]]] [-h *fraction*]  
 [-w *fraction*] [-r *fraction*] [-u *fraction*] [-t] ...

**Description** graph with no options takes pairs of numbers from the standard input as abscissas and ordinates of a graph. Successive points are connected by straight lines. The standard output from graph contains plotting instructions suitable for input to [plot\(1B\)](#) or to the command [lpr -g](#) (see [lpr\(1B\)](#)).

If the coordinates of a point are followed by a nonnumeric string, that string is printed as a label beginning on the point. Labels may be surrounded with quotes ". . .", in which case they may be empty or contain blanks and numbers; labels never contain NEWLINE characters.

A legend indicating grid range is produced with a grid unless the -s option is present.

**Options** Each option is recognized as a separate argument. If a specified lower limit exceeds the upper limit, the axis is reversed.

|                                                                  |                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a <i>spacing</i> [ <i>start</i> ]                               | Supply abscissas automatically (they are missing from the input); <i>spacing</i> is the spacing (default 1). <i>start</i> is the starting point for automatic abscissas (default 0 or lower limit given by -x).                                   |
| -b                                                               | Break (disconnect) the graph after each label in the input.                                                                                                                                                                                       |
| -c <i>string</i>                                                 | <i>String</i> is the default label for each point.                                                                                                                                                                                                |
| -g <i>gridstyle</i>                                              | <i>Gridstyle</i> is the grid style: 0 no grid, 1 frame with ticks, 2 full grid (default).                                                                                                                                                         |
| -l <i>label</i>                                                  | <i>label</i> is label for graph.                                                                                                                                                                                                                  |
| -m <i>connectmode</i>                                            | Mode (style) of connecting lines: 0 disconnected, 1 connected (default). Some devices give distinguishable line styles for other small integers.                                                                                                  |
| -s                                                               | Save screen, do not erase before plotting.                                                                                                                                                                                                        |
| -x [ <i>l</i> ] <i>lower</i> [ <i>upper</i> [ <i>spacing</i> ] ] | If <i>l</i> is present, <i>x</i> axis is logarithmic. <i>lower</i> and <i>upper</i> are lower (and upper) <i>x</i> limits. <i>spacing</i> , if present, is grid spacing on <i>x</i> axis. Normally these quantities are determined automatically. |

- y [  $\ell$  ] lower [ upper [ spacing ] ]

If  $\ell$  is present,  $y$  axis is logarithmic. *lower* and *upper* are lower (and upper)  $y$  limits. *spacing*, if present, is grid spacing on  $y$  axis. Normally these quantities are determined automatically.
- h fraction

fraction of space for height.
- w fraction

fraction of space for width.
- r fraction

fraction of space to move right before plotting.
- u fraction

fraction of space to move up before plotting.
- t

Transpose horizontal and vertical axes. Option -x now applies to the vertical axis.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**See Also** [lpr\(1B\)](#), [plot\(1B\)](#), [spline\(1\)](#), [plot\(3PLOT\)](#), [attributes\(5\)](#)

- Bugs**

graph stores all points internally and drops those for which there is no room.
- Segments that run out of bounds are dropped, not windowed.
- Logarithmic axes may not be reversed.

**Name** grep – search a file for a pattern

**Synopsis** `/usr/bin/grep [-bchilnsvw] limited-regular-expression [filename]...`  
`/usr/xpg4/bin/grep [-E | -F] [-c | -l | -q] [-bhinsvx] -e pattern_list... [-f pattern_file]... [file]...`  
`/usr/xpg4/bin/grep [-E | -F] [-c | -l | -q] [-bhinsvx] [-e pattern_list]... -f pattern_file... [file]...`  
`/usr/xpg4/bin/grep [-E | -F] [-c | -l | -q] [-bhinsvx] pattern [file]...`

**Description** The `grep` utility searches text files for a pattern and prints all lines that contain that pattern. It uses a compact non-deterministic algorithm.

Be careful using the characters `$`, `*`, `[`, `*`, `^`, `|`, `(`, `)`, and `\` in the *pattern\_list* because they are also meaningful to the shell. It is safest to enclose the entire *pattern\_list* in single quotes `'...'`.

If no files are specified, `grep` assumes standard input. Normally, each line found is copied to standard output. The file name is printed before each line found if there is more than one input file.

`/usr/bin/grep` The `/usr/bin/grep` utility uses limited regular expressions like those described on the [regex\(5\)](#) manual page to match the patterns.

`/usr/xpg4/bin/grep` The options `-E` and `-F` affect the way `/usr/xpg4/bin/grep` interprets *pattern\_list*. If `-E` is specified, `/usr/xpg4/bin/grep` interprets *pattern\_list* as a full regular expression (see `-E` for description). If `-F` is specified, `grep` interprets *pattern\_list* as a fixed string. If neither are specified, `grep` interprets *pattern\_list* as a basic regular expression as described on [regex\(5\)](#) manual page.

**Options** The following options are supported for both `/usr/bin/grep` and `/usr/xpg4/bin/grep`:

- `-b` Precedes each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
- `-c` Prints only a count of the lines that contain the pattern.
- `-h` Prevents the name of the file containing the matching line from being prepended to that line. Used when searching multiple files.
- `-i` Ignores upper/lower case distinction during comparisons.
- `-l` Prints only the names of files with matching lines, separated by NEWLINE characters. Does not repeat the names of files when the pattern is found more than once.
- `-n` Precedes each line by its line number in the file (first line is 1).
- `-s` Suppresses error messages about nonexistent or unreadable files.
- `-v` Prints all lines except those that contain the pattern.

-w Searches for the expression as a word as if surrounded by \< and \>.

/usr/xpg4/bin/grep The following options are supported for /usr/xpg4/bin/grep only:

- e *pattern\_list* Specifies one or more patterns to be used during the search for input. Patterns in *pattern\_list* must be separated by a NEWLINE character. A null pattern can be specified by two adjacent newline characters in *pattern\_list*. Unless the -E or -F option is also specified, each pattern is treated as a basic regular expression. Multiple -e and -f options are accepted by grep. All of the specified patterns are used when matching lines, but the order of evaluation is unspecified.
- E Matches using full regular expressions. Treats each pattern specified as a full regular expression. If any entire full regular expression pattern matches an input line, the line is matched. A null full regular expression matches every line. Each pattern is interpreted as a full regular expression as described on the [regex\(5\)](#) manual page, except for \ ( and \), and including:
1. A full regular expression followed by + that matches one or more occurrences of the full regular expression.
  2. A full regular expression followed by ? that matches 0 or 1 occurrences of the full regular expression.
  3. Full regular expressions separated by | or by a new-line that match strings that are matched by any of the expressions.
  4. A full regular expression that is enclosed in parentheses ( ) for grouping.
- The order of precedence of operators is [ ], then \* ? +, then concatenation, then | and new-line.
- f *pattern\_file* Reads one or more patterns from the file named by the path name *pattern\_file*. Patterns in *pattern\_file* are terminated by a NEWLINE character. A null pattern can be specified by an empty line in *pattern\_file*. Unless the -E or -F option is also specified, each pattern is treated as a basic regular expression.
- F Matches using fixed strings. Treats each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line is matched. A null string matches every line. See [fgrep\(1\)](#) for more information.
- q Quiet. Does not write anything to the standard output, regardless of matching lines. Exits with zero status if an input line is selected.
- x Considers only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

**Operands** The following operands are supported:

*file* A path name of a file to be searched for the patterns. If no *file* operands are specified, the standard input is used.

`/usr/bin/grep` *pattern* Specifies a pattern to be used during the search for input.

`/usr/xpg4/bin/grep` *pattern* Specifies one or more patterns to be used during the search for input. This operand is treated as if it were specified as `-e pattern_list`.

**Usage** The `-e pattern_list` option has the same effect as the *pattern\_list* operand, but is useful when *pattern\_list* begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple `-e` and `-f` options are accepted and `grep` uses all of the patterns it is given while matching input text lines. Notice that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.

The `-q` option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if `grep` detected an access or read error on earlier file operands).

**Large File Behavior** See [largefile\(5\)](#) for the description of the behavior of `grep` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Finding All Uses of a Word

To find all uses of the word “Posix” (in any case) in the file `text.mm`, and write with line numbers:

```
example% /usr/bin/grep -i -n posix text.mm
```

**EXAMPLE 2** Finding All Empty Lines

To find all empty lines in the standard input:

```
example% /usr/bin/grep ^$
```

or

```
example% /usr/bin/grep -v .
```

**EXAMPLE 3** Finding Lines Containing Strings

All of the following commands print all lines containing strings `abc` or `def` or both:

```
example% /usr/xpg4/bin/grep 'abc
def'
```

EXAMPLE 3 Finding Lines Containing Strings (Continued)

```
example% /usr/xpg4/bin/grep -e 'abc
def'
example% /usr/xpg4/bin/grep -e 'abc' -e 'def'
example% /usr/xpg4/bin/grep -E 'abc|def'
example% /usr/xpg4/bin/grep -E -e 'abc|def'
example% /usr/xpg4/bin/grep -E -e 'abc' -e 'def'
example% /usr/xpg4/bin/grep -E 'abc
def'
example% /usr/xpg4/bin/grep -E -e 'abc
def'
example% /usr/xpg4/bin/grep -F -e 'abc' -e 'def'
example% /usr/xpg4/bin/grep -F 'abc
def'
example% /usr/xpg4/bin/grep -F -e 'abc
def'
```

EXAMPLE 4 Finding Lines with Matching Strings

Both of the following commands print all lines matching exactly abc or def:

```
example% /usr/xpg4/bin/grep -E '^abc$ ^def$'
example% /usr/xpg4/bin/grep -F -x 'abc def'
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of grep: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

- Exit Status** The following exit values are returned:
- 0 One or more matches were found.
  - 1 No matches were found.
  - 2 Syntax errors or inaccessible files (even if matches were found).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| /usr/bin/grep | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------|----------------|-----------------|
|               | Availability   | SUNWcs          |
|               | CSI            | Not Enabled     |

| /usr/xpg4/bin/grep | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|--------------------|----------------|-----------------|
|                    | Availability   | SUNWxcu4        |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                    |
|---------------------|------------------------------------|
| CSI                 | Enabled                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [egrep\(1\)](#), [fgrep\(1\)](#), [sed\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [regexp\(5\)](#), [standards\(5\)](#)

**Notes**

- `/usr/bin/grep` Lines are limited only by the size of the available virtual memory. If there is a line with embedded nulls, `grep` only matches up to the first null. If the line matches, the entire line is printed.
- `/usr/xpg4/bin/grep` The results are unspecified if input files contain lines longer than `LINE_MAX` bytes or contain binary data. `LINE_MAX` is defined in `/usr/include/limits.h`.

**Name** groups – print group membership of user

**Synopsis** groups [*user*]...

**Description** The command groups prints on standard output the groups to which you or the optionally specified user belong. Each user belongs to a group specified in /etc/passwd and possibly to other groups as specified in /etc/group. Note that /etc/passwd specifies the numerical ID (gid) of the group. The groups command converts gid to the group name in the output.

**Examples** The output takes the following form:

```
example% groups tester01 tester02
tester01 : staff
tester02 : staff
example%
```

**Files** /etc/passwd  
/etc/group

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [group\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

**Name** groups – display a user's group memberships

**Synopsis** /usr/ucb/groups [user]...

**Description** With no arguments, groups displays the groups to which you belong; else it displays the groups to which the user belongs. Each user belongs to a group specified in the password file /etc/passwd and possibly to other groups as specified in the file /etc/group. If you do not own a file but belong to the group which it is owned by then you are granted group access to the file.

**Files** /etc/passwd  
/etc/group

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [getgroups\(2\)](#), [attributes\(5\)](#)

**Notes** This command is obsolete.

**Name** grpck – check group database entries

**Synopsis** /etc/grpck [*filename*]

**Description** The grpck utility checks that a file in [group\(4\)](#) does not contain any errors; it checks the /etc/group file by default.

**Files** /etc/group

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [groups\(1\)](#), [group\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

|                    |                                     |                                                                                                          |
|--------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------|
| <b>Diagnostics</b> | Too many/few fields                 | An entry in the group file does not have the proper number of fields.                                    |
|                    | No group name                       | The group name field of an entry is empty.                                                               |
|                    | Bad character(s) in group name      | The group name in an entry contains characters other than lower-case letters and digits.                 |
|                    | Invalid GID                         | The group ID field in an entry is not numeric or is greater than 65535.                                  |
|                    | Null login name                     | A login name in the list of login names in an entry is null.                                             |
|                    | Logname not found in password file  | A login name in the list of login names in an entry is not in the password file.                         |
|                    | Line too long                       | A line (including the newline character) in the group file exceeds the maximum length of 512 characters. |
|                    | Duplicate logname entry             | A login name appears more than once in the list of login names for a group file entry.                   |
|                    | Out of memory                       | The program cannot allocate memory in order to continue.                                                 |
|                    | Maximum groups exceeded for logname | A login name's group membership exceeds the maximum, NGROUPS_MAX.                                        |

**Name** hash, rehash, unhash, hashstat – evaluate the internal hash table of the contents of directories

**Synopsis** /usr/bin/hash [*utility*]

/usr/bin/hash [-r]

sh hash [-r] [*name*]...

csh rehash

unhash

hashstat

ksh hash [*name*]...

hash [-r]

## Description

/usr/bin/hash The /usr/bin/hash utility affects the way the current shell environment remembers the locations of utilities found. Depending on the arguments specified, it adds utility locations to its list of remembered locations or it purges the contents of the list. When no arguments are specified, it reports on the contents of the list. The -r option causes the shell to forget all remembered locations.

Utilities provided as built-ins to the shell are not reported by hash.

sh For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option to the hash built-in causes the shell to forget all remembered locations. If no arguments are given, hash provides information about remembered commands. The *Hits* column of output is the number of times a command has been invoked by the shell process. The *Cost* column of output is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (\*) adjacent to the *Hits* information. *Cost* will be incremented when the recalculation is done.

csh rehash recomputes the internal hash table of the contents of directories listed in the path environmental variable to account for new commands added.

unhash disables the internal hash table.

hashstat prints a statistics line indicating how effective the internal hash table has been at locating commands (and avoiding execs). An exec is attempted for each component of the *path* where the hash function indicates a possible hit and in each component that does not begin with a '/ '.

**ksh** For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The `-r` option to the `hash` built-in causes the shell to forget all remembered locations. If no arguments are given, `hash` provides information about remembered commands.

**Operands** The following operand is supported by `hash`:

*utility*      The name of a utility to be searched for and added to the list of remembered locations.

**Output** The standard output of `hash` is used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list consists of those utilities named in previous `hash` invocations that have been invoked, and may contain those invoked and found through the normal command search process.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `hash`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH`      Determine the location of *utility*.

**Exit Status** The following exit values are returned by `hash`:

- `0`      Successful completion.
- `>0`      An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also** [csh\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** head – display first few lines of files

**Synopsis** head [-number | -n *number*] [*filename*]...

**Description** The head utility copies the first *number* of lines of each *filename* to the standard output. If no *filename* is given, head copies lines from the standard input. The default value of *number* is 10 lines.

When more than one file is specified, the start of each file will look like:

```
==> filename <==
```

Thus, a common way to display a set of short files, identifying each one, is:

```
example% head -9999 filename1 filename2 ...
```

**Options** The following options are supported:

- n *number*      The first *number* lines of each input file will be copied to standard output. The *number* option-argument must be a positive decimal integer.
- number*          The *number* argument is a positive decimal integer with the same effect as the -n *number* option.

If no options are specified, head will act as if -n 10 had been specified.

**Operands** The following operand is supported:

*file*      A path name of an input file. If no *file* operands are specified, the standard input will be used.

**Usage** See [largefile\(5\)](#) for the description of the behavior of head when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Writing the first ten lines of all files

To write the first ten lines of all files (except those with a leading period) in the directory:

```
example% head *
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of head: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0      Successful completion.
- >0     An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | enabled         |
| Interface Stability | Standard        |

**See Also** [cat\(1\)](#), [more\(1\)](#), [pg\(1\)](#), [tail\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** history, fc – process command history list

**Synopsis** /usr/bin/fc [-r] [-e *editor*] [*first* [*last*]]

/usr/bin/fc -l [-nr] [*first* [*last*]]

/usr/bin/fc -s [*old* = *new*] [*first*]

csch history [-hr] [*n*]

ksh fc -e - [*old* = *new*] [*command*]

fc -s [*old* = *new*] [*command*]

fc [-e *ename*] [-n*lr*] [*first* [*last*]]

## Description

/usr/bin/fc The fc utility lists or edits and reexecutes, commands previously entered to an interactive sh.

The command history list references commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command will not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches the value in HISTSIZE or 32767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, fc will maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.

When commands are edited (when the -l option is not specified), the resulting lines will be entered at the end of the history list and then reexecuted by sh. The fc command that caused the editing will not be entered into the history list. If the editor returns a non-zero exit status, this will suppress the entry into the history list and the command reexecution. Any command-line variable assignments or redirection operators used with fc will affect both the fc command itself as well as the command that results, for example:

```
fc -s -- -1 2>/dev/null
```

reinvokes the previous command, suppressing standard error for both fc and the previous command.

csch Display the history list. If *n* is given, display only the *n* most recent events.

-r Reverse the order of printout to be most recent first rather than oldest first.

-h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the -h option to the csh built-in command, [source\(1\)](#).

## History Substitution:

History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size of which is controlled by the `history` variable. The `history` shell variable may be set to the maximum number of command lines that will be saved in the history file, that is:

```
set history = 200
```

will allow the history list to keep track of the most recent 200 command lines. If not set, the C shell saves only the most recent command.

A history substitution begins with a `!` (although you can change this with the `histchars` variable) and may occur anywhere on the command line; history substitutions do not nest. The `!` can be escaped with `\` to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

### Event Designators:

An event designator is a reference to a command line entry in the history list.

|                                          |                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>!</code>                           | Start a history substitution, except when followed by a space character, tab, newline, <code>=</code> or <code>(</code> .                                                                                                                                                                                                              |
| <code>!!</code>                          | Refer to the previous command. By itself, this substitution repeats the previous command.                                                                                                                                                                                                                                              |
| <code>!n</code>                          | Refer to command line <i>n</i> .                                                                                                                                                                                                                                                                                                       |
| <code>!-n</code>                         | Refer to the current command line minus <i>n</i> .                                                                                                                                                                                                                                                                                     |
| <code>!str</code>                        | Refer to the most recent command starting with <i>str</i> .                                                                                                                                                                                                                                                                            |
| <code>!?str?</code>                      | Refer to the most recent command containing <i>str</i> .                                                                                                                                                                                                                                                                               |
| <code>!?str? additional</code>           | Refer to the most recent command containing <i>str</i> and append <i>additional</i> to that referenced command.                                                                                                                                                                                                                        |
| <code>!{command} additional</code>       | Refer to the most recent command beginning with <i>command</i> and append <i>additional</i> to that referenced command.                                                                                                                                                                                                                |
| <code>^previous_word^replacement^</code> | Repeat the previous command line replacing the string <i>previous_word</i> with the string <i>replacement</i> . This is equivalent to the history substitution:<br><br>Repeat the previous command line replacing the string <i>previous_word</i> with the string <i>replacement</i> . This is equivalent to the history substitution: |

```
!:s/previous_word/replacement/.
```

To re-execute a specific previous command *and* make such a substitution, say, re-executing command #6:

```
!:6s/previous_word/replacement/.
```

### Word Designators:

A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, \$, \*, – or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, !!:1 and !:1 both refer to the first word of the previous command, while !!\$ and !\$ both refer to the last word in the previous command. Word designators include:

- # The entire command line typed so far.
- 0 The first input word (command).
- n* The *n*'th argument.
- ^ The first argument, that is, 1.
- \$ The last argument.
- % The word matched by (the most recent) ?s search.
- x*–*y* A range of words; –*y* abbreviates 0–*y*.
- \*
- x*\* All the arguments, or a null value if there is just one word in the event. Abbreviates *x*–\$.
- x*– Like *x*\* but omitting word \$.

### Modifiers:

After the optional word designator, you can add a sequence of one or more of the following modifiers, each preceded by a :

- h Remove a trailing pathname component, leaving the head.
- r Remove a trailing suffix of the form '.xxx', leaving the basename.
- e Remove all but the suffix, leaving the extension.
- s/oldchars/replacements/* Substitute *replacements* for *oldchars*. *oldchars* is a string that may contain embedded blank spaces, whereas *previous\_word* in the event designator may not.  
^*oldchars*^*replacements*^
- t Remove all leading pathname components, leaving the tail.

|   |                                                                                                             |
|---|-------------------------------------------------------------------------------------------------------------|
| & | Repeat the previous substitution.                                                                           |
| g | Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, g&). |
| p | Print the new command but do not execute it.                                                                |
| q | Quote the substituted words, escaping further substitutions.                                                |
| x | Like q, but break into words at each space character, tab or newline.                                       |

Unless preceded by a g, the modification is applied only to the first string that matches *oldchars*. An error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of /. A backslash quotes the delimiter character. The character &, in the right hand side, is replaced by the text from the left-hand-side. The & can be quoted with a backslash. A null *oldchars* uses the previous string either from a *oldchars* or from a contextual scan string *s* from !?s. You can omit the rightmost delimiter if a newline immediately follows *replacements*; the rightmost ? in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

ksh Using `fc`, in the form of

```
fc -e - [old=new] [command],
```

or

```
fc -s [old=new] [command],
```

the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

Using `fc` in the form of

```
fc [-e ename] [-nlr] [first [last]],
```

a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the -l flag is selected, the commands are listed on standard output. Otherwise, the editor program -e *name* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable FCEDIT (default /bin/ed) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified, it will be set to *first*. If *first* is not specified, the

default is the previous command for editing and -16 for listing. The flag -r reverses the order of the commands and the flag -n suppresses command numbers when listing. (See [ksh\(1\)](#) for more about command line editing.)

|          |                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HISTFILE | If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history.                                                         |
| HISTSIZE | If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128. |

### Command Re-entry:

The text of the last HISTSIZE (default 128) commands entered from a terminal device is saved in a history file. The file `$HOME/.sh_history` is used if the HISTFILE variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named HISTFILE. The special command `fc` is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to `fc` then the value of the variable FCEDIT is used. If FCEDIT is not defined then `/bin/ed` is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name - is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form `old=new` can be used to modify the command before execution. For example, if `r` is aliased to `'fc -e -'` then typing `'r bad=good c'` will re-execute the most recent command which starts with the letter `c`, replacing the first occurrence of the string `bad` with the string `good`.

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

**Options** The following options are supported:

|                  |                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -e <i>editor</i> | Uses the editor named by <i>editor</i> to edit the commands. The <i>editor</i> string is a utility name, subject to search via the PATH variable. The value in the FCEDIT variable is used as a default when -e is not specified. If FCEDIT is null or unset, ed will be used as the editor. |
| -l               | (The letter ell.) Lists the commands rather than invoking an editor on them. The commands will be written in the sequence indicated by the <i>first</i> and <i>last</i> operands, as affected by -r, with each command preceded by the command number.                                       |
| -n               | Suppresses command numbers when listing with -l.                                                                                                                                                                                                                                             |
| -r               | Reverses the order of the commands listed (with -l ) or edited (with neither -l nor -s).                                                                                                                                                                                                     |

-s                    Re-executes the command without invoking an editor.

**Operands**    The following operands are supported:

|                   |                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>first</i>      |                                                                                                                                                                                                                                     |
| <i>last</i>       | Selects the commands to list or edit. The number of previous commands that can be accessed is determined by the value of the HISTSIZE variable. The value of <i>first</i> or <i>last</i> or both will be one of the following:      |
| [+] <i>number</i> | A positive number representing a command number. Command numbers can be displayed with the -l option.                                                                                                                               |
| - <i>number</i>   | A negative decimal number representing the command that was executed <i>number</i> of commands previously. For example, -1 is the immediately previous command.                                                                     |
| <i>string</i>     | A string indicating the most recently entered command that begins with that string. If the <i>old=new</i> operand is not also specified with -s, the string form of the <i>first</i> operand cannot contain an embedded equal sign. |

When the synopsis form with -s is used:

- If *first* is omitted, the previous command will be used.

For the synopsis forms without -s :

- If *last* is omitted, *last* defaults to the previous command when -l is specified; otherwise, it defaults to *first*.
- If *first* and *last* are both omitted, the previous 16 commands will be listed or the previous single command will be edited (based on the -l option).
- If *first* and *last* are both present, all of the commands from *first* to *last* will be edited (without -l ) or listed (with -l). Editing multiple commands will be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If *first* represents a newer command than *last*, the commands will be listed or edited in reverse sequence, equivalent to using -r. For example, the following commands on the first line are equivalent to the corresponding commands on the second:

```
fc -r 10 20 fc 30 40
fc 20 10 fc -r 40 30
```

- When a range of commands is used, it will not be an error to specify *first* or *last* values that are not in the history list. fc will substitute the value representing the oldest or newest command in

the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10:

```
fc -l
fc 1 99
```

will list and edit, respectively, all ten commands.

*old=new* Replace the first occurrence of string *old* in the commands to be reexecuted by the string *new*.

**Output** When the `-l` option is used to list commands, the format of each command in the list is as follows:

```
"%d\t%s\n", <line number>, <command>
```

If both the `-l` and `-n` options are specified, the format of each command is:

```
"\t%s\n", <command>
```

If the *command* consists of more than one line, the lines after the first are displayed as:

```
"\t%s\n", <continued-command>
```

**Examples** **EXAMPLE 1** Using history and `fc`

| csh                          | ksh                          |
|------------------------------|------------------------------|
| % history                    | \$ fc -l                     |
| 1 cd /etc                    | 1 cd /etc                    |
| 2 vi passwd                  | 2 vi passwd                  |
| 3 date                       | 3 date                       |
| 4 cd                         | 4 cd                         |
| 5 du .                       | 5 du .                       |
| 6 ls -t                      | 6 ls -t                      |
| 7 history                    | 7 fc -l                      |
| % !d                         | \$ fc -e - d                 |
| du .                         | du .                         |
| 262 ./SCCS                   | 262 ./SCCS                   |
| 336 .                        | 336 .                        |
| % !da                        | \$ fc -e - da                |
| Thu Jul 21 17:29:56 PDT 1994 | Thu Jul 21 17:29:56 PDT 1994 |
| %                            | \$ alias \!= 'fc -e - '      |
| % !!                         | \$ !                         |
| date                         | alias = 'fc -e - '           |

**EXAMPLE 1** Using history and fc (Continued)

Thu Jul 21 17:29:56 PDT 1994

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of fc: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

- FCEDIT** This variable, when expanded by the shell, determines the default value for the `-e editor` option's *editor* option-argument. If FCEDIT is null or unset, [ed\(1\)](#) will be used as the editor.
- HISTFILE** Determine a pathname naming a command history file. If the HISTFILE variable is not set, the shell may attempt to access or create a file `.sh_history` in the user's home directory. If the shell cannot obtain both read and write access to, or create, the history file, it will use an unspecified mechanism that allows the history to operate properly. (References to history "file" in this section are understood to mean this unspecified mechanism in such cases.) fc may choose to access this variable only when initializing the history file; this initialization will occur when fc or sh first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the ENV variable, or a system startup file such as `/etc/profile`. (The initialization process for the history file can be dependent on the system startup files, in that they may contain commands that will effectively preempt the user's settings of HISTFILE and HISTSIZE. For example, function definition commands are recorded in the history file, unless the `set -o no log` option is set. If the system administrator includes function definitions in some system startup file called before the ENV file, the history file will be initialized before the user gets a chance to influence its characteristics.) The variable HISTFILE is accessed initially when the shell is invoked. Any changes to HISTFILE will not take effect until another shell is invoked.
- HISTSIZE** Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 will be used. The variable HISTSIZE is accessed initially when the shell is invoked. Any changes to HISTSIZE will not take effect until another shell is invoked.

**Exit Status** The following exit values are returned:

- 0 Successful completion of the listing.
- >0 An error occurred.

Otherwise, the exit status will be that of the commands executed by fc.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [csh\(1\)](#), [ed\(1\)](#), [ksh\(1\)](#), [set\(1\)](#), [set\(1F\)](#), [sh\(1\)](#), [source\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name**    `hostid` – print the numeric identifier of the current host

**Synopsis**    `/usr/bin/hostid`

**Description**    The `hostid` command prints the identifier of the current host in hexadecimal. If it is executed within a non-global zone that emulates a host identifier, the emulated host identifier is printed. This numeric value is likely to differ when `hostid` is run on a different machine.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also**    [sysinfo\(2\)](#), [gethostid\(3C\)](#), [attributes\(5\)](#), [zones\(5\)](#)

**Name** hostname – set or print name of current host system

**Synopsis** /usr/bin/hostname [*name-of-host*]

**Description** The `hostname` command prints the name of the current host, as given before the login prompt. The super-user can set the hostname by giving an argument.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [uname\(1\)](#), [attributes\(5\)](#)

**Name** iconv – code set conversion utility

**Synopsis** iconv [-cs] -f *frommap* -t *tomap* [*file*]...  
 iconv -f *fromcode* [-cs] [-t *tocode*] [*file*]...  
 iconv -t *tocode* [-cs] [-f *fromcode*] [*file*]...  
 iconv -l

**Description** The iconv utility converts the characters or sequences of characters in *file* from one code set to another and writes the results to standard output. If no conversion exists for a particular character, an implementation-defined conversion is performed on this character.

The list of supported conversions and the locations of the associated conversion tables are provided in the [iconv\(5\)](#) manual page.

**Options** The following options are supported:

- c Omits any characters that are invalid in the codeset of the input file from the output. When -c is not used, the results of encountering invalid characters in the input stream depend on the specified codesets for the conversion. Invalid characters can be either those that are not valid characters in the codeset of the input file or those that have no corresponding character in the codeset of the output file. The presence or absence of -c does not affect the exit status of iconv. When *fromcode* is specified for the *fromcodeset* of the -f option or *tocode* is specified for the *tocodeset* of the -t option, the specification of -c may be ignored.
- f *fromcodeset* Identifies the code set of the input file. The following two forms of the *fromcodeset* option-argument are recognized:
  - fromcode* The *fromcode* option-argument must not contain a slash (/) character. It is interpreted as the name of one of the codeset descriptions.
  - frommap* The *frommap* option-argument must contain a slash character. It is interpreted as the pathname of a charmap file as defined in [charmap\(5\)](#). If the pathname does not represent a valid, readable charmap file, the results are undefined.

If this option is omitted, the codeset of the current locale is used.
- l Writes all supported *fromcode* and *tocode* values to standard output.
- s Suppresses any messages written to standard error concerning invalid characters. When -s is not used, the results of encountering invalid characters in the input stream depend on the specified codesets for the conversion. Invalid characters can be either those that are not valid characters in the codeset of the input file or those that have no

corresponding character in the codeset of the output file. The presence or absence of `-s` does not affect the exit status of `iconv`. When *fromcode* is specified for the *fromcodeset* of the `-f` option or *tocode* is specified for the *tocodeset* of the `-t` option, the specification of `-s` may be ignored.

**-t *tocodeset*** Identifies the code set used for the output file. The following two forms of the *tocodeset* option-argument are recognized:

*tocode* The *tocode* option-argument must not contain a slash (/) character. It is interpreted as the name of one of the codeset descriptions.

*tomap* The *tomap* option-argument must contain a slash character. It is interpreted as the pathname of a charmap file as defined in [charmap\(5\)](#). If the pathname does not represent a valid, readable charmap file, the results are undefined.

If this option is omitted, the codeset of the current locale is used.

If either `-f` or `-t` represents a charmap file but the other does not, or is omitted, or if both `-f` and `-t` are omitted, `iconv` fails as an error.

**Operands** The following operands are supported:

*file* A path name of an input file. If no file operands are specified, or if a file operand is '-', the standard input is used.

**Examples** **EXAMPLE 1** Converting and storing files

The following example converts the contents of file `mail1` from code set `8859` to `646fr` and stores the results in file `mail.local`:

```
example% iconv -f 8859 -t 646fr mail1 > mail.local
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `iconv`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

0 Successful completion.

1 An error has occurred.

**Files** `/usr/lib/iconv/iconv_data` list of conversions supported by conversion tables

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also** [iconv\(3C\)](#), [iconv\\_open\(3C\)](#), [attributes\(5\)](#), [charmap\(5\)](#), [environ\(5\)](#), [iconv\(5\)](#), [iconv\\_unicode\(5\)](#), [standards\(5\)](#)

**Notes** Make sure that both charmap files use the same symbolic names for characters the two codesets have in common.

The output format of the `-l` option is unspecified. The `-l` option is not intended for shell script usage.

When *fromcode* or *toctype* is specified for the codeset conversion, `iconv` uses the [iconv\\_open\(3C\)](#) function. If `iconv_open(3C)` fails to open the specified codeset conversion, `iconv` searches for an appropriate conversion table. As for the supported codeset conversion by `iconv_open(3C)`, please refer to [iconv\(5\)](#) and `iconv_locale(5)`.

**Name** idnconv – Internationalized Domain Name (IDN) encoding conversion utility

**Synopsis** idnconv

```
[-i in-code | --in in-code | -f in-code | --from in-code]
[-o out-code | --out out-code | -t out-code | --to out-code]
[-a | --asciicheck | --ascii-check]
[-A | --noasciicheck | --no-ascii-check]
[-b | --bidicheck | --bidi-check]
[-B | --nobidicheck | --no-bidi-check]
[-l | --lengthcheck | --length-check]
[-L | --nolengthcheck | --no-length-check]
[-n | --nameprep] [-N | --nonameprep | --no-nameprep]
[-u | --unassigncheck | --unassign-check]
[-U | --nounassigncheck | --no-unassign-check]
[-h | --help] [-v | --version] [file]...
```

**Description** idnconv converts the codeset or encoding of given text, if applicable. You can change the conversion with different options. idnconv reads from file or standard input and writes the results to standard output.

When more than one IDN names or labels are supplied as input, such names or labels can be delimited by using white-space characters of the POSIX locale or the label separators defined in the *RFC 3490*.

The main use for idnconv is to convert Internationalized Domain Names in one codeset or encoding to another codeset or encoding. For instance, you can use the utility to convert IDN names in UTF-8 codeset to ASCII Compatible Encoding (ACE) encoded IDN names in 7-bit ASCII. For any other codeset conversion purposes, use [iconv\(1\)](#) instead.

**Options** The following options are supported:

**-a | --asciicheck | --ascii-check**

During IDN conversion process, enforce ASCII character range checks.

This is identical to setting the UseSTD3ASCIIRules flag described in *RFC 3490*. For more details on the ASCII character range checks, refer to [idn\\_decodename\(3EXT\)](#) and *RFC 3490*. This is the default.

**-A | --noasciicheck | --no-ascii-check**

During IDN conversion process, do not perform ASCII character range checks.

This is identical to unsetting the UseSTD3ASCIIRules flag described in *RFC 3490*. For more details on the ASCII character range checks, refer to [idn\\_decodename\(3EXT\)](#) and *RFC 3490*.

**-b | --bidicheck | --bidi-check**

During IDN conversion process, enforce checkings on bidirectional strings as specified in *RFC 3491* and *RFC 3454*.

This is the default.

**-B** | **--nobidichack** | **--no-bidi-check**

During IDN conversion process, do not perform checkings on bidirectional strings which is specified in *RFC 3491* and *RFC 3454*.

**-h** | **--help**

Print information about the utility and the options it supports.

All other options and operands if any are ignored.

**-i** *in-code* | **--in** *in-code* | **-f** *in-code* | **--from** *in-code*

Identify the input codeset with the *in-code* argument. All *i*conv code conversion names that can be converted to UTF-8 can be used as the value of the *in-code*. If not supplied, the current locale's codeset is assumed as the codeset of the input. The utility also checks each individual name in the actual input and if the name is in ACE, the ACE is assumed as the *in-code* for the name.

**-l** | **--lengthcheck** | **--length-check**

During IDN conversion process, enforce label length check.

See [idn\\_decodename\(3EXT\)](#) and *RFC 3490*. This ensures that the length of each label is in the range of 1 to 63. This is the default.

**-L** | **--nolengthcheck** | **--no-length-check**

During IDN conversion process, do not perform label length check.

See [idn\\_decodename\(3EXT\)](#) and *RFC 3490*.

**-n** | **--nameprep**

During IDN conversion process, enforce Nameprep step as specified in the *RFC 3490*, *RFC 3491*, and *RFC 3454*. This is the default.

**-N** | **--nonameprep** | **--no-nameprep**

During IDN conversion process, do not perform Nameprep step. For more details on the Nameprep, refer to [idn\\_decodename\(3EXT\)](#), *RFC 3490*, *RFC 3491*, and *RFC 3454*.

**-o** *out-code* | **--out** *out-code* | **-t** *out-code* | **--to** *out-code*

Identify the output codeset with the *out-code* argument.

All *i*conv code conversion names that can be converted to UTF-8 can be used as the value of the *out-code*. If not supplied, the current locale's codeset is assumed as the codeset of the output; if the *in-code* is ACE, then, the utility tries to convert names from actual input to non-ACE IDN names in the output codeset.

**-u** | **--unassigncheck** | **--unassign-check**

During IDN conversion process, enforce unassigned character checking.

This is identical to unsetting the AllowUnassigned flag described in the *RFC 3490*. This option is useful when the IDN names are converted for storing purpose or to give the names to server machines. For more details on the unassigned character checking, refer to *RFC 3490*, *RFC 3491*, and *RFC 3454*. This is the default.

`-U | --nounassigncheck | --no-unassign-check`

During IDN conversion process, do not perform unassigned character checking.

This is identical to setting the `AllowUnassigned` flag described in the *RFC 3490*. This option is useful when the IDN names are converted for the query purpose. For more details on the unassigned character checking, refer to *RFC 3490*, *RFC 3491*, and *RFC 3454*.

`-v | --version`

Prints information about the utility's name, version, and legal status. All other options and operands if any are ignored.

**Operands** The following operands are supported:

*file* A path name of the input file to be converted. If file is omitted, the standard input is used.

**Examples** **EXAMPLE 1** Converting IDN Names

The following example converts IDN names.

It reads names in the current locale's codeset from standard input. It converts and writes the converted results to `results.txt` file. If the names given to the utility are in ACE, the results are non-ACE IDN names in the current locale's codeset. If the names given to the utility are in non-ACE IDN names, the results are IDN names in ACE.

```
example% idnconv > results.txt
```

**EXAMPLE 2** Converting an ACE Encoded IDN Name

The following example converts an ACE encoded IDN name into an IDN name in UTF-8.

It reads `xn--1lq90i` which is in ACE encoding from standard input. It writes the converted results to file `Beijing-UTF-8.txt`. The file contains Beijing in two Chinese letters in UTF-8 codeset.

```
example% idnconv -t UTF-8 > Beijing-UTF-8.txt
xn--1lq90i
CTRLd
```

**EXAMPLE 3** Converting Names in KOI8-R Cyrillic Single Byte Codeset

The following example converts names in KOI8-R Cyrillic single byte codeset to ACE encoded names.

It reads from file `inputfile.txt` which is in KOI8-R. It writes the converted results to standard output. The results are in ACE encoding.

```
example% idnconv --in KOI8-R --out ACE inputfile.txt
xn--80adxhks
xn--90aqflb3d1a
```

**EXAMPLE 3** Converting Names in KOI8-R Cyrillic Single Byte Codeset (Continued)

```
xn--80aescdb4a2a8c
example%
```

**EXAMPLE 4** Converting Names for Storing Purpose

The following example converts names for storing purposes.

It reads from file `inputfile.txt` that is in ISO8859-1. It converts and writes the results to the `outputfile.txt` in ACE. It also yields ACE names that are good to be used as server names.

```
example% idnconv --from ISO8859-1 --to ACE --unassign-check\
inputfile.txt > outputfile.txt
```

**EXAMPLE 5** Converting Names for Query Purposes

The following example converts names for query purposes.

It reads from standard input in the current locale's codeset. It converts and writes the results to the `outputfile.txt` in ACE:

```
example% idnconv -U -t ACE > outputfile.txt
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `idnconv`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- |    |                                                                                     |
|----|-------------------------------------------------------------------------------------|
| 0  | Successful completion.                                                              |
| 1  | Not supported in-code or out-code value.                                            |
| 2  | ASCII character range checking has failed.                                          |
| 3  | Checkings on bidirectional strings have failed.                                     |
| 4  | Label length checking has failed.                                                   |
| 5  | Nameprep step reported an error.                                                    |
| 6  | Unassigned character has been found.                                                |
| 7  | Illegal or unknown option has been supplied.                                        |
| 8  | Input file cannot be found.                                                         |
| 9  | Not enough memory.                                                                  |
| 10 | During internal iconv code conversions, conversion error occurred.                  |
| 11 | During internal iconv code conversions, non-identical code conversion has happened. |

>11 Unspecified error occurred.

*STD 3, RFC 1123 Requirements for Internet Hosts -- Applications and Support*

*Unicode Standard Annex #15: Unicode Normalization Forms, Version 3.2.0.* <http://www.unicode.org>

*International Language Environments Guide*

**Notes** For the generic information on IDN in applications, refer to *RFC 3490* and the *International Language Environments Guide*.

There are some distinctions between the storing purpose and the querying purpose when you decide on the names of systems. For more details on the terms and distinctions, refer to *RFC 3454*.

**Name** indicator – display application specific alarms and/or the working indicator

**Synopsis** indicator [-b [*n*]] [-c *column*] [-l *length*] [-o] [-w]  
[*string*]...

**Description** The indicator function displays application specific alarms or the *working* indicator, or both, on the FMLI banner line. The argument *string* is a string to be displayed on the banner line, and should always be the last argument given. Note that *string* is not automatically cleared from the banner line.

- Options**
- b*n*            The -b option rings the terminal bell *n* times, where *n* is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen is flashed instead, if possible.
  - c *column*      The -c option defines the column of the banner line at which to start the indicator string. The argument *column* must be an integer from 0 to DISPLAYW-1. If the -c option is not used, *column* defaults to 0 .
  - l *length*       The -l option defines the maximum length of the string displayed. If *string* is longer than *length* characters, it will be truncated. The argument *length* must be an integer from 1 to DISPLAYW. If the -l option is not used, *length* defaults to DISPLAYW. Note that if *string* doesn't fit it will be truncated.
  - o                The -o option causes indicator to duplicate its output to *stdout* .
  - w                The -w option turns on the *working* indicator.

**Examples** **EXAMPLE 1** Using the indicator Command

When the value entered in a form field is invalid, the following use of indicator will ring the bell three times and display the word WRONG starting at column 1 of the banner line.

```
invalidmsg='indicator -b 3 -c 1 "WRONG"
```

To clear the indicator after telling the user the entry is wrong:

```
invalidmsg='indicator -b 9 -c 1 "WRONG"; sleep 3;
indicator -c 1 " "
```

In this example the value of invalidmsg (in this case the default value Input is not valid), still appears on the FMLI message line.

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [attributes\(5\)](#)

**Name** indxbib – create an inverted index to a bibliographic database

**Synopsis** indxbib *database-file*...

**Description** indxbib makes an inverted index to the named *database-file* (which must reside within the current directory), typically for use by [lookbib\(1\)](#) and [refer\(1\)](#). A *database* contains bibliographic references (or other kinds of information) separated by blank lines.

A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.

indxbib is a shell script that calls two programs: /usr/lib/refer/mkey and /usr/lib/refer/inv. mkey truncates words to 6 characters, and maps upper case to lower case. It also discards words shorter than 3 characters, words among the 100 most common English words, and numbers (dates) < 1000 or > 2099. These parameters can be changed.

indxbib creates an entry file (with a .ia suffix), a posting file (.ib), and a tag file (.ic), in the working directory.

**Files** /usr/lib/refer/mkey  
/usr/lib/refer/inv  
  
x.ia                   entry file  
x.ib                   posting file  
x.ic                   tag file  
x.ig                   reference file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**See Also** [addbib\(1\)](#), [lookbib\(1\)](#), [refer\(1\)](#), [roffbib\(1\)](#), [sortbib\(1\)](#), [attributes\(5\)](#)

**Bugs** All dates should probably be indexed, since many disciplines refer to literature written in the 1800s or earlier.

indxbib does not recognize pathnames.

**Name** install – install files

**Synopsis** /usr/ucb/install [-cs] [-g *group*] [-m *mode*]  
           [-o *owner*] *filename1 filename2*  
           /usr/ucb/install [-cs] [-g *group*] [-m *mode*]  
           [-o *owner*] *filename... directory*  
           /usr/ucb/install -d [-g *group*] [-m *mode*]  
           [-o *owner*] *directory*

**Description** install is used within makefiles to copy new versions of files into a destination directory and to create the destination directory itself.

The first two forms are similar to the [cp\(1\)](#) command with the addition that executable files can be stripped during the copy and the owner, group, and mode of the installed file(s) can be given.

The third form can be used to create a destination directory with the required owner, group and permissions.

Note: install uses no special privileges to copy files from one place to another. The implications of this are:

- You must have permission to read the files to be installed.
- You must have permission to copy into the destination file or directory.
- You must have permission to change the modes on the final copy of the file if you want to use the -m option to change modes.
- You must be superuser if you want to specify the ownership of the installed file with -o. If you are not the super-user, or if -o is not in effect, the installed file will be owned by you, regardless of who owns the original.

**Options**

|                 |                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c              | Copy files. In fact install <i>always</i> copies files, but the -c option is retained for backwards compatibility with old shell scripts that might otherwise break.                                   |
| -d              | Create a directory. Missing parent directories are created as required as in mkdir -p. If the directory already exists, the owner, group and mode will be set to the values given on the command line. |
| -s              | Strip executable files as they are copied.                                                                                                                                                             |
| -g <i>group</i> | Set the group ownership of the installed file or directory. (staff by default.)                                                                                                                        |
| -m <i>mode</i>  | Set the mode for the installed file or directory. (0755 by default.)                                                                                                                                   |
| -o <i>owner</i> | If run as root, set the ownership of the installed file to the user-ID of <i>owner</i> .                                                                                                               |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [chgrp\(1\)](#), [chmod\(1\)](#), [chown\(1\)](#), [cp\(1\)](#), [mkdir\(1\)](#), [strip\(1\)](#), [install\(1M\)](#), [attributes\(5\)](#)

**Name** ipcrm – remove a message queue, semaphore set, or shared memory ID

**Synopsis** ipcrm [-z *zone*] [-m *shmid*] [-q *msqid*] [-s *semid*]  
 [-M *shmkey*] [-Q *msgkey*] [-S *semkey*]

**Description** ipcrm removes one or more messages, semaphores, or shared memory identifiers.

**Options** The following option is supported:

-z *zone* Keys specified by other options refer to facilities in the specified zone (see [zones\(5\)](#)). The default is the zone in which the command is executing. This option is only useful when the command is executed in the global zone.

The identifiers are specified by the following options:

-m *shmid* Removes the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.

-q *msqid* Removes the message queue identifier *msqid* from the system and destroys the message queue and data structure associated with it.

-s *semid* Removes the semaphore identifier *semid* from the system and destroys the set of semaphores and data structure associated with it.

-M *shmkey* Removes the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.

-Q *msgkey* Removes the message queue identifier, created with key *msgkey*, from the system and destroys the message queue and data structure associated with it.

-S *semkey* Removes the semaphore identifier, created with key *semkey*, from the system and destroys the set of semaphores and data structure associated with it.

The details of the removes are described in [msgctl\(2\)](#), [shmctl\(2\)](#), and [semctl\(2\)](#). Use the `ipcs` command to find the identifiers and keys.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ipcrm: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWipc         |
| Interface Stability | Standard        |

**See Also** [ipcs\(1\)](#), [msgctl\(2\)](#), [msgget\(2\)](#), [msgrcv\(2\)](#), [msgsnd\(2\)](#), [semctl\(2\)](#), [semget\(2\)](#), [semop\(2\)](#), [shmctl\(2\)](#), [shmget\(2\)](#), [shmop\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#), [zones\(5\)](#)

**Name** ipcs – report inter-process communication facilities status

**Synopsis** ipcs [-aAbciJmopqstZ] [-D *mtype*] [-z *zone*]

**Description** The `ipcs` utility prints information about active inter-process communication facilities. The information that is displayed is controlled by the options supplied. Without options, information is printed in short format for message queues, shared memory, and semaphores that are currently active in the system.

**Options** The following options are supported:

- m Prints information about active shared memory segments.
- q Prints information about active message queues.
- s Prints information about active semaphores.

If -m, -q, or -s are specified, information about only those indicated is printed. If none of these three is specified, information about all three is printed subject to these options:

- a Uses all XCU5 print options. (This is a shorthand notation for -b, -c, -o, -p, and -t.)
- A Uses all print options. (This is a shorthand notation for -b, -c, -i, -J, -o, -p, and -t.)
- b Prints information on biggest allowable size: maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores. See below for meaning of columns in a listing.
- c Prints creator's login name and group name. See below.
- D *mtype* Displays, in hexadecimal and ASCII, the contents of all messages of type *mtype* found on any message queue that the user invoking `ipcs` has permission to read. If *mtype* is `0`, all messages are displayed. If *mtype* is negative, all messages with type less than or equal to the absolute value of *mtype* are displayed. (See [msgrcv\(2\)](#) and [msgsnap\(2\)](#)).
- i Prints number of ISM attaches to shared memory segments.
- J Prints the creator's project.
- o Prints information on outstanding usage: number of messages on queue and total number of bytes in messages on queue for message queues and number of processes attached to shared memory segments.
- p Prints process number information: process ID of last process to send a message, process ID of last process to receive a message on message queues, process ID of creating process, and process ID of last process to attach or detach on shared memory segments. See below.

- t Prints time information: time of the last control operation that changed the access permissions for all facilities, time of last [msgsnd\(2\)](#) and last [msgrcv\(2\)](#) on message queues, time of last [shmat\(2\)](#) and last [shmdt\(2\)](#) on shared memory (see [shmop\(2\)](#)), time of last [semop\(2\)](#) on semaphores. See below.
- z *zone* Prints information about facilities associated with the specified zone (see [zones\(5\)](#)). The zone can be specified as either a name or a numeric id. The default is to display information about the zone in which the command is executing. Notice that this option is only useful when executing in the global zone.
- Z When executing in the global zone, prints information about all zones. Otherwise, prints information about the zone in which the command is executing. The output includes the zone associated with each facility.

The column headings and the meaning of the columns in an `ipcs` listing are given below. The letters in parentheses indicate the options that cause the corresponding heading to appear and “all” means that the heading always appears. *Note:* These options only determine what information is provided for each facility; they do not determine which facilities are listed.

|            |                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T (all)    | Type of the facility: <ul style="list-style-type: none"> <li>q message queue</li> <li>m shared memory segment</li> <li>s semaphore</li> </ul>                                                                                                                                                                                                                         |
| ID (all)   | The identifier for the facility entry.                                                                                                                                                                                                                                                                                                                                |
| KEY (all)  | The key used as an argument to <a href="#">msgget(2)</a> , <a href="#">semget(2)</a> , or <a href="#">shmget(2)</a> to create the facility entry. ( <i>Note:</i> The key of a shared memory segment is changed to <code>IPC_PRIVATE</code> when the segment has been removed until all processes attached to the segment detach it.)                                  |
| MODE (all) | The facility access modes and flags: The mode consists of 11 characters that are interpreted as follows. The first two characters are: <ul style="list-style-type: none"> <li>R A process is waiting on a <a href="#">msgrcv(2)</a>.</li> <li>S A process is waiting on a <a href="#">msgsnd(2)</a>.</li> <li>- The corresponding special flag is not set.</li> </ul> |

The next nine characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is currently unused.

The permissions are indicated as follows:

- r    Read permission is granted.
- w    Write permission is granted.
- a    Alter permission is granted.
- The indicated permission is not granted.

|                 |                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------|
| OWNER (all)     | The login name of the owner of the facility entry.                                           |
| GROUP (all)     | The group name of the group of the owner of the facility entry.                              |
| CREATOR (a,A,c) | The login name of the creator of the facility entry.                                         |
| CGROUP (a,A,c)  | The group name of the group of the creator of the facility entry.                            |
| CBYTES (a,A,o)  | The number of bytes in messages currently outstanding on the associated message queue.       |
| QNUM (a,A,o)    | The number of messages currently outstanding on the associated message queue.                |
| QBYTES (a,A,b)  | The maximum number of bytes allowed in messages outstanding on the associated message queue. |
| LSPID (a,A,p)   | The process ID of the last process to send a message to the associated queue.                |
| LRPID (a,A,p)   | The process ID of the last process to receive a message from the associated queue.           |
| STIME (a,A,t)   | The time the last message was sent to the associated queue.                                  |
| RTIME (a,A,t)   | The time the last message was received from the associated queue.                            |
| CTIME (a,A,t)   | The time when the associated entry was created or changed.                                   |
| ISMATTCH (a,i)  | The number of ISM attaches to the associated shared memory segments.                         |
| NATTCH (a,A,o)  | The number of processes attached to the associated shared memory segment.                    |
| SEGSZ (a,A,b)   | The size of the associated shared memory segment.                                            |
| CPID (a,A,p)    | The process ID of the creator of the shared memory entry.                                    |
| LPID (a,A,p)    | The process ID of the last process to attach or detach the shared memory segment.            |
| ATIME (a,A,t)   | The time the last attach was completed to the associated shared memory segment.              |

|               |                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| DTIME (a,A,t) | The time the last detach was completed on the associated shared memory segment.                     |
| NSEMS (a,A,b) | The number of semaphores in the set associated with the semaphore entry.                            |
| OTIME (a,A,t) | The time the last semaphore operation was completed on the set associated with the semaphore entry. |
| PROJECT (J,A) | The project name of the creator of the facility entry.                                              |
| ZONE (Z)      | The zone with which the facility is associated.                                                     |

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ipcs: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

TZ Determine the timezone for the time strings written by ipcs.

|              |             |             |
|--------------|-------------|-------------|
| <b>Files</b> | /etc/group  | group names |
|              | /etc/passwd | user names  |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

|---------------------|------------------------------------|
| Availability        | SUNWipc                            |
| Interface Stability | Committed                          |
| Standard            | See <a href="#">standards(5)</a> . |

**See Also** [ipcrm\(1\)](#), [msgget\(2\)](#), [msgids\(2\)](#), [msgrcv\(2\)](#), [msgsnap\(2\)](#), [msgsnd\(2\)](#), [semget\(2\)](#), [semids\(2\)](#), [semop\(2\)](#), [shmctl\(2\)](#), [shmget\(2\)](#), [shmids\(2\)](#), [shmop\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#), [zones\(5\)](#)

**Notes** Things can change while ipcs is running. The information it gives is guaranteed to be accurate only when it was retrieved.

**Name** isainfo – describe instruction set architectures

**Synopsis** isainfo [ [-v] [-b | -n | -k] | [-x]]

**Description** The `isainfo` utility is used to identify various attributes of the instruction set architectures supported on the currently running system. Among the questions it can answer are whether 64-bit applications are supported, or whether the running kernel uses 32-bit or 64-bit device drivers.

When invoked with no options, `isainfo` prints the names of the native instruction sets for applications supported by the current version of the operating system. These are a subset of the list returned by `isalist(1)`. The subset corresponds to the basic applications environments supported by the currently running system.

**Options** The following options are supported:

- b Prints the number of bits in the address space of the native instruction set.
- k Prints the name of the instruction set(s) used by the operating system kernel components such as device drivers and STREAMS modules.
- n Prints the name of the native instruction set used by portable applications supported by the current version of the operating system.
- v When used with the -b, -k or -n options, prints more detailed information.
- x Prints instruction extensions to the native ABI which are supported by the platform.

**Examples** **EXAMPLE 1** Invoking `isainfo` on a 32-bit x86 Platform

The following example invokes `isainfo` on a 32-bit x86 platform:

```
example% isainfo -v
32-bit i386 applications
```

```
example% isainfo -k
i386
```

**EXAMPLE 2** Invoking `isainfo` on a System Running the 64-bit Operating System on a 64-bit SPARC Processor

The following example invokes `isainfo` on a system running the 64-bit operating system on a 64-bit SPARC processor:

```
example% isainfo
sparcv9 sparc
example% isainfo -n
sparcv9
example% isainfo -v
64-bit sparcv9 applications
32-bit sparc applications
example% isainfo -vk
```

**EXAMPLE 2** Invoking `isainfo` on a System Running the 64-bit Operating System on a 64-bit SPARC Processor *(Continued)*

64-bit sparcv9 kernel modules

**EXAMPLE 3** Invoking `isainfo -x` on an AMD Opteron CPU

The following example invokes `isainfo` with the `-x` option on an AMD Opteron CPU:

```
example% isainfo -x
i386: fpu tsc cx8 sep cmov mmx ammx a3dnow a3dnowx fxsr sse sse2 pause
```

**Exit Status** Non-zero Options are not specified correctly, or the command is unable to recognize attributes of the system on which it is running. An error message is printed to `stderr`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [isalist\(1\)](#), [uname\(1\)](#), [psrinfo\(1M\)](#), [sysinfo\(2\)](#), [attributes\(5\)](#), [isalist\(5\)](#)

**Name** isalist – display the native instruction sets executable on this platform

**Synopsis** isalist

**Description** isalist prints the names of the native instruction sets executable on this platform on the standard output, as returned by the SI\_ISALIST command of [sysinfo\(2\)](#).

The names are space-separated and are ordered in the sense of best performance. That is, earlier-named instruction sets may contain more instructions than later-named instruction sets; a program that is compiled for an earlier-named instruction sets will most likely run faster on this machine than the same program compiled for a later-named instruction set.

Programs compiled for instruction sets that do not appear in the list will most likely experience performance degradation or not run at all on this machine.

The instruction set names known to the system are listed in [isalist\(5\)](#). These names may or may not match predefined names or compiler options in the C language compilation system,

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [optisa\(1\)](#), [uname\(1\)](#), [sysinfo\(2\)](#), [attributes\(5\)](#), [isalist\(5\)](#)

**Name** jobs, fg, bg, stop, notify – control process execution

## Synopsis

```
sh jobs [-p | -l] [% job_id...]
 jobs -x command [arguments]
 fg [% job_id...]
 bg [% job_id...]
 stop % job_id...
 stop pid...

csh jobs [-l]
 fg [% job_id]
 bg [% job_id]...
 notify [% job_id]...
 stop % job_id...
 stop pid...

ksh jobs [-lnp] [% job_id...]
 fg [% job_id...]
 bg [% job_id...]
 stop % job_id...
 stop pid...
```

## Description

sh When Job Control is enabled, the Bourne shell built-in `jobs` reports all jobs that are stopped or executing in the background. If `%job_id` is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of `jobs`:

- l Reports the process group ID and working directory of the jobs.
- p Reports only the process group ID of the jobs.
- x Replaces any `job_id` found in `command` or `arguments` with the corresponding process group ID, and then executes `command` passing it `arguments`.

When the shell is invoked as `jsh`, Job Control is enabled in addition to all of the functionality described previously for `sh`. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled every command or pipeline the user enters at the terminal is called a *job\_id*. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows:

1. A job in the *foreground* has read and write access to the controlling terminal.
2. A job in the *background* is denied read access and has conditional write access to the controlling terminal (see [stty\(1\)](#))
3. A *stopped* job is a job that has been placed in a suspended state, usually as a result of a SIGTSTP signal (see [signal.h\(3HEAD\)](#)).

Every job that the shell starts is assigned a positive integer, called a *job\_id number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally, the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`%job_id`

where *job\_id* may be specified in any of the following formats:

- |                              |                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>% or +</code>          | for the current job                                                                                                                                                                                                                                 |
| <code>—</code>               | for the previous job                                                                                                                                                                                                                                |
| <code>?&lt;string&gt;</code> | specify the job for which the command line uniquely contains <i>string</i> .                                                                                                                                                                        |
| <code>n</code>               | for job number <i>n</i> , where <i>n</i> is a job number                                                                                                                                                                                            |
| <code>pref</code>            | where <i>pref</i> is a unique prefix of the command name (for example, if the command <code>ls -l name</code> were running in the background, it could be referred to as <code>%ls</code> ); <i>pref</i> cannot contain blanks unless it is quoted. |

When Job Control is enabled, `fg` resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If `%job_id` is omitted the current job is assumed.

When Job Control is enabled, `bg` resumes the execution of a stopped job in the background. If `%job_id` is omitted the current job is assumed.

`stop` stops the execution of a background job(s) by using its *job\_id*, or of any process by using its *pid*; see [ps\(1\)](#).

- `csh` The C shell built-in, `jobs`, without an argument, lists the active jobs under job control.
- `-l` List process IDs, in addition to the normal information.

The shell associates a numbered *job\_id* with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals

(typically Control-Z). When a command or command sequence (semicolon-separated list) is started in the background using the `&` metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the *current* job and is indicated with a `+`. The previous job is indicated with a `-`; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands.

A reference to a job begins with a `%`. By itself, the percent sign refers to the current job.

`%+ %%`      The current job.

`%-`          The previous job.

`%j`          Refer to job *j* as in: `'kill -9 %j'`. *j* can be a job number, or a string that uniquely specifies the command line by which it was started; `'fg %vi'` might bring a stopped *vi* job to the foreground, for instance.

`%?string`    Specify the job for which the command line uniquely contains *string*.

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the `'stty tostop'` command.

`fg` brings the current or specified *job\_id* into the foreground.

`bg` runs the current or specified jobs in the background.

`stop` stops the execution of a background job(s) by using its *job\_id*, or of any process by using its *pid*; see [ps\(1\)](#).

`noti fy` will notify the user asynchronously when the status of the current job or specified jobs changes.

`ks h jobs` displays the status of the jobs that were started in the current shell environment. When `jobs` reports the termination status of a job, the shell removes its process ID from the list of those "known in the current shell execution environment."

*job\_id* specifies the jobs for which the status is to be displayed. If no *job\_id* is given, the status information for all jobs will be displayed.

The following options will modify/enhance the output of `jobs`:

- l (The letter ell.) Provides more information about each job listed. This information includes the job number, current job, process group ID, state and the command that formed the job.
- n Displays only jobs that have stopped or exited since last notified.
- p Displays only the process IDs for the process group leaders of the selected jobs.

By default, `jobs` displays the status of all the stopped jobs, running background jobs, and all jobs whose status has changed and have not been reported by the shell.

If the `monitor` option of the `set` command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the `jobs` command, and assigns them small integer numbers. When a job is started asynchronously with `&`, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the job, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key `^Z` (Control-Z) which sends a `STOP` signal to the current job. The shell will then normally indicate that the job has been “Stopped” (see `OUTPUT` below), and print another prompt. You can then manipulate the state of this job, putting it in the background with the `bg` command, or run some other commands and then eventually bring the job back into the foreground with the foreground command `fg`. A `^Z` takes effect immediately and is like an interrupt, in that pending output and unread input are discarded when it is typed.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

- `%number` The job with the given number.
- `%string` Any job whose command line begins with *string*; works only in the interactive mode when the history file is active.
- `%%string` Any job whose command line contains *string*; works only in the interactive mode when the history file is active.
- `%%` Current job.
- `%+` Equivalent to `%%`.
- `%-` Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work. When the

monitor mode is on, each background job that completes triggers any trap set for CHLD. When you try to leave the shell while jobs are running or stopped, you will be warned that 'You have stopped (running) jobs.' You may use the `jobs` command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated.

`fg` will move a background job from the current environment into the foreground. Using `fg` to place a job in the foreground will remove its process ID from the list of those "known in the current shell execution environment." The `fg` command is available only on systems that support job control. If *job\_id* is not specified, the current job is brought into the foreground.

`bg` resumes suspended jobs from the current environment by running them as background jobs. If the job specified by *job\_id* is already a running background job, `bg` has no effect and will exit successfully. Using `bg` to place a job into the background causes its process ID to become "known in the current shell execution environment", as if it had been started as an asynchronous list. The `bg` command is available only on systems that support job control. If *job\_id* is not specified, the current job is placed in the background.

`stop` stops the execution of a background job(s) by using its *job\_id*, or of any process by using its *pid*. See [ps\(1\)](#).

**Output** If the `-p` option is specified, the output consists of one line for each process ID:

`%d\n", "process ID"`

Otherwise, if the `-l` option is not specified, the output is a series of lines of the form:

`"[%d] %c %s %s\n", job-number, current, state, command`

where the fields are as follows:

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>current</i>    | The character <code>+</code> identifies the job that would be used as a default for the <code>fg</code> or <code>bg</code> commands. This job can also be specified using the <i>job_id</i> <code>+</code> or <code>%</code> . The character <code>-</code> identifies the job that would become the default if the current default job were to exit; this job can also be specified using the <i>job_id</i> <code>-</code> . For other jobs, this field is a space character. At most, one job can be identified with <code>+</code> and at most one job can be identified with <code>-</code> . If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job. |
| <i>job-number</i> | A number that can be used to identify the process group to the <code>wait</code> , <code>fg</code> , <code>bg</code> , and <code>kill</code> utilities. Using these utilities, the job can be identified by prefixing the job number with <code>%</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>state</i>      | One of the following strings (in the POSIX Locale):                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Running             | Indicates that the job has not been suspended by a signal and has not exited.                                                                      |
| Done                | Indicates that the job completed and returned exit status zero.                                                                                    |
| Done( <i>code</i> ) | Indicates that the job completed normally and that it exited with the specified non-zero exit status, <i>code</i> , expressed as a decimal number. |
| Stopped             |                                                                                                                                                    |
| Stopped (SIGTSTP)   | Indicates that the job was suspended by the SIGTSTP signal.                                                                                        |
| Stopped (SIGSTOP)   | Indicates that the job was suspended by the SIGSTOP signal.                                                                                        |
| Stopped (SIGTTIN)   | Indicates that the job was suspended by the SIGTTIN signal.                                                                                        |
| Stopped (SIGTTOU)   | Indicates that the job was suspended by the SIGTTOU signal.                                                                                        |

The implementation may substitute the string Suspended in place of Stopped. If the job was terminated by a signal, the format of `state` is unspecified, but it will be visibly distinct from all of the other `state` formats shown here and will indicate the name or description of the signal causing the termination.

*command*      The associated command that was given to the shell.

If the `-l` option is specified, a field containing the process group ID is inserted before the `state` field. Also, more processes in a process group may be output on separate lines, using only the process ID and `command` fields.

**Environment Variables**    See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `jobs`, `fg`, and `bg`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status**    The following exit values are returned for `jobs`, `fg`, and `bg`:

- 0      Successful completion.
- >0    An error occurred.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

**Name** join – relational database operator

**Synopsis** join [-a *filename* | -v *filename*] [-1 *fieldnumber*]  
 [-2 *fieldnumber*] [-o *list*] [-e *string*] [-t *char*] *file1 file2*  
 join [-a *filename*] [-j *fieldnumber*] [-j1 *fieldnumber*]  
 [-j2 *fieldnumber*] [-o *list*] [-e *string*] [-t *char*] *file1 file2*

**Description** The join command forms, on the standard output, a join of the two relations specified by the lines of *file1* and *file2*.

There is one line in the output for each pair of lines in *file1* and *file2* that have identical join fields. The output line normally consists of the common field, then the rest of the line from *file1*, then the rest of the line from *file2*. This format can be changed by using the -o option (see below). The -a option can be used to add unmatched lines to the output. The -v option can be used to output only unmatched lines.

The default input field separators are blank, tab, or new-line. In this case, multiple separators count as one field separator, and leading separators are ignored. The default output field separator is a blank.

If the input files are not in the appropriate collating sequence, the results are unspecified.

**Options** Some of the options below use the argument *filename*. This argument should be a 1 or a 2 referring to either *file1* or *file2*, respectively.

- a *filename* In addition to the normal output, produce a line for each unpairable line in file *filename*, where *filename* is 1 or 2. If both -a 1 and -a 2 are specified, all unpairable lines will be output.
- e *string* Replace empty output fields in the list selected by option -o with the string *string*.
- j *fieldnumber* Equivalent to -1*fieldnumber* -2*fieldnumber*.
- j1 *fieldnumber* Equivalent to -1*fieldnumber*.
- j2 *fieldnumber* Equivalent to -2*fieldnumber*. Fields are numbered starting with 1.
- o *list* Each output line includes the fields specified in *list*. Fields selected by *list* that do not appear in the input will be treated as empty output fields. (See the -e option.) Each element of which has the either the form *filename.fieldnumber*, or 0, which represents the join field. The common field is not printed unless specifically requested.
- t *char* Use character *char* as a separator. Every appearance of *char* in a line is significant. The character *char* is used as the field separator for both input and output. With this option specified, the collating term should be the same as sort without the -b option.

- v *filenumber*      Instead of the default output, produce a line only for each unpairable line in *filenumber*, where *filenumber* is 1 or 2. If both -v 1 and -v 2 are specified, all unpairable lines will be output.
- 1 *fieldnumber*      Join on the *fieldnumber*th field of file 1. Fields are decimal integers starting with 1.
- 2 *fieldnumber*      Join on the *fieldnumber*th field of file 2. Fields are decimal integers starting with 1.

**Operands**    The following operands are supported:

- file1*
  - file2*      A path name of a file to be joined. If either of the *file1* or *file2* operands is -, the standard input is used in its place.
- file1* and *file2* must be sorted in increasing collating sequence as determined by LC\_COLLATE on the fields on which they are to be joined, normally the first in each line (see [sort\(1\)](#)).

**Usage**    See [largefile\(5\)](#) for the description of the behavior of join when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**Examples**    **EXAMPLE 1**    Joining the password file and group file

The following command line will join the password file and the group file, matching on the numeric group ID, and outputting the login name, the group name and the login directory. It is assumed that the files have been sorted in ASCII collating sequence on the group ID fields.

```
example% join -j1 4-j2 3 -o 1.1 2.1 1.6 -t:/etc/passwd /etc/group
```

**EXAMPLE 2**    Using the -o option

The -o 0 field essentially selects the union of the join fields. For example, given file phone:

```
!Name Phone Number
Don +1 123-456-7890
Hal +1 234-567-8901
Yasushi +2 345-678-9012
```

and file fax:

```
!Name Fax Number
Don +1 123-456-7899
Keith +1 456-789-0122
Yasushi +2 345-678-9011
```

**EXAMPLE 2** Using the -o option (Continued)

where the large expanses of white space are meant to each represent a single tab character), the command:

```
example% join -t"tab" -a 1 -a 2 -e '(unknown)' -o 0,1.2,2.2 phone fax
```

would produce

| !Name   | Phone Number    | Fax Number      |
|---------|-----------------|-----------------|
| Don     | +1 123-456-7890 | +1 123-456-7899 |
| Hal     | +1 234-567-8901 | (unknown        |
| Keith   | (unknown)       | +1 456-789-012  |
| Yasushi | +2 345-678-9012 | +2 345-678-9011 |

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of join: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, LC\_COLLATE, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 All input files were output successfully.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

**See Also** [awk\(1\)](#), [comm\(1\)](#), [sort\(1\)](#), [uniq\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** With default field separation, the collating sequence is that of sort -b; with -t, the sequence is that of a plain sort.

The conventions of the join, sort, comm, uniq, and awk commands are wildly incongruous.

| <b>Description</b>          | The kbd utility manipulates the state of the keyboard, or displays the keyboard type, or allows the default keyboard abort sequence effect to be changed. The abort sequence also applies to serial console devices. The kbd utility sets the /dev/kbd default keyboard device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Extended Description</b> | <p>The -i option reads and processes default values for the keyclick and keyboard abort settings from the /etc/default/kbd keyboard default file. Only keyboards that support a clicker respond to the -c option. To turn clicking on by default, add or change the value of the KEYCLICK variable in the /etc/default/kbd file to:</p> <pre>KEYCLICK=on</pre> <p>Next, run the command kbd -i to change the setting. Valid settings for the KEYCLICK variable are on and off; all other values are ignored. If the KEYCLICK variable is not specified in the default file, the setting is unchanged.</p> <p>The keyboard abort sequence effect can only be changed by a super-user using the -a option. This sequence is typically Stop-A or L1-A and Shift-Pause on the keyboard on SPARC systems, F1-A and Shift-Pause on x86 systems, and BREAK on the serial console input device on most systems.</p> <p>A BREAK condition that originates from an erroneous electrical signal cannot be distinguished from one deliberately sent by remote DCE. As a remedy, use the -a option with Alternate Break to switch break interpretation. Due to the risk of incorrect sequence interpretation, binary protocols such as SLIP and others should not be run over the serial console port when Alternate Break sequence is in effect.</p> <p>Although PPP is a binary protocol, it has the ability to avoid using characters that interfere with serial operation. The default alternate break sequence is CTRL-m ~ CTRL-b, or 0D 7E 02 in hexadecimal. In PPP, this can be avoided by setting either 0x00000004 or 0x00002000 in the ACCM. This forces an escape for the CTRL-b or CTRL-m characters, respectively.</p> <p>To do this in Solaris PPP 4.0, add:</p> <pre>asynctmap 0x00002000</pre> <p>to the /etc/ppp/options file or any of the other configuration files used for the connection. See <a href="#">pppd(1M)</a>.</p> <p>SLIP has no comparable capability, and must not be used if the Alternate Break sequence is in use.</p> |

The Alternate Break sequence has no effect on the keyboard abort. For more information on the Alternate Break sequence, see [zs\(7D\)](#), [se\(7D\)](#), and [asy\(7D\)](#).

On many systems, the default effect of the keyboard abort sequence is to suspend the operating system and enter the debugger or the monitor. Some systems feature key switches with a secure position. On these systems, setting the key switch to the secure position overrides any software default set with this command.

To permanently change the software default effect of the keyboard abort sequence, first add or change the value of the `KEYBOARD_ABORT` variable in the `/etc/default/kbd` file to:

```
KEYBOARD_ABORT=disable
```

Next, run the command `kbd -i` to change the setting. Valid settings are `enable`, `disable`, and `alternate`; all other values are ignored. If the variable is not specified in the default file, the setting is unchanged.

To set the abort sequence to the hardware BREAK, set the value of the `KEYBOARD_ABORT` variable in the `/etc/default/kbd` file to:

```
KEYBOARD_ABORT=enable
```

To change the current setting, run the command `kbd -i`. To set the abort sequence to the Alternate Break character sequence, first set the current value of the `KEYBOARD_ABORT` variable in the `/etc/default/kbd` file to:

```
KEYBOARD_ABORT=alternate
```

Next, run the command `kbd -i` to change the setting. When the Alternate Break sequence is in effect, only serial console devices are affected.

To set the autorepeat delay by default, set the `REPEAT_DELAY` variable in the file `/etc/default/kbd` to the expected value with units in milliseconds (ms). To avoid making the keyboard unusable due to a typographical error, delay values below `KIOCRPTDELAY_MIN` (defined in `/usr/include/sys/kbio.h`) are rejected with `EINVAL`:

```
REPEAT_DELAY=500
```

To set the autorepeat rate by default, set the `REPEAT_RATE` variable in the file `/etc/default/kbd` to the expected value with units in milliseconds. Negative and zero repeat rates will be rejected with `EINVAL`:

```
REPEAT_RATE=33
```

To change the current settings of *delay* and *rate*, run the command, `kbd -i`. When the Auto Repeat Delay and/or Auto Repeat Rate are in effect, only command line mode is affected.

To set the language by default, set the `LAYOUT` variable in the file `/etc/default/kbd` to the expected language. These languages supported in kernel can be found by running `kbd -s`. Other values are ignored. For example, the following sets Spanish layout to the keyboard:

LAYOUT=Spanish

Next, run the `kbd -i` to change the setting. When Solaris reboots, the Spanish key table is loaded into kernel. These layouts are valid for usb and ps/2 keyboards.

**Options** The following options are supported:

`-a enable | disable | alternate`

Enables, disables, or alternates the keyboard abort sequence effect. By default, a keyboard abort sequence (typically Stop-A or L1-A on the keyboard and BREAK on the serial console device) suspends the operating system on most systems. The default keyboard behavior can be changed using this option. The `-a` option can only be used by a super-user.

`enable` Enables the default effect of the keyboard abort sequence (suspend the operating system and enter the debugger or the monitor).

`disable` Disables the default/alternate effect and ignores keyboard abort sequences.

`alternate` Enables the alternate effect of the keyboard abort sequences (suspend the operating system and enter the debugger or the monitor) upon receiving the Alternate Break character sequence on the console. The Alternate Break sequence is defined by the drivers [zs\(7D\)](#), [se\(7D\)](#), [asy\(7D\)](#). Due to a risk of incorrect sequence interpretation, binary protocols cannot be run over the serial console port when this value is used.

`-c on | off`

Turns the clicking of the keyboard on or off.

`on` Enables clicking

`off` Disables clicking

`-d keyboard device`

Specifies the keyboard device being set. The default setting is `/dev/kbd`.

`-D autorepeat delay`

Sets the autorepeat delay in milliseconds.

`-i`

Sets keyboard defaults from the keyboard default file. With the exception of `-d keyboard device`, this option cannot be used with any other option. The `-i` option instructs the keyboard command to read and process keyclick and keyboard abort default values from the `/etc/default/kbd` file. The `-i` option can only be used by a user or role with the Device Security Rights Profile.

`-l`

Returns the layout code of the keyboard being used, and the autorepeat delay and autorepeat rate being used.

-r  
Resets the keyboard as if power-up.

-R *autorepeat rate*  
Sets the autorepeat rate in milliseconds.

-s [*language*]  
Sets the keyboard layout into kernel.

If *language* is specified, the layout is set to *language*. If *language* is not specified, a list of available layouts are presented, prompting for the user to specify the *language*. See OPERANDS.

-t  
Returns the type of the keyboard being used.

**Operands** The following operands are supported:

*language* The language specified to be set in kernel. If the language is not found, the languages supported are listed for selection. It only applies to -s option.

**Examples** **EXAMPLE 1** Displaying the Keyboard Type

The following command displays the keyboard type:

```
example% kbd -t
Type 4 Sun keyboard
example%
```

**EXAMPLE 2** Setting Keyboard Defaults

The following command sets the keyboard defaults as specified in the keyboard default file:

```
example# kbd -i
example#
```

**EXAMPLE 3** Displaying Information

The following command displays keyboard type and layout code. It also displays auto repeat delay and rate settings.

```
example% kbd -l
type=4
layout=43 (0x2b)
delay(ms)=500
rate(ms)=33
example%
```

**EXAMPLE 4** Setting Keyboard Autorepeat Delay

The following command sets the keyboard autorepeat delay:

EXAMPLE 4 Setting Keyboard Autorepeat Delay (Continued)

```
example% kbd -D 300
example%
```

EXAMPLE 5 Setting Keyboard Autorepeat Rate

The following command sets the keyboard autorepeat rate:

```
example% kbd -R 50
example%
```

EXAMPLE 6 Selecting and Setting the Keyboard Language

The following example selects and sets the keyboard language from a list of languages specified:

```
example% kbd -s
1. Albanian
2. Belarusian
3. Belgian
4. Bulgarian
5. Croatian
6. Danish
7. Dutch
.....
16. Malta_UK
17. Malta_US
18. Norwegian
19. Portuguese
20. Russian
21. Serbia-And-Montenegro
22. Slove
```

To select the keyboard layout, enter a number [default n]:

```
example%
```

The following example sets the keyboard language specified:

```
example% kbd -s Dutch
example%
```

|              |                  |                                                                                 |
|--------------|------------------|---------------------------------------------------------------------------------|
| <b>Files</b> | /dev/kbd         | Keyboard device file.                                                           |
|              | /etc/default/kbd | Keyboard default file containing software defaults for keyboard configurations. |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [loadkeys\(1\)](#), [svcs\(1\)](#), [inetd\(1M\)](#), [inetadm\(1M\)](#), [kadb\(1M\)](#), [svcadm\(1M\)](#), [pppd\(1M\)](#), [keytables\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [kb\(7M\)](#), [zs\(7D\)](#), [se\(7D\)](#), [asy\(7D\)](#)

**Notes** Some server systems have key switches with a secure key position that can be read by system software. This key position overrides the normal default of the keyboard abort sequence effect and changes the default so the effect is disabled. When the key switch is in the secure position on these systems, the keyboard abort sequence effect cannot be overridden by the software default, which is settable with the `kbd` utility.

Currently, there is no way to determine the state of the keyboard click setting.

The `kdb` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/keymap:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

**Name** kdestroy – destroy Kerberos tickets

**Synopsis** /usr/bin/kdestroy [-q] [-c *cache\_name*]

**Description** The `kdestroy` utility destroys the user's active Kerberos authorization tickets by writing zeros to the specified credentials cache that contains them. If the credentials cache is not specified, the default credentials cache is destroyed. If the credentials cache does not exist, `kdestroy` displays a message to that effect.

After overwriting the cache, `kdestroy` removes the cache from the system. The utility displays a message indicating the success or failure of the operation. If `kdestroy` is unable to destroy the cache, it will warn you by making your terminal beep.

If desired, you can place the `kdestroy` command in your `.logout` file so that your tickets are destroyed automatically when you logout.

**Options** The following options are supported:

- c *cache\_name* Uses *cache\_name* as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used.
- q Runs quietly. Your terminal will not beep when `kdestroy` fails to destroy the tickets.

**Environment Variables** `kdestroy` uses the following environment variable:

KRB5CCNAME Location of the credentials (ticket) cache. See [krb5envvar\(5\)](#) for syntax and details.

**Files** /tmp/krb5cc\_*uid* Default credentials cache (*uid* is the decimal UID of the user).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWkrbu        |
| Interface Stability | Evolving        |
| Command arguments   | Evolving        |
| Command output      | Unstable        |

**See Also** [kinit\(1\)](#), [klist\(1\)](#), [attributes\(5\)](#), [kerberos\(5\)](#), [krb5envvar\(5\)](#)

**Bugs** Only the tickets in the specified credentials cache are destroyed. Separate ticket caches are used to hold root instance and password changing tickets. These files should probably be destroyed too, or all of a user's tickets should be kept in a single credential cache.

**Authors** Steve Miller, MIT Project Athena/Digital Equipment Corporation; Clifford Neuman, MIT Project Athena Bill Sommerfeld, MIT Project Athena

**Name** keylogin – decrypt and store secret key with keyserv

**Synopsis** /usr/bin/keylogin [-r]

**Description** The keylogin command prompts for a password, and uses it to decrypt the user's secret key. The key can be found in the /etc/publickey file (see [publickey\(4\)](#)) or the NIS map "publickey.byname" or the NIS+ table "cred.org\_dir" in the user's home domain. The sources and their lookup order are specified in the /etc/nsswitch.conf file. See [nsswitch.conf\(4\)](#). Once decrypted, the user's secret key is stored by the local key server process, [keyserv\(1M\)](#). This stored key is used when issuing requests to any secure RPC services, such as NFS or NIS+. The program [keylogout\(1\)](#) can be used to delete the key stored by keyserv .

keylogin fails if it cannot get the caller's key, or the password given is incorrect. For a new user or host, a new key can be added using [newkey\(1M\)](#), [nisaddcred\(1M\)](#), or [nisclient\(1M\)](#).

If multiple authentication mechanisms are configured for the system, each of the configured mechanism's secret key is decrypted and stored by [keyserv\(1M\)](#). See [nisauthconf\(1M\)](#) for information on configuring multiple authentication mechanisms.

**Options** The following options are supported:

- r Update the /etc/.rootkey file. This file holds the unencrypted secret key of the superuser. Only the superuser can use this option. It is used so that processes running as superuser can issue authenticated requests without requiring that the administrator explicitly run keylogin as superuser at system startup time. See [keyserv\(1M\)](#). The -r option should be used by the administrator when the host's entry in the publickey database has changed, and the /etc/.rootkey file has become out-of-date with respect to the actual key pair stored in the publickey database. The permissions on the /etc/.rootkey file are such that it can be read and written by the superuser but by no other user on the system.

If multiple authentication mechanisms are configured for the system, each of the configured mechanism's secret keys is stored in the /etc/.rootkey file.

**Files** /etc/.rootkey superuser's secret key

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [chkey\(1\)](#), [keylogout\(1\)](#), [login\(1\)](#), [keyserv\(1M\)](#), [newkey\(1M\)](#), [nisaddcred\(1M\)](#), [nisauthconf\(1M\)](#), [nisclient\(1M\)](#), [nsswitch.conf\(4\)](#), [publickey\(4\)](#), [attributes\(5\)](#)

**Notes** NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

**Name** keylogout – delete stored secret key with keyserv

**Synopsis** /usr/bin/keylogout [-f]

**Description** keylogout deletes the key stored by the key server process [keyserv\(1M\)](#). Further access to the key is revoked; however, current session keys might remain valid until they expire or are refreshed.

Deleting the keys stored by keyserv causes any background jobs or scheduled [at\(1\)](#) jobs that need secure RPC services to fail. Since only one copy of the key is kept on a machine, it is a bad idea to place a call to this command in your .logout file since it affects other sessions on the same machine.

If multiple NIS+ authentication mechanisms are configured for the system, then all keys stored by the key server process is deleted, including keys that are no longer configured.

**Options** The following options are supported:

- f Force keylogout to delete the secret key for the superuser. By default, keylogout by the superuser is disallowed because it would break all RPC services, such as NFS, that are started by the superuser.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [at\(1\)](#), [chkey\(1\)](#), [login\(1\)](#), [keylogin\(1\)](#), [keyserv\(1M\)](#), [newkey\(1M\)](#), [nisauthconf\(1M\)](#), [publickey\(4\)](#), [attributes\(5\)](#)

**Notes** NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

**Name** kill – terminate or signal processes

**Synopsis** /usr/bin/kill -s *signal\_name* *pid*...  
 /usr/bin/kill -l [*exit\_status*]  
 /usr/bin/kill [-*signal\_name*] *pid*...  
 /usr/bin/kill [-*signal\_number*] *pid*...

**Description** The kill utility sends a signal to the process or processes specified by each *pid* operand.

For each *pid* operand, the kill utility will perform actions equivalent to the [kill\(2\)](#) function called with the following arguments:

1. The value of the *pid* operand will be used as the *pid* argument.
2. The *sig* argument is the value specified by the -s option, the -*signal\_name* option, or the -*signal\_number* option, or, if none of these options is specified, by SIGTERM.

The signaled process must belong to the current user unless the user is the super-user.

See NOTES for descriptions of the shell built-in versions of kill.

**Options** The following options are supported:

- l (The letter ell.) Writes all values of *signal\_name* supported by the implementation, if no operand is given. If an *exit\_status* operand is given and it is a value of the ? shell special parameter and wait corresponding to a process that was terminated by a signal, the *signal\_name* corresponding to the signal that terminated the process will be written. If an *exit\_status* operand is given and it is the unsigned decimal integer value of a signal number, the *signal\_name* corresponding to that signal will be written. Otherwise, the results are unspecified.
- s *signal\_name* Specifies the signal to send, using one of the symbolic names defined in the <signal.h> description. Values of *signal\_name* will be recognized in a case-independent fashion, without the SIG prefix. In addition, the symbolic name 0 will be recognized, representing the signal value zero. The corresponding signal will be sent instead of SIGTERM.
- signal\_name* Equivalent to -s *signal\_name*.
- signal\_number* Specifies a non-negative decimal integer, *signal\_number*, representing the signal to be used instead of SIGTERM, as the *sig* argument in the effective call to [kill\(2\)](#).

**Operands** The following operands are supported:

*pid* One of the following:

1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative and zero values of the *pid* operand will be as described for the kill function. If process number 0 is specified, all processes in the process group are signaled. If the first *pid* operand is negative, it should be preceded by — to keep it from being interpreted as an option.
2. A job control job ID that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of kill in the current shell execution environment.

*Note:* The job control job ID type of *pid* is available only on systems supporting the job control option.

*exit\_status*     A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

**Usage**     Process numbers can be found by using [ps\(1\)](#).

The job control job ID notation is not required to work as expected when kill is operating in its own utility execution environment. In either of the following examples:

```
example% nohup kill %1 &
example% system("kill %1");
```

kill operates in a different environment and will not share the shell's understanding of job numbers.

**Output**     When the -l option is not specified, the standard output will not be used.

When the -l option is specified, the symbolic name of each signal will be written in the following format:

```
"%s%c", <signal_name>, <separator>
```

where the *<signal\_name>* is in upper-case, without the SIG prefix, and the *<separator>* will be either a newline character or a space character. For the last signal written, *<separator>* will be a newline character.

When both the -l option and *exit\_status* operand are specified, the symbolic name of the corresponding signal will be written in the following format:

```
"%s\n", <signal_name>
```

**Examples**     **EXAMPLE 1**     Sending the kill signal

Any of the commands:

**EXAMPLE 1** Sending the kill signal (Continued)

```
example% kill -9 100 -165
example% kill -s kill 100 -165
example% kill -s KILL 100 -165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

**EXAMPLE 2** Avoiding ambiguity with an initial negative number

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, the former will always be the case. Therefore, to send the default signal to a process group (for example, 123), an application should use a command similar to one of the following:

```
example% kill -TERM -123
example% kill -- -123
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `kill`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 At least one matching process was found for each *pid* operand, and the specified signal was successfully processed for at least one matching process.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | enabled         |
| Interface Stability | Standard        |

**See Also** [csh\(1\)](#), [jobs\(1\)](#), [ksh\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [shell\\_builtins\(1\)](#), [wait\(1\)](#), [kill\(2\)](#), [signal\(3C\)](#), [signal.h\(3HEAD\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes**

- sh The Bourne shell, `sh`, has a built-in version of `kill` to provide the functionality of the `kill` command for processes identified with a *jobid*. The `sh` syntax is:

```
kill [-sig] [pid] [%job]...
kill -l
```

csh The C-shell, csh, also has a built-in `kill` command, whose syntax is:

```
kill [-sig][pid][%job]...
kill -l
```

The csh `kill` built-in sends the `TERM` (terminate) signal, by default, or the signal specified, to the specified process ID, the *job* indicated, or the current *job*. Signals are either given by number or by name. There is no default. Typing `kill` does not send a signal to the current job. If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process is sent a `CONT` (continue) signal as well.

`-l` Lists the signal names that can be sent.

ksh The syntax of the ksh `kill` is:

```
kill [-sig][pid][%job]...
kill -l
```

The ksh `kill` sends either the `TERM` (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in [signal.h\(3HEAD\)](#) stripped of the `SIG` prefix). If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process will be sent a `CONT` (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. In the second form, `kill -l`, the signal numbers and names are listed.

**Name** kinit – obtain and cache Kerberos ticket-granting ticket

**Synopsis** /usr/bin/kinit [-ARvV] [-p | -P] [-f | -F] [-a] [-c *cache\_name*]  
 [-k [-t *keytab\_file*]] [-l *lifetime*]  
 [-r *renewable\_life*] [-s *start\_time*] [-S *service\_name*]  
 [*principal*]

**Description** The `kinit` command is used to obtain and cache an initial ticket-granting ticket (credential) for *principal*. This ticket is used for authentication by the Kerberos system. Notice that only users with Kerberos principals can use the Kerberos system. For information about Kerberos principals, see [kerberos\(5\)](#).

When you use `kinit` without options, the utility prompts for your *principal* and Kerberos password, and tries to authenticate your login with the local Kerberos server. The *principal* can be specified on the command line if desired.

If Kerberos authenticates the login attempt, `kinit` retrieves your initial ticket-granting ticket and puts it in the ticket cache. By default your ticket will be stored in the file `/tmp/krb5cc_uid`, where *uid* specifies your user identification number. Tickets expire after a specified lifetime, after which `kinit` must be run again. Any existing contents of the cache are destroyed by `kinit`.

Values specified in the command line override the values specified in the Kerberos configuration file for *lifetime* and *renewable\_life*.

The [kdestroy\(1\)](#) command may be used to destroy any active tickets before you end your login session.

**Options** The following options are supported:

- a Requests tickets with the local addresses.
- A Requests address-less tickets.
- c *cache\_name* Uses *cache\_name* as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used.
- f Requests forwardable tickets.
- F Not forwardable. Does not request forwardable tickets.

Tickets that have been acquired on one host cannot normally be used on another host. A client can request that the ticket be marked forwardable. Once the `TKT_FLG_FORWARDABLE` flag is set on a ticket, the user can use this ticket to request a new ticket, but with a different IP address. Thus, users can use their current credentials to get credentials valid on another machine. This option allows a user to explicitly obtain a non-forwardable ticket.

- `-k [-t keytab_file]` Requests a host ticket, obtained from a key in the local host's *keytab* file. The name and location of the keytab file may be specified with the `-t keytab_file` option. Otherwise, the default name and location will be used.
- `-l lifetime` Requests a ticket with the lifetime *lifetime*. If the `-l` option is not specified, the default ticket lifetime (configured by each site) is used. Specifying a ticket lifetime longer than the maximum ticket lifetime (configured by each site) results in a ticket with the maximum lifetime. See the Time Formats section for the valid time duration formats that you can specify for *lifetime*. See [kdc.conf\(4\)](#) and [kadmin\(1M\)](#) (for `getprinc` command to verify the lifetime values for the server principal).
- The lifetime of the tickets returned will be the minimum of the following:
- Value specified in the command line.
  - Value specified in the KDC configuration file.
  - Value specified in the Kerberos data base for the server principal. In the case of `kinit`, it is `krbtgt/realmsname`.
  - Value specified in the Kerberos database for the user principal.
- `-p` Requests proxiable tickets.
- `-P` Not proxiable. Does not request proxiable tickets.
- A proxiable ticket is a ticket that allows you to get a ticket for a service with IP addresses other than the ones in the Ticket Granting Ticket. This option allows a user to explicitly obtain a non-proxiable ticket.
- `-r renewable_life` Requests renewable tickets, with a total lifetime of *renewable\_life*. See the Time Formats section for the valid time duration formats that you can specify for *renewable\_life*. See [kdc.conf\(4\)](#) and [kadmin\(1M\)](#) (for `getprinc` command to verify the lifetime values for the server principal).
- The renewable lifetime of the tickets returned will be the minimum of the following:
- Value specified in the command line.
  - Value specified in the KDC configuration file.
  - Value specified in the Kerberos data base for the server principal. In the case of `kinit`, it is `krbtgt/realmsname`.
  - Value specified in the Kerberos database for the user principal.

- R Requests renewal of the ticket-granting ticket. Notice that an expired ticket cannot be renewed, even if the ticket is still within its renewable life.
- s *start\_time* Requests a postdated ticket, valid starting at *start\_time*. Postdated tickets are issued with the *invalid* flag set, and need to be fed back to the KDC before use. See the Time Formats section for either the valid absolute time or time duration formats that you can specify for *start\_time*. kinit attempts to match an absolute time first before trying to match a time duration.
- S *service\_name* Specifies an alternate service name to use when getting initial tickets.
- v Requests that the ticket granting ticket in the cache (with the *invalid* flag set) be passed to the KDC for validation. If the ticket is within its requested time range, the cache is replaced with the validated ticket.
- V Verbose output. Displays further information to the user, such as confirmation of authentication and version.

Time Formats    The following absolute time formats can be used for the -s *start\_time* option. The examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

| Absolute Time Format                      | Example               |
|-------------------------------------------|-----------------------|
| <i>yyymmddhhmm</i> [ <i>ss</i> ]          | 990702133530          |
| <i>hhmm</i> [ <i>ss</i> ]                 | 133530                |
| <i>yy.mm.dd.hh.mm.ss</i>                  | 99:07:02:13:35:30     |
| <i>hh:mm</i> [ <i>:ss</i> ]               | 13:35:30              |
| <i>ldate:ltime</i>                        | 07-07-99:13:35:30     |
| <i>dd-month-yyyy:hh:mm</i> [ <i>:ss</i> ] | 02-july-1999:13:35:30 |

| Variable  | Description                                                       |
|-----------|-------------------------------------------------------------------|
| <i>dd</i> | day                                                               |
| <i>hh</i> | hour (24-hour clock)                                              |
| <i>mm</i> | minutes                                                           |
| <i>ss</i> | seconds                                                           |
| <i>yy</i> | year within century (0-68 is 2000 to 2068; 69-99 is 1969 to 1999) |

| Variable     | Description                              |
|--------------|------------------------------------------|
| <i>yyyy</i>  | year including century                   |
| <i>month</i> | locale's full or abbreviated month name  |
| <i>ldate</i> | locale's appropriate date representation |
| <i>ltime</i> | locale's appropriate time representation |

The following time duration formats can be used for the *-l lifetime*, *-r renewable\_life*, and *-s start\_time* options. The examples are based on the time duration of 14 days, 7 hours, 5 minutes, and 30 seconds.

| Time Duration Format | Example     |
|----------------------|-------------|
| <i>#d</i>            | 14d         |
| <i>#h</i>            | 7h          |
| <i>#m</i>            | 5m          |
| <i>#s</i>            | 30s         |
| <i>#d#h#m#s</i>      | 14d7h5m30s  |
| <i>#h#m[#s]</i>      | 7h5m30s     |
| <i>days-hh:mm:ss</i> | 14-07:05:30 |
| <i>hours:mm[:ss]</i> | 7:05:30     |

| Delimiter | Description       |
|-----------|-------------------|
| <i>d</i>  | number of days    |
| <i>h</i>  | number of hours   |
| <i>m</i>  | number of minutes |
| <i>s</i>  | number of seconds |

| Variable     | Description          |
|--------------|----------------------|
| <i>#</i>     | number               |
| <i>days</i>  | number of days       |
| <i>hours</i> | number of hours      |
| <i>hh</i>    | hour (24-hour clock) |

| Variable  | Description |
|-----------|-------------|
| <i>mm</i> | minutes     |
| <i>ss</i> | seconds     |

- Environment Variables** `kinit` uses the following environment variable:
- `KRB5CCNAME` Location of the credentials (ticket) cache. See [krb5envvar\(5\)](#) for syntax and details.
- Files**
- `/tmp/krb5cc_uid` Default credentials cache (*uid* is the decimal UID of the user).
  - `/etc/krb5/krb5.keytab` Default location for the local host's keytab file.
  - `/etc/krb5/krb5.conf` Default location for the local host's configuration file. See [krb5.conf\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWkrbu        |
| Interface Stability | See below.      |

The command arguments are Evolving. The command output is Unstable.

- See Also** [kdestroy\(1\)](#), [klist\(1\)](#), [kadmin\(1M\)](#), [kttkt\\_warnd\(1M\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#), [krb5envvar\(5\)](#), [pam\\_krb5\(5\)](#)
- Notes** On success, `kinit` notifies [kttkt\\_warnd\(1M\)](#) to alert the user when the initial credentials (ticket-granting ticket) are about to expire.

**Name** klist – list currently held Kerberos tickets

**Synopsis** /usr/bin/klist [-e]  
          [ [-c] [-f] [-s] [-a [-n]] [*cache\_name*]]  
          [-k [-t] [-K] [*keytab\_file*]]

**Description** The `klist` utility prints the name of the credentials cache, the identity of the principal that the tickets are for (as listed in the ticket file), and the principal names of all Kerberos tickets currently held by the user, along with the issue and expiration time for each authenticator. Principal names are listed in the form *name/instance@realm*, with the '/' omitted if the instance is not included, and the '@' omitted if the realm is not included.

If *cache\_file* or *keytab\_name* is not specified, `klist` displays the credentials in the default credentials cache or keytab files as appropriate. By default, your ticket is stored in the file `/tmp/krb5cc_`*uid*, where *uid* is the current user-ID of the user.

**Options** The following options are supported:

- a                   Displays list of addresses in credentials. Uses the configured nameservice to translate numeric network addresses to the associated hostname if possible.
- c [*cache\_name*]   Lists tickets held in a credentials cache. This is the default if neither -c nor -k is specified.
- e                   Displays the encryption types of the session key and the ticket for each credential in the credential cache, or each key in the keytab file.
- f                   Shows the flags present in the credentials, using the following abbreviations:
  - a    Anonymous
  - A    Pre-authenticated
  - d    Post-dated
  - D    Post-dateable
  - f    Forwarded
  - F    Forwardable
  - H    Hardware authenticated
  - i    Invalid
  - I    Initial
  - O    Okay as delegate
  - p    Proxy
  - P    Proxiabile

- R     Renewable
- T     Transit policy checked
- k [*keytab\_file*]     List keys held in a keytab file.
- K     Displays the value of the encryption key in each keytab entry in the keytab file.
- n     Shows numeric IP addresses instead of reverse-resolving addresses. Only valid with -a option.
- s     Causes `klis` to run silently (produce no output), but to still set the exit status according to whether it finds the credentials cache. The exit status is 0 if `klis` finds a credentials cache, and '1 if it does not, or if the local-realm TGT has expired.
- t     Displays the time entry timestamps for each keytab entry in the keytab file.

Environment Variables

klis uses the following environment variable:

KRB5CCNAME     Location of the credentials (ticket) cache. See [krb5envvar\(5\)](#) for syntax and details.

Files

/tmp/krb5cc\_*uid*     Default credentials cache (*uid* is the decimal UID of the user).

/etc/krb5/krb5.keytab     Default location for the local host's keytab file.

/etc/krb5/krb5.conf     Default location for the local host's configuration file. See [krb5.conf\(4\)](#).

**Attributes**     See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWkrbu        |
| Interface Stability | See below.      |

The command arguments are Evolving. The command output is Unstable.

**See Also**     [kdestroy\(1\)](#), [kinit\(1\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [krb5envvar\(5\)](#), [kerberos\(5\)](#)

**Bugs**     When reading a file as a service key file, very little error checking is performed.

**Name** kmdb – in situ kernel debugger

## Synopsis

Boot-time Loading SPARC

```
ok boot [device-specifier] -k [-d] [boot-flags]
```

```
ok boot [device-specifier] kmdb [-d] [boot-flags]
```

x86

```
kernel /platform/i86pc/multiboot -k [-d] [boot-flags]
```

```
kernel /platform/i86pc/multiboot kmdb [ab-d] [boot-flags]
```

Runtime Loading mdb -K

**Description** kmdb is an interactive kernel debugger which implements the user interface and functionality of [mdb\(1\)](#) in a live kernel context. kmdb provides features that allow for the control of kernel execution and for the inspection and modification of live kernel state. kmdb can be loaded at the beginning of a boot session or after the system is booted.

This man page describes the features and functionality that are unique to kmdb or different in kmdb as compared to [mdb\(1\)](#). For more information on [mdb\(1\)](#) or further details on the features and functionality implemented by kmdb, see the [mdb\(1\)](#) man page and the *Solaris Modular Debugger Guide*.

Loading and Unloading Boot-time Loading

When requested, the kernel runtime linker (`krtld`) loads kmdb prior to the transfer of control to the kernel. If the `-d` flag is used, the debugger gains control of the system prior to the execution of the initial function in the 'unix' object. If `-d` is not used, kmdb is loaded but does not gain control until such time as it is explicitly entered. See the Debugger Entry section below. For a list of the boot commands which cause kmdb to be loaded at boot, see the SYNOPSIS section above.

Boot-loaded kmdb can be unloaded only by means of a system reboot.

Some features of kmdb rely on the presence of kernel services and are not immediately available to boot-loaded kmdb. In particular, the loading and unloading of dmods is not available until the module subsystem is initialized. Requests are queued until they can be processed. Similarly, translation of virtual addresses to physical addresses is not be available until the VM system has been initialized. Attempted translations fail until translation facilities are available.

Run-time Loading

kmdb can also be loaded after the system has booted, using the `-K` flag to [mdb\(1\)](#). When loaded in this fashion, it will immediately gain control of the system. Run-time-loaded kmdb can be unloaded using the `-U` flag to [mdb\(1\)](#) or from within the debugger with the `-u` flag to the `::quit` dcmd.

### Terminal types

When loaded, kldb attempts to determine the proper terminal type in use on the system console. If the system being debugged has an attached keyboard and local display that are both used for the system console, kldb uses the terminal type appropriate for the machine: 'sun' for SPARC; 'sun-color' for x86. When a serial console is in use, boot-loaded kldb defaults to a terminal type 'vt100'. Run-time-loaded kldb defaults to the terminal type requested by `mdb(1)`. `mdb(1)` requests the terminal type specified by the value of the TERM environment variable unless overridden by the -T flag. `::term` can be used to view the current terminal type.

**Debugger Entry** Debugger entry can be requested explicitly or implicitly. Implicit entry, encountered when breakpoints or other execution control features are used, is discussed in the Execution Control section.

The primary means for explicit debugger entry is with the keyboard abort sequence for systems with local consoles and the BREAK character for those with serial consoles. The abort sequence is STOP-A or Shift-Pause for SPARC systems with local consoles, and F1-A or Shift-Pause for x86 systems with local consoles. See `kdb(1)` for a discussion of the abort sequence and for instructions on disabling it.

A second way to request entry into the debugger is with the `mdb(1)` command. Invocations of `mdb(1)` with the -K flag after the debugger is loaded trigger debugger entry.

If the kernel panics and kldb is loaded, by default, the panic routine enters kldb for live debugging. If a dump device is specified, and you enter `::cont`, the debugger exits and a crash dump is performed. To prevent the kernel from entering kldb when panicking, you can set the `nopanicdebug` variable to 1. Set the `nopanicdebug` variable to 1 using kldb or including the following line in `/etc/system`:

```
set nopanicdebug = 1
```

This can be useful if you want to keep kldb loaded, but always want a panic to trigger a crash dump without entering the debugger.

**Execution Control** For the most part, the execution control facilities provided by kldb for the kernel mirror those provided by the `mdb(1)` process target. Breakpoints (`::bp`), watchpoints (`::wp`), `::continue`, and the various flavors of `::step` can be used.

In contrast to the unlimited user process watchpoints supplied by the kernel, kldb is restricted to a set of CPU watchpoints that limit the number, size, and type of watchpoints allowed. The `::wp` command does not allow a watchpoint to be created if it is incompatible with the watchpoints supported by the hardware.

**Debugger modules (dmods)** As with `mdb(1)`, kldb is installed with a number of subsystem-specific debugger modules, or dmods. The dmods are loaded and unloaded automatically with the loading and unloading of the subsystems that they support. The dmods can also be explicitly loaded and unloaded using `::load` and `::unload`.

kldb uses kernel facilities to load and unload dmods and must resume system execution to perform each requested action. When a dmod load or unload is complete, the system is stopped and the debugger is automatically re-entered. For a dmod load, processing is completed when the load of a requested dmod succeeds or fails. Status messages are provided in either case.

- Processor-specific functionality Some functionality is specific to an individual processor type. An example of such functionality is the branch tracing provided by various x86 processors. Access to these processor-specific features is provided with processor-specific dcmds that are present only on systems that support them. The availability of processor-specific support is indicated in the output of the `::status` dcmd. The debugger relies on the kernel to determine the processor type. Even though the debugger might provide support for a given processor type, the support is not exposed until the kernel has progressed to the point at which processor identification has completed.
- Kernel Macros The debugger provides access to a set of macros that are precompiled into the debugger. Only the precompiled macros are available. Unlike with `mdb(1)`, the `$<` dcmd may not be used to load macros from arbitrary locations. Use the `$M` command to list the available macros.
- Built-in dcmds This section lists dcmds that are unique to kldb or those with behavior that differs in kldb as compared to `mdb(1)`.

```
[address] ::bp [+/- -dDestT] [-c cmd] [-n count]sym ...
address :b [cmd ...]
```

Set a breakpoint at the specified locations. The `::bp` dcmd sets a breakpoint at each address or symbol specified, including an optional address specified by an explicit expression preceding the dcmd, and each string or immediate value following the dcmd. The arguments can be symbol names or immediate values denoting a particular virtual address of interest.

If a symbol name is specified, the name may refer to a symbol that cannot yet be evaluated. It might consist of an object name and function name in a load object that has not yet been opened. In such a case, the breakpoint is deferred and is not active in the target until an object matching the given name is loaded. The breakpoint is automatically enabled when the load object is opened.

The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd. See `mdb(1)` for a description of `::evset`. If the `:b` form of the dcmd is used, a breakpoint is set only at the virtual address specified by the expression preceding the dcmd. The arguments following the `:b` dcmd are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

```
::branches [-v]
(x86 only)
```

Display the last branches taken by the CPU. This dcmd is supported only on x86 systems, and is available only when processor-specific support is detected and enabled. The number

and type of branches displayed is dependent on the capabilities of the branch tracing facilities provided by the CPU. When the `-v` option is used, the instructions prior to a given branch are displayed.

`[function] :: call [arg [arg ...]]`

Call the specified function using the specified arguments. The called function must be listed as a function in the symbol table for a loaded module. String arguments are passed by reference. When the call completes, the return value of the function is displayed.

This `dcmd` must be used with extreme caution. The kernel will not be resumed when the call is made. The function being called may not make any assumptions regarding the availability of any kernel services, and must not perform operations or calls that may block. The user must also beware of any side-effects introduced by the called function, as kernel stability might be affected.

`[cpuid] :: cpuregs [-c cpuid]`

Display the current general purpose register set for the specified CPU, in the format used by `::regs`.

`[cpuid] :: cpustack [-c cpuid]`

Print a C stack backtrace for the specified CPU. The backtrace displayed is for the point at which the specified CPU entered or was stopped by the debugger.

`addr[,len] :: in [-L len]`

(x86 only)

Read `len` bytes from the I/O port specified by `addr`. The value of the `-L` option, if provided, takes precedence over the value of the repeat count. The read length must be 1, 2, or 4 bytes, and the port address must have the same alignment as the length.

`addr[,len] :: out [-L len] value`

(x86 only)

Write value to the `len`-byte I/O port specified by `addr`. The value of the `-L` option, if provided, takes precedence over the value of the repeat count. The write length must be 1, 2, or 4 bytes and the port address must have the same alignment as the length.

`::quit [-u]`

`$q`

Causes the debugger to exit. When the `-u` option is used, the system is resumed and the debugger is unloaded. The `-u` option may not be used if the debugger was loaded at boot. When the `-u` option is not used, SPARC systems will exit to the boot PROM ok prompt. The `go` command can be used to re-enter the debugger. On x86 systems, a prompt is displayed that requests permission to reboot the machine.

`::step [over|out|branch]`

Step the target one instruction. The optional `over` argument is used to step over subroutine calls. When the optional `out` argument is specified, the target program continues until control returns from the current function.

The optional branch argument is available only on x86 systems when processor-specific support is detected and enabled. When `::step branch` is specified, the target program continues until the next branching instruction is encountered.

On SPARC systems, the `::step dcmd` may not be used to step 'ta' instructions. Similarly, it may not be used on x86 systems to step 'int' instructions. If the step results in a trap that cannot be resolved by the debugger, a message to that effect is printed and the step will fail.

`cpuid::switch`

`cpuid:x`

Use the specified CPU as the representative. Stack traces, general purpose register dumps, and similar functionality use the new representative CPU as the data source. Full execution control functionality is available on the new representative CPU.

`::term`

Display the current terminal type.

`addr[,len]:wp [+/-dDestT] [-rwx] [-pi] [-n count] [-c cmd]`

`addr[,len]:a [cmd ...]`

`addr[,len]:p [cmd ...]`

`addr[,len]:w [cmd ...]`

Set a watchpoint at the specified address, interpreted by default as a virtual address. If the `-p` option is used, the address is interpreted as a physical address. On x86 platforms, watchpoints can be set on I/O ports using the `-i` option. When the `-i` option is used, the address is interpreted as that of an I/O port.

The length in bytes of the watched region can be set by specifying an optional repeat count preceding the dcmd. If no length is explicitly set, the default is one byte. The `::wp dcmd` allows the watchpoint to be configured to trigger on any combination of read (`-r` option), write (`-w` option), or execute (`-x` option) access.

The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset dcmd`. See [mdb\(1\)](#) for a description of `::evset`. The `:a dcmd` sets a read access watchpoint at the specified address. The `:p dcmd` sets an execute access watchpoint at the specified address. The `:w dcmd` sets a write access watchpoint at the specified address. The arguments following the `:a`, `:p`, and `:w` dcmts are concatenated together to form the callback string. If the string contains meta-characters, it must be quoted.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTE VALUE    |
|---------------------|--------------------|
| Availability        | SUNWckr (debugger) |
|                     | SUNWmdbr (dmods)   |
| Interface Stability | Evolving           |

### Notes

- |                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Limitations on Memory Available to the Debugger | The memory region available to the debugger is allocated when the debugger is loaded, and is fixed at that point. If dcmds attempt to allocate more memory than is available, they will, if possible, be terminated. The debugger will attempt to recover gracefully from an out-of-memory situation, but may be unable to, and may be forced to terminate the system. This constraint is especially acute on 32-bit x86 systems. |
| Performance Impact                              | System performance will be negatively impacted by the loading of kmdb, as the debugger will consume kernel memory and other limited system resources.                                                                                                                                                                                                                                                                             |

**Name** kmfcfg – Key Management Policy Configuration Utility

**Synopsis** kmfcfg *subcommand* [*option* ...]

**Description** The kmfcfg command allows users to configure Key Management Framework (KMF) policy databases. The KMF policy database (DB) restricts the use of keys and certificates that are managed through the KMF framework.

kmfcfg provides the ability to list, create, modify, delete, import and export policy definitions either in the system default database file /etc/security/kmfpolicy.xml or a user-defined database file.

**Subcommands** The following subcommands are supported:

create

Adds a new policy into the policy database file.

The format for the create subcommand is as follows:

```
create [dbfile=dbfile] policy=polycname
 [ignore-date=true|false]
 [ignore-unknown-eku=true|false]
 [ignore-trust-anchor=true|false]
 [validity-adjusttime=adjusttime]
 [ta-name=trust anchor subject DN]
 [ta-serial=trust anchor serial number]
 [ocsp-responder=URL]
 [ocsp-proxy=URL]
 [ocsp-use-cert-responder=true|false]
 [ocsp-response-lifetime=timelimit]
 [ocsp-ignore-response-sign=true|false]
 [ocsp-responder-cert-name=Issuer DN]
 [ocsp-responder-cert-serial=serial number]
 [crl-basefilename=basefilename]
 [crl-directory=directory]
 [crl-get-crl-uri=true|false]
 [crl-proxy=URL]
 [crl-ignore-crl-sign=true|false]
 [crl-ignore-crl-date=true|false]
 [keyusage=digitalSignature|nonRepudiation
 |keyEncipherment | dataEncipherment |
 keyAgreement |keyCertSign |
 cRLSign | encipherOnly | decipherOnly],[...]
 [ekunames=serverAuth | clientAuth |
 codeSigning | emailProtection |
 ipsecEndSystem | ipsecTunnel |
 ipsecUser | timeStamping |
 OCSPSigning],[...]
 [ekuoids=OID,OID,OID...]
```

The create subcommand supports the following options:

`crl-basename=filename`

`crl-directory=directory`

These two attributes are used to specify the location for CRL files. The `crl-basename` attribute represents the base filename for a CRL file. The `crl-directory` attribute represents the directory for CRL files, which defaults to the current directory.

If the `crl-get-crl-uri` attribute is set to `true` and the `crl-basename` is not specified, the `basename` for the cached CRL file is the `basename` of the URI used to fetch the CRL file.

If the `crl-get-crl-uri` attribute is set to `false` the `crl-basename` needs to be specified to indicate an input CRL file. The setting for `crl-get-crl-uri` is `false` by default.

These two attributes only apply to the file-based CRL plugins. The current file-based CRL plugins are `file` and `pkcs11` keystores. For the `nss` keystore, the CRL location is always the NSS internal database.

`crl-get-crl-uri=true | false`

Configure if a CRL file is fetched and cached dynamically as part of the certificate validation, using the URI information from the certificate's distribution points extension.

The default for this attribute is `false`.

`crl-ignore-crl-date=true | false`

If `crl-ignore-crl-date` is set to `true`, the validity time period of the CRL is not checked.

The default for this attribute is `false`.

`crl-ignore-crl-sign=true | false`

If `crl-ignore-crl-sign` is set to `true`, the signature of the CRL is not checked.

The default for this attribute is `false`.

`crl-proxy= URL`

Sets the proxy server name and port for dynamically retrieving a CRL file when `crl-get-crl-uri` is set to `true`.

The port number is optional. If the port number is not specified, the default value is `8080`. An example `crl-proxy` setting might be: `crl-proxy=webcache.sfbay:8080`.

`dbfile=dbfile`

The DB file to add the new policy. If not specified, the default is the system KMF policy database file `/etc/security/kmfpolicy.xml`.

**ekuoids=EKUOIDS**

A comma separated list of Extended Key Usage OIDs that are required by the policy being defined. The OIDs are expressed in *dot notation*, for example, 1.2.3.4. An example ekuoids setting might be: ekuoids=1.2.3.4,9.8.7.6.5.

**ekunames=EKUNAMES**

A comma separated list of Extended Key Usage names that are required by the policy being defined. The list of values allowed for *EKUNAMES* are: serverAuth, clientAuth, codeSigning, emailProtection, ipsecEndSystem, ipsecTunnel, ipsecUser, timeStamping, and OCSPSigning

The OCSP, CRL, key usage and extended key usage checkings are off by default. To turn on any one of them, specify one or more attributes for the particular checking. For example, if the ocsf - responder attribute is set, then the OCSP checking is turned on. If the ekuname attribute or the ekuoids attribute is set, then the extended key usage checking is turned on.

**ignore-date=true | false**

Set the Ignore Date option for this policy. By default this value is false. If true is specified, the policy ignores the validity periods defined in the certificates when evaluating their validity.

**ignore-unknown-eku=true | false**

Set the Ignore Unknown ECU option for this policy. By default this value is false. If true, the policy ignores any unrecognized ECU values in the Extended Key Usage extension.

**ignore-trust-anchor=true | false**

Set the Ignore Trust Anchor option for this policy. By default this value is false. If true is specified, the policy does not verify the signature of the subject certificate using trust anchor certificate at validation.

**keyusage=KVALUES**

A comma separated list of key usage values that are required by the policy being defined. The list of values allowed are: digitalSignature, nonRepudiation, keyEncipherment, dataEncipherment, keyAgreement, keyCertSign, cRLSign, encipherOnly, decipherOnly

**ocsp-ignore-response-sign=true | false**

If this attribute is set to true, the signature of the OCSP response is not verified. This attribute value is default to false.

**ocsp-proxy=URL**

Set the proxy server name and port for OCSP. The port number is optional. If the port number is not specified, the default value is 8080. An example ocsp-proxy setting might be: ocsp-proxy="webcache.sfbay:8080"

`ocsp-response-lifetime=timelimit`

Set the *freshness* period that a response must be. The *timelimit* can be specified by *number-day*, *number-hour*, *number-minute*, or *number-second*. An example `ocsp-response-lifetime` setting might be: `ocsp-response-lifetime=6-hour`.

`ocsp-responder-cert-name=IssuerDN`

`ocsp-responder-cert-serial=serialNumber`

These two attributes represent the OCSP responder certificate. The `ocsp-responder-cert-name` is to specify the issuer name of the certificate. See the `ta-name` option for example. The `ocsp-responder-cert-serial` is for the serial number and must be specified as a hex value, for example, `0x0102030405060708090a0b0c0d0e0f`. If an OCSP responder is different from the issuer of the certificate and if the OCSP response needs to be verified, an OCSP responder certificate information should be provided.

`ocsp-responder=URL`

Set the OCSP responder URL for use with the OCSP validation method. For example, `ocsp-responder=http://ocsp.verisign.com/ocsp/status`

`ocsp-use-cert-responder=true | false`

Configure this policy to always use the responder defined in the certificate itself if possible.

`policy=policyname`

The policy record to be created. *policyname* is required.

`validity-adjusttime=adjusttime`

Set the adjust time for both ends of validity period for a certificate. The time can be specified by *number-day*, *number-hour*, *number-minute*, or *number-second*. An example `validity-adjusttime` setting might be: `validity-adjusttime=6-hour`.  
`ta-name="Subject DN" ta-serial=serialNumber`

These two attributes represent the trust anchor certificate and are used to find the trust anchor certificate in the keystore. The *ta-name* is to specify the distinguished name of the trust anchor certificate subject name. For example, `ta-name="O=Sun Microsystems Inc., \ OU=Solaris Security Technologies Group, \ L=Ashburn, ST=VA, C=US, CN=John Smith"` The serial number of the TA certificate. This, along with the Issuer DN, is used to find the TA certificate in the keystore. The serial number must be specified as a hex value, for example, `0x0102030405060708090a0b0c0d0e` The trust anchor attributes need to be set, if the value of `ignore-trust-anchor` attribute is false.

`delete`

Deletes any policy matching the indicated policy name. The system default policy (`default`) cannot be deleted.

The format for the `delete` subcommand is as follows:

`delete [dbfile=dbfile] policy=policyname`

The delete subcommand supports the following options:

- |                                       |                                                                                                                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbfile=<i>dbfile</i></code>     | Read policy definitions from the indicated file. If <i>dbfile</i> is not specified, , the default is the system KMF policy database file: <code>/etc/security/kmfpolicy.xml</code> . |
| <code>policy=<i>polyciname</i></code> | The name of the policy to delete. <i>polyciname</i> is required, if using the system database.                                                                                       |

#### export

Exports a policy from one policy database file to another policy database file.

The format for the export subcommand is as follows:

```
kmfcfg export policy=polyciname outfile=newdbfile [dbfile=dbfile]
```

The export subcommand supports the following options:

- |                                          |                                                                                                                                                                                  |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbfile=<i>dbfile</i></code>        | The DB file where the exported policy is read. If <i>dbfile</i> is not specified, the default is the system KMF policy database file: <code>/etc/security/kmfpolicy.xml</code> . |
| <code>outfile=<i>outputdbfile</i></code> | The DB file where the exported policy is stored.                                                                                                                                 |
| <code>policy=<i>polyciname</i></code>    | The policy record to be exported.                                                                                                                                                |

#### import

Imports a policy from one policy database file to another policy database file.

The format for the import subcommand is as follows:

```
kmfcfg import policy=polyciname infile=inputdbfile [dbfile=dbfile]
```

The import subcommand supports the following options:

- |                                        |                                                                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>policy=<i>polyciname</i></code>  | The policy record to be imported.                                                                                                                  |
| <code>infile=<i>inputdbfile</i></code> | The DB file to read the policy from.                                                                                                               |
| <code>dbfile=<i>outdbfile</i></code>   | The DB file to add the new policy. If not specified, the default is the system KMF policy database file <code>/etc/security/kmfpolicy.xml</code> . |

#### list

Without arguments, lists all policy definitions from the default system database.

The format for the list subcommand is as follows:

```
list [dbfile=dbfile] [policy=polyciname]
```

The list subcommand supports the following options:

- |                                   |                                                                                                                                                                   |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbfile=<i>dbfile</i></code> | Reads policy definitions from the indicated file. If not specified, the default is the system KMF policy database file <code>/etc/security/kmfpolicy.xml</code> . |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`policy=policyname` Only display policy definition for the named policy.

## `modify`

Modifies any policy matching the indicated name. The system default policy (`default`) cannot be modified.

The `modify` subcommand is as follows:

```
modify [dbfile=dbfile] policy=policyname
 [ignore-date=true|false]
 [ignore-unknown-eku=true|false]
 [ignore-trust-anchor=true|false]
 [validity-adjusttime=adjusttime]
 [ta-name=trust anchor subject DN]
 [ta-serial=trust anchor serial number]
 [ocsp-responder=URL]
 [ocsp-proxy=URL]
 [ocsp-use-cert-responder=true|false]
 [ocsp-response-lifetime=timelimit]
 [ocsp-ignore-response-sign=true|false]
 [ocsp-responder-cert-name=Issuer DN]
 [ocsp-responder-cert-serial=serial number]
 [ocsp-none=true|false]
 [crl-basefilename=basefilename]
 [crl-directory=directory]
 [crl-get-crl-uri=true|false]
 [crl-proxy=URL]
 [crl-ignore-crl-sign=true|false]
 [crl-ignore-crl-date=true|false]
 [crl-none=true|false]
 [keyusage=digitalSignature| nonRepudiation
 |keyEncipherment | dataEncipherment |
 keyAgreement |keyCertSign |
 cRLSign | encipherOnly | decipherOnly],[...]
 [keyusage-none=true|false]
 [ekunames=serverAuth | clientAuth |
 codeSigning | emailProtection |
 ipsecEndSystem | ipsecTunnel |
 ipsecUser | timeStamping |
 OCSPSigning],[...]
 [ekuoids=OID,OID,OID]
 [eku-none=true|false]
```

The `modify` subcommand supports many of the same options as the `create` subcommand. For descriptions of shared options, see the `create` subcommand.

The `modify` subcommand supports the following unique options:

`crl-none=true | false` If `crl-none` is set to `true`, CRL checking is turned off. If this attribute is set to `true`, other CRL attributes cannot be set.

|                                         |                                                                                                                                                                                                                                                                          |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dfile=[dbfile]</code>             | The database file to modify a policy. If not specified, the default is the system KMF policy database file <code>/etc/security/kmfpolicy.xml</code> .                                                                                                                    |
| <code>eku-none=true   false</code>      | If <code>eku-none</code> is set to <code>true</code> , extended key usage checking is turned off. The extended key usage attributes, <code>ekuname</code> and <code>ekuoids</code> cannot be set at the same time if <code>eku-none</code> is set to <code>true</code> . |
| <code>keyusage-none=true   false</code> | If <code>keyusage-none</code> is set to <code>true</code> , key usage checking is turned off.<br><br>The <code>keyusage</code> attribute cannot be set at the same time if this attribute is set to <code>true</code> .                                                  |
| <code>ocsp-none=true   false</code>     | If <code>ocsp-none</code> is set to <code>true</code> , OCSP checking is turned off. Any other OCSP attribute is not set at the same time if this attribute is set to <code>true</code> .                                                                                |
| <code>policy=policyname</code>          | The name of the policy to modify. <i>policyname</i> is required. The <i>default</i> policy in the system KMF policy database cannot be modified.                                                                                                                         |
| <code>help</code>                       | Displays help for the <code>kmfcfg</code> command.<br><br>The format for the <code>help</code> subcommand is as follows:<br><br><code>help</code>                                                                                                                        |

**Examples**    **EXAMPLE 1**    Creating a New Policy

The following example creates a new policy called IPSEC in the system database:

```
$ kmfcfg create IPSEC \
ignore-trust-anchor=true \
ocsp-use-cert-responder=true \
keyusage=keyAgreement,keyEncipherment,dataEncipherment \
ekuname=ipsecTunnel,ipsecUser
```

**Exit Status**    The following exit values are returned:

- `0`        Successful completion.
- `>0`      An error occurred.

**Files**    `/etc/security/kmfpolicy.xml`        Default system policy database

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Uncommitted     |

**See Also** [attributes\(5\)](#)

**Name** kpasswd – change a user's Kerberos password

**Synopsis** /usr/bin/kpasswd [*principal*]

**Description** The kpasswd command is used to change a Kerberos principal's password. kpasswd prompts for the current Kerberos password, which is used to obtain a changepw ticket from the KDC for the user's Kerberos realm. If kpasswd successfully obtains the changepw ticket, the user is prompted twice for the new password, and the password is changed.

If the principal is governed by a policy that specifies the length and/or number of character classes required in the new password, the new password must conform to the policy. (The five character classes are lower case, upper case, numbers, punctuation, and all other characters.)

**Operands** The following operand is supported:

*principal*      Change the password for the Kerberos principal *principal*. Otherwise, the principal is derived from the identity of the user invoking the kpasswd command.

**Files** /tmp/ovsec\_adm.xxxxxx      Temporary credentials cache for the lifetime of the password changing operation. (xxxxxx is a random string.)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability  | SUNWkrbu       |
| CSI           | Enabled        |

**See Also** [kerberos\(5\)](#)

**Bugs** If kpasswd is suspended, the changepw tickets may not be destroyed.

**Name** krb5-config – link against the installed Kerberos libraries

**Synopsis** krb5-config  
 [--all | --cflags | --exec-prefix | --help | --libs *library* |  
 --prefix | --vendor | --version]

**Description** krb5-config identifies and displays the special flags that are needed to compile and link programs against the installed Kerberos libraries.

**Options** The following options are supported:

|                       |                                                                  |
|-----------------------|------------------------------------------------------------------|
| --all                 | Displays the version, vendor, prefix and exec-prefix.            |
| --cflags              | Displays the compiler flags with which Kerberos was built.       |
| --exec-prefix         | Displays the exec-prefix with which Kerberos was built.          |
| --help                | Displays the usage message.                                      |
|                       | This is the default.                                             |
| --libs <i>library</i> | Displays compiler options required to link with <i>library</i> . |
|                       | The following <i>library</i> values are supported:               |
|                       | krb5      Kerberos 5 application                                 |
| --prefix              | Displays the prefix with which Kerberos was built.               |
| --vendor              | Displays the vendor of the installed Kerberos implementation.    |
| --version             | Displays the version of the installed Kerberos implementation.   |

**Examples** **EXAMPLE 1** Using the --cflags Option

The following example displays the C compiler flags needed to use [libkrb5\(3LIB\)](#):

```
% krb5-config --cflags
-I/usr/include/kerberosv5
```

**EXAMPLE 2** Using the --libs Option

The following example shows the C compiler options needed to link against [libkrb5\(3LIB\)](#):

```
% krb5-config --libs
-L/usr/lib -R/usr/lib -lkrb5
```

**Exit Status** The following exit values are returned:

|    |                        |
|----|------------------------|
| 0  | Successful completion. |
| >0 | An error occurred.     |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWkrbu        |
| Interface Stability | External        |

**See Also** [cc\(1B\)](#), [libgss\(3LIB\)](#), [libkrb5\(3LIB\)](#), [attributes\(5\)](#)

**Name** ksh, rksh – KornShell, a standard/restricted command and programming language

**Synopsis** /usr/bin/ksh [ $\pm$  abCefhikmnoprstuvx] [ $\pm$  o *option*]...  
[*arg*]...

/usr/bin/ksh -c [ $\pm$  abCefhikmnoprstuvx]  
[ $\pm$  o *option*]... *command\_string*  
[*command\_name* [*arg*...]]

/usr/xpg4/bin/sh [ $\pm$  abCefhikmnoprstuvx]  
[ $\pm$  o *option*]... [*arg*]...

/usr/xpg4/bin/sh -c [ $\pm$  abCefhikmnoprstuvx]  
[ $\pm$  o *option*]... *command\_string*  
[*command\_name* [*arg*...]]

/usr/bin/rksh [ $\pm$  abCefhikmnoprstuvx] [ $\pm$  o *option*]...  
[*arg*]...

/usr/bin/rksh -c [ $\pm$  abCefhikmnoprstuvx]  
[ $\pm$  o *option*]... *command\_string*  
[*command\_name* [*arg*...]]

**Description** The /usr/xpg4/bin/sh utility is a standards compliant shell. This utility provides all the functionality of /usr/bin/ksh, except in cases where differences in behavior exist. See Arithmetic Expansions section for details.

/usr/bin/ksh is a command and programming language that executes commands read from a terminal or a file. rksh is a restricted version of the command interpreter ksh; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. See the Invocation section for the meaning of arguments to the shell.

**Definitions** A *metacharacter* is one of the following characters:

; & ( ) | < > NEWLINE SPACE TAB

A *blank* is a TAB or a SPACE. An *identifier* is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as names for *functions* and *variables*. A *word* is a sequence of *characters* separated by one or more non-quoted *metacharacters*.

A *command* is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A *special-command* is a command that is carried out by the shell without creating a separate process. Except for documented side effects, most special commands can be implemented as separate utilities.

**Commands** A *simple-command* is a sequence of blank-separated words which can be preceded by a variable assignment list. See Environment. The first word specifies the name of the command to be executed. Except as specified, the remaining words are passed as arguments to the

invoked command. The command name is passed as argument 0 (see [exec\(2\)](#)). The *value* of a simple-command is its exit status if it terminates normally. If it terminates abnormally due to receipt of a signal, the *value* is the signal number plus 128. See [signal.h\(3HEAD\)](#) for a list of signal values. Obviously, normal exit status values 129 to 255 cannot be distinguished from abnormal exit caused by receiving signal numbers 1 to 127.

A *pipeline* is a sequence of one or more *commands* separated by `|`. The standard output of each command but the last is connected by a [pipe\(2\)](#) to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.

A *list* is a sequence of one or more *pipelines* separated by `;`, `&`, `&&`, or `|`, and optionally terminated by `;`, `&`, or `|&`. Of these five symbols, `;`, `&`, and `|&` have equal precedence, which is lower than that of `&&` and `|`. The symbols `&&` and `|` also have equal precedence. A semicolon (`;`) causes sequential execution of the preceding pipeline; an ampersand (`&`) causes asynchronous execution of the preceding pipeline (that is, the shell does *not* wait for that pipeline to finish). The symbol `|&` causes asynchronous execution of the preceding command or pipeline with a two-way pipe established to the parent shell.

The standard input and output of the spawned command can be written to and read from by the parent shell using the `-p` option of the special commands `read` and `print` described in Special Commands. The symbol `&& ( | )` causes the *list* following it to be executed only if the preceding pipeline returns 0 (or a non-zero) value. An arbitrary number of new-lines can appear in a *list*, instead of a semicolon, to delimit a command.

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

**for** *identifier* [*in word ...*] ; *do list* ; **done**

Each time a **for** command is executed, *identifier* is set to the next *word* taken from the *in word* list. If *in word ...* is omitted, then the **for** command executes the *do list* once for each positional parameter that is set. See Parameter Substitution. Execution ends when there are no more words in the list.

**select** *identifier* [*in word ...*] ; *do list* ; **done**

A **select** command prints to standard error (file descriptor 2), the set of *words*, each preceded by a number. If *in word ...* is omitted, then the positional parameters are used instead. See Parameter Substitution. The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed *words*, then the value of the variable *identifier* is set to the *word* corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable *identifier* is set to NULL. (See Blank Interpretation about NULL). The contents of the line read from standard input is saved in the shell variable `REPLY`. The *list* is executed for each selection until a break or EOF is encountered. If the `REPLY` variable is set to NULL by the execution of *list*, then the selection list is printed before displaying the PS3 prompt for the next selection.

`case word in [ pattern [ | pattern ] ) list ; ; ] ... esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation. See File Name Generation.

`if list ; then list ; [ elif list ; then list ; ... ] [ else list ; ] fi`

The *list* following `if` is executed and, if it returns an exit status of 0, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is 0, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns 0 exit status.

`while list ; do list ; done`

`until list ; do list ; done`

A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the `do list` is 0, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns 0 exit status. `until` can be used in place of `while` to negate the loop termination test.

`(list)`

Execute *list* in a separate environment. If two adjacent open parentheses are needed for nesting, a space must be inserted to avoid arithmetic evaluation.

`{list}`

*list* is simply executed. Unlike the metacharacters ( and ), { and } are *reserved words* and must occur at the beginning of a line or after a ; in order to be recognized.

`[ [expression ] ]`

Evaluates *expression* and returns 0 exit status when *expression* is true. See Conditional Expressions for a description of *expression*.

`function identifier { list ; }`

`identifier( ) { list ; }`

Define a function which is referenced by *identifier*. The body of the function is the *list* of commands between { and }. See Functions.

`time pipeline`

The *pipeline* is executed and the elapsed time as well as the user and system time are printed to standard error.

The following reserved words are only recognized as the first word of a command and when not quoted:

|          |        |       |       |      |      |      |
|----------|--------|-------|-------|------|------|------|
| !        | if     | then  | else  | elif | fi   | case |
| esac     | for    | while | until | do   | done | { }  |
| function | select | time  | [[ ]] |      |      |      |

Comments A word beginning with # causes that word and all the following characters up to a new-line to be ignored.

**Aliasing** The first word of each command is replaced by the text of an alias if an alias for this word has been defined. An alias name consists of any number of characters excluding metacharacters, quoting characters, file expansion characters, parameter and command substitution characters, and =. The replacement string can contain any valid shell script including the metacharacters listed above. The first word of each command in the replaced text, other than any that are in the process of being replaced, is tested for aliases. If the last character of the alias value is a *blank* then the word following the alias is also be checked for alias substitution. Aliases can be used to redefine special builtin commands but cannot be used to redefine the reserved words listed above. Aliases can be created, listed, and exported with the `alias` command and can be removed with the `unalias` command. Exported aliases remain in effect for scripts invoked by name, but must be reinitialized for separate invocations of the shell. See *Invocation*. To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word is replaced by the value of the alias; otherwise, it is not be replaced.

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect, the `alias` definition command has to be executed before the command which references the alias is read.

Aliases are frequently used as a short hand for full path names. An option to the aliasing facility allows the value of the alias to be automatically set to the full pathname of the corresponding command. These aliases are called *tracked* aliases. The value of a *tracked* alias is defined the first time the corresponding command is looked up and becomes undefined each time the `PATH` variable is reset. These aliases remain *tracked* so that the next subsequent reference redefines the value. Several tracked aliases are compiled into the shell. The `-h` option of the `set` command makes each referenced command name into a tracked alias.

The following *exported aliases* are compiled into (and built-in to) the shell but can be unset or redefined:

```
autoload='typeset -fu'
functions='typeset -f'
history='fc -l'
integer='typeset -i'
nohup='nohup '
r='fc -e -'
```

An example concerning trailing blank characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

the effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of `Hello, World` strings to the screen. However, if the user types:

```
$ foo while
```

the result is an `ls` listing of `/`. Since the alias substitution for `foo` ends in a space character, the next word is checked for alias substitution. The next word, `while`, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

`while` retains its normal reserved-word properties.

**Tilde Substitution** After alias substitution is performed, each word is checked to see if it begins with an unquoted `~`. If it does, then the word up to a `/` is checked to see if it matches a user name. If a match is found, the `~` and the matched login name are replaced by the login directory of the matched user. This is called a *tilde* substitution. If no match is found, the original text is left unchanged. A `~` by itself, or in front of a `/`, is replaced by `$HOME`. A `~` followed by a `+` or `-` is replaced by `$PWD` and `$OLDPWD`, respectively.

In addition, *tilde* substitution is attempted when the value of a *variable assignment* begins with a `~`.

**Tilde Expansion** A *tilde-prefix* consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment, multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible login name from the user database.

A portable login name cannot contain characters outside the set given in the description of the `LOGNAME` environment variable. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix is replaced by the value of the variable `HOME`. If `HOME` is unset, the results are unspecified. Otherwise, the tilde-prefix is replaced by a pathname of the home directory associated with the login name obtained using the `getpwnam` function. If the system does not recognize the login name, the results are undefined.

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

```
PATH=/posix/bin:~dgc/bin
```

is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

```

PATH=$(printf %s ~karels/bin : ~bostic/bin)
for Dir in ~maat/bin ~srb/bin .
do
 PATH=${PATH:+$PATH:}$Dir
done

```

With the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Expressions in operands such as:

```
make -k mumble LIBDIR=~chet/lib
```

do not qualify as shell variable assignments and tilde expansion is not performed (unless the command does so itself, which `make` does not).

The special sequence `$~` has been designated for future implementations to evaluate as a means of forcing tilde expansion in any word.

Because of the requirement that the word not be quoted, the following are not equivalent; only the last causes tilde expansion:

```
\~hlj/ ~h\lj/ ~"hlj"/ ~hlj\ / ~hlj/
```

The results of giving tilde with an unknown login name are undefined because the KornShell `~+` and `~-` constructs make use of this condition, but, in general it is an error to give an incorrect login name with tilde. The results of having `HOME` unset are unspecified because some historical shells treat this as an error.

**Command Substitution** The standard output from a *command* enclosed in parenthesis preceded by a dollar sign (that is, `$(command)`) or a pair of grave accents (``) can be used as part or all of a word. Trailing new-lines are removed. In the second (archaic) form, the string between the quotes is processed for special quoting characters before the command is executed. See *Quoting*. The command substitution `$(cat file)` can be replaced by the equivalent but faster `$(<file)`. Command substitution of most special commands that do not perform input/output redirection are carried out without creating a separate process.

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution occurs when the command is enclosed as follows:

```
$(command)
```

or (backquoted version):

```
`command`
```

The shell expands the command substitution by executing *command* in a subshell environment and replacing the command substitution (the text of *command* plus the enclosing `$( )` or backquotes) with the standard output of the command, removing sequences

of one or more newline characters at the end of the substitution. Embedded newline characters before the end of the output is not be removed; however, they can be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting that is in effect.

Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by:

\$ ' \

(dollar-sign, backquote, backslash). The search for the matching backquote is satisfied by the first backquote found without a preceding backslash. During this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the \$(*command*) form, or a quoted string, undefined results occur. A single- or double-quoted string that begins, but does not end, within the `...` sequence produces undefined results.

With the \$(*command*) form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except:

- A script consisting solely of redirections produces unspecified results.
- See the restriction on single subshells.

The results of command substitution are not field splitting and pathname expansion processed for further tilde expansion, parameter expansion, command substitution or arithmetic expansion. If a command substitution occurs inside double-quotes, it is not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application must precede the inner backquotes with backslashes; for example:

`\`command\`

The \$( ) form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

| Command              | Output |
|----------------------|--------|
| echo '\\$x'          | \\$x   |
| echo `echo '\\$x'`   | \$x    |
| echo \$(echo '\\$x') | \\$x   |

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the new \$( ) form can process any kind of valid embedded script,

the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

|                             |                             |
|-----------------------------|-----------------------------|
| echo `                      | echo \$(                    |
| cat <<eof                   | cat <<eof                   |
| a here-doc with `           | a here-doc with )           |
| eof                         | eof                         |
| `                           | )                           |
| echo `                      | echo \$(                    |
| echo abc # a comment with ` | echo abc # a comment with ) |
| `                           | )                           |
| echo `                      | echo \$(                    |
| echo `"                     | echo `)"                    |
| `                           | )                           |

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

If the command substitution consists of a single subshell, such as:

`$( (command) )`

a portable application must separate the `$(` and `(` into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

**Arithmetic Expansion** An arithmetic expression enclosed in double parentheses preceded by a dollar sign (`$( (arithmetic-expression) )`) is replaced by the value of the arithmetic expression within the double parenthesis. Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion is as follows:

`$( (expression) )`

The expression is treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell expands all tokens in the expression for parameter expansion, command substitution and quote removal.

Next, the shell treats this as an arithmetic expression and substitute the value of the expression. The arithmetic expression is processed according to the rules of the ISO C with the following exceptions:

- Only integer arithmetic is required.
- The `sizeof()` operator and the prefix and postfix `++` and `--` operators are not required.
- Selection, iteration, and jump statements are not supported.
- `/usr/bin/ksh` and `/usr/bin/rksh` treat prefix 0 through 9 as decimal constants. See the following examples:

| Command                           | Result in <code>/bin/ksh</code> | Result in <code>/usr/xpg4/bin/sh</code> |
|-----------------------------------|---------------------------------|-----------------------------------------|
| <code>echo \$((010+10))</code>    | 20                              | 18                                      |
| <code>echo \$((019+10))</code>    | 29                              | error                                   |
| <code>[ 10 -le \$((011)) ]</code> | true                            | false                                   |

As an extension, the shell can recognize arithmetic expressions beyond those listed. If the expression is invalid, the expansion fails and the shell writes a message to standard error indicating the failure.

A simple example using arithmetic expansion:

```
repeat a command 100 times
x=100
while [$x -gt 0]
do
 command
 x=$((x-1))
done
```

Process Substitution

This feature is available in SunOS and only on versions of the UNIX operating system that support the `/dev/fd` directory for naming open files. Each command argument of the form `<(list)` or `>(list)` runs process *list* asynchronously connected to some file in `/dev/fd`. The name of this file becomes the argument to the command. If the form with `>` is selected, then writing on this file provides input for *list*. If `<` is used, then the file passed as an argument contains the output of the *list* process. For example:

```
paste <(cut -f1 file1) <(cut -f3 file2) | tee >(process1) >(process2)
```

`cut`s fields 1 and 3 from the files *file1* and *file2*, respectively, pastes the results together, and sends it to the processes *process1* and *process2*, as well as putting it onto the standard output. The file, which is passed as an argument to the command, is a UNIX [pipe\(2\)](#) so programs that expect to [lseek\(2\)](#) on the file does not work.

Parameter Substitution

A *parameter* is an *identifier*, one or more digits, or any of the characters `*`, `@`, `#`, `?`, `-`, `$`, and `!`. A *variable* (a *parameter* denoted by an *identifier*) has a *value* and zero or more *attributes*. *variables* can be assigned *values* and *attributes* by using the `typeset` special command. The attributes supported by the shell are described later with the `typeset` special command. Exported variables pass values and attributes to the environment.

The shell supports a one-dimensional array facility. An element of an array variable is referenced by a *subscript*. A *subscript* is denoted by a `[`, followed by an *arithmetic expression*, followed by a `]`. See Arithmetic Evaluation. To assign values to an array, use `set -A name value . . .`. The *value* of all subscripts must be in the range of 0 through 4095. Arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array is created if necessary. Referencing an array without a subscript is equivalent to referencing the element 0. If an array *identifier* with subscript `*` or `@` is used, then the value for each of the elements is substituted (separated by a field separator character).

The *value* of a *variable* can be assigned by writing:

```
name=value [name=value] . . .
```

If the integer attribute, `-i`, is set for *name*, the *value* is subject to arithmetic evaluation.

Positional parameters, parameters denoted by a number, can be assigned values with the `set` special command. Parameter `$0` is set from argument zero when the shell is invoked. If *parameter* is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces.

Parameter Expansion    The format for parameter expansion is as follows:

```
${expression}
```

where *expression* consists of all characters until the matching `}`. Any `}` escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions and variable expansions, are not examined in determining the matching `}`.

The simplest form for parameter expansion is:

```
${parameter}
```

The value, if any, of *parameter* is substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is followed by a character that could be interpreted as part of the name. The matching closing brace are determined by counting brace levels, skipping over enclosed quoted strings and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion uses the longest valid name whether or not the symbol represented by that name exists. When the shell is scanning its input to determine the boundaries of a name, it is not bound by its knowledge of what names are already defined. For example, if `F` is a defined shell variable, the command:

```
echo $Fred
```

does not echo the value of `$F` followed by `red`; it selects the longest possible valid name, `Fred`, which in this case might be unset.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion is not performed on the results of the expansion.
- Field splitting is not performed on the results of the expansion, with the exception of @.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*), *word* is subjected to tilde expansion, parameter expansion, command substitution and arithmetic expansion. If *word* is not needed, it is not expanded. The } character that delimits the following parameter expansion modifications is determined as described previously in this section and in `dquote`. (For example, `${foo-bar}xyz` would result in the expansion of `foo` followed by the string `xyz` if `foo` is set, else the string `barxyz`).

|                                    |                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\${parameter:-word}</code>   | Use Default Values . If <i>parameter</i> is unset or null, the expansion of <i>word</i> is substituted. Otherwise, the value of <i>parameter</i> is substituted.                                                                                                                                                                                |
| <code>\${parameter:=word}</code>   | Assign Default Values . If <i>parameter</i> is unset or null, the expansion of <i>word</i> is assigned to <i>parameter</i> . In all cases, the final value of <i>parameter</i> is substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.                                                    |
| <code>\${parameter:?[word]}</code> | Indicate Error if Null or Unset . If <i>parameter</i> is unset or null, the expansion of <i>word</i> (or a message indicating it is unset if <i>word</i> is omitted) is written to standard error and the shell exits with a non-zero exit status. Otherwise, the value of <i>parameter</i> is substituted. An interactive shell need not exit. |
| <code>\${parameter:+[word]}</code> | Use Alternative Value . If <i>parameter</i> is unset or null, null is substituted. Otherwise, the expansion of <i>word</i> is substituted.                                                                                                                                                                                                      |

In the parameter expansions shown previously, use of the colon in the format results in a test for a parameter that is unset or null. Omission of the colon results in a test for a parameter that is only unset. The following two tables summarize the effect of the colon:

|                                  | parameter set and not null  | parameter set and null      |
|----------------------------------|-----------------------------|-----------------------------|
| <code>\${parameter:-word}</code> | substitute <i>parameter</i> | substitute <i>word</i>      |
| <code>\${parameter-word}</code>  | substitute <i>parameter</i> | substitute null             |
| <code>\${parameter:=word}</code> | substitute <i>parameter</i> | assign <i>word</i>          |
| <code>\${parameter=word}</code>  | substitute <i>parameter</i> | substitute <i>parameter</i> |
| <code>\${parameter:?word}</code> | substitute <i>parameter</i> | error, exit                 |
| <code>\${parameter?word}</code>  | substitute <i>parameter</i> | substitute null             |
| <code>\${parameter:+word}</code> | substitute <i>word</i>      | substitute null             |

|                                  | parameter set and not null | parameter set and null |
|----------------------------------|----------------------------|------------------------|
| <code>\${parameter+word}</code>  | substitute <i>word</i>     | substitute <i>word</i> |
|                                  |                            |                        |
|                                  | parameter unset            |                        |
| <code>\${parameter:-word}</code> | substitute <i>word</i>     |                        |
| <code>\${parameter--word}</code> | substitute <i>word</i>     |                        |
| <code>\${parameter:=word}</code> | assign <i>word</i>         |                        |
| <code>\${parameter=word}</code>  | assign null                |                        |
| <code>\${parameter:?word}</code> | error, exit                |                        |
| <code>\${parameter?word}</code>  | error,exit                 |                        |
| <code>\${parameter:+word}</code> | substitute null            |                        |
| <code>\${parameter+word}</code>  | substitute null            |                        |

In all cases shown with “substitute”, the expression is replaced with the value shown. In all cases shown with “assign”, *parameter* is assigned that value, which also replaces the expression.

`${#parameter}`      String Length. The length in characters of the value of *parameter*. If *parameter* is \* or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character).

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see `patmat`), rather than regular expression notation, is used to evaluate the patterns. If *parameter* is \* or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character). Enclosing the full parameter expansion string in double-quotes does not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces has this effect.

`${parameter%word}`      Remove Smallest Suffix Pattern. The *word* is expanded to produce a pattern. The parameter expansion then results in *parameter*, with the smallest portion of the suffix matched by the *pattern* deleted.

`${parameter%%word}`      Remove Largest Suffix Pattern. The *word* is expanded to produce a pattern. The parameter expansion then results in *parameter*, with the largest portion of the suffix matched by the *pattern* deleted.

`${parameter#word}` Remove Smallest Prefix Pattern. The *word* is expanded to produce a pattern. The parameter expansion then results in *parameter*, with the smallest portion of the prefix matched by the *pattern* deleted.

`${parameter##word}` Remove Largest Prefix Pattern. The *word* is expanded to produce a pattern. The parameter expansion then results in *parameter*, with the largest portion of the prefix matched by the *pattern* deleted.

Examples:

`${parameter:-word}`

In this example, `ls` is executed only if `x` is null or unset. (The `$(ls)` command substitution notation is explained in Command Substitution above.)

```
${x:-$(ls)}
```

`${parameter:=word}`

```
unset X
echo ${X:=abc}
abc
```

`${parameter:?word}`

```
unset posix
echo ${posix:?}
sh: posix: parameter null or not set
```

`${parameter:+word}`

```
set a b c
echo ${3:+posix}
posix
```

`${#parameter}`

```
HOME=/usr/posix
echo ${#HOME}
10
```

`${parameter%word}`

```
x=file.c
echo ${x%.c}.o
file.o
```

`${parameter%%word}`

```
x=posix/src/std
echo ${x%%/*}
posix

${parameter#word}

x=$HOME/src/cmd
echo ${x#$HOME}
/src/cmd

${parameter##word}

x=/one/two/three
echo ${x##*/}
three
```

Parameters Set by Shell    The following parameters are automatically set by the shell:

|        |                                                                                                                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| #      | The number of positional parameters in decimal.                                                                                                                                                                                                                                                                                                                    |
| —      | Flags supplied to the shell on invocation or by the set command.                                                                                                                                                                                                                                                                                                   |
| ?      | The decimal value returned by the last executed command.                                                                                                                                                                                                                                                                                                           |
| \$     | The process number of this shell.                                                                                                                                                                                                                                                                                                                                  |
| _      | Initially, the value of _ is an absolute pathname of the shell or script being executed as passed in the <i>environment</i> . Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching MAIL file when checking for mail. |
| !      | The process number of the last background command invoked.                                                                                                                                                                                                                                                                                                         |
| ERRNO  | The value of <code>errno</code> as set by the most recently failed system call. This value is system dependent and is intended for debugging purposes.                                                                                                                                                                                                             |
| LINENO | The line number of the current line within the script or function being executed.                                                                                                                                                                                                                                                                                  |
| OLDPWD | The previous working directory set by the <code>cd</code> command.                                                                                                                                                                                                                                                                                                 |
| OPTARG | The value of the last option argument processed by the <code>getopts</code> special command.                                                                                                                                                                                                                                                                       |
| OPTIND | The index of the last option argument processed by the <code>getopts</code> special command.                                                                                                                                                                                                                                                                       |
| PPID   | The process number of the parent of the shell.                                                                                                                                                                                                                                                                                                                     |
| PWD    | The present working directory set by the <code>cd</code> command.                                                                                                                                                                                                                                                                                                  |

|         |                                                                                                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RANDOM  | Each time this variable is referenced, a random integer, uniformly distributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to RANDOM.                                                   |
| REPLY   | This variable is set by the <code>select</code> statement and by the <code>read</code> special command when no arguments are supplied.                                                                                                                        |
| SECONDS | Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference is the value that was assigned plus the number of seconds since the assignment. |

Variables Used by Shell The following variables are used by the shell:

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CDPATH  | The search path for the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| COLUMNS | If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing <code>select</code> lists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| EDITOR  | If the value of this variable ends in <code>emacs</code> , <code>gmacs</code> , or <code>vi</code> and the <code>VISUAL</code> variable is not set, then the corresponding option is turned on. See the <code>set</code> special command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENV     | <p>This variable, when and only when an interactive shell is invoked, is subjected to parameter expansion by the shell and the resulting value is used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of <code>ENV</code> is not an absolute pathname, the results are unspecified. <code>ENV</code> is ignored if the user's real and effective user IDs or real and effective group IDs are different.</p> <p>This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by <code>ENV</code> differs from <code>\$HOME/.profile</code> in that <code>.profile</code> is typically executed at session startup, whereas the <code>ENV</code> file is executed at the beginning of each shell invocation. The <code>ENV</code> value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no <code>PATH</code> searching is performed. This is used as a guard against Trojan Horse security breaches.</p> |
| FCEDIT  | The default editor name for the <code>fc</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| FPATH   | The search path for function definitions. By default, the <code>FPATH</code> directories are searched after the <code>PATH</code> variable. If an executable file is found, then it is read and executed in the current environment. <code>FPATH</code> is searched before <code>PATH</code> when a function with the <code>-u</code> attribute is referenced. The preset alias <code>autoload</code> causes a function with the <code>-u</code> attribute to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HISTFILE    | If this variable is set when the shell is invoked, then the value is the pathname of the file that is used to store the command history. See <code>Command re-entry</code> .                                                                                                                                                                                                                                                                                                                                                                       |
| HISTSIZE    | If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell is greater than or equal to this number. The default is 128.                                                                                                                                                                                                                                                                                                                                                   |
| HOME        | The default argument (home directory) for the <code>cd</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| IFS         | Internal field separators, normally space, tab, and new-line that are used to separate command words which result from command or parameter substitution and for separating words with the special command <code>read</code> . The first character of the <code>IFS</code> variable is used to separate arguments for the <code>\$*</code> substitution. See <code>Quoting</code> .                                                                                                                                                                |
| LANG        | Provide a default value for the internationalization variables that are unset or null. If any of the internationalization variables contains an invalid setting, the utility behaves as if none of the variables had been defined.                                                                                                                                                                                                                                                                                                                 |
| LC_ALL      | This variable provides a default value for the <code>LC_*</code> variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| LC_COLLATE  | This variable determines the behavior of range expressions, equivalence classes and multi-byte character collating elements within pattern matching.                                                                                                                                                                                                                                                                                                                                                                                               |
| LC_CTYPE    | Determines how the shell handles characters. When <code>LC_CTYPE</code> is set to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. If <code>LC_CTYPE</code> (see <a href="#">environ(5)</a> ) is not set in the environment, the operational behavior of the shell is determined by the value of the <code>LANG</code> environment variable. If <code>LC_ALL</code> is set, its contents are used to override both the <code>LANG</code> and the other <code>LC_*</code> variables. |
| LC_MESSAGES | This variable determines the language in which messages should be written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LINENO      | This variable is set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets <code>LINENO</code> , the variable can lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of <code>LINENO</code> is unspecified.                                                                                                               |
| LINES       | If this variable is set, the value is used to determine the column length for printing select lists. Select lists print vertically until about two-thirds of <code>LINES</code> lines are filled.                                                                                                                                                                                                                                                                                                                                                  |
| MAIL        | If this variable is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> variable is not set, then the shell informs the user of arrival of mail in the specified file.                                                                                                                                                                                                                                                                                                                                                             |

---

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAILCHECK | This variable specifies how often (in seconds) the shell checks for changes in the modification time of any of the files specified by the MAILPATH or MAIL variables. The default value is 600 seconds. When the time has elapsed the shell checks before issuing the next prompt.                                                                                                                                                          |
| MAILPATH  | A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last MAILCHECK seconds. Each file name can be followed by a ? and a message that is printed. The message undergoes parameter substitution with the variable \$_ defined as the name of the file that has changed. The default message is you have mail in \$_. |
| NLSPATH   | Determine the location of message catalogues for the processing of LC_MESSAGES.                                                                                                                                                                                                                                                                                                                                                             |
| PATH      | The search path for commands. See Execution. The user cannot change PATH if executing under rksh (except in .profile).                                                                                                                                                                                                                                                                                                                      |
| PPID      | This variable is set by the shell to the decimal process ID of the process that invoked the shell. In a subshell, PPID is set to the same value as that of the parent of the current shell. For example, echo \$PPID and (echo \$PPID) would produce the same value.                                                                                                                                                                        |
| PS1       | The value of this variable is expanded for parameter substitution to define the primary prompt string which by default is "\$ ". The character ! in the primary prompt string is replaced by the <i>command</i> number. See Command Re-entry. Two successive occurrences of ! produces a single ! when the prompt string is printed.                                                                                                        |
| PS2       | Secondary prompt string, by default "> ".                                                                                                                                                                                                                                                                                                                                                                                                   |
| PS3       | Selection prompt string used within a select loop, by default "#? ".                                                                                                                                                                                                                                                                                                                                                                        |
| PS4       | The value of this variable is expanded for parameter substitution and precedes each line of an execution trace. If omitted, the execution trace prompt is "+ ".                                                                                                                                                                                                                                                                             |
| PWD       | Set by the shell to be an absolute pathname of the current working directory, containing no components of type symbolic link, no components that are dot, and no components that are dot-dot when the shell is initialized. If an application sets or unsets the value of PWD, the behaviors of the cd and pwd utilities are unspecified                                                                                                    |
| SHELL     | The pathname of the <i>shell</i> is kept in the environment. At invocation, if the basename of this variable is rsh, rksh, or krsh, then the shell becomes restricted.                                                                                                                                                                                                                                                                      |

|        |                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TMOUT  | If set to a value greater than zero, the shell terminates if a command is not entered within the prescribed number of seconds after issuing the PS1 prompt. The shell can be compiled with a maximum bound for this value which cannot be exceeded. |
| VISUAL | If the value of this variable ends in <code>emacs</code> , <code>gmacs</code> , or <code>vi</code> , then the corresponding option is turned on. See Special Command set.                                                                           |

The shell gives default values to `PATH`, `PS1`, `PS2`, `PS3`, `PS4`, `MAILCHECK`, `FCEDIT`, `TMOUT`, and `IFS`, while `HOME`, `SHELL`, `ENV`, and `MAIL` are not set at all by the shell (although `HOME` is set by [login\(1\)](#)). On some systems `MAIL` and `SHELL` are also set by `login`.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Blank Interpretation | After parameter and command substitution, the results of substitutions are scanned for the field separator characters (those found in <code>IFS</code> ) and split into distinct arguments where such characters are found. Explicit null arguments ( <code>" "</code> ) or ( <code>' '</code> ) are retained. Implicit null arguments (those resulting from <i>parameters</i> that have no values) are removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| File Name Generation | Following substitution, each command <i>word</i> is scanned for the characters <code>*</code> , <code>?</code> , and <code>[</code> unless the <code>-f</code> option has been set. If one of these characters appears, the word is regarded as a <i>pattern</i> . The word is replaced with lexicographically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. When a <i>pattern</i> is used for file name generation, the character period ( <code>.</code> ) at the start of a file name or immediately following a <code>/</code> , as well as the character <code>/</code> itself, must be matched explicitly. A file name beginning with a period is not matched with a pattern with the period inside parentheses. That is, <code>ls .@(r*)</code> would locate a file named <code>.restore</code> , but <code>ls @(.r*)</code> would not. In other instances of pattern matching, the <code>/</code> and <code>.</code> are not treated specially. <ul style="list-style-type: none"><li><code>*</code> Matches any string, including the null string.</li><li><code>?</code> Matches any single character.</li><li><code>[...]</code> Matches any one of the enclosed characters. A pair of characters separated by <code>–</code> matches any character lexically between the pair, inclusive. If the first character following the opening <code>"["</code> is a <code>!</code>, then any character not enclosed is matched. A <code>–</code> can be included in the character set by putting it as the first or last character.</li></ul> |

A *pattern-list* is a list of one or more patterns separated from each other with a `|`. Composite patterns can be formed with one or more of the following:

|                              |                                                         |
|------------------------------|---------------------------------------------------------|
| <code>?(pattern-list)</code> | Optionally matches any one of the given patterns.       |
| <code>*(pattern-list)</code> | Matches zero or more occurrences of the given patterns. |
| <code>+(pattern-list)</code> | Matches one or more occurrences of the given patterns.  |
| <code>@(pattern-list)</code> | Matches exactly one of the given patterns.              |
| <code>!(pattern-list)</code> | Matches anything, except one of the given patterns.     |

**Quoting** Each of the *metacharacters* listed above (see *Definitions*) has a special meaning to the shell and causes termination of a word unless quoted. A character can be *quoted* (that is, made to stand for itself) by preceding it with a `\`. The pair `\ NEWLINE` is removed. All characters enclosed between a pair of single quote marks (`' '`) are quoted. A single quote cannot appear within single quotes. Inside double quote marks (`"`), parameter and command substitution occur and `\` quotes the characters `\`, `'`, `"`, and `$`. The meaning of `$*` and `$@` is identical when not quoted or when used as a parameter assignment value or as a file name. However, when used as a command argument, `$*` is equivalent to `"$1d $2d . . ."`, where *d* is the first character of the IFS variable, whereas `$@` is equivalent to `$1 $2 . . .`. Inside grave quote marks (```), `\` quotes the characters `\`, `'`, and `$`. If the grave quotes occur within double quotes, then `\` also quotes the character `"`.

The special meaning of reserved words or aliases can be removed by quoting any character of the reserved word. The recognition of function names or special command names listed cannot be altered by quoting them.

**Arithmetic Evaluation** An ability to perform integer arithmetic is provided with the special command `let`. Evaluations are performed using *long* arithmetic. Constants are of the form `[ base# ] n` where *base* is a decimal number between two and thirty-six representing the arithmetic base and *n* is a number in that base. If *base* is omitted then base 10 is used.

An arithmetic expression uses the same syntax, precedence, and associativity of expression as the C language. All the integral operators, other than `++`, `--`, `?:`, and `,` are supported. Variables can be referenced by name within an arithmetic expression without using the parameter substitution syntax. When a variable is referenced, its value is evaluated as an arithmetic expression.

An internal integer representation of a *variable* can be specified with the `-i` option of the `typeset` special command. Arithmetic evaluation is performed on the value of each assignment to a variable with the `-i` attribute. If you do not specify an arithmetic base, the first assignment to the variable determines the arithmetic base. This base is used when parameter substitution occurs.

Since many of the arithmetic operators require quoting, an alternative form of the `let` command is provided. For any command which begins with a `((`, all the characters until a matching `)` are treated as a quoted expression. More precisely, `(( . . . ))` is equivalent to `let " . . . "`.

**Prompting** When used interactively, the shell prompts with the parameter expanded value of `PS1` before reading a command. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (that is, the value of `PS2`) is issued.

Conditional Expressions    A *conditional expression* is used with the `[[` compound command to test attributes of files and to compare strings. Word splitting and file name generation are not performed on the words between `[[` and `]]`. Each expression can be constructed from one or more of the following unary or binary expressions:

- a *file*                    True, if *file* exists.
- b *file*                    True, if *file* exists and is a block special file.
- c *file*                    True, if *file* exists and is a character special file.
- d *file*                    True, if *file* exists and is a directory.
- e *file*                    True, if *file* exists.
- f *file*                    True, if *file* exists and is an ordinary file.
- g *file*                    True, if *file* exists and has its setgid bit set.
- h *file*                    True, if *file* exists and is a symbolic link.
- k *file*                    True, if *file* exists and has its sticky bit set.
- n *string*                True, if length of *string* is non-zero.
- o *option*                True, if option named *option* is on.
- p *file*                    True, if *file* exists and is a fifo special file or a pipe.
- r *file*                    True, if *file* exists and is readable by current process.
- s *file*                    True, if *file* exists and has size greater than zero.
- t *fildes*                True, if file descriptor number *fildes* is open and associated with a terminal device.
- u *file*                    True, if *file* exists and has its setuid bit set.
- w *file*                    True, if *file* exists and is writable by current process.
- x *file*                    True, if *file* exists and is executable by current process. If *file* exists and is a directory, then the current process has permission to search in the directory.
- z *string*                True, if length of *string* is zero.
- L *file*                    True, if *file* exists and is a symbolic link.
- O *file*                    True, if *file* exists and is owned by the effective user id of this process.
- G *file*                    True, if *file* exists and its group matches the effective group id of this process.
- S *file*                    True, if *file* exists and is a socket.

|                                 |                                                                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file1</i> -nt <i>file2</i>   | True, if <i>file1</i> exists and is newer than <i>file2</i> .                                                                                  |
| <i>file1</i> -ot <i>file2</i>   | True, if <i>file1</i> exists and is older than <i>file2</i> .                                                                                  |
| <i>file1</i> -ef <i>file2</i>   | True, if <i>file1</i> and <i>file2</i> exist and refer to the same file.                                                                       |
| <i>string</i>                   | True if the string <i>string</i> is not the null string.                                                                                       |
| <i>string</i> = <i>pattern</i>  | True, if <i>string</i> matches <i>pattern</i> .                                                                                                |
| <i>string</i> != <i>pattern</i> | True, if <i>string</i> does not match <i>pattern</i> .                                                                                         |
| <i>string1</i> < <i>string2</i> | True, if <i>string1</i> comes before <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE. |
| <i>string1</i> > <i>string2</i> | True, if <i>string1</i> comes after <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE.  |
| <i>exp1</i> -eq <i>exp2</i>     | True, if <i>exp1</i> is equal to <i>exp2</i> .                                                                                                 |
| <i>exp1</i> -ne <i>exp2</i>     | True, if <i>exp1</i> is not equal to <i>exp2</i> .                                                                                             |
| <i>exp1</i> -lt <i>exp2</i>     | True, if <i>exp1</i> is less than <i>exp2</i> .                                                                                                |
| <i>exp1</i> -gt <i>exp2</i>     | True, if <i>exp1</i> is greater than <i>exp2</i> .                                                                                             |
| <i>exp1</i> -le <i>exp2</i>     | True, if <i>exp1</i> is less than or equal to <i>exp2</i> .                                                                                    |
| <i>exp1</i> -ge <i>exp2</i>     | True, if <i>exp1</i> is greater than or equal to <i>exp2</i> .                                                                                 |

In each of the above expressions, if *file* is of the form */dev/fd/n*, where *n* is an integer, then the test is applied to the open file whose descriptor number is *n*.

A compound expression can be constructed from these primitives by using any of the following, listed in decreasing order of precedence.

|                                          |                                                                   |
|------------------------------------------|-------------------------------------------------------------------|
| ( <i>expression</i> )                    | True, if <i>expression</i> is true. Used to group expressions.    |
| ! <i>expression</i>                      | True if <i>expression</i> is false.                               |
| <i>expression1</i> && <i>expression2</i> | True, if <i>expression1</i> and <i>expression2</i> are both true. |
| <i>expression1</i>    <i>expression2</i> | True, if either <i>expression1</i> or <i>expression2</i> is true. |

**Input/Output** Before a command is executed, its input and output can be redirected using a special notation interpreted by the shell. The following can appear anywhere in a simple-command or can precede or follow a *command* and are *not* passed on to the invoked command. Command and parameter substitution occur before *word* or *digit* is used except as noted. File name generation occurs only if the pattern matches a single file, and blank interpretation is not performed.

<*word*            Use file *word* as standard input (file descriptor 0).

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&gt;word</code>          | Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist then it is created. If the file exists, and the <code>noclobber</code> option is on, this causes an error; otherwise, it is truncated to zero length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>&gt; word</code>         | Same as <code>&gt;</code> , except that it overrides the <code>noclobber</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&gt;&gt;word</code>      | Use file <i>word</i> as standard output. If the file exists, output is appended to it (by first seeking to the EOF). Otherwise, the file is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>&lt;&gt;word</code>      | Open file <i>word</i> for reading and writing as standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>&lt;&lt; [- ]word</code> | The shell input is read up to a line that is the same as <i>word</i> , or to an EOF. No parameter substitution, command substitution, or file name generation is performed on <i>word</i> . The resulting document, called a <i>here-document</i> , becomes the standard input. If any character of <i>word</i> is quoted, no interpretation is placed upon the characters of the document. Otherwise, parameter and command substitution occur, <code>\NEWLINE</code> is ignored, and <code>\</code> must be used to quote the characters <code>\</code> , <code>\$</code> , <code>'</code> , and the first character of <i>word</i> . If <code>-</code> is appended to <code>&lt;&lt;</code> , then all leading tabs are stripped from <i>word</i> and from the document. |
| <code>&lt;&amp;digit</code>    | The standard input is duplicated from file descriptor <i>digit</i> (see <a href="#">dup(2)</a> ). Similarly for the standard output using <code>&gt;&amp;digit</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&lt;&amp;-</code>        | The standard input is closed. Similarly for the standard output using <code>&gt;&amp;-</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>&lt;&amp;p</code>        | The input from the co-process is moved to standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>&gt;&amp;p</code>        | The output to the co-process is moved to standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If one of the above is preceded by a digit, then the file descriptor number referred to is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

means file descriptor 2 is to be opened for writing as a duplicate of file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates each redirection in terms of the (*file descriptor*, *file*) association at the time of evaluation. For example:

```
... 1>fname 2>&1
```

first associates file descriptor 1 with file *fname*. It then associates file descriptor 2 with the file associated with file descriptor 1 (that is, *fname*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and then file descriptor 1 would be associated with file *fname*.

If a command is followed by & and job control is not active, then the default standard input for the command is the empty file `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

**Environment** The *environment* (see [environ\(5\)](#)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The names must be *identifiers* and the values are character strings. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a variable for each name found, giving it the corresponding value and marking it *export*. Executed commands inherit the environment. If the user modifies the values of these variables or creates new ones, using the `export` or `typeset -x` commands, they become part of the environment. The environment seen by any executed command is thus composed of any name-value pairs originally inherited by the shell, whose values can be modified by the current shell, plus any additions which must be noted in `export` or `typeset -x` commands.

The environment for any *simple-command* or *function* can be augmented by prefixing it with one or more variable assignments. A variable assignment argument is a word of the form *identifier=value*. Thus:

```
TERM=450 cmd args
```

and

```
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of *cmd* is concerned, except for special commands listed that are preceded with an asterisk).

If the `-k` flag is set, *all* variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints `a=b c` and then `c`:

```
echo a=b c
set -k echo
a=b c
```

This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.

**Functions** The function reserved word, described in the [Commands](#) section above, is used to define shell functions. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. See [Execution](#).

Functions execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the

function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller.

A trap on EXIT set inside a function is executed after the function completes in the environment of the caller. This is true only for non-POSIX-style functions, that is, functions declared as

```
function func
```

as opposed to POSIX-style functions, declared as

```
func()
```

Ordinarily, variables are shared between the calling program and the function. However, the `typeset` special command used within a function defines local variables whose scope includes the current function and all functions it calls.

The special command `return` is used to return from function calls. Errors within functions return control to the caller.

The names of all functions can be listed with `typeset -f`. `typeset -f` lists all function names as well as the text of all functions. `typeset -f function-names` lists the text of the named functions only. Functions can be undefined with the `-f` option of the `unset` special command.

Ordinarily, functions are unset when the shell executes a shell script. The `-xf` option of the `typeset` command allows a function to be exported to scripts that are executed without a separate invocation of the shell. Functions that need to be defined across separate invocations of the shell should be specified in the ENV file with the `-xf` option of `typeset`.

Function Definition Command    A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a *function definition command*.

The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named `fname`; it must be a name. An implementation can allow other characters in a function name as an extension. The implementation maintains separate name spaces for functions and variables.

The `()` in the function definition command consists of two operators. Therefore, intermixing blank characters with the `fname`, `(`, and `)` is allowed, but unnecessary.

The argument *compound-command* represents a compound command.

When the function is declared, none of the expansions in `wordexp` is performed on the text in *compound-command* or *io-redirect*; all expansions is performed as normal each time the

function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* is performed during the execution of the function itself, not the function definition.

When a function is executed, it has the syntax-error and variable-assignment properties described for the special built-in utilities.

The *compound-command* is executed whenever the function name is specified as the name of a simple command. The operands to the command temporarily becomes the positional parameters during the execution of the *compound-command*; the special parameter *#* is also changed to reflect the number of operands. The special parameter *0* is unchanged. When the function completes, the values of the positional parameters and the special parameter *#* is restored to the values they had before the function was executed. If the special built-in *return* is executed in the *compound-command*, the function completes and execution resumes with the next command after the function call.

An example of how a function definition can be used wherever a simple command is allowed:

```
If variable i is equal to "yes",
define function foo to be ls -l
#
["$i" = yes] && foo() {
 ls -l
}
```

The exit status of a function definition is *0* if the function was declared successfully; otherwise, it is greater than zero. The exit status of a function invocation is the exit status of the last command executed by the function.

**Jobs** If the *monitor* option of the *set* command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the *jobs* command, and assigns them small integer numbers. When a job is started asynchronously with *&*, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the job, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you can press the key *^Z* (Control-Z) which sends a *STOP* signal to the current job. The shell normally indicates that the job has been 'Stopped', and print another prompt. You can then manipulate the state of this job, putting it in the background with the *bg* command, or run some other commands and then eventually bring the job back into the foreground with the foreground command *fg*. A *^Z* takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

A job being run in the background stops if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command “stty tostop”. If you set this tty option, then background jobs stop when they try to produce output as they do when they try to read input.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

- `%number`    The job with the given number.
- `%string`     Any job whose command line begins with *string*.
- `%?string`    Any job whose command line contains *string*.
- `%%`            Current job.
- `%+`          Equivalent to `%%`.
- `%-`          Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work.

When the monitor mode is on, each background job that completes triggers any trap set for CHLD.

When you try to leave the shell while jobs are running or stopped, you are warned with the message, ‘You have stopped (running) jobs.’ You can use the jobs command to see what they are. If you do this or immediately try to exit again, the shell does not warn you a second time, and the stopped jobs is terminated. If you have jobs running for which the nohup command was invoked and attempt to logout, you are warned with the message:

You have jobs running.

You need to logout a second time to actually logout. However, your background jobs continue to run.

- Signals    The INT and QUIT signals for an invoked command are ignored if the command is followed by `&` and the `monitor` option is not active. Otherwise, signals have the values inherited by the shell from its parent. See the `trap` special command section.
- Execution    Each time a command is executed, the above substitutions are carried out. If the command name matches one of the Special Commands listed, it is executed within the current shell process. Next, the command name is checked to see if it matches one of the user defined functions. If it does, the positional parameters are saved and then reset to the arguments of the function call. When the function completes or issues a return, the positional parameter list is restored and any trap set on EXIT within the function is executed. The value of a function is

the value of the last command executed. A function is also executed in the current shell process. If a command name is not a special command or a user defined function, a process is created and an attempt is made to execute the command using `exec(2)`.

The shell variable `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is `/bin:/usr/bin:` (specifying `/bin`, `/usr/bin`, and the current directory in that order). The current directory can be specified by two or more adjacent colons, or by a colon at the beginning or end of the path list. If the command name contains a / then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not a directory or an `a.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. All non-exported aliases, functions, and variables are removed in this case. A parenthesized command is executed in a sub-shell without removing non-exported quantities.

**Command Re-entry** The text of the last `HISTSIZE` (default 128) commands entered from a terminal device is saved in a history file. The file `$HOME/.sh_history` is used if the `HISTFILE` variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named `HISTFILE`. The special command `fc` is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to `fc` then the value of the variable `FCEDIT` is used. If `FCEDIT` is not defined, then `/bin/ed` is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name `-` is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form `old=new` can be used to modify the command before execution. For example, if `r` is aliased to `'fc -e -'` then typing `'r bad=good c'` re-executes the most recent command which starts with the letter `c`, replacing the first occurrence of the string `bad` with the string `good`.

**In-line Editing Option** Normally, each command line entered from a terminal device is simply typed followed by a new-line (RETURN or LINEFEED). If either the `emacs`, `gmacs`, or `vi` option is active, the user can edit the command line. To be in either of these edit modes set the corresponding option. An editing option is automatically selected each time the `VISUAL` or `EDITOR` variable is assigned a value ending in either of these option names.

The editing features require that the user's terminal accept RETURN as carriage return without line feed and that a space must overwrite the current character on the screen.

The editing modes implement a concept where the user is looking through a window at the current line. The window width is the value of `COLUMNS` if it is defined, otherwise 80. If the window width is too small to display the prompt and leave at least 8 columns to enter input, the prompt is truncated from the left. If the line is longer than the window width minus two, a mark is displayed at the end of the window to notify the user. As the cursor moves and reaches

the window boundaries the window are centered about the cursor. The mark is a > if the line extends on the right side of the window, < if the line extends on the left, and \* if the line extends on both sides of the window.

The search commands in each edit mode provide access to the history file. Only strings are matched, not patterns, although a leading caret (^) in the string restricts the match to begin at the first character in the line.

**emacs Editing Mode** This mode is entered by enabling either the `emacs` or `gmacs` option. The only difference between these two modes is the way they handle ^T. To edit, move the cursor to the point needing correction and then insert or delete characters or words as needed. All the editing commands are control characters or escape sequences. The notation for control characters is caret (^) followed by the character. For example, ^F is the notation for control F. This is entered by depressing 'f' while holding down the CTRL (control) key. The SHIFT key is *not* depressed. (The notation ^? indicates the DEL (delete) key.)

The notation for escape sequences is M- followed by a character. For example, M- f (pronounced Meta f) is entered by depressing ESC (ascii 033) followed by 'f'. (M- F would be the notation for ESC followed by SHIFT (capital) 'F'.)

All edit commands operate from any place on the line (not just at the beginning). Neither the RETURN nor the LINEFEED key is entered after edit commands except when noted.

|           |                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| ^F        | Move cursor forward (right) one character.                                                                                                      |
| M- f      | Move cursor forward one word. (The emacs editor's idea of a word is a string of characters consisting of only letters, digits and underscores.) |
| ^B        | Move cursor backward (left) one character.                                                                                                      |
| M- b      | Move cursor backward one word.                                                                                                                  |
| ^A        | Move cursor to start of line.                                                                                                                   |
| ^E        | Move cursor to end of line.                                                                                                                     |
| ^]char    | Move cursor forward to character <i>char</i> on current line.                                                                                   |
| M- ^]char | Move cursor backward to character <i>char</i> on current line.                                                                                  |
| ^X^X      | Interchange the cursor and mark.                                                                                                                |
| erase     | (User defined erase character as defined by the <code>stty(1)</code> command, usually ^H or #.) Delete previous character.                      |
| ^D        | Delete current character.                                                                                                                       |
| M- d      | Delete current word.                                                                                                                            |
| M- ^H     | (Meta-backspace) Delete previous word.                                                                                                          |

---

|             |                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| M-h         | Delete previous word.                                                                                                                                                                                                                                                                                                                          |
| M-^?        | (Meta-DEL) Delete previous word (if your interrupt character is ^? (DEL, the default) then this command does not work).                                                                                                                                                                                                                        |
| ^T          | Transpose current character with next character in emacs mode. Transpose two previous characters in gmacs mode.                                                                                                                                                                                                                                |
| ^C          | Capitalize current character.                                                                                                                                                                                                                                                                                                                  |
| M-c         | Capitalize current word.                                                                                                                                                                                                                                                                                                                       |
| M-l         | Change the current word to lower case.                                                                                                                                                                                                                                                                                                         |
| ^K          | Delete from the cursor to the end of the line. If preceded by a numerical parameter whose value is less than the current cursor position, then delete from given position up to the cursor. If preceded by a numerical parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position. |
| ^W          | Kill from the cursor to the mark.                                                                                                                                                                                                                                                                                                              |
| M-p         | Push the region from the cursor to the mark on the stack.                                                                                                                                                                                                                                                                                      |
| <i>kill</i> | (User defined kill character as defined by the <a href="#">stty(1)</a> command, usually ^G or @.) Kill the entire current line. If two <i>kill</i> characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals).                                                               |
| ^Y          | Restore last item removed from line. (Yank item back to the line.)                                                                                                                                                                                                                                                                             |
| ^L          | Line feed and print current line.                                                                                                                                                                                                                                                                                                              |
| ^@          | (null character) Set mark.                                                                                                                                                                                                                                                                                                                     |
| M-space     | (Meta space) Set mark.                                                                                                                                                                                                                                                                                                                         |
| J           | (New line) Execute the current line.                                                                                                                                                                                                                                                                                                           |
| M           | (Return) Execute the current line.                                                                                                                                                                                                                                                                                                             |
| <i>eof</i>  | End-of-file character, normally ^D, is processed as an End-of-file only if the current line is null.                                                                                                                                                                                                                                           |
| ^P          | Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command.                                                                                                                                                                         |
| M-<         | Fetch the least recent (oldest) history line.                                                                                                                                                                                                                                                                                                  |
| M->         | Fetch the most recent (youngest) history line.                                                                                                                                                                                                                                                                                                 |
| ^N          | Fetch next command line. Each time ^N is entered the next command line forward in time is accessed.                                                                                                                                                                                                                                            |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>^Rstring</code>  | Reverse search history for a previous command line containing <i>string</i> . If a parameter of zero is given, the search is forward. <i>string</i> is terminated by a RETURN or NEW LINE. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is omitted, then the next command line containing the most recent <i>string</i> is accessed. In this case a parameter of zero reverses the direction of the search. |
| <code>^O</code>        | Operate. Execute the current line and fetch the next line relative to current line from the history file.                                                                                                                                                                                                                                                                                                                                                             |
| <code>M-digits</code>  | (Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are ^F, ^B, <i>erase</i> , ^C, ^D, ^K, ^R, ^P, ^N, ^J, M-., M-^J, M-_, M-b, M-c, M-d, M-f, M-h, M-l and M-^H.                                                                                                                                                                                                                        |
| <code>M-letter</code>  | Soft-key. Your alias list is searched for an alias by the name <code>_letter</code> and if an alias of this name is defined, its value is inserted on the input queue. The <i>letter</i> must not be one of the above meta-functions.                                                                                                                                                                                                                                 |
| <code>M-[letter</code> | Soft-key. Your alias list is searched for an alias by the name <code>__letter</code> and if an alias of this name is defined, its value is inserted on the input queue. The can be used to program functions keys on many terminals.                                                                                                                                                                                                                                  |
| <code>M-.</code>       | The last word of the previous command is inserted on the line. If preceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word.                                                                                                                                                                                                                                                                             |
| <code>M-__</code>      | Same as M-..                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>M-*</code>       | An asterisk is appended to the end of the word and a file name expansion is attempted.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>M-ESC</code>     | File name completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory.                                                                                                                                                                                       |
| <code>M-=</code>       | List files matching current word pattern if an asterisk were appended.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>^U</code>        | Multiply parameter of next command by 4.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>\</code>         | Escape next character. Editing characters, the user's erase, kill and interrupt (normally ^?) characters can be entered in a command line or in a search string if preceded by a \ . The \ removes the next character's editing features (if any).                                                                                                                                                                                                                    |
| <code>^V</code>        | Display version of the shell.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>M-#</code>       | Insert a # at the beginning of the line and execute it. This causes a comment to be inserted in the history file.                                                                                                                                                                                                                                                                                                                                                     |

**vi Editing Mode** There are two typing modes. Initially, when you enter a command you are in the *input* mode. To edit, enter *control* mode by typing ESC (033) and move the cursor to the point needing correction and then insert or delete characters or words as needed. Most control commands accept an optional repeat *count* prior to the command.

When in vi mode on most systems, canonical processing is initially enabled and the command is echoed again if the speed is 1200 baud or greater and it contains any control characters or less than one second has elapsed since the prompt was printed. The ESC character terminates canonical processing for the remainder of the command and the user can then modify the command line. This scheme has the advantages of canonical processing with the type-ahead echoing of raw mode.

If the option `vi raw` is also set, the terminal always have canonical processing disabled. This mode is implicit for systems that do not support two alternate end of line delimiters, and can be helpful for certain terminals.

**Input Edit Commands** By default the editor is in input mode.

*erase* (User defined erase character as defined by the `stty(1)` command, usually ^H or #.)  
Delete previous character.

^W Delete the previous blank separated word.

^D Terminate the shell.

^V Escape next character. Editing characters and the user's erase or kill characters can be entered in a command line or in a search string if preceded by a ^V. The ^V removes the next character's editing features (if any).

\ Escape the next *erase* or *kill* character.

**Motion Edit Commands** The following commands move the cursor:

[*count*]l Cursor forward (right) one character.

[*count*]w Cursor forward one alpha-numeric word.

[*count*]W Cursor to the beginning of the next word that follows a blank.

[*count*]e Cursor to end of word.

[*count*]E Cursor to end of the current blank delimited word.

[*count*]h Cursor backward (left) one character.

[*count*]b Cursor backward one word.

[*count*]B Cursor to preceding blank separated word.

[*count*]| Cursor to column *count*.

[*count*]fc Find the next character *c* in the current line.

|                    |                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ <i>count</i> ]Fc | Find the previous character <i>c</i> in the current line.                                                                                                                                           |
| [ <i>count</i> ]tc | Equivalent to f followed by h.                                                                                                                                                                      |
| [ <i>count</i> ]Tc | Equivalent to F followed by l.                                                                                                                                                                      |
| [ <i>count</i> ];  | Repeats <i>count</i> times, the last single character find command, f, F, t, or T.                                                                                                                  |
| [ <i>count</i> ],  | Reverses the last single character find command <i>count</i> times.                                                                                                                                 |
| 0                  | Cursor to start of line.                                                                                                                                                                            |
| ^                  | Cursor to first non-blank character in line.                                                                                                                                                        |
| \$                 | Cursor to end of line.                                                                                                                                                                              |
| %                  | Moves to balancing ( , ) , { , } , [ , or ] . If cursor is not on one of the above characters, the remainder of the line is searched for the first occurrence of one of the above characters first. |

Search Edit Commands These commands access your command history.

|                   |                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ <i>count</i> ]k | Fetch previous command. Each time k is entered the previous command back in time is accessed.                                                                                                                                                                                      |
| [ <i>count</i> ]– | Equivalent to k.                                                                                                                                                                                                                                                                   |
| [ <i>count</i> ]j | Fetch next command. Each time j is entered, the next command forward in time is accessed.                                                                                                                                                                                          |
| [ <i>count</i> ]+ | Equivalent to j.                                                                                                                                                                                                                                                                   |
| [ <i>count</i> ]G | The command number <i>count</i> is fetched. The default is the least recent history command.                                                                                                                                                                                       |
| / <i>string</i>   | Search backward through history for a previous command containing <i>string</i> . <i>string</i> is terminated by a RETURN or NEWLINE. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is NULL, the previous string is used. |
| ? <i>string</i>   | Same as / except that search is in the forward direction.                                                                                                                                                                                                                          |
| n                 | Search for next match of the last pattern to / or ? commands.                                                                                                                                                                                                                      |
| N                 | Search for next match of the last pattern to / or ?, but in reverse direction. Search history for the <i>string</i> entered by the previous / command.                                                                                                                             |

Text Modification Edit Commands These commands modifies the line.

|   |                                                              |
|---|--------------------------------------------------------------|
| a | Enter input mode and enter text after the current character. |
| A | Append text to the end of the line. Equivalent to \$a.       |

---

|                             |                                                                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[count]cmotion</code> |                                                                                                                                                                                                                                                                                             |
| <code>c[count]motion</code> | Delete current character through the character that <i>motion</i> would move the cursor to and enter input mode. If <i>motion</i> is <code>c</code> , the entire line is deleted and input mode entered.                                                                                    |
| <code>C</code>              | Delete the current character through the end of line and enter input mode. Equivalent to <code>c\$</code> .                                                                                                                                                                                 |
| <code>[count]s</code>       | Delete <i>count</i> characters and enter input mode.                                                                                                                                                                                                                                        |
| <code>S</code>              | Equivalent to <code>cc</code> .                                                                                                                                                                                                                                                             |
| <code>D</code>              | Delete the current character through the end of line. Equivalent to <code>d\$</code> .                                                                                                                                                                                                      |
| <code>[count]dmotion</code> |                                                                                                                                                                                                                                                                                             |
| <code>d[count]motion</code> | Delete current character through the character that <i>motion</i> would move to. If <i>motion</i> is <code>d</code> , the entire line is deleted.                                                                                                                                           |
| <code>i</code>              | Enter input mode and insert text before the current character.                                                                                                                                                                                                                              |
| <code>I</code>              | Insert text before the beginning of the line. Equivalent to <code>0i</code> .                                                                                                                                                                                                               |
| <code>[count]P</code>       | Place the previous text modification before the cursor.                                                                                                                                                                                                                                     |
| <code>[count]p</code>       | Place the previous text modification after the cursor.                                                                                                                                                                                                                                      |
| <code>R</code>              | Enter input mode and replace characters on the screen with characters you type overlay fashion.                                                                                                                                                                                             |
| <code>[count]rc</code>      | Replace the <i>count</i> character(s) starting at the current cursor position with <i>c</i> , and advance the cursor.                                                                                                                                                                       |
| <code>[count]x</code>       | Delete current character.                                                                                                                                                                                                                                                                   |
| <code>[count]X</code>       | Delete preceding character.                                                                                                                                                                                                                                                                 |
| <code>[count].</code>       | Repeat the previous text modification command.                                                                                                                                                                                                                                              |
| <code>[count]~</code>       | Invert the case of the <i>count</i> character(s) starting at the current cursor position and advance the cursor.                                                                                                                                                                            |
| <code>[count]_</code>       | Causes the <i>count</i> word of the previous command to be appended and input mode entered. The last word is used if <i>count</i> is omitted.                                                                                                                                               |
| <code>*</code>              | Causes an <code>*</code> to be appended to the current word and file name generation attempted. If no match is found, it rings the bell. Otherwise, the word is replaced by the matching pattern and input mode is entered.                                                                 |
| <code>\</code>              | Filename completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a <code>/</code> is appended if the file is a directory and a space is appended if the file is not a directory. |

Other Edit Commands   Miscellaneous commands.

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[count]ymotion</code> |                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>y[count]motion</code> | Yank current character through character that <i>motion</i> would move the cursor to and puts them into the delete buffer. The text and cursor are unchanged.                                                                                                                                                                                                                                                       |
| <code>Y</code>              | Yanks from current position to end of line. Equivalent to <code>y\$</code> .                                                                                                                                                                                                                                                                                                                                        |
| <code>u</code>              | Undo the last text modifying command.                                                                                                                                                                                                                                                                                                                                                                               |
| <code>U</code>              | Undo all the text modifying commands performed on the line.                                                                                                                                                                                                                                                                                                                                                         |
| <code>[count]v</code>       | Returns the command <code>fc -e \${VISUAL:-\${EDITOR:-vi}}</code> <i>count</i> in the input buffer. If <i>count</i> is omitted, then the current line is used.                                                                                                                                                                                                                                                      |
| <code>^L</code>             | Line feed and print current line. Has effect only in control mode.                                                                                                                                                                                                                                                                                                                                                  |
| <code>J</code>              | (New line) Execute the current line, regardless of mode.                                                                                                                                                                                                                                                                                                                                                            |
| <code>M</code>              | (Return) Execute the current line, regardless of mode.                                                                                                                                                                                                                                                                                                                                                              |
| <code>#</code>              | If the first character of the command is a <code>#</code> , then this command deletes this <code>#</code> and each <code>#</code> that follows a newline. Otherwise, sends the line after inserting a <code>#</code> in front of each line in the command. Useful for causing the current line to be inserted in the history as a comment and removing comments from previous comment commands in the history file. |
| <code>=</code>              | List the file names that match the current word if an asterisk were appended it.                                                                                                                                                                                                                                                                                                                                    |
| <code>@letter</code>        | Your alias list is searched for an alias by the name <code>_letter</code> and if an alias of this name is defined, its value is inserted on the input queue for processing.                                                                                                                                                                                                                                         |

Special Commands   The following *simple-commands* are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is 0. Commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

\* : [ *arg* ... ]

The command only expands parameters.

\* . *file* [ *arg* ... ]

Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by *PATH* is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

\*\* alias [ -tx ] [ *name*[=*value*] ] ...

*alias* with no arguments prints the list of aliases in the form *name=value* on standard output. An *alias* is defined for each *name* whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The -t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of *PATH* is reset but the aliases remained tracked. Without the -t flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The -x flag is used to set or print *exported aliases*. An *exported alias* is defined for scripts invoked by name. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.

bg [ %*job*... ]

This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See Jobs section above for a description of the format of *job*.

\* break [ *n* ]

Exit from the enclosed *for*, *while*, *until*, or *select* loop, if any. If *n* is specified then break *n* levels. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be exited.

\* continue [ *n* ]

Resume the next iteration of the enclosed *for*, *while*, *until*, or *select* loop. If *n* is specified then resume at the *n*-th enclosed loop. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be used.

cd [ -L ] [ -P ] [ *arg* ]

cd *old new*

This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is – the directory is changed to the previous directory. The shell variable *HOME* is the default *arg*. The environment variable *PWD* is set to the current directory. If the *PWD* is changed, the *OLDPWD* environment variable shall also be changed to the value of the old working directory, that is, the current working directory immediately prior to the call to change directory (*cd*). The shell variable *CDPATH* defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (:). The default path is null (specifying the current directory). The current directory is specified by a null path name, which can appear immediately after the equal sign or between the

colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*. If unsuccessful, *cd* attempts to change directories to the pathname formed by the concatenation of the value of *PWD*, a slash character, and *arg*.

- L     Handles the operation dot-dot ( . . ) logically. Symbolic link components are *not* resolved before dot-dot components are processed.
- P     Handles the operand dot-dot physically. Symbolic link components *are* resolved before dot-dot components are processed.

If both -L and -P options are specified, the last option to be invoked is used and the other is ignored. If neither -L nor -P is specified, the operand is handled dot-dot logically.

The second form of *cd* substitutes the string *new* for the string *old* in the current directory name, *PWD*, and tries to change to this new directory. The *cd* command cannot be executed by *rksh*.

command [-p] [*command\_name*] [argument ...]

command [-v | -V] *command\_name*

The *command* utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The -p flag performs the command search using a default value for *PATH* that is guaranteed to find all of the standard utilities. The -v flag writes a string to standard output that indicates the pathname or command that is used by the shell, in the current shell execution environment, to invoke *command\_name*. The -V flag writes a string to standard output that indicates how the name given in the *command\_name* operand is interpreted by the shell, in the current shell execution environment.

echo [ *arg* ... ]

See [echo\(1\)](#) for usage and description.

\* eval [ *arg* ... ]

The arguments are read as input to the shell and the resulting command(s) executed.

\* exec [ *arg* ... ]

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments can appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

\* exit [ *n* ]

Causes the calling shell or shell script to exit with the exit status specified by *n*. The value is the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When *exit* occurs when executing a trap, the last command

refers to the command that executed before the trap was invoked. An EOF also causes the shell to exit except for a shell which has the `ignoreeof` option turned on. See `set`.

```
** export [name[=value]] ...
```

```
** export -p
```

The given *names* are marked for automatic export to the environment of subsequently-executed commands.

When `-p` is specified, `export` writes to the standard output the names and values of all exported variables in the following format:

```
"export %s=%s\n", name, value
```

if *name* is set, and:

```
"export %s\n", name
```

if *name* is unset.

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except for the following:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output are not reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

```
fc [-e ename] [-n l r] [first [last]]
```

```
fc -e - [old=new] [command]
```

```
fc -s [old=new] [command]
```

In the first form, a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* can be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the `-l` flag is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable FCEDIT (default `/bin/ed`) is used as the editor.

When editing is complete, the edited command(s) is executed. If *last* is not specified then it is set to *first*. If *first* is not specified the default is the previous command for editing and `-16` for listing. The flag `-r` reverses the order of the commands and the flag `-n` suppresses command numbers when listing. In the second form the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

```
fg [%job...]
```

This command is only on systems that support job control. Each *job* specified is brought to the foreground. Otherwise, the current job is brought into the foreground. See “Jobs” section above for a description of the format of *job*.

`getopts optstring name [ arg ... ]`

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument - ends the options. *optstring* contains the letters that `getopts` recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

`getopts` places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in `OPTARG`. The option argument, if any, gets stored in `OPTARG`.

A leading : in *optstring* causes `getopts` to store the letter of an invalid option in `OPTARG`, and to set *name* to ? for an unknown option and to : when a required option is missing. Otherwise, `getopts` prints an error message. The exit status is non-zero when there are no more options. See `getoptcv(1)` for usage and description.

`getopts` supports both traditional single-character short options and long options defined by Sun's Command Line Interface Paradigm (CLIP).

Each long option is an alias for a short option and is specified in parentheses following its equivalent short option. For example, you can specify the long option `file` as an alias for the short option `f` using the following script line:

```
getopts "f(file)" opt
```

Precede long options on the command line with -- or ++. In the example above, --file on the command line would be the equivalent of -f, and ++file on the command line would be the equivalent of +f.

Each short option can have multiple long option equivalents, although this is in violation of the CLIP specification and should be used with caution. You must enclose each long option equivalent parentheses, as follows:

```
getopts "f:(file)(input-file)o:(output-file)"
```

In the above example, both --file and --input-file are the equivalent of -f, and --output-file is the equivalent of -o.

The variable name is always set to a short option. When a long option is specified on the command line, name is set to the short-option equivalent.

`hash [ name ... ]`

`hash [ -r ]`

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a relative directory in the search path, after changing to that

directory, the stored location of that command is recalculated. Commands for which this is done are indicated by an asterisk (\*) adjacent to the *hits* information. *Cost* is incremented when the recalculation is done.

`jobs [ -l np ] [ %job ... ]`

Lists information about each given job; or all active jobs if *job* is omitted. The `-l` flag lists process ids in addition to the normal information. The `-n` flag displays only jobs that have stopped or exited since last notified. The `-p` flag causes only the process group to be listed. See Jobs section above and [jobs\(1\)](#) for a description of the format of *job*.

`kill [ -sig ] %job ...`

`kill [ -sig ] pid ...`

`kill -l`

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in [signal.h\(3HEAD\)](#) stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Jobs for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed.

`let arg...`

Each *arg* is a separate *arithmetic expression* to be evaluated. See the Arithmetic Evaluation section above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

`login argument ...`

Equivalent to 'exec login *argument*....' See [login\(1\)](#) for usage and description.

`* newgrp [ arg ... ]`

Equivalent to `exec /bin/newgrp arg ....`

`print [ -Rnprsu[n] ] [ arg ... ]`

The shell output mechanism. With no flags or with flag `-` or `-`, the arguments are printed on standard output as described by [echo\(1\)](#). The exit status is 0, unless the output file is not open for writing.

`-n` Suppresses NEWLINE from being added to the output.

`-R | -r` Raw mode. Ignores the escape conventions of echo. The `-R` option prints all subsequent arguments and options other than `-n`.

`-p` Writes the arguments to the pipe of the process spawned with `|&` instead of standard output.

`-s` Writes the arguments to the history file instead of standard output.

`-u [ n ]` Specifies a one digit file descriptor unit number *n* on which the output is placed. The default is 1.

`pwd [ -L | -P ]`

Writes to the standard output an absolute pathname of the current working directory, which does not contain the filenames dot (.) or dot-dot (..).

- L If the PWD environment variable contains an absolute pathname of the current directory that does not contain the filenames dot or dot-dot, `pwd` writes this pathname to standard output. Otherwise, the -L option behaves like the -P option.
- P The absolute pathname written shall not contain filenames that, in the context of the pathname, refer to files of type symbolic link.

If both -L and -P are specified, the last one applies. If neither -L nor -P is specified, `pwd` behaves as if -L had been specified.

`read [ -prsu[ n ] ] [ name?prompt ] [ name ... ]`

The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, -r, the \ character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The -p option causes the input line to be taken from the input pipe of a process spawned by the shell using |&. If the -s flag is present, the input is saved as a command in the history file. The flag -u can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is 0. If *name* is omitted then REPLY is used as the default *name*. The exit status is 0 unless the input file is not open for reading or an EOF is encountered. An EOF with the -p option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an EOF is encountered.

**\*\*** `readonly [ name[=value] ] ...`

**\*\*** `readonly -p`

The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

When -p is specified, `readonly` writes to the standard output the names and values of all read-only variables, in the following format:

"readonly %s=%s\n", *name*, *value*

if *name* is set, and:

"readonly \$s\n", *name*

if *name* is unset.

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and `readonly` attribute-setting results in a shell execution environment in which:

1. Variables with values set at the time they were output do not have the readonly attribute set.
2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is reinput to the shell.

\* **return** [ *n* ]

Causes a shell function or ' . ' script to return to the invoking script with the return status specified by *n*. The value is the least significant 8 bits of the specified status. If *n* is omitted then the return status is that of the last command executed. If **return** is invoked while not in a function or a ' . ' script, then it is the same as an **exit**.

**set** [ *±abCefhkmnopstuvx* ] [ *±o option* ] . . . [ *±A name* ] [ *arg ...* ]

The flags for this command have meaning as follows:

- A    Array assignment. Unsets the variable *name* and assigns values sequentially from the list *arg*. If +A is used, the variable *name* is not unset first.
- a    All subsequent variables that are defined are automatically exported.
- b    Causes the shell to notify the user asynchronously of background job completions. The following message is written to standard error:

```
"[%d]%c %s%s\n", <job-number>, <current>, <status>, \
 <job-name>
```

where the fields are as follows:

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <current>    | The character + identifies the job that would be used as a default for the <b>fg</b> or <b>bg</b> utilities. This job can also be specified using the <i>job_id</i> %+ or %%. The character - identifies the job that would become the default if the current default job were to exit; this job can also be specified using the <i>job_id</i> %-. For other jobs, this field is a space character. At most one job can be identified with + and at most one job can be identified with -. If there is any suspended job, then the current job is a suspended job. If there are at least two suspended jobs, then the previous job is also a suspended job. |
| <job-number> | A number that can be used to identify the process group to the <b>wait</b> , <b>fg</b> , <b>bg</b> , and <b>kill</b> utilities. Using these utilities, the job can be identified by prefixing the job number with %.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <status>     | Unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <job-name>   | Unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

When the shell notifies the user a job has been completed, it can remove the job's process ID from the list of those known in the current shell execution environment. Asynchronous notification is not enabled by default.

- C Prevents existing files from being overwritten by the shell's > redirection operator. The >| redirection operator overrides this noclobber option for an individual file.
- e If a command has a non-zero exit status, executes the ERR trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs runs in a separate process group and a line prints upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Reads commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o Writes the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same option settings.
- o The following argument can be one of the following option names:

|           |                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------|
| allexport | Same as -a.                                                                                                            |
| errexit   | Same as -e.                                                                                                            |
| bgnice    | All background jobs are run at a lower priority. This is the default mode.                                             |
| emacs     | Puts you in an emacs style in-line editor for command entry.                                                           |
| gmacs     | Puts you in a gmacs style in-line editor for command entry.                                                            |
| ignoreeof | The shell does not exit onEOF. The command exit must be used.                                                          |
| keyword   | Same as -k.                                                                                                            |
| markdirs  | All directory names resulting from file name generation have a trailing / appended.                                    |
| monitor   | Same as -m.                                                                                                            |
| noclobber | Prevents redirection > from truncating existing files. Require >  to truncate a file when turned on. Equivalent to -C. |
| noexec    | Same as -n.                                                                                                            |
| noglob    | Same as -f.                                                                                                            |
| nolog     | Do not save function definitions in history file.                                                                      |

---

|                         |                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>notify</code>     | Equivalent to <code>-b</code> .                                                                                                                                             |
| <code>nounset</code>    | Same as <code>-u</code> .                                                                                                                                                   |
| <code>privileged</code> | Same as <code>-p</code> .                                                                                                                                                   |
| <code>verbose</code>    | Same as <code>-v</code> .                                                                                                                                                   |
| <code>trackall</code>   | Same as <code>-h</code> .                                                                                                                                                   |
| <code>vi</code>         | Puts you in insert mode of a <code>vi</code> style in-line editor until you hit escape character <code>033</code> . This puts you in control mode. A return sends the line. |
| <code>viraw</code>      | Each character is processed as it is typed in <code>vi</code> mode.                                                                                                         |
| <code>xtrace</code>     | Same as <code>-x</code> .                                                                                                                                                   |

If no option name is supplied, the current option settings are printed.

- `-p` Disables processing of the `$HOME/.profile` file and uses the file `/etc/suid_profile` instead of the `ENV` file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
- `-s` Sorts the positional parameters lexicographically.
- `-t` Exits after reading and executing one command.
- `-u` Treats unset parameters as an error when substituting.
- `-v` Prints shell input lines as they are read.
- `-x` Prints commands and their arguments as they are executed.
- `-` Turns off `-x` and `-v` flags and stops examining arguments for flags.
- `—` Does not change any of the flags. Useful in setting `$1` to a value beginning with `-`. If no arguments follow this flag then the positional parameters are unset.

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in `$-`. Unless `-A` is specified, the remaining arguments are positional parameters and are assigned, in order, to `$1 $2 ....` If no arguments are given, the names and values of all variables are printed on the standard output.

`* shift [ n ]`

The positional parameters from `$n+1 $n+1 . . .` are renamed `$1 . . .`, default *n* is 1.

The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to `$#`.

`stop%jobid ...`

`stop pid ...`

`stop` stops the execution of a background job(s) by using its *jobid*, or of any process by using its *pid*. See [ps\(1\)](#).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`test expression`

Evaluates conditional expressions. See Conditional Expressions section above and [test\(1\)](#) for usage and description.

`* times`

Prints the accumulated user and system times for the shell and for processes run from the shell.

`* trap [ arg sig ... ]`

*arg* is a command to be read and executed when the shell receives signal(s) *sig*. *arg* is scanned once when the trap is set and once when the trap is taken. *sig* can be specified as a signal number or signal name. `trap` commands are executed in order of signal number. Any attempt to set a trap on a signal number that was ignored on entry to the current shell is ineffective.

If *arg* is `—`, the shell resets each *sig* to the default value. If *arg* is null ( `' '` ), the shell ignores each specified *sig* if it arises. Otherwise, *arg* is read and executed by the shell when one of the corresponding *sigs* arises. The action of the trap overrides a previous action (either default action or one explicitly set). The value of `$?` after the trap action completes is the value it had before the trap was invoked.

*sig* can be `EXIT`, `0` (equivalent to `EXIT`) or a signal specified using a symbolic name, without the `SIG` prefix, for example, `HUP`, `INT`, `QUIT`, `TERM`. If *sig* is `0` or `EXIT` and the `trap` statement is executed inside the body of a function, then the command *arg* is executed after the function completes. If *sig* is `0` or `EXIT` for a `trap` set outside any function, the command *arg* is executed on exit from the shell. If *sig* is `ERR`, *arg* is executed whenever a command has a non-zero exit status. If *sig* is `DEBUG`, *arg* is executed after each command.

The environment in which the shell executes a trap on `EXIT` is identical to the environment immediately after the last command executed before the trap on `EXIT` was taken.

Each time the trap is invoked, *arg* is processed in a manner equivalent to `eval "$arg"`.

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell can reset or catch signals ignored on entry. Traps remain in place for a given shell until explicitly changed with another `trap` command.

When a subshell is entered, traps are set to the default args. This does not imply that the `trap` command cannot be used within the subshell to set new traps.

The `trap` command with no arguments writes to standard output a list of commands associated with each *sig*. The format is:

trap — %s %s ... <arg>, <sig> ...

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
...
eval "$save_traps"
```

If the trap name or number is invalid, a non-zero exit status is returned. Otherwise, 0 is returned. For both interactive and non-interactive shells, invalid signal names or numbers are not considered a syntax error and do not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on CHLD won't be executed until the foreground job terminates.

type *name* ...

For each *name*, indicates how it would be interpreted if used as a command name.

\*\* typeset [ ±HLRZfilrtux[*n*] ] [ *name*[=*value*] ] ...

Sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and type are restored when the function completes. The following list of attributes can be specified:

- H This flag provides UNIX to host-name file mapping on non-UNIX machines.
- L Left justifies and removes leading blanks from *value*. If *n* is non-zero it defines the width of the field. Otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off.
- R Right justifies and fills with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off.
- Z Right justifies and fills with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If *n* is non-zero it defines the width of the field. Otherwise, it is determined by the width of the value of first assignment.
- f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u, and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable is searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name.
- i Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.

- l All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off.
- r The given *names* are marked readonly and these names cannot be changed by subsequent assignment.
- t Tags the variables. Tags are user definable and have no special meaning to the shell.
- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *names* are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute cannot be specified along with -R, -L, -Z, or -f.

Using + rather than – causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than – keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

`ulimit [ -HSacdfnstv ] [ limit ]`

Sets or displays a resource limit. The available resources limits are listed in the following section. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified with each resource, or the value `unlimited`. The H and S flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the H or S options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless H is specified. When more than one resource is specified, the limit name and unit is printed before the value.

- a Lists all of the current resource limits.
- c The number of 512-byte blocks on the size of core dumps.
- d The number of K-bytes on the size of the data area.
- f The number of 512-byte blocks on files written by child processes (files of any size can be read).
- n The number of file descriptors plus 1.
- s The number of K-bytes on the size of the stack area.
- t The number of seconds to be used by each process.
- v The number of K-bytes for virtual memory.

If no option is given, -f is assumed.

`umask [-S] [ mask ]`

The user file-creation mask is set to *mask* (see [umask\(2\)](#)). *mask* can either be an octal number or a symbolic value as described in [chmod\(1\)](#). If a symbolic value is given, the new umask value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed. The -S flag produces symbolic output.

`unalias name ...`

`unalias -a`

The aliases given by the list of *names* are removed from the alias list. The -a option removes all alias definitions from the current execution environment.

`unset [-f] name ...`

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. readonly variables cannot be unset. If the -f flag is set, then the names refer to *function* names. Unsetting ERRNO, LINENO, MAILCHECK, OPTARG, OPTIND, RANDOM, SECONDS, TMOUT, and \_ removes their special meaning even if they are subsequently assigned to.

`*wait [job]`

Waits for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See Jobs for a description of the format of *job*.

`whence [-pv] name ...`

For each *name*, indicates how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if name is an alias, a function, or a reserved word.

**Invocation** If the shell is invoked by [exec\(2\)](#), and the first character of argument zero (\$0) is -, then the shell is assumed to be a login shell and commands are read from `/etc/profile` and then from either `.profile` in the current directory or `$HOME/.profile`, if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable ENV if the file exists. If the -s flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any `setuid` and `setgid` settings are ignored. If the script is not found on the path, *arg* is processed as if it named a builtin command or function. Commands are then read as described as follows. The following flags are interpreted by the shell when it is invoked:

- c Reads commands from the *command\_string* operand. Sets the value of special parameter 0 from the value of the *command\_name* operand and the positional parameters (\$1, \$2, and so on) in sequence from the remaining *arg* operands. No commands are read from the standard input.

- s If the -s flag is present or if no arguments remain, commands are read from the standard input. Shell output, except for the output of the Special Commands listed above, is written to file descriptor 2.
- i If the -i flag is present or if the shell input and output are attached to a terminal (as told by `ioctl(2)`), then this shell is *interactive*. In this case, TERM is ignored (so that `kill 0` does not kill an interactive shell) and INTR is caught and ignored (so that wait is interruptible). In all cases, QUIT is ignored by the shell.
- r If the -r flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the `set` command above.

**rksh Only** rksh is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of rksh are identical to those of ksh, except that the following are disallowed:

- changing directory (see `cd(1)`)
- setting the value of SHELL, ENV, or PATH
- specifying path or command names containing /
- redirecting output (>, >|, <>, and >>)
- changing group (see `newgrp(1)`).

The restrictions above are enforced after `.profile` and the ENV files are interpreted.

When a command to be executed is found to be a shell procedure, rksh invokes ksh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the `.profile` has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, `/usr/rbin`) that can be safely invoked by rksh.

**Errors** Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets ([1]) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility causes the shell to write a diagnostic message to standard error and exit as shown in the following table:

| Error                                          | Special Built-in | Other Utilities |
|------------------------------------------------|------------------|-----------------|
| Shell language syntax error                    | exits            | exits           |
| Utility syntax error (option or operand error) | exits            | does not exit   |
| Redirection error                              | exits            | does not exit   |
| Variable assignment error                      | exits            | does not exit   |
| Expansion error                                | exits            | exits           |
| Command not found                              | n/a              | might exit      |
| Dot script not found                           | exits            | n/a             |

An expansion error is one that occurs when the shell expansions are carried out (for example, `${x!y}`, because `!` is not a valid operator). An implementation can treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as “might exit” or “exits” occur in a subshell, the subshell exits or might exit with a non-zero status, but the script containing the subshell does not exit because of the error.

In all of the cases shown in the table, an interactive shell writes a diagnostic message to standard error without exiting.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `ksh` and `rksh` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Exit Status** Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status is 127. If the command name is found, but it is not an executable utility, the exit status is 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status is greater than zero.

When reporting the exit status with the special parameter `?`, the shell reports the full eight bits of exit status available. The exit status of a command that terminated because it received a signal reported as greater than 128.

**Files** /etc/profile  
/etc/suid\_profile  
\$HOME/.profile  
/tmp/sh\*  
/dev/null

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/ksh,  
/usr/bin/rksh

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

/usr/xpg4/bin/sh

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

Morris I. Bolsky and David G. Korn, *The KornShell Command and Programming Language*, Prentice Hall, 1989.

**Warnings** The use of setuid shell scripts is *strongly* discouraged.

**Notes** If a command which is a *tracked alias* is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell continues to exec the original command. Use the `-t` option of the `alias` command to correct this situation.

Some very old shell scripts contain a `^` as a synonym for the pipe character `|`.

Using the `fc` built-in command within a compound command causes the whole command to disappear from the history file.

The built-in command `.file` reads the whole file before any commands are executed. Therefore, `alias` and `unalias` commands in the file does not apply to any functions defined in the file.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

**Name** ktutil – Kerberos keytab maintenance utility

**Synopsis** /usr/bin/ktutil

**Description** The `ktutil` command is an interactive command-line interface utility for managing the keylist in keytab files. You must read in a keytab's keylist before you can manage it. Also, the user running the `ktutil` command must have read/write permissions on the keytab. For example, if a keytab is owned by root, which it typically is, `ktutil` must be run as root to have the appropriate permissions.

|                 |                                  |                                                                                                                                                                                               |
|-----------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Commands</b> | <code>clear_list</code>          |                                                                                                                                                                                               |
|                 | <code>clear</code>               | Clears the current keylist.                                                                                                                                                                   |
|                 | <code>read_kt file</code>        |                                                                                                                                                                                               |
|                 | <code>rkt file</code>            | Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.                                                                                                       |
|                 | <code>write_kt file</code>       |                                                                                                                                                                                               |
|                 | <code>wkt file</code>            | Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file. |
|                 | <code>add_entry number</code>    |                                                                                                                                                                                               |
|                 | <code>addent number</code>       | Adds an entry to the current keylist. Specify the entry by the keylist slot number.                                                                                                           |
|                 | <code>delete_entry number</code> |                                                                                                                                                                                               |
|                 | <code>delent number</code>       | Deletes an entry from the current keylist. Specify the entry by the keylist slot number.                                                                                                      |
|                 | <code>list</code>                |                                                                                                                                                                                               |
|                 | <code>l</code>                   | Lists the current keylist.                                                                                                                                                                    |
|                 | <code>list_request</code>        |                                                                                                                                                                                               |
|                 | <code>lr</code>                  | Lists available requests (commands).                                                                                                                                                          |
|                 | <code>quit</code>                |                                                                                                                                                                                               |
|                 | <code>exit</code>                |                                                                                                                                                                                               |
|                 | <code>q</code>                   | Exits utility.                                                                                                                                                                                |

**Examples** **EXAMPLE 1** Deleting a principal from a file

The following example deletes the `host/denver@ACME.com` principal from the `/etc/krb5/krb5.keytab` file. Notice that if you want to delete an entry from an existing keytab, you must first write the keylist to a temporary keytab and then overwrite the existing keytab with the the temporary keytab. This is because the `wkt` command actually appends the current keylist to an existing keytab, so you can't use it to overwrite a keytab.

```
example# /usr/krb5/bin/ktutil
ktutil: rkt /etc/krb5/krb5.keytab
```

**EXAMPLE 1** Deleting a principal from a file      *(Continued)*

```
ktutil: list
slot KVNO Principal

1 8 host/vail@ACME.COM
2 5 host/denver@ACME.COM
ktutil:delent 2
ktutil:l
slot KVNO Principal

1 8 host/vail@ACME.COM
ktutil:wkt /tmp/krb5.keytab
ktutil:q
example# mv /tmp/krb5.keytab /etc/krb5/krb5.keytab
```

**Files** /etc/krb5/krb5.keytab      keytab file for Kerberos clients

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWkrbu        |
| Interface Stability | See below.      |

The command arguments are Evolving. The command output is Unstable.

**See Also** [kadmin\(1M\)](#), [k5srvutil\(1M\)](#), [attributes\(5\)](#), [kerberos\(5\)](#)

**Name** lari – link analysis of runtime interfaces

**Synopsis** lari [-bCDsv] [-a | -i | -o] *file* | *directory*...

lari [-CDosv] [-m [-d *mapdir*]] *file*

**Description** The `lari` utility analyzes the interface requirements of dynamic ELF objects. Two basic modes of operation are available. The first mode displays runtime interface information. The second mode generates interface definitions.

Dynamic objects offer symbolic definitions that represent the interface that the object provides for external consumers. At runtime, bindings are established from the symbolic references of one object to the symbolic definitions of another object. `lari` analyzes both the interface definitions and runtime bindings of the specified objects.

When displaying runtime interface information, `lari` can analyze a number of files and/or directories. `lari` analyzes each *file* that is specified on the command line. `lari` recursively descends into each *directory* that is specified on the command line, processing each file that is found.

When generating interface definitions, `lari` can only process a single *file* specified on the command line.

Without the `-D` option, `lari` processes files as dynamic ELF objects by using [ldd\(1\)](#). This processing uses the following options:

`-r` and `-e LD_DEBUG=files,bindings,detail`

These options provide information on all bindings that are established as part of loading the object. Notice that by using `ldd`, the specified object is not executed, and hence no user controlled loading of objects, by [dlopen\(3C\)](#) for example, occurs. To capture all binding information from an executing process, the following environment variables can be passed directly to the runtime linker, [ld.so.1\(1\)](#):

```
LD_DEBUG=files,bindings,detail LD_DEBUG_OUTPUT=lari.dbg \
LD_BIND_NOW=yes
```

The resulting debug output, `lari.dbg.pid`, can be processed by `lari` using the `-D` option.

*Note:* `lari` attempts to analyze each object that has been processed using the path name defined in the debug output. Each object must therefore be accessible to `lari` for a complete, accurate analysis to be provided. The debug output file must be generated in the C locale.

When displaying interface information, `lari` analyzes the interfaces of the processed dynamic objects and, by default, displays any interesting information. See [Interesting Information](#) under [EXTENDED DESCRIPTION](#). The information that is displayed is also suitable for piping to other tools. This capability can aid developers in analyzing process bindings or debugging complex binding scenarios.

The generation of interface definitions by `lari` can be used to refine the interface requirements of the dynamic objects that are processed. When creating a dynamic object, you should define an explicit, versioned interface. This definition controls the symbol definitions that are available to external users. In addition, this definition frequently reduces the overall runtime execution cost of the object. Interface definitions can be assigned to an object during its creation by the link-editor using the `-M` option and the associated *mapfile* directives. See the [Linker and Libraries Guide](#) for more details on using *mapfiles* to version objects. An initial version of these *mapfiles* can be created by `lari`.

**Options** The following options are supported.

- a Displays all interface information for the objects analyzed. *Note:* The output from this option can be substantial, but is often useful for piping to other analysis tools.
- b Limits the interface information to those symbols that have been explicitly bound to. *Note:* Symbols defined as protected might have been bound to from within the defining object. This binding is satisfied at link-edit time and is therefore not visible to the runtime environment. Protected symbols are displayed with this option.
- C Demangles C++ symbol names. This option is useful for augmenting runtime interface information. When generating interface definitions, demangled names are added to the *mapfiles* as comments.
- d *mapdir* Defines the directory, *mapdir*, in which *mapfiles* are created. By default, the current working directory is used.
- D Interprets any input *files* as debugging information rather than as dynamic objects.
- i Displays interesting interface binding information. This mode is the default if no other output controlling option is supplied. See Interesting Information under EXTENDED DESCRIPTION.
- m Creates *mapfiles* for each dynamic object that is processed. These *mapfiles* reflect the interface requirements of each object as required by the input file being processed.
- o Limits the interface information to those symbols that are deemed an overhead. When creating *mapfiles*, any overhead symbols are itemized as local symbols. See Overhead Information under EXTENDED DESCRIPTION.
- s Saves the bindings information produced from `ldd(1)` for further analysis. See FILES.
- v Ignores any objects that are already versioned. Versioned objects have had their interfaces defined, but can contribute to the interface

information displayed. For example, a versioned shared object might reveal overhead symbols for a particular process. Shared objects are frequently designed for use by multiple processes, and thus the interfaces these objects provide can extend beyond the requirements of any one process. The `-v` option therefore, can reduce noise when displaying interface information.

The runtime interface information produced from `lari` has the following format:

[information]: *symbol-name* [demangled-name]: *object-name*

Each line describes the interface symbol, *symbol-name*, together with the object, *object-name*, in which the symbol is defined. If the symbol represents a function, the symbol name is followed by `()`. If the symbol represents a data object, the symbol name is followed by the symbols size, enclosed within `[]`. If the `-C` option is used, the symbol name is accompanied by the symbols demangled name, *demangled-name*. The information field provides one or more of the following tokens that describe the symbol's use:

- cnt:bnd* Two decimal values indicate the symbol count, *cnt*, and the number of bindings to this object, *bnd*. The symbol count is the number of occurrences of this symbol definition that have been found in the objects that are analyzed. A count that is greater than 1 indicates multiple instances of a symbol definition. The number of bindings indicate the number of objects that have been bound to this symbol definition by the runtime linker.
- E This symbol definition has been bound to from an external object.
- S This symbol definition has been bound to from the same object.
- D This symbol definition has been directly bound to.
- I This object explicitly identifies itself as an interposor. See the `-z interpose` option of `ld(1)`, and the `LD_PRELOAD` variable of `ld.so.1(1)`.
- C This symbol definition is the reference data of a copy-relocation.
- F This symbol definition resides in a filtee.
- P This symbol is defined as protected. This symbol might have an internal binding from the object in which the symbol is declared. Any internal bindings with this attribute can not be interposed upon by another symbol definition.
- A This symbol definition is the address of a procedure linkage table entry within a dynamic executable.
- U This symbol lookup originated from a user request, for example, `dlsym(3C)`.
- R This symbol definition is acting as a filter, and provides for redirection to a filtee.
- N This symbol definition explicitly prohibits directly binding to the definition.

See the *Linker and Libraries Guide* for more details of these symbol classifications.

## Extended Description

### Interesting Information

By default, or specifically using the `-i` option, `lari` filters any runtime interface information to present interesting events. This filtering is carried out mainly to reduce the amount of information that can be generated from large applications. In addition, this information is intended to be the focus in debugging complex binding scenarios, and often highlights problem areas. However, classifying what information is interesting for any particular application is an inexact science. You are still free to use the `-a` option and to search the binding information for events that are unique to the application being investigated.

When an interesting symbol definition is discovered, all other definitions of the same symbol are output.

The focus of interesting interface information is the existence of multiple definitions of a symbol. In this case, one symbol typically interposes on one or more other symbol definitions. This interposition is seen when the binding count, `bnd`, of one definition is non-zero, while the binding count of all other definitions is zero. Interposition that results from the compilation environment, or the linking environment, is not characterized as interesting. Examples of these interposition occurrences include copy relocations (`[C]`) and the binding to procedure linkage addresses (`[A]`).

Interposition is often desirable. The intent is to overload, or replace, the symbolic definition from a shared object. Interpositioning objects can be explicitly tagged (`[I]`), using the `-z` interpose option of `ld(1)`. These objects can safely interpose on symbols, no matter what order the objects are loaded in a process. However, be cautious when non-explicit interposition is employed, as this interposition is a consequence of the load-order of the objects that make up the process.

User-created, multiply-defined symbols are output from `lari` as interesting. In this example, two definitions of `interpose1()` exist, but only the definition in `main` is referenced:

```
[2:1E]: interpose1(): ./main
[2:0]: interpose1(): ./libA.so
```

Interposition can also be an undesirable and surprising event, caused by an unexpected symbol name clash. A symptom of this interposition might be that a function is never called although you know a reference to the function exists. This scenario can be identified as a multiply defined symbol, as covered in the previous example. However, a more surprising scenario is often encountered when an object both defines and references a specific symbol.

An example of this scenario is if two dynamic objects define and reference the same function, `interpose2()`. Any reference to this symbol binds to the first dynamic object loaded with the process. In this case, the definition of `interpose2()` in object `libA.so` interposes on, and hides, the definition of `interpose2()` in object `libB.so`. The output from `lari` might be:

```
[2:2ES]: interpose2(): ./libA.so
[2:0]: interpose2(): ./libB.so
```

Multiply defined symbols can also be bound to separately. Separate bindings can be the case when direct bindings are in effect ([D]), or because a symbol has protected visibility ([P]). Although separate bindings can be explicitly established, instances can exist that are unexpected and surprising. Directly bound symbols, and symbols with protected visibility, are output as interesting information.

**Overhead Information** When using the `-o` option, `lari` displays symbol definitions that might be considered overhead.

Global symbols that are not referenced are considered an overhead. The symbol information that is provided within the object unnecessarily adds to the size of the object's text segment. In addition, the symbol information can increase the processing required to search for other symbolic references within the object at runtime.

Global symbols that are only referenced from the same object have the same characteristics. The runtime search for a symbolic reference, that results in binding to the same object that made the reference, is an additional overhead.

Both of these symbol definitions are candidates for reduction to local scope by defining the object's interface. Interface definitions can be assigned to a file during its creation by the link-editor using the `-M` option and the associated *mapfile* directives. See the [Linker and Libraries Guide](#) for more details on *mapfiles*. Use `lari` with the `-m` option to create initial versions of these *mapfiles*.

If `lari` is used to generate *mapfiles*, versioned shared objects will have *mapfiles* created indicating that their overhead symbols should be reduced to locals. This model allows `lari` to generate *mapfiles* for comparison with existing interface definitions. Use the `-v` option to ignore versioned shared objects when creating *mapfiles*.

Copy-relocations are also viewed as an overhead and generally should be avoided. The size of the copied data is a definition of its interface. This definition restricts the ability to change the data size in newer versions of the shared object in which the data is defined. This restriction, plus the cost of processing a copy relocation, can be avoided by referencing data using a functional interface. The output from `lari` for a copy relocation might be:

```
[2:1EC]: __iob[0x140]: ./main
[2:0]: __iob[0x140]: ./libA.so.1
```

Notice that a number of small copy relocations, such as `__iob` used in the previous example, exist because of historic programming interactions with system libraries.

Another example of overhead information is the binding of a dynamic object to the procedure linkage table entry of a dynamic executable. If a dynamic executable references an external function, a procedure linkage table entry is created. This structure allows the reference

binding to be deferred until the function call is actually made. If a dynamic object takes the address of the same referenced function, the dynamic object binds to the dynamic executables procedure linkage table entry. An example of this type of event reveals the following:

```
[2:1EA]: foo(): ./main
[2:1E]: foo(): ./libA.so
```

A small number of bindings of this type are typically not cause for concern. However, a large number of these bindings, perhaps from a jump-table programming technique, can contribute to start up overhead. Address relocation bindings of this type require relocation processing at application start up, rather than the deferred relocation processing used when calling functions directly. Use of this address also requires an indirection at runtime.

### Examples **EXAMPLE 1** Analyzing a case of multiple bindings

The following example shows the analysis of a process in which multiple symbol definitions exist. The shared objects `libX.so` and `libY.so` both call the function `interpose()`. This function exists in both the application `main`, and the shared object `libA.so`. Because of interposition, both references bind to the definition of `interpose()` in `main`.

The shared objects `libX.so` and `libY.so` also both call the function `foo()`. This function exists in the application `main`, and the shared objects `libA.so`, `libX.so`, and `libY.so`. Because both `libX.so` and `libY.so` were built with direct bindings enabled, each object binds to its own definition.

```
example% lari ./main
[3:0]: foo(): ./libA.so
[3:1SD]: foo(): ./libX.so
[3:1SD]: foo(): ./libY.so
[2:0]: interpose(): ./libA.so
[2:2EP]: interpose(): ./main
```

To analyze binding information more thoroughly, the bindings data can be saved for further inspection. For example, the previous output indicates that the function `interpose()` was called from two objects external to `main`. Inspection of the binding output reveals where the references to this function originated.

```
example% lari -s ./main
lari: ./main: bindings information saved as: /usr/tmp/lari.dbg.main
.....
example% fgrep foo /usr/tmp/lari.dbg.main
binding file=./libX.so to file=./main: symbol 'interpose'
binding file=./libY.so to file=./main: symbol 'interpose'
```

*Note:* The bindings output is typically more extensive than shown here, as the output is accompanied with process identifier, address and other bindings information.

**EXAMPLE 2** Generating an interface definition

The following example creates interface definitions for an application and its dependency, while ignoring any versioned system libraries. The application main makes reference to the interfaces `one()`, `two()`, and `three()` in `foo.so`:

```
example% lari -omv ./main
example% cat mapfile-foo.so
#
Interface Definition mapfile for:
Dynamic Object: ./foo.so
Process: ./main
#
foo.so {
 global:
 one;
 three;
 two;
 local:
 _one;
 _three;
 _two;
 *;
};
```

**Files** `$TMPDIR/lari.dbg.file` Binding output produced by `ldd(1)`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWtoo         |
| Interface Stability | See below.      |

Human readable output is Unstable. Options are Evolving.

**See Also** [ld\(1\)](#), [ldd\(1\)](#), [ld.so.1\(1\)](#), [dlopen\(3C\)](#), [dlsym\(3C\)](#), [attributes\(5\)](#)

*[Linker and Libraries Guide](#)*

**Name** last – display login and logout information about users and terminals

**Synopsis** last [-a] [-n *number* | -number] [-f *filename*]  
[*name* | *tty*]...

**Description** The `last` command looks in the `/var/adm/wtmpx` file, which records all logins and logouts, for information about a user, a terminal, or any group of users and terminals. Arguments specify names of users or terminals of interest. If multiple arguments are given, the information applicable to any of the arguments is printed. For example, `last root console` lists all of root's sessions, as well as all sessions on the console terminal. `last` displays the sessions of the specified users and terminals, most recent first, indicating the times at which the session began, the duration of the session, and the terminal on which the session took place. `last` also indicates whether the session is continuing or was cut short by a reboot.

The pseudo-user `reboot` logs in when the system is shutdown and when it reboots. Thus,

```
last reboot
```

gives an approximate record of when the operating system instance was shutdown and when it rebooted. This can be used to calculate the availability of the operating system over time.

`last` with no arguments displays a record of all logins and logouts, in reverse order.

If `last` is interrupted, it indicates how far the search has progressed in `/var/adm/wtmpx`. If interrupted with a quit signal (generated by a CTRL-\\), `last` indicates how far the search has progressed, and then continues the search.

**Options** The following options are supported:

- a Displays the hostname in the last column.
- f *filename* Uses *filename* as the name of the accounting file instead of `/var/adm/wtmpx`.
- n *number* | -*number* Limits the number of entries displayed to that specified by *number*. These options are identical; the -*number* option is provided as a transition tool only and is removed in future releases.

**Environment Variables** Date and time format is based on locale specified by the `LC_ALL`, `LC_TIME`, or `LANG` environments, in that order of priority.

**Files** `/var/adm/wtmpx` accounting file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**See Also** [utmpx\(4\)](#), [attributes\(5\)](#)

**Name** lastcomm – display the last commands executed, in reverse order

**Synopsis** lastcomm [-f *file*] [-x] [*command-name*] ... [*user-name*] ...  
[*terminal-name*] ...

**Description** The lastcomm command gives information on previously executed commands. lastcomm with no arguments displays information about all the commands recorded during the current accounting file's lifetime. If called with arguments, lastcomm only displays accounting entries with a matching *command-name*, *user-name*, or *terminal-name*. If extended process accounting is active (see [acctadm\(1M\)](#)) and is recording the appropriate data items, lastcomm attempts to take data from the current extended process accounting file. If standard process accounting is active, lastcomm takes data from the current standard accounting file (see [acct\(2\)](#)).

If *terminal-name* is '-', there was no controlling TTY for the process. The process was probably executed during boot time. If *terminal-name* is '??', the controlling TTY could not be decoded into a printable name.

For each process entry, lastcomm displays the following items of information:

- The command name under which the process was called.
- One or more flags indicating special information about the process. The flags have the following meanings:
  - F The process performed a fork but not an exec.
  - S The process ran as a set-user-id program.
- The name of the user who ran the process.
- The terminal which the user was logged in on at the time (if applicable).
- The amount of CPU time used by the process (in seconds).
- The date and time the process exited.

**Options** The following options are supported:

- f *file* Uses *file* as the source of accounting data. *file* may be either an extended process accounting file or a standard process accounting file.
- x Uses the currently active extended process accounting file. If extended processing accounting is inactive, no output will be produced.

**Examples** EXAMPLE 1 Listing executions of named commands

The command

```
example% lastcomm a.out root term/01
```

produces a listing of all the executions of commands named a.out by user root while using the terminal term/01.

**EXAMPLE 2** Listing all user commands

The command

example% **lastcomm root**

produces a listing of all the commands executed by user root.

**Files**    /var/adm/pacct                standard accounting file  
          /var/adm/exacct/proc        extended accounting file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

**Name** ld – link-editor for object files

**Synopsis** /usr/ccs/bin/ld [-64] [-a | -r] [-b] [-c *name*] [-C] [-G] [-i] [-m] [-s] [-t] [-V] [-Bdirect | nodirect] [-B dynamic | static] [-B group] [-B local] [-B eliminate] [-B reduce] [-B symbolic] [-d y | n] [-D *token*,...] [-e *epsym*] [-F *name* | -f *name*] [-h *name*] [-I *name*] [-L *path*] [-l *x*] [-M *mapfile*] [-N *string*] [-o *outfile*] [-p *auditlib*] [-P *auditlib*] [-Q y | n] [-R *path*] [-S *supportlib*] [-u *symname*] [-Y P,*dirlist*] [-z absexec] [-z allextract | defaultextract | weakextract] [-z combrelloc] [-z defs | nodefs] [-z direct | nodirect] [-z endfiltee] [-z finiarray=*function*] [-z globalaudit] [-z groupper | nogroupper] [-z ignore | record] [-z initarray=*function*] [-z initfirst] [-z interpose] [-z lazyload | nolazyload] [-z ld32=*arg1*,*arg2*,...] [-z ld64=*arg1*,*arg2*,...] [-z loadfltr] [-z muldefs] [-z nocompstrtab] [-z nodefaultlib] [-z nodelete] [-z nodlopen] [-z nodump] [-z noldynsym] [-z nopartial] [-z noversion] [-z now] [-z origin] [-z preinitarray=*function*] [-z redlocsym] [-z rescan] [-z text | textwarn | textoff] [-z verbose] *filename*...

**Description** The ld command combines relocatable object files, performs relocation, and resolves external symbols. ld operates in two modes, static or dynamic, as governed by the -d option. In all cases, the output of ld is left in a.out by default. See NOTES.

In static mode, -dn, relocatable object files that are provided as arguments are combined to produce a static executable file. If the -r option is specified, relocatable object files are combined to produce one relocatable object file. See Static Executables.

In dynamic mode, -dy, the default, relocatable object files that are provided as arguments are combined to produce an executable object file. This file is linked at execution with any shared object files that are provided as arguments. If the -G option is specified, relocatable object files are combined to produce a shared object.

If any argument is a library, ld by default searches the library exactly once at the point the library is encountered on the argument list. The library can be either a shared object or relocatable archive. See [ar.h\(3HEAD\)](#).

For an archive library, ld loads only those routines that define an unresolved external reference. ld searches the symbol table of the archive library sequentially to resolve external references that can be satisfied by library members. This search is repeated until no external references can be resolved by the archive. Thus, the order of members in the library is functionally unimportant, unless multiple library members exist that define the same external symbol. Archive libraries that have interdependencies can require multiple command-line definitions, or use of the -z rescan option.

A shared object consists of an indivisible, whole unit that has been generated by a previous link-edit of one or more input files. When the link-editor processes a shared object, the entire contents of the shared object become a logical part of the resulting output file image. The shared object is not physically copied during the link-edit as its actual inclusion is deferred until process execution. This logical inclusion means that all symbol entries defined in the shared object are made available to the link-editing process.

No command-line option is required to distinguish 32-bit objects or 64-bit objects. The link-editor uses the ELF class of the first relocatable object file that is found on the command line, to govern the mode in which to operate. The mixing of 32-bit objects and 64-bit objects is not permitted. See also the `-64` option and the `LD_NOEXEC_64` environment variable.

**Static Executables** The creation of static executables has been discouraged for many releases. In fact, 64-bit system archive libraries have never been provided. Because a static executable is built against system archive libraries, the executable contains system implementation details. This self-containment has a number of drawbacks.

- The executable is immune to the benefits of system patches delivered as shared objects. The executable therefore, must be rebuilt to take advantage of many system improvements.
- The ability of the executable to run on future releases can be compromised.
- The duplication of system implementation details negatively affects system performance.

With Solaris 10, 32-bit system archive libraries are no longer provided. Without these libraries, specifically `libc.a`, the creation of static executables is no longer achievable without specialized system knowledge. Note, that the link-editor's capability to process static linking options, and the processing of archive libraries, remains unchanged.

**Options** The following options are supported:

`-64`

Creates a 64-bit object. By default, the class of the object being generated is determined from the first ELF object processed from the command line. This option is useful when creating an object directly with `ld` whose input is solely from an archive library or a `mapfile`. See the `-M` option.

`-a`

In static mode only, produces an executable object file. Undefined references are not permitted. This option is the default behavior for static mode. `-a` can not be used with the `-r` option. See **Static Executables** under **DESCRIPTION**.

`-b`

In dynamic mode only, does no special processing for relocations that reference symbols in shared objects. Without the `-b` option, the link-editor creates special position-independent relocations for references to functions defined in shared objects. In addition, the link-editor arranges for data objects that are defined in shared objects to be copied into the memory image of an executable at runtime.

The `-b` option is intended for specialized dynamic objects and is not recommended for general use. Its use suppresses all specialized processing required to insure an object's shareability, and can even prevent the relocation of 64-bit executables.

#### `-B direct | nodirect`

Options governing direct binding. `-B direct` establishes direct binding information by recording the relationship between each symbol reference and the dependency that provides the definition. In addition, direct binding information is established between each symbol reference and an associated definition within the object being created. The runtime linker uses this information to search directly for a symbol in the associated object rather than to carry out a default symbol search.

Direct binding information can only be established to dependencies specified with the `link-edit`. Thus, you should use the `-z defs` option. Objects that wish to interpose on symbols in a direct binding environment should identify themselves as interposers with the `-z interpose` option. The use of `-B direct` enables `-z lazyload` for all dependencies.

`-B nodirect` prevents any direct binding to the interfaces offered by the object being created. The object being created can continue to directly bind to external interfaces by specifying the `-z direct` option.

#### `-B dynamic | static`

Options governing library inclusion. `-B dynamic` is valid in dynamic mode only. These options can be specified any number of times on the command line as toggles: if the `-B static` option is given, no shared objects are accepted until `-B dynamic` is seen. See also the `-l` option.

#### `-B eliminate`

Causes any global symbols, not assigned to a version definition, to be eliminated from the symbol table. Version definitions can be supplied by means of a `mapfile` to indicate the global symbols that should remain visible in the generated object. This option achieves the same symbol elimination as the *auto-elimination* directive that is available as part of a `mapfile` version definition. This option can be useful when combining versioned and non-versioned relocatable objects. See also the `-B reduce` option.

#### `-B group`

Establishes a shared object and its dependencies as a group. Objects within the group are bound to other members of the group at runtime. The runtime processing of an object containing this flag mimics that which occurs if the object is added to a process using `dlopen(3C)` with the `RTLD_GROUP` mode. An object that has an explicit dependency on an object identified as a group, becomes a member of the group.

As the group must be self contained, use of the `-B group` option also asserts the `-z defs` option.

#### `-B local`

Causes any global symbols, not assigned to a version definition, to be reduced to local. Version definitions can be supplied by means of a `mapfile` to indicate the global symbols

that should remain visible in the generated object. This option achieves the same symbol reduction as the *auto-reduction* directive that is available as part of a `mapfile` version definition. This option can be useful when combining versioned and non-versioned relocatable objects. See also the `-B eliminate` option.

**-B reduce**

When generating a relocatable object, causes the reduction of symbolic information defined by any version definitions. Version definitions can be supplied by means of a `mapfile` to indicate the global symbols that should remain visible in the generated object. By default, when a relocatable object is generated, version definitions are only recorded in the output image. The actual reduction of symbolic information is carried out when the object is used in the construction of a dynamic executable or shared object. This option is applied automatically when a dynamic executable, or shared object is created.

**-B symbolic**

In dynamic mode only. When building a shared object, binds references to global symbols to their definitions, if available, within the object. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available. This model allows definitions of the same symbol in an executable or other shared object to override the object's own definition. `ld` issues warnings for undefined symbols unless `-z defs` overrides.

The `-B symbolic` option is intended for specialized dynamic objects and is not recommended for general use. To reduce the runtime relocation overhead of an object, the creation of a version definition is recommended.

**-c name**

Records the configuration file *name* for use at runtime. Configuration files can be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See [crle\(1\)](#).

**-C**

Demangles C++ symbol names displayed in diagnostic messages.

**-d y | n**

When `-d y`, the default, is specified, `ld` uses dynamic linking. When `-d n` is specified, `ld` uses static linking. See `Static Executables` under `DESCRIPTION`, and `-B dynamic|static`.

**-D token,...**

Prints debugging information, as specified by each *token*, to the standard error. The special token `help` indicates the full list of tokens available.

**-e epsym**

Sets the entry point address for the output file to be the symbol *epsym*.

**-f *name***

Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an auxiliary filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option can not be combined with the -F option.

**-F *name***

Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option can not be combined with the -f option.

**-G**

In dynamic mode only, produces a shared object. Undefined symbols are allowed.

**-h *name***

In dynamic mode only, when building a shared object, records *name* in the object's dynamic section. *name* is recorded in any dynamic objects that are linked with this object rather than the object's file system name. Accordingly, *name* is used by the runtime linker as the name of the shared object to search for at runtime.

**-i**

Ignores LD\_LIBRARY\_PATH. This option is useful when an LD\_LIBRARY\_PATH setting is in effect to influence the runtime library search, which would interfere with the link-editing being performed.

**-I *name***

When building an executable, uses *name* as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter. In dynamic mode, the default is the name of the runtime linker, [ld.so.1\(1\)](#). Either case can be overridden by -I *name*. [exec\(2\)](#) loads this interpreter when the a.out is loaded, and passes control to the interpreter rather than to the a.out directly.

**-l *x***

Searches a library *libx.so* or *libx.a*, the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the -B static option is in effect, ld searches each directory specified in the library search path for a *libx.so* or *libx.a* file. The directory search stops at the first directory containing either. ld chooses the file ending in .so if -l *x* expands to two files with names of the form *libx.so* and *libx.a*. If no *libx.so* is found, then ld accepts *libx.a*. In static mode, or when the -B static option is in effect, ld selects only the file ending in .a. ld searches a library when the library is encountered, so the placement of -l is significant.

**-L *path***

Adds *path* to the library search directories. ld searches for libraries first in any directories specified by the -L options and then in the standard directories. This option is useful only if the option precedes the -l options to which the -L option applies. The environment variable LD\_LIBRARY\_PATH can be used to supplement the library search path. See LD\_LIBRARY\_PATH under ENVIRONMENT VARIABLES.

- m  
Produces a memory map or listing of the input/output sections, together with any non-fatal multiply-defined symbols, on the standard output.
- M *mapfile*  
Reads *mapfile* as a text file of directives to ld. This option can be specified multiple times. If *mapfile* is a directory, then all regular files, as defined by [stat\(2\)](#), within the directory are processed. See the [Linker and Libraries Guide](#) for a description of mapfiles. Example mapfiles are provided in `/usr/lib/ld`. See FILES.
- N *string*  
This option causes a DT\_NEEDED entry to be added to the .dynamic section of the object being built. The value of the DT\_NEEDED string is the *string* that is specified on the command line. This option is position dependent, and the DT\_NEEDED .dynamic entry is relative to the other dynamic dependencies discovered on the link-edit line. This option is useful for specifying dependencies within device driver relocatable objects when combined with the -dy and -r options.
- o *outfile*  
Produces an output object file that is named *outfile*. The name of the default object file is `a.out`.
- p *auditlib*  
Identifies an audit library, *auditlib*. This audit library is used to audit the object being created at runtime. A shared object identified as requiring auditing with the -p option, has this requirement inherited by any object that specifies the shared object as a dependency. See the -P option.
- P *auditlib*  
Identifies an audit library, *auditlib*. This audit library is used to audit the dependencies of the object being created at runtime. Dependency auditing can also be inherited from dependencies that are identified as requiring auditing. See the -p option.
- Q y | n  
Under -Q y, an ident string is added to the .comment section of the output file. This string identifies the version of the link-editor used to create the file. This results in multiple ld ident s when there have been multiple linking steps, such as when using ld -r. This identification is identical with the default action of the cc command. -Q n suppresses version identification.
- r  
Combines relocatable object files to produce one relocatable object file. ld does not complain about unresolved references. This option cannot be used with the -a option.
- R *path*  
A colon-separated list of directories used to specify library search directories to the runtime linker. If present and not NULL, the path is recorded in the output object file and passed to the runtime linker. Multiple instances of this option are concatenated together with each *path* separated by a colon.

- s  
Strips symbolic information from the output file. Any debugging information, that is, `.line`, `.debug*`, and `.stab*` sections, and their associated relocation entries are removed. Except for relocatable files, a symbol table `SHT_SYMTAB` and its associated string table section are not created in the output object file. Note, the elimination of a `SHT_SYMTAB` symbol table can compromise the `.stab*` debugging information that is generate using the compiler drivers `-g` option. See the `-z relocsym` option.
- S *supportlib*  
The shared object *supportlib* is loaded with the link-editor and given information regarding the linking process. Support shared objects can also be supplied using the `SGS_SUPPORT` environment variable. See the [Linker and Libraries Guide](#) for more details.
- t  
Turns off the warning for multiply-defined symbols that have different sizes or different alignments.
- u *symname*  
Enters *symname* as an undefined symbol in the symbol table. This option is useful for loading entirely from an archive library. In this instance, an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant. This option must be placed before the library that defines the symbol.
- V  
Outputs a message giving information about the version of `ld` being used.
- Y *P, dirlist*  
Changes the default directories used for finding libraries. *dirlist* is a colon-separated path list.
- z *absexec*  
Useful only when building a dynamic executable. Specifies that references to external absolute symbols should be resolved immediately instead of being left for resolution at runtime. In very specialized circumstances, this option removes text relocations that can result in excessive swap space demands by an executable.
- z *allextract | defaultextract | weakextract*  
Alters the extraction criteria of objects from any archives that follow. By default, archive members are extracted to satisfy undefined references and to promote tentative definitions with data definitions. Weak symbol references do not trigger extraction. Under `-z allextract`, all archive members are extracted from the archive. Under `-z weakextract`, weak references trigger archive extraction. `-z defaultextract` provides a means of returning to the default following use of the former extract options.
- z *combreloc*  
Combines multiple relocation sections. Historically, relocation sections are maintained in a one-to-one relationship with the sections to which the relocations must be applied. When building an executable or shared object, `ld` sorts the entries of data relocation sections by

their symbol reference. This sorting reduces the runtime symbol lookup. Combining multiple data relocation sections allows optimal sorting and hence the least relocation overhead when objects are loaded into memory.

**-z defs | nodefs**

The `-z defs` option forces a fatal error if any undefined symbols remain at the end of the link. This mode is the default when an executable is built. For historic reasons, this mode is *not* the default when building a shared object. Use of the `-z defs` option is recommended, as this mode assures the object being built is self-contained. A self-contained object has all symbolic references resolved internally, or to the object's immediate dependencies.

The `-z nodefs` option allows undefined symbols. For historic reasons, this mode is the default when a shared object is built. When used with executables, the behavior of references to such undefined symbols is unspecified. Use of the `-z nodefs` option is not recommended

**-z direct | nodirect**

Enables or disables direct binding to any dependencies that follow on the command line.

These options allow finer control over direct binding than the global counterpart `-B direct`. The `-z direct` option also differs from the `-B direct` option in the following areas. Direct binding information is not established between a symbol reference and an associated definition within the object being created. Lazy loading is not enabled.

**-z endfiltee**

Marks a filtee so that when processed by a filter, the filtee terminates any further filtee searches by the filter.

**-z finiarray=*function***

Appends an entry to the `.finiarray` section of the object being built. If no `.finiarray` section is present, a section is created. The new entry is initialized to point to *function*. See the [Linker and Libraries Guide](#) for more details.

**-z globalaudit**

This option supplements an audit library definition that has been recorded with the `-P` option. This option is only meaningful when building a dynamic executable. Audit libraries that are defined within an object with the `-P` option typically allow for the auditing of the immediate dependencies of the object. The `-z globalaudit` promotes the auditor to a global auditor, thus allowing the auditing of all dependencies. An auditor established with the `-P` option and the `-z globalaudit` option, is equivalent to the auditor being established with the `LD_AUDIT` environment variable. See [ld.so.1\(1\)](#).

**-z groupperm | nogroupperm**

Assigns, or deassigns each dependency that follows to a unique group. The assignment of a dependency to a group has the same effect as if the dependency had been built using the `-B group` option.

**-z ignore | record**

Ignores, or records, dynamic dependencies that are not referenced as part of the link-edit. Ignores, or records, unreferenced ELF sections from the relocatable objects that are read as part of the link-edit. By default, **-z record** is in effect.

If an ELF section is ignored, the section is eliminated from the output file being generated. A section is ignored when three conditions are true. The eliminated section must contribute to an allocatable segment. The eliminated section must provide no global symbols. No other section from any object that contributes to the link-edit, must reference an eliminated section.

**-z initarray=function**

Appends an entry to the `.initarray` section of the object being built. If no `.initarray` section is present, a section is created. The new entry is initialized to point to *function*. See the [Linker and Libraries Guide](#) for more details.

**-z initfirst**

Marks the object so that its runtime initialization occurs before the runtime initialization of any other objects brought into the process at the same time. In addition, the object runtime finalization occurs after the runtime finalization of any other objects removed from the process at the same time. This option is only meaningful when building a shared object.

**-z interpose**

Marks the object as an interposer. When direct bindings are in effect, the runtime linker searches for symbols in any interposers before the object associated to the direct binding. See **-B direct**.

**-z lazyload | nolazyload**

Enables or disables the marking of dynamic dependencies to be lazily loaded. Dynamic dependencies which are marked **lazyload** are not loaded at initial process start-up. These dependencies are delayed until the first binding to the object is made. *Note:* Lazy loading requires the correct declaration of dependencies, and associated runpaths for each dynamic object used within a process. See the [Linker and Libraries Guide](#) for more details.

**-z ld32=arg1,arg2,...****-z ld64=arg1,arg2,...**

The class of the link-editor is affected by the class of the output file being created and by the capabilities of the underlying operating system. This option provides a means of defining any link-editor argument, so that the argument is only interpreted, respectively, by the 32-bit class or 64-bit class of the link-editor.

For example, support libraries are class specific, so the correct class of support library can be insured using:

```
ld ... -z ld32=-Saudit32.so.1 -z ld64=-Saudit64.so.1 ...
```

*Note:* The class of link-editor that is invoked is determined from the ELF class of the first input relocatable file that is seen on the command line. This determination is carried out *prior* to any **-z ld[32|64]** processing.

**-z loadfltr**

Marks a filter to indicate that filtees must be processed immediately at runtime. Normally, filter processing is delayed until a symbol reference is bound to the filter. The runtime processing of an object that contains this flag mimics that which occurs if the `LD_LOADFLTR` environment variable is in effect. See the [ld.so.1\(1\)](#).

**-z muldefs**

Allows multiple symbol definitions. By default, multiple symbol definitions that occur between relocatable objects result in a fatal error condition. This option, suppresses the error condition, allowing the first symbol definition to be taken.

**-z nocompstrtab**

Disables the compression of ELF string tables.

**-z nodefaultlib**

Marks the object so that the runtime default library search path, used after any `LD_LIBRARY_PATH` or `runpaths`, is ignored. This option implies that all dependencies of the object can be satisfied from its `runpath`.

**-z nodelete**

Marks the object as non-deletable at runtime. The runtime processing of an object that contains this flag mimics that which occurs if the object is added to a process using [dlopen\(3C\)](#) with the `RTLD_NODELETE` mode.

**-z nodlopen**

Marks the object as not available to [dlopen\(3C\)](#), either as the object specified by the `dlopen()`, or as any form of dependency required by the object specified by the `dlopen()`. This option is only meaningful when building a shared object.

**-z nodump**

Marks the object as not available to [dldump\(3C\)](#).

**-z nopartial**

Partially initialized symbols, that are defined within the input relocatable object files, are expanded in the output file being generated.

**-z noversion**

Does not record any versioning sections. Any version sections or associated `.dynamic` section entries are not generated in the output image.

**-z now**

Marks the object as requiring non-lazy runtime binding. This mode is similar to adding the object to the process by using [dlopen\(3C\)](#) with the `RTLD_NOW` mode, or having the `LD_BIND_NOW` environment variable in effect. See the [ld.so.1\(1\)](#).

**-z origin**

Marks the object as requiring immediate `$ORIGIN` processing at runtime. This option is only maintained for historic compatibility, as the runtime analysis of objects to provide for `$ORIGIN` processing is now default.

**-z preinitarray=***function*

Appends an entry to the `.preinitarray` section of the object being built. If no `.preinitarray` section is present, a section is created. The new entry is initialized to point to *function*. See the [Linker and Libraries Guide](#) for more details.

**-z redlocsym**

Eliminates all local symbols except for the SECT symbols from the symbol table `SHT_SYMTAB`. All relocations that refer to local symbols are updated to refer to the corresponding SECT symbol. This option allows specialized objects to greatly reduce their symbol table sizes. Note, eliminated local symbols can compromise the `.stab*` debugging information that is generate using the compiler drivers `-g` option. See the `-s` option.

**-z rescan**

Rescans the archive files that are provided to the link-edit. By default, archives are processed once as the archives appear on the command line. Archives are traditionally specified at the end of the command line so that their symbol definitions resolve any preceding references. However, specifying archives multiple times to satisfy their own interdependencies, can be necessary.

The `-z rescan` option causes the entire archive list to be reprocessed in an attempt to locate additional archive members that resolve symbol references. This archive rescanning continues until a pass over the archive list occurs in which no new members are extracted.

**-z text**

In dynamic mode only, forces a fatal error if any relocations against non-writable, allocatable sections remain. For historic reasons, this mode is not the default when building an executable or shared object. However, its use is recommended to insure that the text segment of the dynamic object being built is shareable between multiple running processes. A shared text segment incurs the least relocation overhead when loaded into memory.

**-z textoff**

In dynamic mode only, allows relocations against all allocatable sections, including non-writable ones. This mode is the default when building a shared object.

**-z textwarn**

In dynamic mode only, lists a warning if any relocations against non-writable, allocatable sections remain. This mode is the default when building an executable.

**-z verbose**

This option provides additional warning diagnostics during a link-edit. Presently, this option conveys suspicious use of displacement relocation. In future, this option might be enhanced to provide additional diagnostics that are deemed too noisy to be generated by default.

**Environment Variables** **LD\_LIBRARY\_PATH**

A list of directories in which to search for the libraries specified using the `-l` option. Multiple directories are separated by a colon. In the most general case, this environment variable contains two directory lists separated by a semicolon:

*dirlist1;dirlist2*

If `ld` is called with any number of occurrences of `-L`, as in:

```
ld ... -Lpath1 ... -Lpathn ...
```

then the search path ordering is:

```
dirlist1 path1 ... pathn dirlist2 LIBPATH
```

When the list of directories does not contain a semicolon, the list is interpreted as *dirlist2*.

The `LD_LIBRARY_PATH` environment variable also affects the runtime linker's search for dynamic dependencies.

This environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes and overrides any non-suffixed version of the environment variable that is in effect.

#### **LD\_NOEXEC\_64**

Suppresses the automatic execution of the 64-bit link-editor. By default, the link-editor executes the 64-bit version when the ELF class of the first input relocatable file identifies a 64-bit object. The 64-bit image that a 32-bit link-editor can create, has some limitations. However, some link-edits might find the use of the 32-bit link-editor faster.

#### **LD\_OPTIONS**

A default set of options to `ld`. `LD_OPTIONS` is interpreted by `ld` just as though its value had been placed on the command line, immediately following the name used to invoke `ld`, as in:

```
ld $LD_OPTIONS ... other-arguments ...
```

#### **LD\_RUN\_PATH**

An alternative mechanism for specifying a runpath to the link-editor. See the `-R` option. If both `LD_RUN_PATH` and the `-R` option are specified, `-R` supersedes.

#### **SGS\_SUPPORT**

Provides a colon-separated list of shared objects that are loaded with the link-editor and given information regarding the linking process. This environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to the 32-bit or 64-bit class of `ld` and overrides any non-suffixed version of the environment variable that is in effect. See the `-S` option.

Notice that environment variable-names that begin with the characters `'LD_'` are reserved for possible future enhancements to `ld` and [ld.so.1\(1\)](#).

#### **Files** `libx.so`

shared object libraries.

#### `libx.a`

archive libraries.

`a.out`  
default output file.

### *LIBPATH*

For 32-bit libraries, the default search path is `/usr/ccs/lib`, followed by `/lib`, and finally `/usr/lib`. For 64-bit libraries, the default search path is `/lib/64`, followed by `/usr/lib/64`.

### `/usr/lib/ld`

A directory containing several `mapfiles` that can be used during link-editing. These `mapfiles` provide various capabilities, such as defining memory layouts, aligning `bss`, and defining non-executable stacks.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

### *Linker and Libraries Guide*

**Notes** Default options applied by `ld` are maintained for historic reasons. In today's programming environment, where dynamic objects dominate, alternative defaults would often make more sense. However, historic defaults must be maintained to insure compatibility with existing program development environments. Historic defaults are called out wherever possible in this manual. For a description of the current recommended options, see the Link-Editor Quick Reference in the *Linker and Libraries Guide*.

If the file being created by `ld` already exists, the file is truncated after all input files have been processed. The existing file is overridden with the new file contents. `ld` does not create a temporary file as part of the link-edit, since multiple instances of large output files frequently exhaust system resources. The drawback of overriding an existing file occurs if the file is in use by a running process. In this case, the process might be prematurely terminated as the output files image is created. This situation can be avoided by removing the output file before performing the link-edit. This removal is not detrimental to the running process. The removal frees up the file system namespace, not the actual disk space, for the new output file creation. The disk space of a removed file is freed when the last process referencing the file terminates.

**Name** ld – link editor, dynamic link editor

**Synopsis** /usr/ucb/ld [*options*]

**Description** /usr/ucb/ld is the link editor for the BSD Compatibility Package. /usr/ucb/ld is identical to /usr/ccs/bin/ld (see [ld\(1\)](#)) except that BSD libraries and routines are included *before* the base libraries and routines.

**Options** /usr/ucb/ld accepts the same options as /usr/ccs/bin/ld, with the following exceptions:

- L*dir* Add *dir* to the list of directories searched for libraries by /usr/ccs/bin/ld. Directories specified with this option are searched before /usr/ucblib and /usr/lib.
- Y LU,*dir* Change the default directory used for finding libraries. Warning: This option may have unexpected results, and should not be used.

**Files** /usr/lib  
/usr/lib/libx.a  
/usr/ucblib  
/usr/ucblib/libx.a

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [ar\(1\)](#), [as\(1\)](#), [cc\(1B\)](#), [ld\(1\)](#), [lorder\(1\)](#), [strip\(1\)](#), [tsort\(1\)](#), [attributes\(5\)](#)

**Name** ldap – LDAP as a naming repository

**Description** LDAP refers to Lightweight Directory Access Protocol, which is an industry standard for accessing directory servers. By initializing the client using `ldapclient(1M)` and using the keyword `ldap` in the name service switch file, `/etc/nsswitch.conf`, Solaris clients can obtain naming information from an LDAP server. Information such as usernames, hostnames, and passwords are stored on the LDAP server in a Directory Information Tree or DIT. The DIT consists of entries which in turn are composed of attributes. Each attribute has a type and one or more values.

Solaris LDAP clients use the LDAP v3 protocol to access naming information from LDAP servers. The LDAP server must support the object classes and attributes defined in *RFC2307bis (draft)*, which maps the naming service model on to LDAP. As an alternate to using the schema defined in *RFC2307bis (draft)*, the system can be configured to use other schema sets and the schema mapping feature is configured to map between the two. Refer to the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* for more details.

The `ldapclient(1M)` utility can make a Solaris machine an LDAP client by setting up the appropriate directories, files, and configuration information. The LDAP client caches this configuration information in local cache files. This configuration information is accessed through the `ldap_cachemgr(1M)` daemon. This daemon also refreshes the information in the configuration files from the LDAP server, providing better performance and security. The `ldap_cachemgr` must run at all times for the proper operation of the naming services.

There are two types of configuration information, the information available through a profile, and the information configured per client. The profile contains all the information as to how the client accesses the directory. The credential information for proxy user is configured on a per client basis and is not downloaded through the profile.

The profile contains server-specific parameters that are required by all clients to locate the servers for the desired LDAP domain. This information could be the server's IP address and the search base Distinguished Name (DN), for instance. It is configured on the client from the default profile during client initialization and is periodically updated by the `ldap_cachemgr` daemon when the expiration time has elapsed.

Client profiles can be stored on the LDAP server and can be used by the `ldapclient` utility to initialize an LDAP client. Using the client profile is the easiest way to configure a client machine. See `ldapclient(1M)`.

Credential information includes client-specific parameters that are used by a client. This information could be the Bind DN (LDAP “login” name) of the client and the password. If these parameters are required, they are manually defined during the initialization through `ldapclient(1M)`.

The naming information is stored in containers on the LDAP server. A container is a non-leaf entry in the DIT that contains naming service information. Containers are similar to maps in

NIS and tables in NIS+. A default mapping between the NIS databases and the containers in LDAP is presented below. The location of these containers as well as their names can be overridden through the use of `serviceSearchDescriptors`. For more information, see [ldapclient\(1M\)](#).

| Database   | Object Class                  | Container                 |
|------------|-------------------------------|---------------------------|
| passwd     | posixAccount<br>shadowAccount | ou=people,dc=...          |
| group      | posixGroup                    | ou=Group,dc=...           |
| services   | ipService                     | ou=Services,dc=...        |
| protocols  | ipProtocol                    | ou=Protocols,dc=...       |
| rpc        | oncRpc                        | ou=Rpc,dc=...             |
| hosts      | ipHost                        | ou=Hosts,dc=...           |
| ipnodes    | ipHost                        | ou=Hosts,dc=...           |
| ethers     | ieee802Device                 | ou=Ethers,dc=...          |
| bootparams | bootableDevice                | ou=Ethers,dc=...          |
| networks   | ipNetwork                     | ou=Networks,dc=...        |
| netmasks   | ipNetwork                     | ou=Networks,dc=...        |
| netgroup   | nisNetgroup                   | ou=Netgroup,dc=...        |
| aliases    | mailGroup                     | ou=Aliases,dc=...         |
| publickey  | nisKeyObject                  |                           |
| generic    | nisObject                     | nisMapName=...,dc=...     |
| printers   | printerService                | ou=Printers,dc=...        |
| auth_attr  | SolarisAuthAttr               | ou=SolarisAuthAttr,dc=... |
| prof_attr  | SolarisProfAttr               | ou=SolarisProfAttr,dc=... |
| exec_attr  | SolarisExecAttr               | ou=SolarisProfAttr,dc=... |
| user_attr  | SolarisUserAttr               | ou=people,dc=...          |
| audit_user | SolarisAuditUser              | ou=people,dc=...          |

The security model for clients is defined by a combination of the credential level to be used, the authentication method, and the PAM modules to be used. The credential level defines what credentials the client should use to authenticate to the directory server, and the

authentication method defines the method of choice. Both these can be set with multiple values. The Solaris LDAP supports the following values for credential level :

```
anonymous
proxy
self
```

The Solaris LDAP supports the following values for authentication method:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

When the credential level is configured as `self`, DNS must be configured and the authentication method must be `sasl/GSSAPI`. The `hosts` and `ipnodes` in `/etc/nsswitch.conf` must be configured to use DNS, for example `hosts: dns files` and `ipnodes: dns files`.

`sasl/GSSAPI` automatically uses GSSAPI confidentiality and integrity options, if they are configured on the directory server.

The credential level of `self` enables per-user naming service lookups, or lookups that use the GSSAPI credentials of the user when connecting to the directory server. Currently the only GSSAPI mechanism supported in this model is Kerberos V5. Kerberos must be configured before you can use this credential level. See [kerberos\(5\)](#) for details.

More protection can be provided by means of access control, allowing the server to grant access for certain containers or entries. Access control is specified by Access Control Lists (ACLs) that are defined and stored in the LDAP server. The Access Control Lists on the LDAP server are called Access Control Instructions (ACIs) by the the SunOne Directory Server. Each ACL or ACI specifies one or more directory objects, for example, the `cn` attribute in a specific container, one or more clients to whom you grant or deny access, and one or more access rights that determine what the clients can do to or with the objects. Clients can be users or applications. Access rights can be specified as read and write, for example. Refer to the [System Administration Guide: Naming and Directory Services \(DNS, NIS, and LDAP\)](#) regarding the restrictions on ACLs and ACIs when using LDAP as a naming repository.

A sample `nsswitch.conf(4)` file called `nsswitch.ldap` is provided in the `/etc` directory. This is copied to `/etc/nsswitch.conf` by the `ldapclient(1M)` utility. This file uses LDAP as a repository for the different databases in the `nsswitch.conf` file.

The following is a list of the user commands related to LDAP:

**idsconfig(1M)**      Prepares a SunOne Directory Server to be ready to support Solaris LDAP clients.

**ldapaddent(1M)**    Creates LDAP entries from corresponding /etc files.

**ldapclient(1M)**    Initializes LDAP clients, or generates a configuration profile to be stored in the directory.

**ldaplist(1)**        Lists the contents of the LDAP naming space.

**Files**    /var/ldap/ldap\_client\_cred  
          /var/ldap/ldap\_client\_file      Files that contain the LDAP configuration of the client. Do not manually modify these files. Their content is not guaranteed to be human readable. Use **ldapclient(1M)** to update them.

          /etc/nsswitch.conf              Configuration file for the name-service switch.

          /etc/nsswitch.ldap              Sample configuration file for the name-service switch configured with LDAP and files.

          /etc/pam.conf                  PAM framework configuration file.

**See Also** **ldaplist(1)**, **idsconfig(1M)**, **ldap\_cachemgr(1M)**, **ldapaddent(1M)**, **ldapclient(1M)**, **nsswitch.conf(4)**, **pam.conf(4)**, **kerberos(5)**, **pam\_authok\_check(5)**, **pam\_authok\_get(5)**, **pam\_authok\_store(5)**, **pam\_dhkeys(5)**, **pam\_ldap(5)**, **pam\_passwd\_auth(5)**, **pam\_unix\_account(5)**, **pam\_unix\_auth(5)**, **pam\_unix\_session(5)**

*System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*

**Notes**    The **pam\_unix(5)** module is no longer supported. Similar functionality is provided by **pam\_authok\_check(5)**, **pam\_authok\_get(5)**, **pam\_authok\_store(5)**, **pam\_dhkeys(5)**, **pam\_passwd\_auth(5)**, **pam\_unix\_account(5)**, **pam\_unix\_auth(5)**, and **pam\_unix\_session(5)**.

**Name** ldapdelete – ldap delete entry tool

**Synopsis** ldapdelete [-n] [-v] [-c] [-d *debuglevel*] [-f *file*]  
 [-D *bindDN*] [-w *passwd* | -j *file*] [-J [:criticality]]  
 [-?] [-H] [-h *ldaphost*] [-V *version*] [-i *locale*]  
 [-k *path*] [-P *path*] [-N *certificate*] [-y *proxyid*]  
 [-p *ldapport*] [-O *hoplimit*] [-o *attributename=value*]  
 [-W *password*] [*dn*]...

**Description** The ldapdelete utility opens a connection to an LDAP server, then binds and deletes one or more entries. If one or more *dn* arguments are provided, entries with those distinguished names are deleted. If no *dn* arguments are provided, a list of DN's is read from *file*, if the -f option is specified, or from standard input.

**Options** The following options are supported:

- a Bypass confirmation question when deleting a branch.
- c Continuous operation mode. Errors are reported, but ldapdelete will continue with deletions. The default is to exit after reporting an error.
- d *debuglevel* Sets the LDAP debugging level. Useful levels of debugging for ldapdelete are:
 

|     |                |
|-----|----------------|
| 1   | Trace          |
| 2   | Packets        |
| 4   | Arguments      |
| 32  | Filters        |
| 128 | Access control |

 To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a *debuglevel* of 33.
- D *bindDN* Uses the distinguished name *bindDN* to bind to the directory.
- E Ask server to expose (report) bind identity by means of authentication response control.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f <i>file</i>     | Reads the entry deletion information from <i>file</i> instead of from standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -?                 | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -H                 | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -h <i>ldaphost</i> | Specifies an alternate host on which the LDAP server is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -i <i>locale</i>   | <p>Specify the character set to use for command-line input. The default is the character set specified in the LANG environment variable. You might want to use this option to perform the conversion from the specified character set to UTF8, thus overriding the LANG setting.</p> <p>Using this argument, you can input the bind DN and the target DN in the specified character set. The <code>ldapdelete</code> tool converts the input from these arguments before it processes the search request. For example, <code>-i no</code> indicates that the bind DN and target DN are provided in Norwegian.</p> <p>This option affects only the command-line input. That is, if you specify a file containing DN's (with the <code>-f</code> option), <code>ldapdelete</code> will not convert the data in the file.</p> |
| -j <i>filename</i> | Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the <code>-w</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                        | and -w options. The -j option is the more secure alternative between -j and -w/-W.                                                                                                                                                                                                                                                                                                                                     |
| -J [:criticality[:value ::b64value b64value :fileurl]] | Criticality is a boolean value (default is false).                                                                                                                                                                                                                                                                                                                                                                     |
| -k path                                                | Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.                                                                                                                                                                                                            |
| -M                                                     | Manage smart referrals. When they are the target of the operation, delete the actual entry containing the referral instead of the entry obtained by following the referral.                                                                                                                                                                                                                                            |
| -n                                                     | Shows what would be done, but does not actually delete entries. Useful in conjunction with options -v and -d for debugging.                                                                                                                                                                                                                                                                                            |
| -N certificate                                         | Specify the certificate name to use for certificate-based client authentication. For example: -N "Directory-Cert".                                                                                                                                                                                                                                                                                                     |
| -o attributename=value                                 | For SASL mechanisms and other options such as security properties, mode of operation, authorization ID, authentication ID, and so forth.<br><br>The different attribute names and their values are as follows:<br><br>secProp="number"      For defining SASL security properties.<br><br>realm="value"          Specifies SASL realm (default is realm=none).<br><br>authzid="value"        Specify the authorization |

|                                                         |                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                         | ID name for SASL bind.                                                                                                                                                                                                                                                              |
| <code>authid="value"</code>                             | Specify the authentication ID for SASL bind.                                                                                                                                                                                                                                        |
| <code>mech="value"</code>                               | Specifies the various SASL mechanisms.                                                                                                                                                                                                                                              |
| <code>-O hopLimit</code>                                | Specify the maximum number of referral hops to follow while finding an entry to delete. By default, there is no limit.                                                                                                                                                              |
| <code>-p ldapport</code>                                | Specifies an alternate TCP port where the LDAP server is listening.                                                                                                                                                                                                                 |
| <code>-P path</code>                                    | <p>Specify the path and filename of the client's certificate database. For example:</p> <p><code>-P /home/uid/.netscape/cert7.db</code></p> <p>When using the command on the same host as the directory server, you can use the server's own certificate database. For example:</p> |
| <code>-P installDir/lapd-serverID/alias/cert7.db</code> | Use the <code>-P</code> option alone to specify server authentication only.                                                                                                                                                                                                         |
| <code>-v</code>                                         | Uses verbose mode, with diagnostics written to standard output.                                                                                                                                                                                                                     |
| <code>-V version</code>                                 | Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.                                                                                             |
| <code>-W password</code>                                | Specify the password for the client's key database given in the <code>-P</code> option. This option is required for certificate-based client authentication. Specifying                                                                                                             |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <p><i>password</i> on the command line has security issues because the password can be seen by others on the system by means of the <code>ps</code> command. Use the <code>-j</code> instead to specify the password from the file. This option is mutually exclusive of <code>-j</code>.</p>                                                                                                                                                                                                                                                             |
| <code>-w password</code> | <p>Use <i>password</i> as the password for authentication to the directory. When you use <code>-w password</code> to specify the password to be used for authentication, the password is visible to other users of the system by means of the <code>ps</code> command, in script files or in shell history. If you use the <code>ldapdelete</code> command without this option, the command will prompt for the password and read it from standard in. When used without the <code>-w</code> option, the password will not be visible to other users.</p> |
| <code>-Y proxyid</code>  | <p>Specify the proxy DN (proxied authorization id) to use for the delete operation, usually in double quotes ("" ) for the shell.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-Z</code>          | <p>Specify that SSL be used to provide certificate-based client authentication. This option requires the <code>-N</code> and SSL password and any other of the SSL options needed to identify the certificate and the key database.</p>                                                                                                                                                                                                                                                                                                                   |

**Operands** The following operand is supported:

*dn* Specifies one or several distinguished names of entries to delete.

**Examples** **EXAMPLE 1** Deleting an Entry

To delete the entry named with commonName Delete Me directly below the XYZ Corporation organizational entry, use the following command:

```
example% ldapdelete -D "cn=Administrator, o=XYZ, c=US" \
 "cn=Delete Me, o=XYZ, c=US"
```

**EXAMPLE 2** Deleting an Entry Using SASL Authentication

To delete the entry named with commonName "Delete Me" directly below the XYZ Corporation organizational entry, use the following command:

```
example% ldapdelete -o mech=DIGEST-MD5 -o secProp=noanonymous \
-o realm=none -o authid="dn:uid=foo,o=XYZ, c=US" \
"cn=Delete Me, o=XYZ, c=US"
```

**Attributes** See [attributes\(5\)](#) for a description of the following attributes:

| ATTRIBUTETYPE   | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- Non-zero An error occurred. A diagnostic message is written to standard error.

**Notes** The -M *authentication* option is obsolete.

**Name** ldaplist – search and list naming information from an LDAP directory using the configured profile

**Synopsis** /usr/bin/ldaplist [-dlv] [*database* [*key*]....]

/usr/bin/ldaplist -h

**Description** The ldaplist utility searches for and lists the naming information from the LDAP directory service defined in the LDAP configuration files generated by [ldapclient\(1M\)](#) during the client initialization phase. The Solaris LDAP client must be set up in order to use this utility.

The database is either a container name or a database name as defined in [nsswitch.conf\(4\)](#). A container is a non-leaf entry in the Directory Information Tree (DIT) that contains naming service information. The container name is the LDAP Relative Distinguished Name (RDN) of the container relative to the defaultSearchBase as defined in the configuration files. For example, for a container named ou=people, the database name is the database specified in [nsswitch.conf](#). This database is mapped to a container, for example, passwd maps to ou=people. If an invalid database is specified, it is mapped to a generic container, for example, nisMapName=name).

The key is the attribute value to be searched in the database. You can specify more than one key to be searched in the same database. The key can be specified in either of two forms: *attribute=value* or *value*. In the first case, ldaplist passes the search key to the server. In the latter case, an attribute is assigned depending on how the database is specified. If the database is a container name, then the “cn” attribute type is used. If the database is a valid database name as defined in the [nsswitch.conf](#), then a predefined attribute type is used (see table below). If the database is an invalid database name, then cn is used as the attribute type.

The ldaplist utility relies on the Schema defined in the *RFC 2307bis*, currently an IETF draft. The data stored on the LDAP server must be stored based on this Schema, unless the profile contains schema mapping definitions. For more information on schema mapping see [ldapclient\(1M\)](#). The following table lists the default mapping from the database names to the container, the LDAP object class, and the attribute type used if not defined in the key.

| Database   | Object Class   | Attribute Type  | Container               |
|------------|----------------|-----------------|-------------------------|
| aliases    | mailGroup      | cn              | ou=Aliases              |
| automount  | nisObject      | cn              | automountMapName=auto_* |
| bootparams | bootableDevice | cn              | ou=Ethers               |
| ethers     | ieee802Device  | cn              | ou=Ethers               |
| group      | posixgroup     | cn              | ou=Group                |
| hosts      | ipHost         | cn              | ou=Hosts                |
| ipnodes    | ipHost         | cn              | ou=Hosts                |
| netgroup   | ipNetgroup     | cn              | ou=Netgroup             |
| netmasks   | ipNetwork      | ipnetworknumber | ou=Networks             |
| networks   | ipNetwork      | ipnetworknumber | ou=Networks             |
| passwd     | posixAccount   | uid             | ou=People               |

|            |                  |             |                    |
|------------|------------------|-------------|--------------------|
| protocols  | ipProtocol       | cn          | ou=Protocols       |
| publickey  | nisKeyObject     | uidnumber   | ou=People          |
|            |                  | cn          | ou=Hosts           |
| rpc        | oncRpc           | cn          | ou=Rpc             |
| services   | ipService        | cn          | ou=Services        |
| printers   | printerService   | printer-uri | ou=printers        |
| auth_attr  | SolarisAuthAttr  | nameT       | ou=SolarisAuthAttr |
| prof_attr  | SolarisProfAttr  | nameT       | ou=SolarisProfAttr |
| exec_attr  | SolarisExecAttr  | nameT       | ou=SolarisProfAttr |
| user_attr  | SolarisUserAttr  | uidT        | ou=people          |
| audit_user | SolarisAuditUser | uidT        | ou=people          |

The following databases are available only if the system is configured with Trusted Extensions:

|        |                |                    |           |
|--------|----------------|--------------------|-----------|
| tnrhtp | ipTnetTemplate | ipTnetTemplateName | ou=ipTnet |
| tnrhdb | ipTnetHost     | ipTnetNumber       | ou=ipTnet |

- For the automount database, `auto_*`, in the container column, represents `auto_home`, `auto_direct`, ...
- For the publickey database, if the key starts with a digit, it is interpreted as an uid number. If the key starts with a non-digit, it is interpreted as a host name.

The `ldaplist` utility supports substring search by using the wildcard “\*” in the key. For example, “my\*” matches any strings that starts with “my”. In some shell environments, keys containing the wildcard may need to be quoted.

If the key is not specified, all the containers in the current search baseDN is listed.

**Options** The following options are supported:

- d Lists the attributes for the specified database, rather than the entries. By default, the entries are listed.
- h Lists the database mapping.
- l Lists all the attributes for each entry matching the search criteria. By default, `ldaplist` lists only the Distinguished Name of the entries found.
- v Sets verbose mode. The `ldaplist` utility also prints the filter used to search for the entry. The filter is prefixed with “+++”.

**Examples** **EXAMPLE 1** Listing All Entries in the Hosts Database

The following example lists all entries in the hosts database:

```
example% ldaplist hosts
```

**EXAMPLE 2** Listing All Entries in a Non-Standard Database `ou=new`

The following example lists all entries in a non-standard database:

```
example% ldaplist ou=new
```

**EXAMPLE 3** Finding `user1` in the `passwd` Database

The following example finds `user1` in the `passwd` database:

```
example% ldaplist passwd user1
```

**EXAMPLE 4** Finding the Entry With Service Port of `4045` in the `services` Database

The following example finds the entry with the service port of `4045` in the `services` database:

```
example% ldaplist services ipServicePort=4045
```

**EXAMPLE 5** Finding All Users With Username Starting with `new` in the `passwd` Database

The following example finds all users with the username starting with `new` in the `passwd` database:

```
example% ldaplist passwd 'new*'
```

**EXAMPLE 6** Listing the Attributes for the `hosts` Database

The following example lists the attributes for the `hosts` database:

```
example% ldaplist -d hosts
```

**Exit Status** The following exit values are returned:

- 0     Successfully matched some entries.
- 1     Successfully searched the table and no matches were found.
- 2     An error occurred. An error message is output.

**Files** `/var/ldap/ldap_client_file`  
`/var/ldap/ldap_client_cred`

Files that contain the LDAP configuration of the client. Do not manually modify these files. Their content is not guaranteed to be human readable. To update these files, use [ldapclient\(1M\)](#)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWnisu        |
| Interface Stability | Evolving        |

**Notes** *RFC 2307bis* is an IETF informational document in draft stage that defines an approach for using LDAP as a naming service.

**Name** ldapmodify, ldapadd – ldap entry addition and modification tools

**Synopsis** ldapmodify [-a] [-c] [-r] [-n] [-v] [-F] [-b] [-A] [-q]  
 [-H] [-?] [-E] [-J] [-Z] [-M] [-d *debuglevel*]  
 [-D *bindDN*] [-j *filename*] [-J [:criticality]]  
 [-B *baseDN*] [-V *version*] [-Y *proxyDN*] [-O *hopLimit*]  
 [-i *locale*] [-k *path*] [-e *errorFile*] [-P *path*]  
 [-N *certificate*] [-w *passwd*] [-o *attributename=value*]  
 [-h *ldaphost*] [-W *password*] [-p *ldapport*] [-f *file*]  
 [-l *nb-ldap-connections*]

ldapadd [-c] [-n] [-v] [-F]  
 [-b] [-A] [-q] [-H] [-?] [-E] [-J] [-Z] [-M] [-d *debuglevel*]  
 [-D *bindDN*] [-j *filename*] [-B *baseDN*] [-V *version*]  
 [-Y *proxyDN*] [-O *hopLimit*] [-i *locale*] [-k *path*]  
 [-e *errorFile*] [-P *path*] [-N *certificate*] [-w *passwd*]  
 [-o *attributename=value*] [-h *ldaphost*] [-W *password*]  
 [-p *ldapport*] [-f *file*] [-l *nb-ldap-connections*]

**Description** The `ldapmodify` utility opens a connection to an LDAP server, binds and modifies or adds entries. The entry information is read from standard input or from *file*, specified using the `-f` option. The `ldapadd` utility is implemented as a hard link to the `ldapmodify` tool. When invoked as `ldapadd`, the `-a` (add new entry) option is turned on automatically.

Both `ldapadd` and `ldapmodify` reject duplicate attribute-name/value pairs for the same entry.

**Options** The following options are supported:

- a Adds new entries. The default for `ldapmodify` is to modify existing entries. If invoked as `ldapadd`, this option is always set.
- A Non-ASCII mode: display non-ASCII values, in conjunction with the `-v` option.
- b Handle binary files. The `ldapmodify` tool will scan every attribute value in the input to determine whether it is a valid file reference. If the reference is valid, it will use the contents of the file as the attribute's value. This option is used to input binary data, such as a JPEG image, for an attribute. For example, the corresponding LDIF input would be: "jpegPhoto: /tmp/photo.jpg" The `ldapmodify` tool

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |       |   |         |   |           |    |         |     |                |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|-------|---|---------|---|-----------|----|---------|-----|----------------|
|                      | also supports the LDIF <code>:&lt; URL</code> notation for directly including file contents.                                                                                                                                                                                                                                                                                                                                                                                                        |   |       |   |         |   |           |    |         |     |                |
| -B <i>baseDN</i>     | Specify the base DN when performing additions, usually in double quotes (") for the shell. All entries will be placed under this suffix, thus providing bulk import functionality.                                                                                                                                                                                                                                                                                                                  |   |       |   |         |   |           |    |         |     |                |
| -c                   | Specifies continuous operation mode. Errors are reported, but <code>ldapmodify</code> and <code>ldapadd</code> continue with modifications. The default is to exit after reporting an error.                                                                                                                                                                                                                                                                                                        |   |       |   |         |   |           |    |         |     |                |
| -D <i>bindDN</i>     | Uses the distinguished name <i>bindDN</i> to bind to the directory.                                                                                                                                                                                                                                                                                                                                                                                                                                 |   |       |   |         |   |           |    |         |     |                |
| -d <i>debuglevel</i> | Sets the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are:<br><table><tr><td>1</td><td>Trace</td></tr><tr><td>2</td><td>Packets</td></tr><tr><td>4</td><td>Arguments</td></tr><tr><td>32</td><td>Filters</td></tr><tr><td>128</td><td>Access control</td></tr></table> To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33. | 1 | Trace | 2 | Packets | 4 | Arguments | 32 | Filters | 128 | Access control |
| 1                    | Trace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |       |   |         |   |           |    |         |     |                |
| 2                    | Packets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |   |       |   |         |   |           |    |         |     |                |
| 4                    | Arguments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |       |   |         |   |           |    |         |     |                |
| 32                   | Filters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |   |       |   |         |   |           |    |         |     |                |
| 128                  | Access control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |   |       |   |         |   |           |    |         |     |                |
| -e <i>errorFile</i>  | Invalid update statements in the input will be copied to the <i>errorFile</i> for debugging. Use with the <code>-c</code> option to correct errors when processing large LDIF input.                                                                                                                                                                                                                                                                                                                |   |       |   |         |   |           |    |         |     |                |
| -E                   | Ask server to expose (report) bind identity by means of authentication response control.                                                                                                                                                                                                                                                                                                                                                                                                            |   |       |   |         |   |           |    |         |     |                |
| -F                   | Forces application of all changes regardless of the content of input lines                                                                                                                                                                                                                                                                                                                                                                                                                          |   |       |   |         |   |           |    |         |     |                |

|                                                                     |                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     | that begin with <code>replica:</code> . By default, <code>replica:</code> lines are compared against the LDAP server host and port in use to decide whether a relog record should be applied.                                                                                                                                         |
| <code>-f file</code>                                                | Reads the entry modification information from <i>file</i> instead of from standard input.                                                                                                                                                                                                                                             |
| <code>-?</code>                                                     | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                       |
| <code>-H</code>                                                     | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                       |
| <code>-h ldaphost</code>                                            | Specifies an alternate host on which the LAPD server is running.                                                                                                                                                                                                                                                                      |
| <code>-i locale</code>                                              | Specify the character set to use for the <code>-f LDIFfile</code> or standard input. The default is the character set specified in the <code>LANG</code> environment variable. You might choose to use this option to perform the conversion from the specified character set to UTF8, thus overriding the <code>LANG</code> setting. |
| <code>-j filename</code>                                            | Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the <code>-w</code> and <code>-W</code> options.                                          |
| <code>-J [:criticality[:value ::b64value b64value :fileurl]]</code> | Criticality is a boolean value (default is false).                                                                                                                                                                                                                                                                                    |
| <code>-k path</code>                                                | Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.                                                                                                                           |
| <code>-l nb-ldap-connections</code>                                 | Specifies the number of LDAP connections that <code>ldapadd</code> or                                                                                                                                                                                                                                                                 |

- M  
ldapmodify will open to process the modifications in the directory. The default is one connection.  
Manage smart referrals. When they are the target of the operation, modify the entry containing the referral instead of the entry obtained by following the referral.
- n  
Previews modifications, but makes no changes to entries. Useful in conjunction with -v and -d for debugging.
- N *certificate*  
Specify the certificate name to use for certificate-based client authentication. For example: -N "Directory-Cert".
- o *attributename=value*  
For SASL mechanisms and other options such as security properties, mode of operation, authorization ID, authentication ID, and so forth.

The different attribute names and their values are as follows:

- secProp="number"      For defining SASL security properties.
- realm="value"      Specifies SASL realm (default is realm=none).
- authzid="value"      Specify the authorization ID name for SASL bind.
- authid="value"      Specify the authentication ID for SASL bind.
- mech="value"      Specifies the various SASL

mechanisms.

*-O hopLimit*

Specify the maximum number of referral hops to follow while finding an entry to modify. By default, there is no limit.

*-p ldapport*

Specifies an alternate TCP port where the secure LDAP server is listening.

*-P path*

Specify the path and filename of the client's certificate database. For example:

*-P /home/uid/.netscape/cert7.db*

When using the command on the same host as the directory server, you can use the server's own certificate database. For example:

*-P installDir/ldap-serverID/alias/cert7.db*

Use the *-P* option alone to specify server authentication only.

*-r*

Replaces existing value with the specified value. This is the default for *ldapmodify*. When *ldapadd* is called, or if the *-a* option is specified, the *-r* option is ignored.

*-v*

Uses verbose mode, with diagnostics written to standard output.

*-V version*

Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.

*-W password*

Specify the password for the client's key database given in the *-P* option. This option is required for certificate-based client authentication. Specifying *password* on the command line has security issues because the password can be seen by others on the system by

**-w** *passwd*

means of the `ps` command. Use the `-j` instead to specify the password from the file. This option is mutually exclusive of `-j`.

Use *passwd* as the password for authentication to the directory. When you use `-w passwd` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history. If you use either the `ldapmodify` command or the `ldapadd` command without this option, the command will prompt for the password and read it from standard in. When used without the `-w` option, the password will not be visible to other users.

**-Y** *proxyid*

Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes ("" ) for the shell.

**-Z**

Specify that SSL be used to provide certificate-based client authentication. This option requires the `-N` and SSL password and any other of the SSL options needed to identify the certificate and the key database.

**Exit Status** The following exit values are returned:

0 Successful completion.

Non-zero An error occurred. A diagnostic message is written to standard error.

**Examples** The format of the content of *file* (or standard input if no `-f` option is specified) is illustrated in the following examples.

**EXAMPLE 1** Modifying an Entry

The file `/tmp/entrymods` contains the following modification instructions:

```
dn: cn=Modify Me, o=XYZ, c=US
changetype: modify
```

**EXAMPLE 1** Modifying an Entry (Continued)

```

replace: mail
mail: modme@atlanta.xyz.com
-
add: title
title: System Manager
-
add: jpegPhoto
jpegPhoto:< file:///tmp/modme.jpeg
-
delete: description
-

```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

modifies the Modify Me entry as follows:

1. The current value of the mail attribute is replaced with the value, modme@atlanta.xyz.com.
2. A title attribute with the value, System Manager, is added.
3. A jpegPhoto attribute is added, using the contents of the file, /tmp/modme.jpeg, as the attribute value.
4. The description attribute is removed.

**EXAMPLE 2** Creating a New Entry

The file, /tmp/newentry, contains the following information for creating a new entry:

```

dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones

```

The command

```
example% ldapadd -f /tmp/newentry
```

adds a new entry for Ann Jones, using the information in the file.

**EXAMPLE 3** Creating a New Entry on an IPv6 Server

The file, /tmp/newentry, contains the following information for creating a new entry: on an IPv6 server.

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command

```
example% ldapadd -c -v -h '["fec0::111:a00:20ff:feaa:a364"]':389 \
-D cn=Directory Manager -w secret \
-f /tmp/entry
```

adds a new entry for Directory Manager, using the information in the file.

**EXAMPLE 4** Deleting an Entry

The file, /tmp/badentry, contains the following information about an entry to be deleted:

```
dn: cn=Ann Jones, o=XYZ, c=US
changetype: delete
```

The command:

```
example% ldapmodify -f /tmp/badentry
```

removes Ann Jones' entry.

**Attributes** See [attributes\(5\)](#) for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**See Also** [ldap\(1\)](#), [ldapdelete\(1\)](#), [ldaplist\(1\)](#), [ldapmodrdn\(1\)](#), [ldapsearch\(1\)](#), [ldapaddent\(1M\)](#), [ldap\\_cachemgr\(1M\)](#), [ldap\\_get\\_option\(3LDAP\)](#), [ldap\\_set\\_option\(3LDAP\)](#), [attributes\(5\)](#)

**Name** ldapmodrdn – ldap modify entry RDN tool

**Synopsis** ldapmodrdn [-r] [-n] [-v] [-c] [-E] [-H] [-?] [-M] [-R]  
 [-Z] [-V *version*] [-d *debuglevel*] [-D *bindDN*]  
 [-w *passwd*] [-h *ldaphost*] [-i *locale*] [-j *filename*]  
 [-J [:criticality]] [-k *path*] [-N *certificate*]  
 [-O *hopLimit*] [-P *path*] [-W *password*] [-p *ldapport*]  
 [-o *attributename=value*] [-f *file*] [-Y *proxyDN*]  
 [*dn rdn*]

**Description** ldapmodrdn opens a connection to an LDAP server, binds, and modifies the RDN of entries. The entry information is read from standard input, from *file* through the use of the -f option, or from the command-line pair *dn* and *rdn*.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b> -c    | Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.                                                                                                                                                                                                                                                             |
| -D <i>bindDN</i>     | Use the distinguished name <i>binddn</i> to bind to the directory.                                                                                                                                                                                                                                                                                                                                        |
| -d <i>debuglevel</i> | Set the LDAP debugging level. Useful values of <i>debuglevel</i> for ldapmodrdn are:<br><div style="margin-left: 20px;"> 1      Trace<br/> 2      Packets<br/> 4      Arguments<br/> 32     Filters<br/> 128    Access control </div> To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33. |
| -E                   | Ask server to expose (report) bind identity by means of authentication response control.                                                                                                                                                                                                                                                                                                                  |
| -f <i>file</i>       | Read the entry modification information from <i>file</i> instead of from standard input or the command-line.                                                                                                                                                                                                                                                                                              |
| -?                   | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                                                                                           |

|                                                              |                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -H                                                           | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                       |
| -h <i>ldaphost</i>                                           | Specify an alternate host on which the LDAP server is running.                                                                                                                                                                                                                                        |
| -i <i>locale</i>                                             | Specify the character set to use for the -f <i>LDIFfile</i> or standard input. The default is the character set specified in the LANG environment variable. You might choose to use this option to perform the conversion from the specified character set to UTF8, thus overriding the LANG setting. |
| -J <i>[:criticality[:value :b64value b64value :fileurl]]</i> | Criticality is a boolean value (default is false).                                                                                                                                                                                                                                                    |
| -j <i>filename</i>                                           | Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w and -W options.                                    |
| -k <i>path</i>                                               | Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.                                                                                           |
| -M                                                           | Manage smart referrals. When they are the target of the operation, modify the entry containing the referral instead of the entry obtained by following the referral.                                                                                                                                  |
| -n                                                           | Previews modifications, but makes no changes to entries. Useful in conjunction with -v and -d for debugging.                                                                                                                                                                                          |
| -N <i>certificate</i>                                        | Specify the certificate name to use for certificate-based client authentication. For example: -N "Directory-Cert".                                                                                                                                                                                    |

---

|                                     |                                                                                                                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n</code>                     | Show what would be done, but do not actually change entries. Useful in conjunction with <code>-v</code> for debugging.                                                                                         |
| <code>-o attributename=value</code> | For SASL mechanisms and other options such as security properties, mode of operation, authorization ID, authentication ID, and so forth.<br><br>The different attribute names and their values are as follows: |
| <code>secProp="number"</code>       | For defining SASL security properties.                                                                                                                                                                         |
| <code>realm="value"</code>          | Specifies SASL realm (default is <code>realm=none</code> ).                                                                                                                                                    |
| <code>authzid="value"</code>        | Specify the authorization ID name for SASL bind.                                                                                                                                                               |
| <code>authid="value"</code>         | Specify the authentication ID for SASL bind.                                                                                                                                                                   |
| <code>mech="value"</code>           | Specifies the various SASL mechanisms.                                                                                                                                                                         |
| <code>-O hopLimit</code>            | Specify the maximum number of referral hops to follow while finding an entry to modify. By default, there is no limit.                                                                                         |
| <code>-P path</code>                | Specify the path and filename of the client's certificate database. For example:<br><br><code>-P /home/uid/.netscape/cert7.db</code>                                                                           |

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                          | When using the command on the same host as the directory server, you can use the server's own certificate database. For example:                                                                                                                                                                                                                                                                                                                                |
| <code>-P installDir/\lapd-serverID/alias/cert7.db</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                                          | Use the <code>-P</code> option alone to specify server authentication only.                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-p ldappport</code>                                | Specify an alternate TCP port where the secure LAPD server is listening.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-R</code>                                          | Do not automatically follow referrals returned while searching.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-r</code>                                          | Remove old RDN values from the entry. By default, old values are kept.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-V version</code>                                  | Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.                                                                                                                                                                                                                                                                         |
| <code>-v</code>                                          | Use verbose mode, with diagnostics written to standard output.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-W password</code>                                 | Specify the password for the client's key database given in the <code>-P</code> option. This option is required for certificate-based client authentication. Specifying <i>password</i> on the command line has security issues because the password can be seen by others on the system by means of the <code>ps</code> command. Use the <code>-j</code> instead to specify the password from the file. This option is mutually exclusive of <code>-j</code> . |
| <code>-w passwd</code>                                   | Use <i>passwd</i> as the password for authentication to the directory. When you use <code>-w passwd</code> to specify the password to be used for authentication, the password is visible to other users of the system by means of the <code>ps</code> command, in script files or in shell                                                                                                                                                                     |

history. If you use the `ldapmodrdn` command without this option, the command will prompt for the password and read it from standard in. When used without the `-w` option, the password will not be visible to other users.

`-Y proxyid`

Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes (""") for the shell.

`-Z`

Specify that SSL be used to provide certificate-based client authentication. This option requires the `-N` and SSL password and any other of the SSL options needed to identify the certificate and the key database.

**Input Format** If the command-line arguments *dn* and *rdn* are given, *rdn* replaces the RDN of the entry specified by the DN, *dn*.

Otherwise, the contents of *file* (or standard input if the `-f` option is not specified) must consist of one or more pair of lines:

```
Distinguished Name (DN)
Relative Distinguished Name (RDN)
```

Use one or more blank lines to separate each DN/RDN pair.

**Examples** The file `/tmp/entrymods` contains:

```
cn=Modify Me, o=XYZ, c=US
cn=The New Me
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

changes the RDN of the "Modify Me" entry from "Modify Me" to "The New Me" and the old cn, "Modify Me" is removed.

**Attributes** See [attributes\(5\)](#) for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**See Also** [ldapadd\(1\)](#), [ldapdelete\(1\)](#), [ldapmodify\(1\)](#), [ldapsearch\(1\)](#), [attributes\(5\)](#)

**Diagnostics** Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

**Name** ldapsearch – ldap search tool

**Synopsis** ldapsearch [-n] [-u] [-v] [-t] [-A] [-B] [-L] [-R] [-H]  
 [-?] [-t] [-T] [-B] [-E] [-J] [-e] [-l] [-Z] [-r]  
 [-M] [-d *debuglevel*] [-F *sep*] [-f *file*] [-D *bindDN*]  
 [-j *filename*] [-V *version*] [-Y *proxyDN*] [-O *hopLimit*]  
 [-i *locale*] [-k *path*] [-S [-] *attribute*] [-C *pattern*]  
 [-c *authzid*] [-P *path*] [-N *certificate*] [-w *passwd*]  
 [-h *ldaphost*] [-p *ldapport*] [-o *attributename=value*]  
 [-b *searchbase*] [-s *scope*] [-a *deref*] [-l *timelimit*]  
 [-z *sizelimit*] *filter* [*attrs*]...

**Description** The ldapsearch utility opens a connection to an LDAP server, binds, and performs a search using the *filter*.

If ldapsearch finds one or more entries, the attributes specified by *attrs* are retrieved and the entries and values are printed to standard output. If no *attrs* are listed, all attributes are returned.

**Output Format** If one or more entries are found, each entry is written to standard output in the form:

```
dn: Distinguished Name (DN)
 attributename: value
 attributename: value
 attributename: value
...
```

Multiple entries are separated with a single blank line. If the -F option is used to specify a different separator character, this character is used instead of the : character. If the -t option is used, the name of a temporary file is returned in place of the actual value. If the -A option is given, only the “attributename” is returned and not the attribute value.

**Options** The following options are supported:

- A Retrieve attributes only (no values). This is useful when you just want to see whether an attribute is present in an entry and are not interested in the specific value.
- a *deref* Specify how aliases dereferencing is done. The possible values for *deref* are never, always, search, or find to specify respectively that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |       |   |         |   |           |    |         |     |                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|-------|---|---------|---|-----------|----|---------|-----|----------------|
|                      | finding the base object for the search. The default is to never dereference aliases.                                                                                                                                                                                                                                                                                                                                                                         |   |       |   |         |   |           |    |         |     |                |
| -B                   | Display non-ASCII values and use the old non-LDIF format. This option disables the default -L option.                                                                                                                                                                                                                                                                                                                                                        |   |       |   |         |   |           |    |         |     |                |
| -b <i>searchbase</i> | Use <i>searchbase</i> as the starting point for the search instead of the default.                                                                                                                                                                                                                                                                                                                                                                           |   |       |   |         |   |           |    |         |     |                |
| -C <i>pattern</i>    | Persistent search. Perform a search that keeps the connection open and displays results whenever entries matching the scope and filter of the search are added, modified, or removed. With this option, the ldapsearch tool runs indefinitely; you must type Control-c to stop it. The pattern has the following format:<br><br>ps:changeType[:changesOnly[:entryChangeControls]]                                                                            |   |       |   |         |   |           |    |         |     |                |
| -c <i>authzid</i>    | Specifies the getEffectiveRights control <i>authzid</i> . For example:<br><br>dn:uid=bjensen,dc=example,dc=com                                                                                                                                                                                                                                                                                                                                               |   |       |   |         |   |           |    |         |     |                |
| -D <i>bindDN</i>     | Use the distinguished name <i>bindDN</i> to bind to the directory.                                                                                                                                                                                                                                                                                                                                                                                           |   |       |   |         |   |           |    |         |     |                |
| -d <i>debuglevel</i> | Set the LDAP debugging level. Useful levels of debugging for ldapsearch are:<br><br><table><tr><td>1</td><td>Trace</td></tr><tr><td>2</td><td>Packets</td></tr><tr><td>4</td><td>Arguments</td></tr><tr><td>32</td><td>Filters</td></tr><tr><td>128</td><td>Access control</td></tr></table><br>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a debuglevel of 33. | 1 | Trace | 2 | Packets | 4 | Arguments | 32 | Filters | 128 | Access control |
| 1                    | Trace                                                                                                                                                                                                                                                                                                                                                                                                                                                        |   |       |   |         |   |           |    |         |     |                |
| 2                    | Packets                                                                                                                                                                                                                                                                                                                                                                                                                                                      |   |       |   |         |   |           |    |         |     |                |
| 4                    | Arguments                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |       |   |         |   |           |    |         |     |                |
| 32                   | Filters                                                                                                                                                                                                                                                                                                                                                                                                                                                      |   |       |   |         |   |           |    |         |     |                |
| 128                  | Access control                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |       |   |         |   |           |    |         |     |                |

---

|                    |                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -E                 | Ask server to expose (report) bind identity by means of authentication response control.                                                                                                                                                                                                                                                       |
| -e                 | Minimize base-64 encoding of values.                                                                                                                                                                                                                                                                                                           |
| -F <i>sep</i>      | Use <i>sep</i> as the field separator between attribute names and values. If this option has been specified, the -L option is ignored.                                                                                                                                                                                                         |
| -f <i>file</i>     | Read a series of lines from <i>file</i> , performing one LDAP search for each line. In this case, the <i>filter</i> given on the command line is treated as a pattern where the first occurrence of %s is replaced with a line from <i>file</i> . If <i>file</i> is a single - character, then the lines are read from standard input.         |
| -G <i>pattern</i>  | Virtual list view. Retrieve only a portion of all results, as determined by the index or value of the search target and the number of entries to be returned before and after the target. This option always requires the -S and -x options to specify the sorting order on the server.                                                        |
| -?                 | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                                |
| -H                 | Display the usage help text that briefly describes all options.                                                                                                                                                                                                                                                                                |
| -h <i>ldaphost</i> | Specify an alternate host on which the secure LDAP server is running.                                                                                                                                                                                                                                                                          |
| -i <i>locale</i>   | Specify the character set to use for command-line input. The default is the character set specified in the LANG environment variable. You might want to use this option to perform the conversion from the specified character set to UTF8, thus overriding the LANG setting. Using this argument, you can input the bind DN, base DN, and the |

|                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     | <p>search filter pattern in the specified character set. The <code>ldapsearch</code> tool converts the input from these arguments before it processes the search request. For example, <code>-i no</code> indicates that the bind DN, base DN, and search filter are provided in Norwegian. This argument only affects the command-line input. If you specify a file containing a search filter (with the <code>-f</code> option), <code>ldapsearch</code> does not convert the data in the file.</p> |
| <code>-j filename</code>                                            | <p>Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the <code>-w</code> and <code>-W</code> options.</p>                                                                                                                                                                                                   |
| <code>-J [:criticality[:value]::b64value b64value :fileurl]]</code> | <p>Criticality is a boolean value (default is <code>false</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-k path</code>                                                | <p>Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.</p>                                                                                                                                                                                                                                                                                    |
| <code>-L</code>                                                     | <p>Display search results in LDIF format. This option also turns on the <code>-B</code> option. This behavior is the default.</p>                                                                                                                                                                                                                                                                                                                                                                     |

| <code>-r</code>                                         | <p>Display the output of the <code>ldapsearch</code> command in the old format.</p>                                                                                                                                                                                                                                            |
| <code>-S [-]attribute</code>                            | <p>Specify an attribute for sorting the entries returned by the search. The sort criteria is alphabetical on the attribute's value or reverse alphabetical with the form <code>-attribute</code>. You can give multiple <code>-S</code> options to refine the sorting. For example:</p> <p><code>-S sn -S givenname</code></p> |
|                                                         | <p>By default, the entries are not sorted. Use the <code>-x</code> option to perform server-side sorting.</p>                                                                                                                                                                                                                  |
| <code>-s scope</code>                                   | <p>Specify the scope of the search. The possible values of <i>scope</i> are <i>base</i>, <i>one</i>, or <i>sub</i> to specify respectively a base object, one-level, or subtree search. The default is <i>sub</i>.</p>                                                                                                         |
| <code>-T</code>                                         | <p>Format the output of search results so that no line breaks are used within individual attribute values.</p>                                                                                                                                                                                                                 |
| <code>-t</code>                                         | <p>Write retrieved values to a set of temporary files. This is useful for dealing with non-ASCII values such as <i>jpegPhoto</i> or <i>audio</i>.</p>                                                                                                                                                                          |
| <code>-U</code>                                         | <p>URL format (valid only with the <code>-t</code> option). When using temporary file</p>                                                                                                                                                                                                                                      |

output, the standard output of the tool includes the URL of the file instead of the attributes value. For example:

```
jpegPhoto:< file:/tmp/ldapsearch-jpegPhoto-YzaOMh
```

- u Include the user-friendly form of the Distinguished Name (DN) in the output.
- V *version* Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.
- v Run in verbose mode, with diagnostics written to standard output.
- W *password* Specify the password for the client's key database given in the -P option. This option is required for certificate-based client authentication. Specifying *password* on the command line has security issues because the password can be seen by others on the system by means of the ps command. Use the -j instead to specify the password from the file. This option is mutually exclusive of -j.
- w *passwd* Use *passwd* as the password for authentication to the directory. When you use -w *passwd* to specify the password to be used for authentication, the password is visible to other users of the system by means of the ps command, in script files or in shell history. If you use the ldapsearch command without this option, the command prompts for the password and read it from standard in. When used without the -w option, the password is not visible to other users.

|                     |                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -x                  | Use with the -S option to specify that search results be sorted on the server rather than by the <code>ldapsearch</code> command running on the client. This is useful if you want to sort according to a matching rule, as with an international search. It is usually faster to sort on the server, if that is supported, rather than on the client. |
| -Y <i>proxyDN</i>   | Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes (“ ”) for the shell.                                                                                                                                                                                                                         |
| -Z                  | Specify that SSL be used to provide certificate-based client authentication. This option requires the -N and SSL password and any other of the SSL options needed to identify the certificate and the key database.                                                                                                                                    |
| -z <i>sizelimit</i> | Retrieve at most <i>sizelimit</i> entries for a search to complete.                                                                                                                                                                                                                                                                                    |

### Examples **EXAMPLE 1** Performing a Subtree Search

The following command performs a subtree search (using the default search base) for entries with a `commonName` of “mark smith”. The `commonName` and `telephoneNumber` values is retrieved and printed to standard output. Use the -r option to display this output in the old format.

```
example% ldapsearch "cn=mark smith" cn telephoneNumber
```

The output looks something like this:

```
dn: Mark D Smith, ou=Sales, ou=Atlanta, ou=People, o=XYZ, c=US
cn: Mark Smith
cn: Mark David Smith
cn: Mark D Smith 1
cn: Mark D Smith
telephoneNumber: +1 123 456-7890
```

```
dn: Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
cn: Mark Smith
cn: Mark C Smith 1
cn: Mark C Smith
telephoneNumber: +1 123 456-9999
```

**EXAMPLE 2** Performing a Subtree Search Using the Default Search Base

The following command performs a subtree search using the `-r` option to display in old style format with a default search base for entries with user id of `mcs`. The user-friendly form of the entry's DN is output after the line that contains the DN itself, and the `jpegPhoto` and `audio` values are retrieved and written to temporary files.

```
ldapsearch -r -u -t "uid=mcs" -r jpegPhoto audio
```

The output might look like this if one entry with one value for each of the requested attributes is found:

```
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
Mark C Smith, Distribution, Atlanta, People, XYZ, US
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

**EXAMPLE 3** Performing a One-Level Search

The following command performs a one-level search at the `c=US` level for all organizations whose `organizationName` begins with `XY`.

```
example% ldapsearch -s one -b "c=US" "o=XY*" o description
```

The `organizationName` and `description` attribute values are retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=XYZ c=US
 o: XYZ
 description: XYZ Corporation

dn: o="XY Trading Company", c=US
 o: XY Trading Company
 description: Import and export specialists

dn: o=XYInternational, c=US
 o: XYInternational
 o: XYI
 o: XY International
```

**EXAMPLE 4** Performing a Subtree Search on an IPv6 Server

The following command performs a subtree search using the default search base for entries with a user id of `mcs` on an IPv6 (that is, `-h`) server:

```
example% ldapsearch -u -h '["fec0::111:a00:20ff:fea3:edcf"]' \
-t "uid=mcs" jpegPhoto audio
```

**Exit Status** The following exit values are returned:

0      Successful completion.

>0     An error occurred. A diagnostic message is written to standard error.

**Attributes**   See [attributes\(5\)](#) for a description of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Evolving        |

**See Also**   [ldapadd\(1\)](#), [ldapdelete\(1\)](#), [ldapmodify\(1\)](#), [ldapmodrdn\(1\)](#), [attributes\(5\)](#)

**Name** ldd – list dynamic dependencies of executable files or shared objects

**Synopsis** ldd [-d | -r] [-c] [-e *envvar*] [-f] [-i] [-L] [-l] [-s]  
 [-U | -u] [-v] *filename*...

**Description** The ldd utility lists the dynamic dependencies of executable files or shared objects. ldd uses the runtime linker, ld.so.1, to generate the diagnostics. The runtime linker takes the object being inspected and prepares the object as would occur in a running process. By default, ldd triggers the loading of any lazy dependencies.

ldd lists the path names of all shared objects that would be loaded when *filename* is loaded. ldd expects the shared objects that are being inspected to have execute permission. If a shared object does not have execute permission, ldd issues a warning before attempting to process the file.

ldd processes its input one file at a time. For each file, ldd performs one of the following:

- Lists the object dependencies if the dependencies exist.
- Succeeds quietly if dependencies do not exist.
- Prints an error message if processing fails.

The dynamic objects that are inspected by ldd are not executed. Therefore, ldd does not list any shared objects explicitly attached using [dlopen\(3C\)](#). To display all the objects in use by a process, or a core file, use [pldd\(1\)](#).

**Options** ldd can also check the compatibility of *filename* with the shared objects *filename* uses. With each of the following options, ldd prints warnings for any unresolved symbol references that would occur when *filename* is loaded.

- d Check *immediate* references.
- r Check both *immediate* references and *lazy* references.

Only one of the options -d or -r can be specified during any single invocation of ldd. *immediate* references are typically to data items used by the executable or shared object code. *immediate* references are also pointers to functions, and even calls to functions made from a position *dependent* shared object. *lazy* references are typically calls to global functions made from a position *independent* shared object, or calls to external functions made from an executable. For more information on these types of reference, see When Relocations Are Performed in the [Linker and Libraries Guide](#). Object loading can also be affected by relocation processing. See Lazy Loading under USAGE for more details.

ldd can also check dependency use. With each of the following options, ldd prints warnings for any unreferenced, or unused dependencies that are loaded when *filename* is loaded. Only when a symbol reference is bound to a dependency, is that dependency deemed used. These options are therefore only useful when symbol references are being checked. If the -r option is not in effect, the -d option is enabled.

A dependency that is defined by an object but is not bound to from that object is an unreferenced dependency. A dependency that is not bound to by any other object when *filename* is loaded is an unused object.

- U Displays any unreferenced, or unused dependencies. If an unreferenced dependency is not bound to by other objects loaded with *filename*, the dependency is also flagged as unused. Cyclic dependencies that are not bound to from objects outside of the cycle are also deemed unreferenced.
- u Displays any unused objects.

Only one of the options -U or -u can be specified during any single invocation of `ldd`, although -U is a superset of -u. Objects that are found to be unreferenced, or unused when using the -r option, should be removed as dependencies. These objects provide no references, but result in unnecessary overhead when *filename* is loaded. When using the -d option, any objects that are found to be unreferenced, or unused are not immediately required when *filename* is loaded. These objects are candidates for lazy loading. See *Lazy Loading* under *USAGE* for more details.

The removal of unused dependencies reduces runtime-linking overhead. The removal of unreferenced dependencies reduces runtime-linking overhead to a lesser degree. However, the removal of unreferenced dependencies guards against a dependency being unused when combined with different objects, or as the other object dependencies evolve.

The following additional options are supported:

- c Disables any configuration file use. Configuration files can be employed to alter default search paths, and provide alternative object dependencies. See [crle\(1\)](#).
- e *envvar* Sets the environment variable *envvar*.  
  
This option is useful for experimenting with environment variables that are recognized by the runtime linker that can adversely affect `ldd`, for example, `LD_PRELOAD`.  
  
This option is also useful for extracting additional information solely from the object under inspection, for example, `LD_DEBUG`. See [ld.so.1\(1\)](#) and [lari\(1\)](#).
- f Forces `ldd` to check for an executable file that is not secure. When `ldd` is invoked by a superuser, by default `ldd` does not process any executable that is not secure. An executable is not considered secure if the interpreter that the executable specifies does not reside under `/lib`, `/usr/lib` or `/etc/lib`. An executable is also not considered secure if the interpreter cannot be determined. See *Security* under *USAGE*.
- i Displays the order of execution of initialization sections. The order that is discovered can be affected by use of the -d or -r options. See *Initialization Order* under *USAGE*.

- L        Enables lazy loading. Lazy loading is the default mode of operation when the object under inspection is loaded as part of a process. In this case, any lazy dependencies, or filters, are only loaded into the process when reference is made to a symbol that is defined within the lazy object. The -d or -r options, together with the -L option, can be used to inspect the dependencies, and their order of loading as would occur in a running process.
- l        Forces the immediate processing of any filters so that all filtees, and their dependencies, are listed. The immediate processing of filters is now the default mode of operation for ldd. However, under this default any auxiliary filtees that cannot be found are silently ignored. Under the -l option, missing auxiliary filtees generate an error message.
- s        Displays the search path used to locate shared object dependencies.
- v        Displays all dependency relationships incurred when processing *filename*. This option also displays any dependency version requirements. See [pvs\(1\)](#).

## Usage

**Security** A superuser should use the -f option only if the executable to be examined is known to be trustworthy. The use of -f on an untrustworthy executable while superuser can compromise system security. If an executables trustworthyness is unknown, a superuser should temporarily become a regular user. Then invoke ldd as this regular user.

Untrustworthy objects can be safely examined with [dump\(1\)](#) and with [mdb\(1\)](#), as long as the :r subcommand is not used. In addition, a non-superuser can use either the :r subcommand of mdb, or [truss\(1\)](#) to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using ldd, adb :r, or truss on an untrustworthy executable, use the UID "nobody".

**Lazy Loading** Lazy loading can be applied directly by specified lazy dependencies. See the -z lazyload option of [ld\(1\)](#). Lazy loading can also be applied indirectly through filters. See the -f option and -F option of [ld\(1\)](#). Objects that employ lazy loading techniques can experience variations in ldd output due to the options used. If an object expresses all its dependencies as lazy, the default operation of ldd lists all dependencies in the order in which the dependencies are recorded in that object:

```
example% ldd main
libelf.so.1 => /lib/libelf.so.1
libnsl.so.1 => /lib/libnsl.so.1
libc.so.1 => /lib/libc.so.1
```

The lazy loading behavior that occurs when this object is used at runtime can be enabled using the -L option. In this mode, lazy dependencies are loaded when reference is made to a symbol

that is defined within the lazy object. Therefore, combining the `-L` option with use of the `-d` and `-r` options reveals the dependencies that are needed to satisfy the immediate, and lazy references respectively:

```
example% ldd -L main
example% ldd -d main
 libc.so.1 => /lib/libc.so.1
example% ldd -r main
 libc.so.1 => /lib/libc.so.1
 libelf.so.1 => /lib/libelf.so.1
```

Notice that in this example, the order of the dependencies that are listed is not the same as displayed from `ldd` with no options. Even with the `-r` option, the lazy reference to dependencies might not occur in the same order as would occur in a running program.

Observing lazy loading can also reveal objects that are not required to satisfy any references. These objects, in this example, `libnsl.so.1`, are candidates for removal from the link-line used to build the object being inspected.

**Initialization Order** Objects that do not explicitly define their required dependencies might observe variations in the initialization section order displayed by `ldd` due to the options used. For example, a simple application might reveal:

```
example% ldd -i main
 libA.so.1 => ./libA.so.1
 libc.so.1 => /lib/libc.so.1
 libB.so.1 => ./libB.so.1

 init object=./libB.so.1
 init object=./libA.so.1
 init object=/lib/libc.so.1
```

whereas, when relocations are applied, the initialization section order is:

```
example% ldd -ir main

 init object=/lib/libc.so.1
 init object=./libB.so.1
 init object=./libA.so.1
```

In this case, `libB.so.1` makes reference to a function in `/usr/lib/libc.so.1`. However, `libB.so.1` has no explicit dependency on this library. Only after a relocation is discovered is a dependency then established. This implicit dependency affects the initialization section order.

Typically, the initialization section order established when an application is executed, is equivalent to `ldd` with the `-d` option. The optimum order can be obtained if all objects fully define their dependencies. Use of the [ld\(1\)](#) options `-z defs` and `-z ignore` when building dynamic objects is recommended.

Cyclic dependencies can result when one or more dynamic objects reference each other. Cyclic dependencies should be avoided, as a unique initialization sort order for these dependencies can not be established.

Users that prefer a more static analysis of object files can inspect dependencies using tools such as [dump\(1\)](#) and [elfdump\(1\)](#).

**Files** `/usr/lib/lddstub` Fake 32-bit executable loaded to check the dependencies of shared objects.

`/usr/lib/64/lddstub` Fake 64-bit executable loaded to check the dependencies of shared objects.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

**See Also** [crle\(1\)](#), [dump\(1\)](#), [elfdump\(1\)](#), [lari\(1\)](#), [ld\(1\)](#), [ld.so.1\(1\)](#), [mdb\(1\)](#), [pldd\(1\)](#), [pvs\(1\)](#), [truss\(1\)](#), [dlopen\(3C\)](#), [attributes\(5\)](#)

*Linker and Libraries Guide*

**Diagnostics** `ldd` prints the record of shared object path names to `stdout`. The optional list of symbol resolution problems is printed to `stderr`. If *filename* is not an executable file or a shared object, or if *filename* cannot be opened for reading, a non-zero exit status is returned.

**Notes** Use of the `-d` or `-r` option with shared objects can give misleading results. `ldd` does a "worst case" analysis of the shared objects. However, in practice, the symbols reported as unresolved might be resolved by the executable file referencing the shared object. The runtime linker's preloading mechanism can be employed to add dependencies to the object being inspected. See `LD_PRELOAD`.

`ldd` uses the same algorithm as the runtime linker to locate shared objects.

**Name** ld.so.1 – runtime linker for dynamic objects

**Synopsis** /lib/ld.so.1

/lib/ld.so.1 [-e *envar*] *dynamic-object* [*object args*]...

**Description** Dynamic applications consist of one or more dynamic objects. A dynamic application is typically a dynamic executable and one or more shared object dependencies. As part of the initialization and execution of a dynamic application, an *interpreter* is called. This interpreter completes the binding of the application to its shared object dependencies. In Solaris, this interpreter is referred to as the runtime linker.

During the link-editing of a dynamic executable, a special `.interp` section, together with an associated program header, is created. This section contains a path name specifying the program's interpreter. An interpreter path name can be specified when the executable is constructed using the `-I` option to [ld\(1\)](#), the link-editor. The default name supplied by the link-editor is the name of the runtime linker, `ld.so.1`.

During the process of executing a dynamic executable, the kernel maps the file, and locates the required interpreter. See [exec\(2\)](#) and [mmap\(2\)](#). The kernel maps in, and transfers control to, this interpreter. Sufficient information is passed to the interpreter to allow the interpreter to continue to bind, and then execute the application.

In addition to initializing an application, the runtime linker provides services that allow the application to extend its address space. Additional shared objects can be mapped, and symbols within the shared objects can be bound to.

The runtime linker performs the following functions:

- A configuration file, if in existence, is processed. Configuration files can be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See [crle\(1\)](#). By default, for 32-bit objects, the configuration file `/var/ld/ld.config` is used. For 64-bit objects, the default configuration file `/var/ld/64/ld.config` is used. Alternative configuration files can be specified with the `LD_CONFIG` environment variable. Alternative configuration files can also be encoded within a dynamic executable by using the `-c` option of [ld\(1\)](#).
- The runtime linker analyzes the application's dynamic information section, `.dynamic`, to determine which shared object dependencies are required.
- The runtime linker then locates and maps in these dependencies. The dynamic information section of each dependency is then analyzed to determine if any additional dependencies are required.
- Once all the shared object dependencies are loaded, the runtime linker performs any necessary relocations. These relocations bind the shared objects in preparation for process execution.

- Any initialization functions provided by the shared object dependencies and, possibly, by the dynamic executable are called. The functions are called in the reverse order of the topologically sorted dependencies. If cyclic dependencies exist, the initialization functions are called using the sorted order with the cycle removed. [ldd\(1\)](#) can be used to display the initialization order of shared object dependencies.
- Control is passed to the application.
- During the application's execution, the runtime linker can be called upon to perform any delayed function binding.
- If any shared objects are deleted from the process, finalization functions are called. By default, these functions are called in the order of the topologically sorted dependencies.
- The application can also call upon the services of the runtime linker to acquire additional shared objects by using [dlopen\(3C\)](#). Symbols provided by these objects, can be bound to using [dlsym\(3C\)](#).

Further details on each of the previous topics can be found in the [Linker and Libraries Guide](#).

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the runpath recorded in the object, followed by a series of defaults. For 32-bit objects, the defaults are `/lib` followed by `/usr/lib`. For 64-bit objects, the defaults are `/lib/64` followed by `/usr/lib/64`. These defaults component can be modified using a configuration file that is created with [crle\(1\)](#). The runpath is specified when the dynamic object is constructed using the `-R` option to [ld\(1\)](#). The environment variable `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

**Command Line Usage** Typically, the runtime linker is invoked indirectly through executing a dynamic executable that declares the runtime linker as its interpreter. The runtime linker can also be executed directly from the command line. This mechanism is most often employed to experiment with new implementations of the runtime linker. Arguments that are supplied on the command line consist of options that are applicable to the runtime linker. Following these options is the name of the dynamic object to be executed, and any options required by this object. Effectively, the runtime linker replaces any interpreter specified by the dynamic object.

The following option is supported:

`-e envvar` Specify a runtime linker specific environment variable. See `ENVIRONMENT VARIABLES`.

**Environment Variables** Each environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes. This environment variable overrides any non-suffixed version of the environment variable that may be in effect. Environment variables specified without a value, that have a `_32` or `_64` suffix, effectively cancel any associated generic environment variable setting.

**LD\_AUDIT, LD\_AUDIT\_32, and LD\_AUDIT\_64**

A colon-separated list of objects that are loaded by the runtime linker. As each object is loaded, the object is examined for *Link-Auditing* interface routines. The routines that are present are called as specified in the *Link-Auditing* interface described in the [Linker and Libraries Guide](#). Also, see the `-p` and `-P` options of [ld\(1\)](#).

**LD\_BIND\_LAZY, LD\_BIND\_LAZY\_32, and LD\_BIND\_LAZY\_64**

The runtime linker's default mode of performing lazy binding can be enforced by setting the environment variable `LD_BIND_LAZY` to any non-null value. This setting causes the runtime linker to perform only *lazy* reference relocations for all objects that are loaded into the process. Individual objects can request that *lazy* reference relocations are performed when the object is loaded. See the `-z now` option of [ld\(1\)](#), and [dlopen\(3C\)](#) with the mode `RTLD_NOW`. Such requests to perform *lazy* reference relocations are suppressed when `LD_BIND_LAZY` is in effect.

If both `LD_BIND_LAZY` and `LD_BIND_NOW` are specified, then `LD_BIND_NOW` takes precedence.

**LD\_BIND\_NOW, LD\_BIND\_NOW\_32, and LD\_BIND\_NOW\_64**

The runtime linker's default mode of performing lazy binding can be overridden by setting the environment variable `LD_BIND_NOW` to any non-null value. This setting causes the runtime linker to perform both *immediate* reference and *lazy* reference relocations for all objects that are loaded into the process. Individual objects can request that *lazy* reference relocations are performed when the object is loaded. See the `-z now` option of [ld\(1\)](#), and [dlopen\(3C\)](#) with the mode `RTLD_NOW`.

If both `LD_BIND_NOW` and `LD_BIND_LAZY` are specified, then `LD_BIND_NOW` takes precedence.

**LD\_CONFIG, LD\_CONFIG\_32, and LD\_CONFIG\_64**

Provides an alternative configuration file. Configuration files can be employed to alter default search paths, provide a directory cache, and provide alternate object dependencies. See [crle\(1\)](#).

**LD\_DEBUG, LD\_DEBUG\_32, and LD\_DEBUG\_64**

Provides a comma, or colon-separated list of tokens to cause the runtime linker to print debugging information to standard error. The special token `help` indicates the full list of tokens available. The environment variable `LD_DEBUG_OUTPUT` can also be supplied to specify a file to which the debugging information is sent. The filename is suffixed with the process ID of the application generating the debugging information. See [lari\(1\)](#).

**LD\_DEMANGLE, LD\_DEMANGLE\_32, and LD\_DEMANGLE\_64**

Any symbol name used as part of a diagnostic message is shown as defined within an ELF file. When `LD_DEMANGLE` is set to any non-null value, the runtime linker attempts to decode (demangle) any C++ symbol name.

**LD\_FLAGS, LD\_FLAGS\_32, and LD\_FLAGS\_64**

Provides an alternative means of supplying environment variable information. Any of the `LD_XXX` environment variables can be specified as a `xxx` token. Multiple tokens can be supplied separated by commas. See `EXAMPLES`.

**LD\_LIBRARY\_PATH, LD\_LIBRARY\_PATH\_32, and LD\_LIBRARY\_PATH\_64**

The LD\_LIBRARY\_PATH environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies. LD\_LIBRARY\_PATH specifies a colon-separated list of directories that are searched before the default directories. Also notice that LD\_LIBRARY\_PATH adds additional semantics to [ld\(1\)](#).

**LD\_LOADFLTR, LD\_LOADFLTR\_32, and LD\_LOADFLTR\_64**

Filters are a form of shared object. Filters allow an alternative shared object to be selected at runtime that provide the implementation for any symbols that are defined within the filter. See the -f and -F options of [ld\(1\)](#). By default, the alternative shared object processing is deferred until symbol resolution occurs against the filter. When LD\_LOADFLTR is set to any non-null value, any filters are processed immediately when the filter is loaded. Also, see the -z loadfltr option of [ld\(1\)](#).

**LD\_NOAUDIT, LD\_NOAUDIT\_32, and LD\_NOAUDIT\_64**

Local auditing libraries can be defined within applications and shared objects. See the -p and -P options of [ld\(1\)](#). When LD\_NOAUDIT is set to any non-null value, the runtime linker ignores any local auditing libraries.

**LD\_NOAUXFLTR, LD\_NOAUXFLTR\_32, and LD\_NOAUXFLTR\_64**

Auxiliary filters are a form of shared object. Auxiliary filters allow an alternative shared object to be selected at runtime which provides the implementation for any symbols that are defined within the filter. See the -f option of [ld\(1\)](#). When LD\_NOAUXFLTR is set to any non-null value, the runtime linker disables this alternative shared object lookup.

**LD\_NOCONFIG, LD\_NOCONFIG\_32, and LD\_NOCONFIG\_64**

By default the runtime linker attempts to open and process a configuration file. When LD\_NOCONFIG is set to any non-null value, the runtime linker disables this configuration file processing.

**LD\_NODIRCONFIG, LD\_NODIRCONFIG\_32, and LD\_NODIRCONFIG\_64**

Provides a subset of LD\_NOCONFIG in that any directory cache information provided in a configuration file is ignored.

**LD\_NODIRECT, LD\_NODIRECT\_32, and LD\_NODIRECT\_64**

Direct binding information instructs the runtime linker to search directly for a symbol in an associated object. See the -B direct option of [ld\(1\)](#). Without direct binding, the symbol search performed by the runtime linker follows the default model. When LD\_NODIRECT is set to any non-null value, the runtime linker ignores any direct binding information.

**LD\_NOENVCONFIG, LD\_NOENVCONFIG\_32, and LD\_NOENVCONFIG\_64**

Provides a subset of LD\_NOCONFIG in that any environment variables provided in a configuration file are ignored.

**LD\_NOLAZYLOAD, LD\_NOLAZYLOAD\_32, and LD\_NOLAZYLOAD\_64**

Dependencies that are labeled for lazy loading are not loaded into memory until explicit reference to the dependency has been made. See the -z lazyload option of [ld\(1\)](#). When LD\_NOLAZYLOAD is set to any non-null value, the runtime linker ignores a dependencies lazy loading label and loads the dependency immediately.

**LD\_NOOBJALTER, LD\_NOOBJALTER\_32, and LD\_NOOBJALTER\_64**

Provides a subset of LD\_NOCONFIG in that any alternative object dependencies provided in a configuration file are ignored.

**LD\_NOVERSION, LD\_NOVERSION\_32, and LD\_NOVERSION\_64**

By default, the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When LD\_NOVERSION is set to any non-null value, the runtime linker disables this version checking.

**LD\_ORIGIN, LD\_ORIGIN\_32, and LD\_ORIGIN\_64**

The immediate processing of \$ORIGIN can be triggered by setting the environment variable LD\_ORIGIN to any non-null value. Before Solaris 9, this option was useful for applications that invoked [chdir\(2\)](#) prior to locating dependencies that employed the \$ORIGIN string token. The establishment of the current working directory by the runtime linker is now default thus making this option redundant.

**LD\_PRELOAD, LD\_PRELOAD\_32, and LD\_PRELOAD\_64**

Provides a list of shared objects, separated by spaces. These objects are loaded after the program being executed but before any other shared objects that the program references. Symbol definitions provided by the preloaded objects interpose on references made by the shared objects that the program references. Symbol definitions provided by the preloaded objects do not interpose on the symbol definitions provided by the program.

**LD\_PROFILE, LD\_PROFILE\_32, and LD\_PROFILE\_64**

Defines a shared object to be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a `.profile` extension. By default, this buffer is placed under `/var/tmp`. The environment variable LD\_PROFILE\_OUTPUT can also be supplied to indicate an alternative directory in which to place the profiling buffer.

The profiling buffer contains [profil\(2\)](#) and call count information. This information is similar to the *gmon.out* information generated by programs that have been linked with the `-xpg` option of `cc`. Any applications that use the named shared object and run while this environment variable is set, accumulate data in the profile buffer. See also NOTES. The profile buffer information can be examined using [gprof\(1\)](#).

The LD\_PROFILE profiling technique is an alternative to other techniques that might be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and LD\_PROFILE should not be combined with a profile-instrumented application. See the [Linker and Libraries Guide](#) for more information on profiling shared objects.

**LD\_SIGNAL, LD\_SIGNAL\_32, and LD\_SIGNAL\_64**

Provides a *numeric* signal number that the runtime linker uses to kill the process in the event of a fatal runtime error. See [thr\\_kill\(3C\)](#). By default, SIGKILL is used. For example, providing the alternative signal number 6 (SIGABRT), can provide for the creation of a core file to aid debugging. See also the RTLD\_DI\_SETSIGNAL request to [dldinfo\(3C\)](#).

Notice that environment variable names beginning with the characters 'LD\_' are reserved for possible future enhancements to [ld\(1\)](#) and `ld.so.1`.

**Security** Secure processes have some restrictions applied to the evaluation of their dependencies and runpaths to prevent malicious dependency substitution or symbol interposition.

The runtime linker categorizes a process as secure if the [issetugid\(2\)](#) system call returns true for the process.

For 32-bit objects, the default trusted directories that are known to the runtime linker are `/lib/secure` and `/usr/lib/secure`. For 64-bit objects, the default trusted directories are `/lib/secure/64` and `/usr/lib/secure/64`. The utility [crle\(1\)](#) can be used to specify additional trusted directories that are applicable for secure applications. Administrators who use this technique should ensure that the target directories are suitably protected from malicious intrusion.

If an `LD_LIBRARY_PATH` family environment variable is in effect for a secure process, only the *trusted* directories specified by this variable are used to augment the runtime linker's search rules.

In a secure process, runpath components that are provided by the application or any of its dependencies are used, provided the component is a full path name, that is, the path name starts with a '/'.

In a secure process, the expansion of the `$ORIGIN` string is allowed only if the string expands to a *trusted* directory. However, should a `$ORIGIN` expansion match a directory that has already provided dependencies, then the directory is implicitly secure. This directory can be used to provide additional dependencies.

In a secure process, `LD_CONFIG` is ignored. A secure process uses the default configuration file, if a configuration file exists. See [crle\(1\)](#).

In a secure process, `LD_SIGNAL` is ignored.

Additional objects can be loaded with a secure process using the `LD_PRELOAD`, or `LD_AUDIT` environment variables. These objects must be specified as *full* path names or *simple* file names. Full path names are restricted to known *trusted* directories. Simple file names, in which no '/' appears in the name, are located subject to the search path restrictions previously described. Simple file names resolve only to known *trusted* directories.

In a secure process, any dependencies that consist of simple filenames are processed using the path name restrictions previously described. Dependencies expressed as full path names or relative path names are used as is. Therefore, the developer of a secure process should ensure that the target directory referenced as a full path name or relative path name dependency is suitably protected from malicious intrusion.

When creating a secure process, relative path names should *not* be used to express dependencies, or to construct [dlopen\(3C\)](#) path names. This restriction should be applied to the application and to *all* dependencies.

**Examples**    **EXAMPLE 1**    Using LD\_FLAGS to group environment variable information

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_BIND\_NOW and LD\_LIBRARY\_PATH for 32-bit applications:

```
example% LD_FLAGS_32=bind_now,library_path=/lib/one:/lib/two
```

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_LIBRARY\_PATH and LD\_PRELOAD for 64-bit applications:

```
example% LD_FLAGS_64=library_path=/lib/one/64,preload=foo.so
```

*Linker and Libraries Guide*

**Notes** Care should be exercised when using `LD_PROFILE` in combination with other process monitoring techniques, such as users of [proc\(4\)](#). Multiple process monitoring techniques can result in deadlock conditions that leave the profile buffer locked. A locked buffer blocks any processes that try to record profiling information. To reduce this likelihood, the runtime linker's profile implementation determines if the process is being monitored at startup. If so, profiling of the process is silently disabled. However, this mechanism can not catch monitoring processes that attach to the process during its execution.

The user compatibility library `/usr/lib/0@0. so. 1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation occurs in these applications when a null character pointer is accessed. If this library is added to such an application at runtime using `LD_PRELOAD`, the library provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.

**Name**    `let` – shell built-in function to evaluate one or more arithmetic expressions

**Synopsis**

`ksh`   `let` *arg*...

**Description**

`ksh`   Each *arg* is a separate "arithmetic expression" to be evaluated.

**Exit Status**   The following exit values are returned:

- `0`      The value of the last expression is non-zero.
- `1`      The value of the last expression is zero.

**Attributes**   See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also**   [ksh\(1\)](#), [set\(1\)](#), [typeset\(1\)](#), [attributes\(5\)](#)

**Name** lex – generate programs for lexical tasks

**Synopsis** lex [-cntv] [-e | -w] [-V -Q [y | n]] [*file*]....

**Description** The lex utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to yacc. The C programs are generated from lex source code and conform to the ISO C standard. Usually, the lex utility writes the program it generates to the file lex.yy.c. The state of this file is unspecified if lex exits with a non-zero exit status. See EXTENDED DESCRIPTION for a complete description of the lex input language.

**Options** The following options are supported:

- c Indicates C-language action (default option).
- e Generates a program that can handle EUC characters (cannot be used with the -w option). yytext[ ] is of type unsigned char[ ].
- n Suppresses the summary of statistics usually written with the -v option. If no table sizes are specified in the lex source code and the -v option is not specified, then -n is implied.
- t Writes the resulting program to standard output instead of lex.yy.c.
- v Writes a summary of lex statistics to the standard error. (See the discussion of lex table sizes under the heading Definitions in lex.) If table sizes are specified in the lex source code, and if the -n option is not specified, the -v option may be enabled.
- w Generates a program that can handle EUC characters (cannot be used with the -e option). Unlike the -e option, yytext[ ] is of type wchar\_t[ ].
- V Prints out version information on standard error.
- Q[y|n] Prints out version information to output file lex.yy.c by using -Qy. The -Qn option does not print out version information and is the default.

**Operands** The following operand is supported:

- file* A pathname of an input file. If more than one such *file* is specified, all files will be concatenated to produce a single lex program. If no *file* operands are specified, or if a *file* operand is –, the standard input will be used.

**Output** The lex output files are described below.

**Stdout** If the -t option is specified, the text file of C source code output of lex will be written to standard output.

**Stderr** If the -t option is specified informational, error and warning messages concerning the contents of lex source code input will be written to the standard error.

If the -t option is not specified:

1. Informational error and warning messages concerning the contents of `lex` source code input will be written to either the standard output or standard error.
2. If the `-v` option is specified and the `-n` option is not specified, `lex` statistics will also be written to standard error. These statistics may also be generated if table sizes are specified with a `%` operator in the `Definitions in lex` section (see `EXTENDED DESCRIPTION`), as long as the `-n` option is not specified.

**Output Files** A text file containing C source code will be written to `lex.yy.c`, or to the standard output if the `-t` option is present.

**Extended Description** Each input file contains `lex` source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.

When `lex.yy.c` is compiled and linked with the `lex` library (using the `-l lex` operand with `c89` or `cc`), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.

When an expression is matched, these actions will occur:

- The input string that was matched is left in `yytext` as a null-terminated string; `yytext` is either an external character array or a pointer to a character string. As explained in `Definitions in lex`, the type can be explicitly selected using the `%array` or `%pointer` declarations, but the default is `%array`.
- The external `int yyleng` is set to the length of the matching string.
- The expression's corresponding program fragment, or action, is executed.

During pattern matching, `lex` searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.

The general format of `lex` source is:

*Definitions*

%%

*Rules*

%%

*User Subroutines*

The first `%%` is required to mark the beginning of the rules (regular expressions and actions); the second `%%` is required only if user subroutines follow.

Any line in the `Definitions in lex` section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the `lex.yy.c` file. Similarly, anything in the `Definitions in lex` section included between delimiter lines containing only `%{` and `%}` will also be copied unchanged to the external definition area of the `lex.yy.c` file.

Any such input (beginning with a blank character or within `%{` and `%}` delimiter lines) appearing at the beginning of the *Rules* section before any rules are specified will be written to `lex.yy.c` after the declarations of variables for the `yyllex` function and before the first line of code in `yyllex`. Thus, user variables local to `yyllex` can be declared here, as well as application code to execute upon entry to `yyllex`.

The action taken by `lex` when encountering any input beginning with a blank character or within `%{` and `%}` delimiter lines appearing in the *Rules* section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the `yyllex` function.

**Definitions in lex** Definitions in `lex` appear before the first `%%` delimiter. Any line in this section not contained between `%{` and `%}` lines and not beginning with a blank character is assumed to define a `lex` substitution string. The format of these lines is:

*name substitute*

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string `{ name }` when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the Definitions in `lex` section, any line beginning with a `%` (percent sign) character and followed by an alphanumeric word beginning with either `s` or `S` defines a set of start conditions. Any line beginning with a `%` followed by a word beginning with either `x` or `X` defines a set of exclusive start conditions. When the generated scanner is in a `%s` state, patterns with no state specified will be also active; in a `%x` state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in *Regular expressions in lex*.

Implementations accept either of the following two mutually exclusive declarations in the Definitions in `lex` section:

`%array`      Declare the type of *yytext* to be a null-terminated character array.

`%pointer`    Declare the type of *yytext* to be a pointer to a null-terminated character string.

*Note:* When using the `%pointer` option, you may not also use the `yylless` function to alter *yytext*.

`%array` is the default. If `%array` is specified (or neither `%array` nor `%pointer` is specified), then the correct way to make an external reference to *yytext* is with a declaration of the form:

```
extern char yytext[]
```

If `%pointer` is specified, then the correct external reference is of the form:

```
extern char *yytext;
```

lex will accept declarations in the `Definitions in lex` section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex

| Declaration       | Description                        | Default |
|-------------------|------------------------------------|---------|
| <code>%pn</code>  | Number of positions                | 2500    |
| <code>%nn</code>  | Number of states                   | 500     |
| <code>%a n</code> | Number of transitions              | 2000    |
| <code>%en</code>  | Number of parse tree nodes         | 1000    |
| <code>%kn</code>  | Number of packed character classes | 10000   |

Programs generated by lex need either the `-e` or `-w` option to handle input that contains EUC characters from supplementary codesets. If neither of these options is specified, `yytext` is of the type `char[ ]`, and the generated program can handle only ASCII characters.

When the `-e` option is used, `yytext` is of the type `unsigned char[ ]` and `yylen` gives the total number of *bytes* in the matched string. With this option, the macros `input()`, `unput(c)`, and `output(c)` should do a byte-based I/O in the same way as with the regular ASCII lex. Two more variables are available with the `-e` option, `yywtext` and `yywleng`, which behave the same as `yytext` and `yylen` would under the `-w` option.

When the `-w` option is used, `yytext` is of the type `wchar_t[ ]` and `yylen` gives the total number of *characters* in the matched string. If you supply your own `input()`, `unput(c)`, or `output(c)` macros with this option, they must return or accept EUC characters in the form of wide character (`wchar_t`). This allows a different interface between your program and the lex internals, to expedite some programs.

**Rules in lex** The `Rules in lex` source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

```
ERE action
ERE action
...
```

The extended regular expression (ERE) portion of a row will be separated from *action* by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The blank characters appear within double-quotes or square brackets.
- Each blank character is preceded by a backslash character.

User Subroutines in lex Anything in the user subroutines section will be copied to `lex.yy.c` following `yyllex`.

Regular Expressions in lex The `lex` utility supports the set of Extended Regular Expressions (EREs) described on [regex\(5\)](#) with the following additions and exceptions to the syntax:

- . . . Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, "`\ 01\"`" represents a single string: the octal value 1 followed by the character 1.

`<state>r`

`<state1, state2, ...>r` The regular expression *r* will be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so forth. For more information, see [Actions in lex](#). As an exception to the typographical conventions of the rest of this document, in this case `<state>` does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol. The start condition is recognized as such only at the beginning of a regular expression.

`r/x`

The regular expression *r* will be matched only if it is followed by an occurrence of regular expression *x*. The token returned in *yytext* will only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the \$ (match-end-of-line) operator; *x* cannot include the ^ (match-beginning-of-line) operator, nor trailing context, nor the \$ operator. That is, only one occurrence of trailing context is allowed in a `lex` regular expression, and the ^ operator only can be used at the beginning of such an expression. A further restriction is that the trailing-context operator / (slash) cannot be grouped within parentheses.

`{name}`

When *name* is one of the substitution symbols from the [Definitions](#) section, the string, including the enclosing braces, will be replaced by the *substitute* value. The *substitute* value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if `{name}` occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character ( `\`, `\ a`, `\ b`, `\ f`, `\ n`, `\ r`, `\ t`, `\ v`) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence `\ n` can be used to represent a newline character. A newline character cannot be matched by a period operator.

Escape Sequences in lex

| Escape Sequences in lex |                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Escape Sequence         | Description                                                                                                                                                                                                                     | Meaning                                                                                                                                                                                                                             |
| <code>\digits</code>    | A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.           | The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte. |
| <code>\xdigits</code>   | A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.           | The character whose encoding is represented by the hexadecimal integer.                                                                                                                                                             |
| <code>\c</code>         | A backslash character followed by any character not described in this table. ( <code>\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\en</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ). | The character <code>c</code> , unchanged.                                                                                                                                                                                           |

The order of precedence given to extended regular expressions for `lex` is as shown in the following table, from high to low.

*Note:* The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

| ERE Precedence in lex                    |                                                              |
|------------------------------------------|--------------------------------------------------------------|
| <i>collation-related bracket symbols</i> | <code>[ = ]</code> <code>[ : : ]</code> <code>[ . . ]</code> |
| <i>escaped characters</i>                | <code>\&lt;special character&gt;</code>                      |

| ERE Precedence in lex                  |                 |
|----------------------------------------|-----------------|
| <i>bracket expression</i>              | [ ]             |
| <i>quoting</i>                         | ". . ."         |
| <i>grouping</i>                        | ( )             |
| <i>definition</i>                      | { <i>name</i> } |
| <i>single-character RE duplication</i> | * + ?           |
| <i>concatenation</i>                   |                 |
| <i>interval expression</i>             | { <i>m,n</i> }  |
| <i>alternation</i>                     |                 |

The ERE anchoring operators ( `^` and `$` ) do not appear in the table. With `lex` regular expressions, these operators are restricted in their use: the `^` operator can only be used at the beginning of an entire regular expression, and the `$` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `(^abc) |(def$)` is undefined; it can instead be written as two separate rules, one with the regular expression `^abc` and one with `def$`, which share a common action via the special `|` action (see below). If the pattern were written `^abc|def$`, it would match either of `abc` or `def` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical `lex` implementations. An example of embedded anchoring would be for patterns such as `(^)foo($)` to match `foo` when it exists as a complete word. This functionality can be obtained using existing `lex` features:

```
^foo/[\ n]|
" foo"/[\ n] /* found foo as a separate word */
```

Notice also that `$` is a form of trailing context (it is equivalent to `/\ n` and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator `/` (slash) can be used as an ordinary character if presented within double-quotes, `" / "`; preceded by a backslash, `\ /`; or within a bracket expression, `[ / ]`. The start-condition `<` and `>` operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between `lex` regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form `r/x`, the string matching `r` is always returned; confusion may arise when the beginning of `x` matches the trailing portion of `r`. For example, given the regular expression `a*b/cc` and the input `aaabcc`,

*yytext* would contain the string *aaab* on this match. But given the regular expression  $x^*/xy$  and the input *xxxxy*, the token *xxx*, not *xx*, is returned by some implementations because *xxx* matches  $x^*$ .

In the rule  $ab^*/bc$ , the  $b^*$  at the end of *r* will extend *r*'s match into the beginning of the trailing context, so the result is unspecified. If this rule were  $ab/bc$ , however, the rule matches the text *ab* when it is followed by the text *bc*. In this latter case, the matching of *r* cannot extend into the beginning of *x*, so the result is specified.

**Actions in lex** The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `;` is a valid action; any string in the `lex.yy.c` input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action `lex` takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a `lex.yy.c` program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by `lex` is to read the input and copy it to the output, a minimal `lex` source program that has just `%%` generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

|  |                               |
|--|-------------------------------|
|  | ECHO;      REJECT;      BEGIN |
|--|-------------------------------|

|  |                                                                                                                                                                                                                                                           |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | The action <code> </code> means that the action for the next rule is the action for this rule. Unlike the other three actions, <code> </code> cannot be enclosed in braces or be semicolon-terminated. It must be specified alone, with no other actions. |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|       |                                                                |
|-------|----------------------------------------------------------------|
| ECHO; | Writes the contents of the string <i>yytext</i> on the output. |
|-------|----------------------------------------------------------------|

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REJECT; | Usually only a single expression is matched by a given string in the input. <code>REJECT</code> means "continue to the next expression that matches the current input," and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions <i>xyz</i> and <i>xy</i> and the input <i>xyz</i> , usually only the regular expression <i>xyz</i> would match. The next attempted match would start after <i>z</i> . If the last action in the <i>xyz</i> rule is <code>REJECT</code> , both this rule and the <i>xy</i> rule would be executed. The <code>REJECT</code> action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a <code>goto</code> to another part of <code>yylex</code> . The use of <code>REJECT</code> may result in somewhat larger and slower scanners. |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**BEGIN**      The action:

**BEGIN** *newstate*;

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the **Definitions in lex** section, the results are unspecified. The initial state is indicated by the digit 0 or the token **INITIAL**.

The functions or macros described below are accessible to user code included in the **lex** input. It is unspecified whether they appear in the C code output of **lex**, or are accessible only through the **-l l** operand to **c89** or **cc** (the **lex** library).

|                                |                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int yylex(void)</code>   | Performs lexical analysis on the input; this is the primary function generated by the <b>lex</b> utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.                                                                                                               |
| <code>int yymore(void)</code>  | When called, indicates that when the next input string is recognized, it is to be appended to the current value of <i>yytext</i> rather than replacing it; the value in <i>yyleng</i> is adjusted accordingly.                                                                                                                                                                 |
| <code>int yyless(int n)</code> | Retains <i>n</i> initial characters in <i>yytext</i> , NUL-terminated, and treats the remaining characters as if they had not been read; the value in <i>yyleng</i> is adjusted accordingly.                                                                                                                                                                                   |
| <code>int input(void)</code>   | Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer <i>yyin</i> , although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of <i>yyin</i> is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner. |
| <code>int unput(int c)</code>  | Returns the character <i>c</i> to the input; <i>yytext</i> and <i>yyleng</i> are undefined until the next expression is matched. The result of using <i>unput</i> for more characters than have been input is unspecified.                                                                                                                                                     |

The following functions appear only in the **lex** library accessible through the **-l l** operand; they can therefore be redefined by a portable application:

|                               |                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int yywrap(void)</code> | Called by <i>yylex</i> at end-of-file; the default <i>yywrap</i> always will return 1. If the application requires <i>yylex</i> to continue processing with another source of input, then the application can include a function <i>yywrap</i> , which associates another file with the external variable <code>FILE *yyin</code> and will return a value of zero. |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
int main(int argc, char *argv[]) Calls yylex to perform lexical analysis, then exits.
 The user code can contain main to perform
 application-specific operations, calling yylex as
 applicable.
```

The reason for breaking these functions into two lists is that only those functions in `libl.a` can be reliably redefined by a portable application.

Except for `input`, `unput` and `main`, all external and static names generated by `lex` begin with the prefix `yy` or `YY`.

**Usage** Portable applications are warned that in the `Rules` in `lex` section, an ERE without an action is not acceptable, but need not be detected as erroneous by `lex`. This may result in compilation or run-time errors.

The purpose of `input` is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The `lex` utility is not fully internationalized in its treatment of regular expressions in the `lex` source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the `lex` source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current `lex` technology. Furthermore, the very nature of the lexical analyzers produced by `lex` must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

### Examples **EXAMPLE 1** Using `lex`

The following is an example of a `lex` program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* need this for the call to atof() below */
#include <math.h>
/* need this for printf(), fopen() and stdin below */
#include <stdio.h>
}%

DIGIT [0-9]
ID [a-z][a-z0-9]*
%%

{DIGIT}+ {
 printf("An integer: %s (%d)\n", yytext,
 atoi(yytext));
```

**EXAMPLE 1** Using `lex` (Continued)

```

 }

{DIGIT}+".{DIGIT}* {
 printf("A float: %s (%g)\n", yytext,
 atof(yytext));
}

if|then|begin|end|procedure|function {
 printf("A keyword: %s\n", yytext);
}

{ID} printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"|" "/" printf("An operator: %s\n", yytext);

"{"[^}\n]*}" /* eat up one-line comments */

[\t\n]+ /* eat up white space */

. printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
 ++argv, --argc; /* skip over program name */
 if (argc > 0)
 yyin = fopen(argv[0], "r");
 else
 yyin = stdin;

 yylex();
}

```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `lex`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0      Successful completion.
- >0     An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWbtool       |
| Interface Stability | Standard        |

**See Also** [yacc\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [standards\(5\)](#)

**Notes** If routines such as `yyback()`, `yywrap()`, and `yylock()` in `.l` (ell) files are to be external C functions, the command line to compile a C++ program must define the `__EXTERN_C__` macro. For example:

```
example% CC -D__EXTERN_C__ ... file
```

**Name** limit, ulimit, unlimit – set or get limitations on the system resources available to the current shell and its descendents

**Synopsis** /usr/bin/ulimit [-f] [*blocks*]

sh ulimit [- [HS] [a | cdfnstv]]

ulimit [- [HS] [c | d | f | n | s | t | v]] *limit*

csh limit [-h] [*resource* [*limit*]]

unlimit [-h] [*resource*]

ksh ulimit [-HSacdfnstv] [*limit*]

## Description

/usr/bin/ulimit The `ulimit` utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.

sh The Bourne shell built-in function, `ulimit`, prints or sets hard or soft resource limits. These limits are described in [getrlimit\(2\)](#).

If *limit* is not present, `ulimit` prints the specified limits. Any number of limits may be printed at one time. The `-a` option prints all limits.

If *limit* is present, `ulimit` sets the specified limit to *limit*. The string `unlimited` requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit. See [su\(1M\)](#).

The `-H` option specifies a hard limit. The `-S` option specifies a soft limit. If neither option is specified, `ulimit` will set both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- c maximum core file size (in 512-byte blocks)
- d maximum size of data segment or heap (in kbytes)
- f maximum file size (in 512-byte blocks)
- n maximum file descriptor plus 1
- s maximum size of stack segment (in kbytes)
- t maximum CPU time (in seconds)
- v maximum size of virtual memory (in kbytes)

**cs**h The C-shell built-in function, `limit`, limits the consumption by the current process or any process it spawns, each not to exceed *limit* on the specified *resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits.

-h Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

*resource* is one of:

|                           |                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cputime</code>      | Maximum CPU seconds per process.                                                                                                                                                                                                                                                         |
| <code>filesize</code>     | Largest single file allowed. Limited by the size of the filesystem (see <a href="#">df(1M)</a> ).                                                                                                                                                                                        |
| <code>datasize</code>     | The maximum size of a process's heap in kilobytes.                                                                                                                                                                                                                                       |
| <code>stacksize</code>    | Maximum stack size for the process. The default stack size is 2 <sup>64</sup> .                                                                                                                                                                                                          |
| <code>coredumpsize</code> | Maximum size of a core dump (file). This is limited to the size of the filesystem.                                                                                                                                                                                                       |
| <code>descriptors</code>  | Maximum number of file descriptors. Run the <a href="#">sysdef(1M)</a> command to obtain the maximum possible limits for your system. The values reported by <code>sysdef</code> are in hexadecimal, but can be translated into decimal numbers using the <a href="#">bc(1)</a> command. |
| <code>memorysize</code>   | Maximum size of virtual memory.                                                                                                                                                                                                                                                          |

*limit* is a number, with an optional scaling factor, as follows:

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <code>nh</code>    | Hours (for <code>cputime</code> ).                                         |
| <code>nk</code>    | <i>n</i> kilobytes. This is the default for all but <code>cputime</code> . |
| <code>nm</code>    | <i>n</i> megabytes or minutes (for <code>cputime</code> ).                 |
| <code>mm:ss</code> | Minutes and seconds (for <code>cputime</code> ).                           |

`unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.

-h Remove corresponding hard limits. Only the privileged user may do this.

**ks**h The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is specified, the limit applies to both. The current resource limit

is printed when *limit* is omitted. In this case, the soft limit is printed unless -H is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a Lists all of the current resource limits.
- c The number of 512-byte blocks on the size of core dumps.
- d The number of K-bytes on the size of the data area.
- f The number of 512-byte blocks on files written by child processes (files of any size may be read).
- n The number of file descriptors plus 1.
- s The number of K-bytes on the size of the stack area.
- t The number of seconds (CPU time) to be used by each process.
- v The number of K-bytes for virtual memory.

If no option is given, -f is assumed.

**Per-Shell Memory Parameters** The *heapsize*, *datasize*, and *stacksize* parameters are not system tunables. The only controls for these are hard limits, set in a shell startup file, or system-wide soft limits, which, for the current version of the Solaris OS, is  $2^{64}$  bytes.

**Options** The following option is supported by *ulimit*:

- f Sets (or reports, if no *blocks* operand is present), the file size limit in blocks. The -f option is also the default case.

**Operands** The following operand is supported by *ulimit*:

*blocks* The number of 512-byte blocks to use as the new file size limit.

## Examples

*/usr/bin/ulimit* **EXAMPLE 1** Limiting the Stack Size

The following example limits the stack size to 512 kilobytes:

```
example% ulimit -s 512
example% ulimit -a
time(seconds) unlimited
file(blocks) 100
data(kbytes) 523256
stack(kbytes) 512
coredump(blocks) 200
nofiles(descriptors) 64
memory(kbytes) unlimited
```

**sh/ksh EXAMPLE 2** Limiting the Number of File Descriptors

The following command limits the number of file descriptors to 12:

```
example$ ulimit -n 12
example$ ulimit -a
time(seconds) unlimited
file(blocks) 41943
data(kbytes) 523256
stack(kbytes) 8192
coredump(blocks) 200
nofiles(descriptors) 12
vmemory(kbytes) unlimited
```

**csh EXAMPLE 3** Limiting the Core Dump File Size

The following command limits the size of a core dump file size to 0 kilobytes:

```
example% limit coredumpsize 0
example% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize 0 kbytes
descriptors 64
memorysize unlimited
```

**EXAMPLE 4** Removing the limitation for core file size

The following command removes the above limitation for the core file size:

```
example% unlimited coredumpsize
example% limit
cputime unlimited
filesize unlimited
datasize 523256 kbytes
stacksize 8192 kbytes
coredumpsize unlimited
descriptors 64
memorysize unlimited
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ulimit`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned by `ulimit`:

- `0`      Successful completion.
- `>0`     A request for a higher limit was rejected or an error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also** [bc\(1\)](#), [csh\(1\)](#), [ksh\(1\)](#), [sh\(1\)](#), [df\(1M\)](#), [su\(1M\)](#), [swap\(1M\)](#), [sysdef\(1M\)](#), [getrlimit\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** line – read one line

**Synopsis** line

**Description** The `line` utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.

**Exit Status** Exit status is:

0 Successful completion

>0 End-of-file on input.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [sh\(1\)](#), [read\(2\)](#), [attributes\(5\)](#)

- 
- Name** lint – C program verifier
- Synopsis** /usr/ucb/lint [*options*]
- Description** /usr/ucb/lint is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link /usr/ccs/bin/ucblint to the C program verifier. /usr/ccs/bin/ucblint is available only with the SPROcc package, whose default location is /opt/SUNWspro. /usr/ucb/lint is identical to /usr/ccs/bin/ucblint, except that BSD headers are used and BSD libraries are linked *before* base libraries. The /opt/SUNWspro/man/man1/lint.1 man page is available only with the SPROcc package.
- Options** /usr/ucb/lint accepts the same options as /usr/ccs/bin/ucblint, with the following exceptions:
- I*dir* Search *dir* for included files whose names do not begin with a slash ( / ) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing *sourcefile*, and then in directories named with -I options (if any), then /usr/ucbinclude, and finally, in /usr/include.
  - L*dir* Add *dir* to the list of directories searched for libraries by /usr/ccs/bin/ld. This option is passed to /usr/ccs/bin/ld. Directories specified with this option are searched before /usr/ucblib and /usr/lib.
  - Y P, *dir* Change the default directory used for finding libraries.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
  - >0 An error occurred.
- Files**
- |                    |                                                         |
|--------------------|---------------------------------------------------------|
| /usr/lint/bin/ld   | link editor                                             |

| Availability   | SUNWscpu        |

**See Also** [ld\(1\)](#), [a.out\(4\)](#), [attributes\(5\)](#)

**Name** list\_devices – list allocatable devices

**Synopsis** list\_devices [-s] [-U *uid*] [-z *zonename*] [-a [-w]]  
           -l | -n | -u [*device*] | [-l | -n | -u] -c *dev-class*  
           list\_devices [-s] -d *dev-type*

**Description** The list\_devices utility lists the allocatable devices in the system according to specified qualifications.

The *device* and all device special files associated with the device are listed. The device argument is optional and, if it is not present, all relevant devices are listed. If *dev-class* is present, devices belonging to the specified *dev-class* are listed. There is no default *dev-class*.

**Options** The following options are supported:

- l [-c *dev-class* | *device*]      Lists the pathnames of the device special files associated with the *device* that are allocatable to the current process.  
  
                                          If *dev-class* is specified, lists only the files associated with all devices of the specified device class.  
  
                                          If *device* is specified, lists only the files associated with the specified device.
- n [-c *dev-class* | *device*]      Lists the pathnames of the device special files associated with the device that are allocatable to the current process but are not currently allocated.  
  
                                          If *dev-class* is specified, lists only the files associated with all devices of the specified device class.  
  
                                          If *device* is specified, lists only the files associated with the specified device.
- s                                      Silent. Suppresses any diagnostic output.
- u [-c *dev-class* | *device*]      Lists the pathnames of device special files associated with the device that are allocated to the owner of the current process.  
  
                                          If *dev-class* is specified, lists only the files associated with all devices of the specified device class.  
  
                                          If *device* is specified, lists only the files associated with the specified device.
- U *uid*                                Uses the user ID *uid* instead of the real user ID of the current process when performing the list\_devices operation. Only a user with the solaris.device.revoke authorization can use this option.

The following options are supported when the system is configured with Trusted Extensions:

- a Lists attributes like authorizations, cleaning programs and labels associated with a device.

The list is a single line of semicolon ( ; ) separated *key=value* pairs for each device in the format:

```
device=device-name;type=device-type;\
auths=auths;clean=device-exec;\
device-attributes;\
files=device-list
```

where *device-attributes* is the contents of the reserved1 field of [device\\_allocate\(4\)](#). The field is colon ( : ) separated.)

See [device\\_allocate\(4\)](#) for a description of these attributes and their format.

The -a output has the following keys:

- |        |                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------|
| auths  | Specifies the list of authorizations. The value is auths is described in <a href="#">device_allocate(4)</a> .       |
| clean  | Specifies the device cleaning script. The value is device-exec as described in <a href="#">device_allocate(4)</a> . |
| device | Specifies the device name. The value is device-name as described in <a href="#">device_allocate(4)</a> .            |
| files  | Specifies the device file paths. The value is device-list as described in <a href="#">device_maps(4)</a> .          |
| type   | Specifies the device type. The value is device-type as described in <a href="#">device_allocate(4)</a> .            |
- d Displays the system-supplied default attributes for the device types managed by device allocation. If *dev-type* is specified, it lists the default attributes for only that device type.
  - w This option can be used with -a to list the current owner of the device as the key value pair *owner=value*. *value* is the uid of the current owner of the device. If the device is unallocated, value is /FREE. If the device is in error state, value is /ERROR. This option also suppresses any diagnostic output.
  - z *zonename* When specified with the -l option, lists only those non-allocated devices whose label range includes the label of the zonename, and of the allocated devices, only those that are allocated at the same label as that of *zonename*.

When specified with the `-n` option, lists only those non-allocated devices whose label range includes the label of the *zonename*.

When specified with the `-u` option, lists only those devices that are allocated at the same label as that of *zonename*.

### Examples **EXAMPLE 1** Listing All Devices

The following example lists all devices available to the caller for allocation:

```
% list_devices -l
device: audio type: audio\
files: /dev/audio /dev/audioctrl /dev/sound/0 /dev/sound/0ctl
```

### **EXAMPLE 2** Listing Attributes of All Devices

On a system configured with Trusted Extensions, the following example lists attributes of all devices available to the caller for allocation:

```
% list_devices -al
device=audio1;type=audio;\
auths=solaris.device.allocate;\
clean=/etc/security/lib/audio_clean;\
minlabel=admin_low:maxlabel=admin_high;\
files=/dev/audio1 /dev/audio1ctl /dev/sound/1 /dev/sound/1ctl
```

### **EXAMPLE 3** Listing Attributes Including the Device Owner

On a system configured with Trusted Extensions, the following example lists attributes including the device owner of all devices allocated to the user:

```
% list_devices -auw
device=audio2;type=audio;auths=solaris.device.allocate;\
clean=/etc/security/lib/audio_clean;\
minlabel=admin_low:maxlabel=admin_high:zone=public;\
owner=1234;\
files=/dev/audio2 /dev/audio2ctl /dev/sound/2 /dev/sound/2ctl
```

**Exit Status** The following exit values are returned:

|                    |                                    |
|--------------------|------------------------------------|
| 0                  | Successful completion.             |
| 20                 | No entry for the specified device. |
| <i>other value</i> | An error occurred.                 |

**Files** /etc/security/device\_allocate

/etc/security/device\_maps

/etc/security/dev/\*

/usr/security/lib/\*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | See below.      |

The invocation is Uncommitted. The options are Uncommitted. The output from the -a and -w options is Uncommitted. All other output is Not-an-Interface.

**See Also** [allocate\(1\)](#), [deallocate\(1\)](#), [bsmconv\(1M\)](#), [dminfo\(1M\)](#), [mkdevalloc\(1M\)](#), [mkdevmaps\(1M\)](#), [device\\_allocate\(4\)](#), [device\\_maps\(4\)](#), [attributes\(5\)](#)

*Controlling Access to Devices*

**Notes** The functionality described in this man page is available only if Solaris Auditing has been enabled. See [bsmconv\(1M\)](#) for more information.

On systems configured with Trusted Extensions, the functionality is enabled by default.

[/etc/security/dev](#), [mkdevalloc\(1M\)](#), and [mkdevmaps\(1M\)](#) might not be supported in a future release of the Solaris Operating Environment.

**Name** listusers – list user login information

**Synopsis** listusers [-g *groups*] [-l *logins*]

**Description** Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by `/etc/nsswitch.conf`.

**Options** The following options are supported:

- g *groups* Lists all user logins belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list.
- l *logins* Lists the user login or logins specified by *logins*, sorted by login. Multiple logins can be specified as a comma-separated list.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [nsswitch.conf\(4\)](#), [attributes\(5\)](#)

**Notes** A user login is one that has a UID of 100 or greater.

The -l and -g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.

**Name** llc2\_autoconfig – generate LLC2 configuration files

**Synopsis** /usr/lib/llc2/llc2\_autoconfig [-f]

**Description** The llc2\_autoconfig utility is used to generate LLC2 configuration files (/etc/llc2/default/llc2.\*). If there is no configuration file in /etc/llc2\_default/, it detects all the available interfaces in the system and generates corresponding default configuration files.

If there are existing configuration files in /etc/llc2\_default/, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set llc2\_on in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.

**Options** The following option is supported:

- f Erases all configuration files in /etc/llc2/default/. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.

**Files** /etc/llc2/default/llc2.\* LLC2 configuration files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWllc         |

**See Also** [llc2\\_config\(1\)](#), [llc2\(4\)](#), [attributes\(5\)](#), [llc2\(7D\)](#)

**Name** llc2\_config – configure LLC2 interface parameters

**Synopsis** /usr/lib/llc2/llc2\_config  
[-P | -U | -d | -q | -i *ppa* | -r *ppa*]

**Description** The llc2\_config utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.

**Options** The following options are supported:

- d Turns on debug mode. Extra debugging information will be printed out.
- i *ppa* Initializes the corresponding interface using the file /etc/llc2/default/llc2.*ppa*.
- P Reads in all /etc/llc2/default/llc2.\* configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, llc2\_config -q will not show anything.
- q Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module:

| PPA | State | ID   | MACAddr      | Type     | MaxSDU | MinSDU | Mode |
|-----|-------|------|--------------|----------|--------|--------|------|
| 0   | up    | 0000 | 0800208a217e | ethernet | 1500   | 0      | 3    |

The fields displayed are described below:

**PPA** The relative logical position of the interface.

**State** The state of the interface:

- up* The interface is initialized and operational.
- down* The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.
- bad* The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics.

**ID** The interface ID.

**MACAddr** The MAC address currently in effect for the interface.

**Type** The MAC type. Current types supported include:

- csma/cd 10 Megabit Ethernet
- ethernet Ethernet type device
- tkn-ring 4/16 Megabit Token Ring

- `fddi`      100 Megabit Fiber Distributed Data Interface
- `MaxSDU`    The Maximum Service Data Unit size transmitted on this interface.
- `Mode`      The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in `/usr/include/sys/dlpi.h`.
- `-r ppa`    Uninitializes the corresponding interface. By using this option, and then using the `-i` option, the parameters associated with an interface can be changed.
- `-U`        Destroys all streams used by the LLC2 subsystem. This is the reverse of the `-P` option. After this is executed, `llc2_config -q` will not show anything.

**Files**    `/etc/llc2/default/llc2.*`    LLC2 configuration files

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWllc         |

**See Also**    [llc2\\_autoconfig\(1\)](#), [llc2\(4\)](#), [attributes\(5\)](#), [llc2\(7D\)](#)

- 
- Name** llc2\_stats – LLC2 Station, SAP, and Connection Statistics
- Synopsis** llc2\_stats *ppa* [-r] [-s *sap*] [-c *connection*]
- Description** The llc2\_stats command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.
- Options** The following options are supported:
- c *connection* Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.
  - r Resets the specified counters to zero after reading them. This option is only valid if the *root* user is executing the command.
  - s *sap* Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.
- Operands** The following operand is supported:
- ppa* The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.
- Examples** **EXAMPLE 1** Station Statistics
- The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented.
- ```
example% /usr/lib/llc2/llc2_stats 4
```
- ```
Station values received:
ppa = 0x00000004 clearFlag = 0x00
of saps (hex) = 0x0002
saps (hex) = 02 aa
state = 0x01
nullSapXidCmdRcvd = 0x00000000
nullSapXidRspSent = 0x00000000
nullSapTestCmdRcvd = 0x00000000
nullSapTestRspSent = 0x00000000
outOfState = 0x00000000
allocFail = 0x00000000
protocolError = 0x00000000
```
- The fields are described as follows:
- ppa* The logical number used to address the adapter.
  - clearFlag* This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).

**EXAMPLE 1** Station Statistics      *(Continued)*

|                    |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| # of saps          | The number of SAPs currently bound on this station.                                                                            |
| saps               | The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.        |
| state              | A number indicating the current state of the station component (0 = down, 1 = up).                                             |
| nullSapXidCmdRcvd  | The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).                           |
| nullSapXidRspSent  | The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.                        |
| nullSapTestCmdRcvd | The number of TEST command PDUs received for the null SAP address.                                                             |
| nullSapTestRspSent | The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.                      |
| outOfState         | The number of events received in an invalid state.                                                                             |
| allocFail          | The number of buffer allocation failures.                                                                                      |
| protocolError      | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |

**EXAMPLE 2** SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa = 0x00000004 clearFlag = 0x00
sap = 0x02
state = 0x01
of cons (hex) = 0x0000000a
connections (hex) = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent = 0x00000000
xidCmdRcvd = 0x00000000
xidRspSent = 0x00000000
xidRspRcvd = 0x00000000
testCmdSent = 0x00000000
testCmdRcvd = 0x00000000
```

**EXAMPLE 2** SAP Statistics (Continued)

```

testRspSent = 0x00000000
testRspRcvd = 0x00000000
uiSent = 0x00000000
uiRcvd = 0x00000000
outOfState = 0x00000000
allocFail = 0x00000000
protocolError = 0x00000000

```

The fields are described as follows:

|             |                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| ppa         | The logical number used to address the adapter.                                                                                       |
| clearFlag   | This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0). |
| sap         | The specified Service Access Point (SAP) logical interface value for the station.                                                     |
| state       | A number indicating the current state of the SAP component (0 = inactive, 1 = active).                                                |
| # of cons   | The number of active connections on this SAP.                                                                                         |
| connections | The array of active connection indexes.                                                                                               |
| xidCmdSent  | The number of XID command PDUs sent (Source SAP = this sap).                                                                          |
| xidCmdRcvd  | The number of XID command PDUs received (Destination SAP = this sap).                                                                 |
| xidRspSent  | The number of XID response PDUs sent (Source SAP = this sap).                                                                         |
| xidRspRcvd  | The number of XID response PDUs received (Source SAP = this sap).                                                                     |
| testCmdSent | The number of TEST command PDUs sent (Source SAP = this sap).                                                                         |
| testCmdRcvd | The number of TEST command PDUs received (Destination SAP = this sap).                                                                |
| testRspSent | The number of TEST response PDUs sent (Source SAP = this sap).                                                                        |
| testRspRcvd | The number of TEST response PDUs received (Source SAP = this sap).                                                                    |
| uiSent      | The number of Unnumbered Information Frames sent.                                                                                     |
| uiRcvd      | The number of Unnumbered Information Frames received.                                                                                 |
| outOfState  | The number of events received in an invalid state.                                                                                    |
| allocFail   | The number of buffer allocation failures.                                                                                             |

**EXAMPLE 2** SAP Statistics *(Continued)*

**protocolError**      The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

**EXAMPLE 3** Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa = 0x0004 clearFlag = 0x00
sap = 0x02 con = 0x0001 sid = 0x0201

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>ppa</b>         | The logical number used to address the adapter.                                                                                     |
| <b>clearFlag</b>   | This flag indicates if the statistics will be reset to zero after reading (set to 1) or if the statistics are read only (set to 0). |
| <b>sap</b>         | The specified Service Access Point (SAP) logical interface value for the station.                                                   |
| <b>con</b>         | The specified connection index value for the SAP.                                                                                   |
| <b>stateOldest</b> | A number representing the state of the connection component prior to stateOlder.                                                    |
| <b>stateOlder</b>  | A number representing the state of the connection component prior to stateOld.                                                      |

**EXAMPLE 3** Connection Statistics (Continued)

|              |                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stateOld     | A number representing the state of the connection component prior to state.                                                                                        |
| state        | A number representing the most current state of the connection component. See Table 1.                                                                             |
| sid          | The Station Identifier composed of the SAP (upper byte) and connection index (lower byte).                                                                         |
| dl_nodeaddr  | The Data Link Node Address. This is the destination node's MAC address.                                                                                            |
| dl_sap       | The destination node's SAP.                                                                                                                                        |
| flag         | The connection component processing flag. See Table 3.                                                                                                             |
| dataFlag     | A number representing the status of the data units from received I-frame PDUs (0 = not discarded, 1 = discarded, 2 = busy state entered with REJ PDU outstanding). |
| timerOn      | A number representing the timer activity flag, with each bit representing an active timer for this connection. See Table 2 for timer definitions.                  |
| vs           | The sequence number of the next I-frame PDU to send.                                                                                                               |
| vr           | The expected sequence number of the next I-frame PDU to be received.                                                                                               |
| nrRcvd       | The sequence number plus 1 of the last sent I-frame PDU acknowledged by the remote node.                                                                           |
| k            | The transmit window size.                                                                                                                                          |
| retryCount   | The retryCount is incremented whenever a timer expiration occurs. These timers protect outbound frames.                                                            |
| numToBeAcked | The number of outbound I-frames awaiting acknowledgement.                                                                                                          |
| numToResend  | The number of outbound I-frames to be retransmitted.                                                                                                               |
| macOutSave   | No longer used.                                                                                                                                                    |
| macOutDump   | No longer used.                                                                                                                                                    |
| iSent        | The number of I-frames sent.                                                                                                                                       |
| iRcvd        | The number of I-frames received.                                                                                                                                   |
| frmrSent     | The number of Frame Reject PDUs (FRMR) sent.                                                                                                                       |

**EXAMPLE 3** Connection Statistics      *(Continued)*

|                 |                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------|
| frmrRcvd        | The number of Frame Reject PDUs (FRMR) received.                                                                               |
| rrSent          | The number of Receiver Ready PDUs (RR) sent.                                                                                   |
| rrRcvd          | The number of Receiver Ready PDUs (RR) received.                                                                               |
| rnrSent         | The number of Receiver Not Ready PDUs (RNR) sent.                                                                              |
| rnrRcvd         | The number of Receiver Not Ready PDUs (RNR) received.                                                                          |
| rejSent         | The number of Reject PDUs (REJ) sent.                                                                                          |
| rejRcvd         | The number of Reject PDUs (REJ) received.                                                                                      |
| sabmeSent       | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) sent.                                                       |
| sabmeRcvd       | The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) received.                                                   |
| uaSent          | The number of Unnumbered Acknowledgment PDUs (UA) sent.                                                                        |
| uaRcvd          | The number of Unnumbered Acknowledgment PDUs (UA) received.                                                                    |
| discSent        | The number of Disconnect PDUs (DISC) sent.                                                                                     |
| outOfState      | The number of events received in an invalid state.                                                                             |
| allocFail       | The number of buffer allocation failures.                                                                                      |
| protocolError   | The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected. |
| localBusy       | The number of times this component was in local busy state and could not accept I-frames.                                      |
| remoteBusy      | The number of times the remote connection component was busy and could not accept I-frames.                                    |
| maxRetryFail    | The number of failures that occurred because maxRetry was reached.                                                             |
| ackTimerExp     | The number of expirations of the Acknowledgement timer.                                                                        |
| pollTimerExp    | The number of expirations of the Poll timer.                                                                                   |
| rejTimerExp     | The number of expirations of the Reject timer.                                                                                 |
| remBusyTimerExp | The number of expirations of the Remote Busy timer.                                                                            |
| inactTimerExp   | The number of expirations of the Inactivity timer.                                                                             |
| sendAckTimerExp | The number of expirations of the Send Acknowledgement timer.                                                                   |

EXAMPLE 3 Connection Statistics (Continued)

| Table 1: LLC2 States |      |
|----------------------|------|
| STATION              |      |
| ~~DOWN               | 0x00 |
| ~~UP                 | 0x01 |
| SAP                  |      |
| ~~INACTIVE           | 0x00 |
| ~~ACTIVE             | 0x01 |
| CONNECTION           |      |
| ~~ADM                | 0x00 |

|---------------------|------|
| P_FLAG              | 0x80 |
| F_FLAG              | 0x40 |
| S_FLAG              | 0x20 |
| REMOTE_BUSY         | 0x10 |
| RESEND_PENDING      | 0x08 |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWllc         |

**Files** /dev/llc2      clone device

**See Also** [attributes\(5\)](#)

**Notes** For further information on the LLC2 components, states and flags, see the International Standards Organization document, ISO 8802-2: 1994, Section 7.

**Name** ln – make hard or symbolic links to files

**Synopsis** /usr/bin/ln [-fns] *source\_file* [*target*]  
 /usr/bin/ln [-fns] *source\_file*... *target*  
 /usr/xpg4/bin/ln [-fs] *source\_file* [*target*]  
 /usr/xpg4/bin/ln [-fs] *source\_file*... *target*

**Description** In the first synopsis form, the ln utility creates a new directory entry (link) for the file specified by *source\_file*, at the destination path specified by *target*. If *target* is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.

In the second synopsis form, the ln utility creates a new directory entry for each file specified by a *source\_file* operand, at a destination path in the existing directory named by *target*.

The ln utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.

ln by default creates hard links. *source\_file* is linked to *target*. If *target* is a directory, another file named *source\_file* is created in *target* and linked to the original *source\_file*.

If *target* is an existing file and the -f option is not specified, ln will write a diagnostic message to standard error, do nothing more with the current *source\_file*, and go on to any remaining *source\_files*.

A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.

File permissions for *target* may be different from those displayed with an -l listing of the [ls\(1\)](#) command. To display the permissions of *target*, use [ls -lL](#). See [stat\(2\)](#) for more information.

/usr/bin/ln If /usr/bin/ln determines that the mode of *target* forbids writing, it prints the mode (see [chmod\(1\)](#)), asks for a response, and reads the standard input for one line. If the response is affirmative, the link occurs, if permissible. Otherwise, the command exits.

/usr/xpg4/bin/ln When creating a hard link, and the source file is itself a symbolic link, the target will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (*source\_file*).

**Options** The following options are supported for both /usr/bin/ln and /usr/xpg4/bin/ln:

- f Links files without questioning the user, even if the mode of *target* forbids writing. This is the default if the standard input is not a terminal.

-s      Creates a symbolic link.

If the -s option is used with two arguments, *target* may be an existing directory or a non-existent file. If *target* already exists and is not a directory, an error is returned. *source\_file* may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from *target*. If *target* is an existing directory, a file is created in directory *target* whose name is *source\_file* or the last component of *source\_file*. This file is a symbolic link that references *source\_file*. If *target* does not exist, a file with name *target* is created and it is a symbolic link that references *source\_file*.

If the -s option is used with more than two arguments, *target* must be an existing directory or an error will be returned. For each *source\_file*, a link is created in *target* whose name is the last component of *source\_file*. Each new *source\_file* is a symbolic link to the original *source\_file*. The files and *target* may reside on different file systems.

/usr/bin/ln    The following option is supported for /usr/bin/ln only:

-n      If *target* is an existing file, writes a diagnostic message to stderr and goes on to any remaining *source\_files*. The -f option overrides this option. This is the default behavior for /usr/bin/ln and /usr/xpg4/bin/ln, and is silently ignored.

**Operands**    The following operands are supported:

*source\_file*    A path name of a file to be linked. This can be either a regular or special file. If the -s option is specified, *source\_file* can also be a directory.

*target*          The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.

**Usage**        See [largefile\(5\)](#) for the description of the behavior of ln when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**Environment Variables**    See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ln: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status**    The following exit values are returned:

0        All the specified files were linked successfully

>0      An error occurred.

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| /usr/bin/ln | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-------------|----------------|-----------------|
|             | Availability   | SUNWcsu         |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| CSI            | Enabled         |

/usr/xpg4/bin/ln

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

**See Also** [chmod\(1\)](#), [ls\(1\)](#), [stat\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** A symbolic link to a directory behaves differently than you might expect in certain cases. While an [ls\(1\)](#) command on such a link displays the files in the pointed-to directory, entering `ls -l` displays information about the link itself:

```
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir
```

When you change to a directory (see [cd\(1\)](#)) through a symbolic link, using `/usr/bin/sh` or `/usr/bin/csh`, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. This will also happen when using `cd` with the `-P` option from `/usr/bin/ksh` or `/usr/xpg4/bin/sh`. For instance, in the following case, the final working directory is `/usr` and not `/home/user/linktest`.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd . .
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

**Name** ln – make hard or symbolic links to files

**Synopsis** /usr/ucb/ln [-fs] *filename* [*linkname*]  
/usr/ucb/ln [-fs] *pathname*... *directory*

**Description** The /usr/ucb/ln utility creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.

*filename* is the name of the original file or directory. *linkname* is the new name to associate with the file or filename. If *linkname* is omitted, the last component of *filename* is used as the name of the link.

If the last argument is the name of a directory, symbolic links are made in that directory for each *pathname* argument; /usr/ucb/ln uses the last component of each *pathname* as the name of each link in the named *directory*.

A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.

A symbolic link, made with the -s option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.

A symbolic link to a directory behaves differently than you might expect in certain cases. While an [ls\(1\)](#) on such a link displays the files in the pointed-to directory, an 'ls -l' displays information about the link itself:

```
example% /usr/ucb/ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user 7 Jan 11 23:27 link -> dir
```

When you use [cd\(1\)](#) to change to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is /usr and not /home/user/linktest.

```
example% pwd
/home/user/linktest
example% /usr/ucb/ln -s /var/tmp symlink
example% cd symlink
```

```
example% cd . .
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

- Options**
- f Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
  - s Create a symbolic link or links.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** **EXAMPLE 1** The `/usr/ucb/ln` command

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```
example% /usr/ucb/ln file link
example% ls -F file link
file link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file symlink@
example% ls -li file link symlink
10606 -rw-r--r-- 2 user 0 Jan 12 00:06 file
10606 -rw-r--r-- 2 user 0 Jan 12 00:06 link
10607 lrwxrwxrwx 1 user 4 Jan 12 00:06 symlink -> file
example% /usr/ucb/ln -s nonesuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x* y* z*

/tmp/bin:
x@ y@ z@
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [cp\(1\)](#), [ls\(1\)](#), [mv\(1\)](#), [rm\(1\)](#), [link\(2\)](#), [readlink\(2\)](#), [stat\(2\)](#), [symlink\(2\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Notes** When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln -s file /tmp
example% ls -l /tmp/file
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file -> file
example% cat /tmp/file
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the PWD variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln -s $PWD/file /tmp
lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file ->
/home/user/subdir/file
```

**Name** loadkeys, dumpkeys – load and dump keyboard translation tables

**Synopsis** loadkeys [*filename*]

dumpkeys

**Description** loadkeys reads the file specified by *filename*, and modifies the keyboard streams module's translation tables. If no file is specified, loadkeys loads the file: `/usr/share/lib/keytables/type_tt/layout_dd`, where *tt* is the value returned by the `KIOCTYPE ioctl`, and *dd* is the value returned by the `KIOCLAYOUT ioctl` (see [kb\(7M\)](#)). These keytable files specify only the entries that change between the specified layout and the default layout for the particular keyboard type. On self-identifying keyboards, the value returned by the `KIOCLAYOUT ioctl` is set from the DIP switches.

dumpkeys writes the current contents of the keyboard streams module's translation tables, in the format specified by [keytables\(4\)](#), to the standard output.

**Files** `/usr/share/lib/keytables/layout_dd` default keytable files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

**See Also** [kbd\(1\)](#), [keytables\(4\)](#), [attributes\(5\)](#), [kb\(7M\)](#), [usbkbm\(7M\)](#)

**Name** locale – get locale-specific information

**Synopsis** locale [-a | -m]  
locale [-ck] *name*...

**Description** The `locale` utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a *public locale* is one provided by the implementation that is accessible to the application.

When `locale` is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.

When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:

- Specifying a keyword name selects the named keyword and the category containing that keyword.
- Specifying a category name selects the named category and all keywords in that category.

**Options** The following options are supported:

- a Writes information about all available public locales. The available locales include POSIX, representing the POSIX locale.
- c Writes the names of selected locale categories. The -c option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the -k option.
- k Writes the names and values of selected keywords. The implementation may omit values for some keywords; see OPERANDS.
- m Writes names of available charmaps; see [localedef\(1\)](#).

**Operands** The following operand is supported:

*name* The name of a locale category, the name of a keyword in a locale category, or the reserved name `charmap`. The named category or keyword will be selected for output. If a single *name* represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as *name* operands, in any sequence.

**Examples** **EXAMPLE 1** Examples of the locale utility

In the following examples, the assumption is that locale environment variables are set as follows:

```
LANG=locale_x LC_COLLATE=locale_y
```

The command `locale` would result in the following output:

EXAMPLE 1 Examples of the locale utility (Continued)

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_NUMERIC="locale_x"
LC_TIME="locale_x"
LC_COLLATE=locale_y
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The command

```
LC_ALL=POSIX locale -ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | /usr/xpg4/bin/grep -Eq\
 "${locale yesexpr}"
then
 affirmative processing goes here
else
 non-affirmative processing goes here
fi
```

Environment Variables

See [environ\(5\)](#) for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out. These environment variables will be used if the `-a` option is not specified.

**Exit Status** The following exit values are returned:

- 0 All the requested information was found and output successfully.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| CSI                 | Enabled         |
| Interface Stability | Standard        |

**See Also** [localedef\(1\)](#), [attributes\(5\)](#), [charmap\(5\)](#), [environ\(5\)](#), [locale\(5\)](#), [standards\(5\)](#)

**Notes** If LC\_CTYPE or keywords in the category LC\_CTYPE are specified, only the values in the range 0x00-0x7f are written out.

If LC\_COLLATE or keywords in the category LC\_COLLATE are specified, no actual values are written out.

**Name** localedef – define locale environment

**Synopsis** localedef [-c] [-C *compiler\_options*] [-f *charmap*]  
 [-i *sourcefile*] [-L *linker\_options*] [-m *model*]  
 [-u *code\_set\_name*] [-W *cc, arg*] [-x *extensions\_file*] *localename*

**Description** The localedef utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see [environ\(5\)](#).

The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the -i option (if specified) or from standard input.

Each category source definition is identified by the corresponding environment variable name and terminated by an END *category-name* statement. The following categories are supported.

|             |                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------|
| LC_CTYPE    | Defines character classification and case conversion.                                         |
| LC_COLLATE  | Defines collation rules.                                                                      |
| LC_MONETARY | Defines the format and symbols used in formatting of monetary information.                    |
| LC_NUMERIC  | Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing. |
| LC_TIME     | Defines the format and content of date and time information.                                  |
| LC_MESSAGES | Defines the format and values of affirmative and negative responses.                          |

**Options** The following options are supported:

|                            |                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c                         | Creates permanent output even if warning messages have been issued.                                                                                                                                                                                                                                                                                 |
| -C <i>compiler_options</i> | Passes the <i>compiler_options</i> to the C compiler (cc). If more than one option is specified, then the options must be enclosed in quotes (" ").<br><br>This is an old option. Use the -W <i>cc,arg</i> option instead.                                                                                                                          |
| -f <i>charmap</i>          | Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a collating-symbol keyword) are used. If the -f option is not present, the default character mapping will be used. |
| -i <i>sourcefile</i>       | The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.                                                                                                                                                                                                      |

- L *linker\_options***

Passes the *linker\_options* to the C compiler (cc) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (" ").

This is an old option. Use the **-W cc,arg** option instead.
- m *model***

Specifies whether `localedef` will generate a 64-bit or a 32-bit locale object.

Specify *model* as `ilp32` to generate a 32-bit locale object. Specify `lp64` to generate a 64-bit locale object. If the **-m** option is not specified, `localedef` generates a 32-bit locale object. And if no other options than **-c**, **-f**, and **-i** options are specified and if the system running `localedef` supports the 64-bit environment, `localedef` additionally generates a 64-bit locale object.
- u *code\_set\_name***

Specifies the name of a codeset used as the target mapping of character symbols and collating element symbols whose encoding values are defined in terms of the ISO/IEC 10646-1: 2000 standard position constant values. See NOTES.
- W cc,arg**

Passes *arg* options to the C compiler. Each argument must be separated from the preceding by only a comma. A comma can be part of an argument by escaping it with an immediately preceding backslash character; the backslash is removed from the resulting argument.

Use this option instead of the **-C** and **-L** options.
- x *extensions\_file***

Specifies the name of an extension file where various `localedef` options are listed. See [locale\(5\)](#).

**Operands** The following operand is supported:

- localename*

Identifies the locale. If the name contains one or more slash characters, *localename* will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one *localename*, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

**Output** `localedef` creates a temporary C source file that represents the locale's data. `localedef` then calls the C compiler to compile this C source file into a shared object.

If the **-m ilp32** option is specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If the **-m lp64** option is specified, `localedef` calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If the `-m` option is not specified, `localedef` calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If no other options than `-c`, `-f`, and `-i` options are specified and if the system running `localedef` supports the 64-bit environment, `localedef` additionally calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If no option to the C compiler is explicitly specified using the `-W`, `-C`, or `-L` options, `localedef` calls the C compiler with appropriate C compiler options to generate a locale object or objects.

If the `-m ilp32` option is specified, `localedef` generates a 32-bit locale object named:

*localename.so.version\_number*

If the `-m lp64` option is specified, `localedef` generates a 64-bit locale object named:

*localename.so.version\_number*

If the `-m` option is not specified, `localedef` generates a 32-bit locale object named:

*localename.so.version\_number*

and, if appropriate, generates a 64-bit locale object named:

*64-bit\_architecture\_name/localename.so.version\_number*

The shared object for the 32-bit environment must be moved to:

*/usr/lib/locale/localename/localename.so.version\_number*

The shared object for the 64-bit environment on SPARC must be moved to:

*/usr/lib/locale/localename/sparcv9/localename.so.version\_number*

The shared object for the 64-bit environment on AMD64 must be moved to:

*/usr/lib/locale/<localename>/amd64/<localename>.so.<version\_number>*

`localedef` also generates a text file named *localename* that is used for information only.

**Environment Variables** See [environ\(5\)](#) for definitions of the following environment variables that affect the execution of `localedef`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 No errors occurred and the locales were successfully created.
- 1 Warnings occurred and the locales were successfully created.

- 2     The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
- 3     The capability to create new locales is not supported by the implementation.
- >3    Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

**Files**    /usr/lib/localedef/extensions/generic\_eucbc.x  
          Describes what a generic EUC locale uses in the system. This file is used by default.

          /usr/lib/localedef/extensions/single\_byte.x  
          Describes a generic single-byte file used in the system.

          /usr/lib/locale/localename/localename.so.version\_number  
          The shared object for the 32-bit environment.

          /usr/lib/locale/localename/sparcv9/localename.so.version\_number  
          The shared object for the 64-bit environment on SPARC.

          /usr/lib/locale/<localename>/amd64/<localename>.so.<version\_number>  
          The shared object for the 64-bit environment on AMD64.

**Attributes**   See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also**   [locale\(1\)](#), [iconv\\_open\(3C\)](#), [nl\\_langinfo\(3C\)](#), [strftime\(3C\)](#), [attributes\(5\)](#), [charmap\(5\)](#), [environ\(5\)](#), [extensions\(5\)](#), [locale\(5\)](#), [standards\(5\)](#)

- Warnings**   If warnings occur, permanent output will be created if the -c option was specified. The following conditions will cause warning messages to be issued:
- If a symbolic name not found in the *charmap* file is used for the descriptions of the LC\_CTYPE or LC\_COLLATE categories (for other categories, this will be an error conditions).
  - If optional keywords not supported by the implementation are present in the source.

**Notes**     When the -u option is used, the *code\_set\_name* option-argument is interpreted as a name of a codeset to which the ISO/IEC 10646-1: 2000 standard position constant values are converted. Both the ISO/IEC 10646-1: 2000 standard position constant values and other formats (decimal, hexadecimal, or octal) are valid as encoding values within the charmap file. The codeset can be any codeset that is supported by the [iconv\\_open\(3C\)](#) function on the system.

When conflicts occur between the charmap specification of *code\_set\_name*, *mb\_cur\_max*, or *mb\_cur\_min* and the corresponding value for the codeset represented by the *-u* option-argument *code\_set\_name*, the `localedef` utility fails as an error.

When conflicts occur between the charmap encoding values specified for symbolic names of characters of the portable character set and the character encoding values defined by the US-ASCII, the result is unspecified.

If a non-printable character in the charmap has a width specified that is not -1, `localedef` generates a warning.

**Name** logger – add entries to the system log

**Synopsis** logger [-i] [-f *file*] [-p *priority*] [-t *tag*] [*message*] ...

**Description** The `logger` command provides a method for adding one-line entries to the system log file from the command line. One or more *message* arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with `-f` or the standard input is added to the log. Otherwise, a *file* can be specified, in which case each line in the file is logged. If neither is specified, `logger` reads and logs messages on a line-by-line basis from the standard input.

**Options** The following options are supported:

- f *file* Uses the contents of *file* as the message to log.
- i Logs the process ID of the `logger` process with each line.
- p *priority* Enters the message with the specified *priority*. The message priority can be specified numerically, or as a *facility.level* pair. For example, '`-p local3.info`' assigns the message priority to the `info` level in the `local3` facility. The default priority is `user.notice`.
- t *tag* Marks each line added to the log with the specified *tag*.

**Operands** The following operand is supported:

- message* One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.

**Examples** **EXAMPLE 1** Examples of the `logger` command

The following example:

```
example% logger System rebooted
```

logs the message 'System rebooted' to the default priority level `notice` to be treated by `syslogd` as are other messages to the facility `user`.

The next example:

```
example% logger -p local0.notice -t HOSTIDM -f /dev/idmc
```

reads from the file `/dev/idmc` and logs each line in that file as a message with the tag 'HOSTIDM' at priority level `notice` to be treated by `syslogd` as are other messages to the facility `local0`.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `logger`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLS_PATH`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.

>0     An error occurred.

**Attributes**   See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**See Also**   [mailx\(1\)](#), [write\(1\)](#), [syslogd\(1M\)](#), [syslog\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** logger – add entries to the system log

**Synopsis** /usr/ucb/logger [-f *filename*] [-i] [-p *priority*] [-t *tag*] mm  
[*message*]. . .

**Description** The logger utility provides a method for adding one-line entries to the system log file from the command line. One or more *message* arguments can be given on the command line, in which case each is logged immediately. If *message* is unspecified, either the file indicated with -f or the standard input is added to the log. Otherwise, a *filename* can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.

**Options** The following options are supported:

- i Log the process ID of the logger process with each line.
- f *filename* Use the contents of *filename* as the message to log.
- p *priority* Enter the message with the specified *priority*. The message priority can be specified numerically, or as a *facility.level* pair. For example, ‘-p local3.info’ assigns the message priority to the info level in the local3 facility. The default priority is user.notice.
- t *tag* Mark each line added to the log with the specified *tag*.

**Examples** **EXAMPLE 1** Logging a message  
The command:

example% **logger System rebooted**

will log the message ‘System rebooted’ to the facility at priority notice to be treated by syslogd as other messages to the facility notice are.

**EXAMPLE 2** Logging messages from a file  
The command:

example% **logger -p local0.notice -t HOSTIDM -f /dev/idmc**

will read from the file /dev/idmc and will log each line in that file as a message with the tag ‘HOSTIDM’ at priority notice to be treated by syslogd as other messages to the facility local0 are.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**See Also** [syslogd\(1M\)](#), [syslog\(3C\)](#), [attributes\(5\)](#)

**Name** login – sign on to the system

**Synopsis** login [-p] [-d *device*] [-R *repository*] [-s *service*]  
[-t *terminal*] [-u *identity*] [-U *ruser*]  
[-h *hostname* [*terminal*] | -r *hostname*]  
[*name* [*environ*]...]

**Description** The login command is used at the beginning of each terminal session to identify oneself to the system. login is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the exit command.

If login is invoked as a command, it must replace the initial command interpreter. To invoke login in this fashion, type:

**exec login**

from the initial shell. The C shell and Korn shell have their own builtins of login. See [ksh\(1\)](#) and [csh\(1\)](#) for descriptions of login builtins and usage.

login asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.

If you make any mistake in the login procedure, the message:

Login incorrect

is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in /var/adm/loginlog, if it exists. The TTY line will be dropped.

If password aging is turned on and the password has "aged" (see [passwd\(1\)](#) for more information), the user is forced to change the password. In this case the /etc/nsswitch.conf file is consulted to determine password repositories (see [nsswitch.conf\(4\)](#)). The password update configurations supported are limited to the following five cases.

- passwd: files
- passwd: files nis
- passwd: files nisplus
- passwd: compat (==> files nis)
- passwd: compat (==> files nisplus)
- passwd\_compat: nisplus

Failure to comply with the configurations will prevent the user from logging onto the system because [passwd\(1\)](#) will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.

After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the `/etc/logindevperm` file, and the time you last logged in is printed (see [logindevperm\(4\)](#)).

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually `ksh`) is started.

The basic *environment* is initialized to:

```
HOME=your-login-directory
LOGNAME=your-login-name
PATH=/usr/bin:
SHELL=last-field-of-passwd-entry
MAIL=/var/mail/
TZ=timezone-specification
```

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/.login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/.login` files check quotas (see [quota\(1M\)](#)), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to `-` (dash), followed by the last component of the interpreter's path name, for example, `-sh`.

If the *login-shell* field in the password file (see [passwd\(4\)](#)) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is `*` (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an `=` (equal sign) are placed in the environment as:

```
Ln=xxx
```

where *n* is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an `=` (equal sign) are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a `\` (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to

the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the login line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the `/etc/default/login` file by inserting a `#` (pound sign) before the `CONSOLE=/dev/console` entry. See FILES.

**Security** For accounts in name services which support automatic account locking, the account may be configured to be automatically locked (see [user\\_attr\(4\)](#) and [policy.conf\(4\)](#)) if successive failed login attempts equals or exceeds RETRIES. Currently, only the "files" repository (see [passwd\(4\)](#) and [shadow\(4\)](#)) supports automatic account locking. See also [pam\\_unix\\_auth\(5\)](#).

The login command uses [pam\(3PAM\)](#) for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for login. Here is a partial `pam.conf` file with entries for the login command using the UNIX authentication, account management, and session management modules:

```
login auth required pam_authtok_get.so.1
login auth required pam_dhkeys.so.1
login auth required pam_unix_auth.so.1
login auth required pam_dial_auth.so.1

login account requisite pam_roles.so.1
login account required pam_projects.so.1
login account required pam_unix_account.so.1

login session required pam_unix_session.so.1
```

The Password Management stack looks like the following:

```
other password required pam_dhkeys.so.1
other password requisite pam_authtok_get.so.1
other password requisite pam_authtok_check.so.1
other password required pam_authtok_store.so.1
```

If there are no entries for the service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When login is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet`, respectively.

**Options** The following options are supported:

`-d device` login accepts a device option, *device*. *device* is taken to be the path name of the TTY port login is to operate on. The use of the device option can be expected to improve login performance, since login will not need to call [ttyname\(3C\)](#). The `-d` option is

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | available only to users whose UID and effective UID are root. Any other attempt to use <code>-d</code> will cause <code>login</code> to quietly exit.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-h hostname [ terminal ]</code> | Used by <a href="#">in.telnetd(1M)</a> to pass information about the remote host and terminal type.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                       | Terminal type as a second argument to the <code>-h</code> option should not start with a hyphen ( <code>-</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-p</code>                       | Used to pass environment variables to the login shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-r hostname</code>              | Used by <a href="#">in.rlogind(1M)</a> to pass information about the remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-R repository</code>            | Used to specify the PAM repository that should be used to tell PAM about the “identity” (see option <code>-u</code> below). If no “identity” information is passed, the repository is not used.                                                                                                                                                                                                                                                                                                                                       |
| <code>-s service</code>               | Indicates the PAM service name that should be used. Normally, this argument is not necessary and is used only for specifying alternative PAM service names. For example: “ <code>ktelnet</code> ” for the Kerberized telnet process.                                                                                                                                                                                                                                                                                                  |
| <code>-u identity</code>              | Specifies the “identity” string associated with the user who is being authenticated. This will usually <i>not</i> be the same as that user’s Unix login name. For Kerberized login sessions, this will be the Kerberos principal name associated with the user.                                                                                                                                                                                                                                                                       |
| <code>-U ruser</code>                 | Indicates the name of the person attempting to login on the remote side of the <code>rlogin</code> connection. When <a href="#">in.rlogind(1M)</a> is operating in Kerberized mode, that daemon will process the terminal and remote user name information prior to invoking <code>login</code> , so the “ <code>ruser</code> ” data is indicated using this command line parameter. Normally (non-Kerberos authenticated <code>rlogin</code> ), the <code>login</code> daemon will read the remote user information from the client. |

**Exit Status** The following exit values are returned:

0                      Successful operation.

non-zero              Error.

|              |                                |                                                                |
|--------------|--------------------------------|----------------------------------------------------------------|
| <b>Files</b> | <code>\$HOME/.cshrc</code>     | initial commands for each <code>csh</code>                     |
|              | <code>\$HOME/.hushlogin</code> | suppresses login messages                                      |

| <code>/etc/default/login</code>         | Default value can be set for the following flags in <code>/etc/default/login</code> . Default values are specified as comments in the <code>/etc/default/login</code> file, for example, <code>TIMEZONE=EST5EDT</code> .<br><br>TIMEZONE                Sets the TZ environment variable of the shell (see <a href="#">environ(5)</a> ).<br><br>HZ                      Sets the HZ environment variable of the shell.<br><br>ULIMIT                  Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit).<br><br>CONSOLE                If set, root can login on that device only. This will not prevent execution of remote commands with <a href="#">rsh(1)</a> . Comment out this line to allow login by root.<br><br>PASSREQ                Determines if login requires a non-null password. |

| ALTSHELL    | Determines if login should set the SHELL environment variable.                                                                                                                                                                                                                                                                                                                                                                                                    |
| PATH        | Sets the initial shell PATH variable.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SUPATH      | Sets the initial shell PATH variable for root.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TIMEOUT     | Sets the number of seconds (between 0 and 900) to wait before abandoning a login session.                                                                                                                                                                                                                                                                                                                                                                         |
| UMASK       | Sets the initial shell file creation mode mask. See <a href="#">umask(1)</a> .                                                                                                                                                                                                                                                                                                                                                                                    |
| SYSLOG      | Determines whether the <a href="#">syslog(3C)</a> LOG_AUTH facility should be used to log all root logins at level LOG_NOTICE and multiple failed login attempts at LOG_CRIT.                                                                                                                                                                                                                                                                                     |
| DISABLETIME | If present, and greater than zero, the number of seconds that login will wait after RETRIES failed attempts or the PAM framework returns PAM_ABORT. Default is 20 seconds. Minimum is 0 seconds. No maximum is imposed.                                                                                                                                                                                                                                           |
| SLEEPTIME   | If present, sets the number of seconds to wait before the login failure message is printed to the screen. This is for any login failure other than PAM_ABORT. Another login attempt is allowed, providing RETRIES has not been reached or the PAM framework is returned PAM_MAXTRIES. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.<br><br>Both <a href="#">su(1M)</a> and <a href="#">slogin(1M)</a> are affected by the value of SLEEPTIME. |
| RETRIES     | Sets the number of retries for logging in (see <a href="#">pam(3PAM)</a> ). The default is 5. The maximum number of retries is 15. For accounts configured with                                                                                                                                                                                                                                                                                                   |

automatic locking (see SECURITY above), the account is locked and login exits. If automatic locking has not been configured, login exits without locking the account.

**SYSLOG\_FAILED\_LOGINS** Used to determine how many failed login attempts will be allowed by the system before a failed login message is logged, using the [syslog\(3C\)](#) LOG\_NOTICE facility. For example, if the variable is set to 0, login will log *all* failed login attempts.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

|                    |                                                      |                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Diagnostics</b> | Login incorrect                                      | The user name or the password cannot be matched.                                                                                                                                                                                                                               |
|                    | Not on system console                                | Root login denied. Check the CONSOLE setting in /etc/default/login.                                                                                                                                                                                                            |
|                    | No directory! Logging in with home=/<br><br>No shell | The user's home directory named in the <a href="#">passwd(4)</a> database cannot be found or has the wrong permissions. Contact your system administrator.<br><br>Cannot execute the shell named in the <a href="#">passwd(4)</a> database. Contact your system administrator. |

NO LOGINS: System going down in  $N$  minutes      The machine is in the process of being shut down and logins have been disabled.

**Warnings** Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.

If you use the `CONSOLE` setting to disable root logins, you should arrange that remote command execution by root is also disabled. See [rsh\(1\)](#), [rcmd\(3SOCKET\)](#), and [hosts.equiv\(4\)](#) for further details.

**Notes** The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), [pam\\_unix\\_session\(5\)](#), [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), and [pam\\_passwd\\_auth\(5\)](#).

**Name** logname – return user's login name

**Synopsis** logname

**Description** The logname utility will write the user's login name to standard output. The login name is the string that would be returned by the [getlogin\(3C\)](#) function. Under the conditions where `getlogin()` would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of logname: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following error values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files** /etc/profile environment for user at login time  
/var/adm/utmpx user and accounting information

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWesu         |
| Interface Stability | Standard        |

**See Also** [env\(1\)](#), [login\(1\)](#), [getlogin\(3C\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Name** logout – shell built-in function to exit from a login session

**Synopsis**

    csh logout

**Description**

    csh Terminate a login shell.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [csh\(1\)](#), [login\(1\)](#), [attributes\(5\)](#)

**Name** look – find words in the system dictionary or lines in a sorted list

**Synopsis** /usr/bin/look [-d] [-f] [-tc] *string* [*filename*]

**Description** The look command consults a sorted *filename* and prints all lines that begin with *string*.

If no *filename* is specified, look uses /usr/share/lib/dict/words with collating sequence -df.

look limits the length of a word to search for to 256 characters.

- Options**
- d Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.
  - f Fold case. Upper case letters are not distinguished from lower case in comparisons.
  - tc Set termination character. All characters to the right of *c* in *string* are ignored.

**Files** /usr/share/lib/dict/words spelling list

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**See Also** [grep\(1\)](#), [sort\(1\)](#), [attributes\(5\)](#)

**Name** lookbib – find references in a bibliographic database

**Synopsis** lookbib *database*

**Description** A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.

The lookbib utility uses an inverted index made by `indxbib` to find sets of bibliographic references. It reads keywords typed after the '>' prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another '>' prompt.

It is possible to search multiple databases, as long as they have a common index made by `indxbib(1)`. In that case, only the first argument given to `indxbib` is specified to `lookbib`.

If `lookbib` does not find the index files (the `.i[abc]` files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a `.ig` suffix, suitable for use with `fgrep` (see `grep(1)`). `lookbib` then uses this `fgrep` file to find references. This method is simpler to use, but the `.ig` file is slower to use than the `.i[abc]` files, and does not allow the use of multiple reference files.

**Files** `x.ia`  
`x.ib`  
`x.ic` index files  
`x.ig` reference file

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**See Also** `addbib(1)`, `grep(1)`, `indxbib(1)`, `refer(1)`, `roffbib(1)`, `sortbib(1)`, `attributes(5)`

**Bugs** Probably all dates should be indexed, since many disciplines refer to literature written in the 1800s or earlier.

**Name** lorder – find ordering relation for an object or library archive

**Synopsis** lorder *filename...*

**Description** The input is one or more object or library archive *filenames* (see [ar\(1\)](#)). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by [tsort\(1\)](#) to find an ordering of a library suitable for one-pass access by ld. Note that the link editor ld is capable of multiple passes over an archive in the portable archive format (see [ar.h\(3HEAD\)](#)) and does not require that lorder be used when building an archive. The usage of the lorder command may, however, allow for a more efficient access of the archive during the link edit process.

The following example builds a new library from existing .o files.

```
ar -cr library `lorder *.o | tsort`
```

**Files** TMPDIR/\*symref temporary files  
TMPDIR/\*symdef temporary files  
TMPDIR usually /var/tmp but can be redefined by setting the environment variable TMPDIR (see tempnam() in [tmpnam\(3C\)](#))

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**See Also** [ar\(1\)](#), [ld\(1\)](#), [tsort\(1\)](#), [tmpnam\(3C\)](#), [ar.h\(3HEAD\)](#), [attributes\(5\)](#)

**Notes** lorder will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be .o.

The length of the filename for TMPDIR is limited to whatever sed allows.

**Name** lp – submit print request

**Synopsis** lp [-c] [-m] [-p] [-s] [-w] [-d *destination*] [-f *form-name*]  
 [-H *special-handling*] [-n *number*] [-o *option*]  
 [-P *page-list*] [-q *priority-level*]  
 [-S *character-set* | *print-wheel*] [-t *title*]  
 [-T *content-type* [-r]] [-y *mode-list*] [*file*]...

lp -i *request-ID*... [-c] [-m] [-p] [-s] [-w]  
 [-d *destination*] [-f *form-name*] [-H *special-handling*]  
 [-n *number*] [-o *option*] [-P *page-list*]  
 [-q *priority-level*] [-S *character-set* | *print-wheel*]  
 [-t *title*] [-T *content-type* [-r]] [-y *mode-list*]

**Description** The lp utility submits print requests to a destination. There are two formats of the lp command.

The first form of lp prints files (*file*) and associated information (collectively called a *print request*). If *file* is not specified, lp assumes the standard input. Use a hyphen (–) with *file* to specify the standard input. Files are printed in the order in which they appear on the command line.

The second form of lp changes print request options. This form of lp can only be used with print services and protocols that support job modification. The LP print service allows print requests to be modified when they are in a queue local to the system that the lp commands was executed on. The Internet Print Protocol (IPP) allows job modification on remote ipp print services.

The print request identified by *request-ID* is changed according to the printing options specified. The printing options available are the same as those with the first form of the lp. If the request has finished printing when the lp command is executed, the change is rejected. If the request is in the process of printing, it is stopped and restarted from the beginning (unless the -P option has been given).

The print client commands locate destination information using the “printers” database in the name service switch. See [nsswitch.conf\(4\)](#), [printers\(4\)](#), and [printers.conf\(4\)](#) for details.

**Options** Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. lp handles print requests sent to such destinations differently (see NOTES).

The following options are supported:

-c Copies *file* before printing.

Unless -c is specified, users should not remove any *file* before the print request has completely printed. Changes made to *file* after the print request is made but before it is printed might be reflected in the printed output. *file* is linked (as opposed to copied).

- 
- d *destination*** Prints *file* on a specific destination. The **-d** option is used to set the destination only when the job is first created. (*Note:* To move existing jobs to a different destination, see [lpmove\(1M\)](#).) *destination* can be either a printer or a class of printers (see [lpadmin\(1M\)](#)). Specify *destination* using atomic, URI-style (*scheme://endpoint*), or POSIX-style (*server:destination*) names. See [printers.conf\(4\)](#) for more information.
- f *form-name*** Prints *file* on *form-name*. The LP print service ensures that the form is mounted on the printer. The print request is rejected if the printer does not support *form-name*, if *form-name* is not defined for the system, or if the user is not allowed to use *form-name* (see [lpforms\(1M\)](#)).
- H *special-handling*** Prints the print request according to the value of *special-handling*. The following *special-handling* values are acceptable:
- |                  |                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hold</b>      | Do not print the print request until notified. If printing has already begun, stop it. Other print requests are placed ahead of a request that has been put on hold ( <i>held print request</i> ) until the print request is resumed.                                                                                                        |
| <b>resume</b>    | Resume a held print request. If the print request had begun to print when held, it is the next print request printed, unless it is superseded by an <i>immediate</i> print request.                                                                                                                                                          |
| <b>immediate</b> | Print the print request next. If more than one print request is assigned, the most recent print request is printed next. If a print request is currently printing on the desired printer, a <b>hold</b> request must be issued to allow the immediate request to print. The <b>immediate</b> request is only available to LP administrators. |
- i *request-ID*** Changes options for the print request identified by *request-ID*. There must be a space between **-i** and *request-ID*.
- This option applies to jobs that are in a local queue on a print server. This also applies to remote queues on when the remote print server supports IPP with job modification.
- m** Sends mail after *file* has printed (see [mail\(1\)](#)). By default, no mail is sent upon normal completion of a print request.
- n *number*** Prints a specific number of copies of *file*. Specify *number* as a digit. The default for *number* is 1.

`-o option` Specifies printer-dependent *options*. Specify several options by specifying `-o option` multiple times (`-o option -o option -o option`). Printer-dependent options can also be specified using the `-o` keyletter once, followed by a list of options enclosed in double quotes (`-o“option option option”`).

*options* take the following forms:

- `key=value` Associates information with the request for use by the backend print service. The keys and values that can be used are specific to the backend print service and queue configuration.
- `[no]key` Associates boolean information with the request for use by the backend print service. The keys that can be used are specific to the backend print service and queue configuration.

The following options are commonly used with the LP print service:

- `nobanner` Does not print a banner page with the request. This option can be disallowed by the LP administrator.  
  
On a system that is configured with Trusted Extensions, use of this option requires the `solaris.print.nobanner` authorization.
- `nofilebreak` Prints multiple files without inserting a form feed between them.
- `nolabels` On a system that is configured with Trusted Extensions, specifies suppression of page header and footer labels. Use of this option requires the `solaris.print.unlabeled` authorization.
- `length=numberi | numberc | number` Prints the print request with pages of a specific

length in inches, centimeters, or number of lines. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of lines by specifying *number* alone. `length=66` indicates a page length of 66 lines. `length=11i` indicates a page length of 11 inches. `length=27.94c` indicates a page length of 27.94 centimeters.

This option can not be used with the `-f` option.

`width=numberi | numberc | number`

Prints the print request with pages of a specific width in inches, centimeters, or number of columns. Append the letter *i* for inches or *c* for centimeters to *number*. Indicate the number of columns by specifying *number* alone. `width=65` indicates a page width of 65 columns. `width=6.5i` indicates a page width of 6.5 inches. `width=10c` indicates a page width of 10 centimeters.

This option can not be used with the `-f` option.

`lpi=number`

Prints the print request with the line pitch set to *number* lines in an inch. Use *number* to specify the number of lines in an inch.

|                                       |                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       |                                                                                                                                                                                                                           | This option can not be used with the -f option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                       | <code>cpi=<i>n</i> pica elite compressed</code>                                                                                                                                                                           | Prints the print request with the character pitch set to <i>number</i> characters in an inch. Use <i>number</i> to specify the number of characters in an inch. Use <i>pica</i> to set character pitch to pica (10 characters per inch), or <i>elite</i> to set character pitch to elite (12 characters per inch) Use <i>compressed</i> to set character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the terminfo database (see <a href="#">terminfo(4)</a> ) for the default character pitch for your printer. This option can not be used with the -f option. |
|                                       | <code>stty=<i>stty-option-list</i></code>                                                                                                                                                                                 | Prints the request using a list of options valid for the stty command (see <a href="#">stty(1)</a> ). Enclose the list in single quotes (') if it contains blanks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-P <i>page-list</i></code>      | Prints the pages specified in <i>page-list</i> in ascending order. Specify <i>page-list</i> as a of range of numbers, single page number, or a combination of both.                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                       | The -P option can only be used if there is a filter available to handle it; otherwise, the print request is rejected.                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-p</code>                       | Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-q <i>priority-level</i></code> | Assigns the print request a priority in the print queue. Specify <i>priority-level</i> as an integer between from 0 and 39. Use 0 to indicate the highest priority; 39 to indicate the lowest priority. If no priority is |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

specified, the default priority for a print service is assigned by the LP administrator. The LP administrator can also assign a default priority to individual users.

**-s** Suppresses the display of messages sent from `lp`.

**-S *character-set* |  
-S *print-wheel***

Prints the request using the *character-set* or *print-wheel*. If a form was requested and requires a character set or print wheel other than the one specified with the `-S` option, the request is rejected. Printers using mountable print wheels or font cartridges use the print wheel or font cartridge mounted at the time of the print request, unless the `-S` option is specified.

Printers Using Print Wheels: If `print wheel` is not one listed by the LP administrator as acceptable for the printer the request is rejected unless the print wheel is already mounted on the printer.

Printers Using Selectable or Programmable Character Sets: If the `-S` option is not specified, `lp` uses the standard character set. If *character-set* is not defined in the `terminfo` database for the printer (see [terminfo\(4\)](#)), or is not an alias defined by the LP administrator, the request is rejected.

**-t *title*** Prints a title on the banner page of the output. Enclose *title* in quotes if it contains blanks. If *title* is not specified, the name of the file is printed on the banner page.

**-T*content-type* [-r]** Prints the request on a printer that can support the specified *content-type*. If no printer accepts this type directly, a filter is used to convert the content into an acceptable type. If the `-r` option is specified, a filter is not used. If `-r` is specified, and no printer accepts the *content-type* directly, the request is rejected. If the *content-type* is not acceptable to any printer, either directly or with a filter, the request is rejected.

**-w** Writes a message on the user's terminal after the *files* have been printed. If the user is not logged in, then mail is sent instead.

**-y *mode-list*** Prints the request according to the printing modes listed in *mode-list*. The allowed values for *mode-list* are locally defined.

This option can be used only if there is a filter available to handle it; otherwise, the print request is rejected.

**Operands** The following operand is supported:

*file*      The name of the file to be printed. Specify *file* as a pathname or as a hyphen (–) to indicate the standard input. If *file* is not specified, lp uses the standard input.

**Usage**    See [largefile\(5\)](#) for the description of the behavior of lp when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

- Environment Variables**    See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of lp: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, NLSPATH, and PATH.
- LC\_TIME      Determine the format and contents of date and time strings displayed in the lp banner page, if any.
- LPDEST      Determine the destination. If the LPDEST environment variable is not set, the PRINTER environment variable shall be used. The -d *dest* option takes precedence over LPDEST. Results are undefined when -d is not specified and LPDEST contains a value that is not a valid destination name.
- PRINTER     Determine the output device or destination. If the LPDEST and PRINTER environment variables are not set, an unspecified output device is used. The -d *dest* option and the LPDEST environment variable shall take precedence over PRINTER. Results are undefined when -d is not specified, LPDEST is unset, and PRINTER contains a value that is not a valid device or destination name.
- TZ           Determine the timezone used to calculate date and time strings displayed in the lp banner page, if any. If TZ is unset or null, an unspecified default timezone shall be used.

**Exit Status**    The following exit values are returned:

- 0            Successful completion.
- non-zero    An error occurred.

- Files**       /etc/printers.conf      System printer configuration database
- \$HOME/.printers        User-configurable printer database
- ou=printers      LDAP version of /etc/printers.conf
- printers.conf.byname    NIS version of /etc/printers.conf
- printers.org\_dir      NIS+ version of /etc/printers.conf

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE     |
|----------------|---------------------|
| Availability   | SUNWlp-cmds         |
| CSI            | Enabled. See NOTES. |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

**See Also** `cancel(1)`, `enable(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `mail(1)`, `postprint(1)`, `pr(1)`, `stty(1)`, `accept(1M)`, `lpadmin(1M)`, `lpfilter(1M)`, `lpforms(1M)`, `lpmove(1M)`, `lpsched(1M)`, `lpshut(1M)`, `lpssystem(1M)`, `lpusers(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**Notes** CSI-capability assumes that printer names are composed of ASCII characters.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

When using the BSD printing protocol to send print requests to a remote print service, functionality is limited.

Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

- 1. Print requests with more than 52 filenames are truncated to 52 files.
- 2. The `-f`, `-H`, `-o`, `-P`, `-p`, `-q`, `-S`, `-T`, and `-y` options might require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer's `printer-uri-supported` (or `bsdaddr`) entry in `/etc/printers.conf`. Changing the `printer-uri-supported` entry in `/etc/printers.conf` to:

```
printer-uri-supported=lpd://server/printers/destination#Solaris
bsdaddr=server,destination,Solaris
```

Adding `Solaris` to either of these values causes the `lp` command to generate a set of BSD print protocol extensions that can be processed by a Solaris print server.

As a result of several limitations in the BSD print protocol, it is recommended that the IPP protocol be used for communication with print servers.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

**Name** lpc – line printer control program

**Synopsis** /usr/ucb/lpc [*command* [*parameter...*]]

**Description** The lpc utility controls the operation of local printers.

Use lpc to perform the following functions:

- start or stop a printer,
- disable or enable a printer's spooling queue,
- rearrange the order of jobs in a print queue, or
- display the status of a printer print queue and printer daemon.

lpc can be run from the command line or interactively. Specifying lpc with the optional *command* and *parameter* arguments causes lpc to interpret the first argument as an lpc command, and all other arguments as parameters to that command. Specifying lpc without arguments causes it to run interactively, prompting the user for lpc commands with lpc>. By redirecting the standard input, lpc can read commands from a file.

**Usage** lpc commands can be typed in their entirety or abbreviated to an unambiguous substring. Some lpc commands are available to all users; others are available only to super-users.

All users can execute the following lpc commands:

|                                                        |                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ? [ <i>command ...</i> ]   help [ <i>command ...</i> ] | Displays a short description of <i>command</i> . <i>command</i> is an lpc command. If <i>command</i> is not specified, displays a list of lpc commands.                                                                                                                                                                                                      |
| exit   quit                                            | Exits from lpc.                                                                                                                                                                                                                                                                                                                                              |
| status [all   <i>printer ...</i> ]                     | Displays the status of print daemons and print queues. all specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names. |

Only a super-user can execute the following lpc commands:

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| abort [all   <i>printer ...</i> ] | Terminates an active spooling daemon. Disables printing (by preventing new daemons from being started by <a href="#">lpr(1B)</a> ) for <i>printer</i> . all specifies this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names. |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`clean [all | printer ...]`

Removes files created in the print spool directory by the print daemon from *printer*'s print queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See [printers.conf\(4\)](#) for information regarding naming conventions for atomic names.

`disable [all | printer ...]`

Turns off the print queue for *printer*. Prevents new printer jobs from being entered into the print queue for *printer* by [lpr\(1B\)](#). *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See [printers.conf\(4\)](#) for information regarding naming conventions for atomic names.

`down [all | printer ...] [message]`

Turns the queue for *printer* off and disables printing on *printer*. Inserts *message* in the printer status file. *message* does not need to be quoted; multiple arguments to *message* are treated as arguments are to [echo\(1\)](#). Use `down` to take a printer down and inform users. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See [printers.conf\(4\)](#) for information regarding naming conventions for atomic names.

`enable [all | printer ...]`

Enables [lpr\(1B\)](#) to add new jobs in the spool queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See [printers.conf\(4\)](#) for information regarding naming conventions for atomic names.

`restart [all | printer ...]`

Attempts to start a new printer daemon. `restart` is useful when a print daemon dies unexpectedly and leaves jobs in the print queue. *all* specifies that this command is performed on all locally attached printers. *printer* indicates that this command is

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                           | performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names.                                                                                                                                                                                                                                                                                                                            |
| <code>start [all   <i>printer</i> ...]</code>                             | Enables printing. Starts a spooling daemon for the <i>printer</i> . <code>all</code> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates the command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names.                                                                                                                    |
| <code>stop [all   <i>printer</i> ...]</code>                              | Stops a spooling daemon after the current job is complete. Disables printing at that time. <code>all</code> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names.                                                                                            |
| <code>topq <i>printer</i>[<i>request-ID</i> ...] [<i>user</i> ...]</code> | Moves <i>request-ID</i> or print jobs belonging to <i>user</i> on <i>printer</i> to the beginning of the print queue. Specify <i>user</i> as a user's login name. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names.                                                                                                                                                                                          |
| <code>up [all   <i>printer</i> ...]</code>                                | Turns the queue for <i>printer</i> on and enables printing on <i>printer</i> . Deletes the message in the printer status file (inserted by down). Use up to undo the effects of down. <code>all</code> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <a href="#">printers.conf(4)</a> for information regarding naming conventions for atomic names. |

**Exit Status** The following exit values are returned:

|          |                        |
|----------|------------------------|
| 0        | Successful completion. |
| non-zero | An error occurred.     |

- Files**    `/etc/printers.conf`        System printer configuration database  
          `$HOME/.printers`            User-configurable printer database  
          `printers.conf.byname`    NIS version of `/etc/printers.conf`  
          `printers.org_dir`        NIS+ version of `/etc/printers.conf`  
          `ou=printers`            LDAP version of `/etc/printers.conf`

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlpr-cmds    |
| Interface Stability | Standard        |

**See Also**    [lpq\(1B\)](#), [lpr\(1B\)](#), [lprm\(1B\)](#), [lpstat\(1\)](#), [lpsched\(1M\)](#), [lpshut\(1M\)](#), [svcadm\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#)

**Diagnostics**    Use the [svcs\(1\)](#) utility to check if `svc:/application/print/server` is running. If it is not running, use `svcadm enable svc:/application/print/server` to start `lpsched`. See [svcadm\(1M\)](#).

**Notes**        When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Name</b>        | lpq – display the content of a print queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Synopsis</b>    | <code>/usr/ucb/lpq [-P <i>destination</i>] [-l] [+ [<i>interval</i>]]</code><br><code>[<i>request-ID</i>...] [<i>user</i>]...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>The lpq utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed.</p> <p>lpq displays the following information to the standard output:</p> <ul style="list-style-type: none"> <li>▪ the username of the person associated with a print request,</li> <li>▪ the position of a print request in the print queue,</li> <li>▪ the name of file or files comprising a print request,</li> <li>▪ the job number of a print request, and</li> <li>▪ the size of the file requested by a print request. File size is reported in bytes.</li> </ul> <p>Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.</p> <p>The print client commands locate destination information using the printers database in the name service switch. See <a href="#">nsswitch.conf(4)</a>, <a href="#">printers(4)</a>, and <a href="#">printers.conf(4)</a> for details.</p> |
| <b>Options</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-l                      Displays information in long format. Long format includes the name of the host from which a print request originated in the display.</li> <li>-P <i>destination</i>      Displays information about printer or class of printers (see <a href="#">lpadmin(1M)</a>). Specify <i>destination</i> using atomic, URI-style (<i>scheme://endpoint</i>), or POSIX-style (<i>server:destination</i>) names. See <a href="#">printers.conf(4)</a> for information regarding destination names.</li> <li>+ [<i>interval</i>]          Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify <i>interval</i> as the number of seconds between displays. If <i>interval</i> is not specified only executes once.</li> </ul>                                                                                                                                                                 |
| <b>Operands</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>request-ID</i>          The job number associated with a print request.</li> <li><i>user</i>                  The name of the user about whose jobs lpq reports information. Specify <i>user</i> as a valid username.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Exit Status</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0                      Successful completion.</li> <li>non-zero              An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Attributes**    See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlpr-cmds    |
| Interface Stability | Standard        |

**See Also**    [lp\(1\)](#), [lpc\(1B\)](#), [lpr\(1B\)](#), [lprm\(1B\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

**Notes**    When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

**Name** lpr – submit print requests

**Synopsis** /usr/ucb/lpr [-P *destination*] [-# *number*] [-C *class*]  
 [-J *job*] [-T *title*] [-i [*indent*]]  
 [-1 | -2 | -3 | -4 *font*] [-w *cols*] [-m] [-h] [-s]  
 [-filter\_option] [*file*]...

**Description** The lpr utility submits print requests to a destination. lpr prints files (*file*) and associated information, collectively called a *print request*. If *file* is not specified, lpr assumes the standard input.

The print client commands locate destination information using the “printers” database in the name service switch. See [nsswitch.conf\(4\)](#), [printers\(4\)](#), and [printers.conf\(4\)](#) for details.

Print requests with more than 52 *files* specified is truncated to 52 files when the BSD print protocol is used for job submission.

**Options** The following options are supported:

- C *class* Prints *class* as the job classification on the banner page of the output. Enclose *class* in double quotes if it contains blanks. If *class* is not specified, the name of the system (as returned by [hostname\(1\)](#)) is printed as the job classification. See [hostname\(1\)](#).
- h Suppresses printing of the banner page of the output.
- i *indent* Indents the output a specific number of SPACE characters. Use *indent* to indicate the number of SPACE characters to be indented. Specify *indent* as a positive integer. If the optional argument to indent is not specified, then eight SPACE characters is the default. The -i option is ignored unless it is specified with the -p filter option.
- J *job* Prints *job* as the *job name* on the banner page of the output. Enclose *job* in double quotes if it contains blanks. If *job* is not specified, *file* (or in the case of multiple files, the first *file* specified on the command line) is printed as the job name on the banner page of the output.
- m Sends mail after *file* has printed. See [mail\(1\)](#). By default, no mail is sent upon normal completion of a print request.
- P *destination* Prints *file* on a specific printer or class of printers (see [lpadmin\(1M\)](#)). Specify *destination* using atomic, URI-style (*scheme://endpoint*), or POSIX-style (*server:destination*) names. See [printers.conf\(4\)](#) for information regarding destination names.
- s Prints files by reference rather than copying them. This means that files should not be modified or removed until they have completed printing. This option only prevents copying of files when the print queue is on the local machine and the files are specified on the command line.

- T *title*** Prints a title on the page header of the output. Enclose *title* in double quotes if it contains blanks. The -T option is ignored unless it is specified with the -p filter option.
- w *cols*** Prints *file* with pages of a specific width. *cols* indicates the number of columns wide. The -w option is ignored unless it is specified with the -p filter option.
- 1|-2|-3|-4 *font*** Mounts the specified font in the font position 1, 2, 3, or 4. Specify *font* as a valid font name.
- *filter\_option*** Notifies the print spooler that *file* is not a standard text file. Enables the spooling daemon to use the appropriate filters to print *file*.
- filter\_options* offer a standard user interface. All filter options might not be available for, or applicable to, all printers.
- Specify *filter\_option* as a single character.
- If *filter\_option* is not specified and the printer can interpret PostScript®, inserting '%!' as the first two characters of *file* causes *file* to be interpreted as PostScript.
- The following filter options are supported:
- c** *file* contains data produced by *cifplot*.
  - d** *file* contains tex data in DVI format from Stanford.
  - f** Interprets the first character of each line as a standard FORTRAN carriage control character.
  - g** *file* contains standard plot data produced by *plot(1B)* routines.
  - l** Print control characters and suppress page breaks.
  - n** *file* contains *d i t r o f f* data from device independent troff.
  - p** Use *pr* to format the files. See *pr(1)*.
  - t** *file* contains *t r o f f* (cat phototypesetter) binary data.
  - v** *file* contains a raster image. *printer* must support an appropriate imaging model such as PostScript in order to print the image.
- # *number*** Prints a specific number of copies. Specify *number* as a positive integer. The default for *number* is 1.

**Operands** The following operand is supported:

- file*** The name of the file to be printed. Specify *file* as a pathname. If *file* is not specified, *lpr* uses the standard input.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `lpr` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Exit Status** The following exit values are returned:

- `0` Successful completion.
- non-zero An error occurred.

- Files**
- `/etc/printers.conf` System printer configuration database
  - `$HOME/.printers` User-configurable printer database
  - `ou=printers` LDAP version of `/etc/printers.conf`
  - `printers.conf.byname` NIS version of `/etc/printers.conf`
  - `printers.org_dir` NIS+ version of `/etc/printers.conf`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE       | ATTRIBUTE VALUE    |
|----------------------|--------------------|
| Availability         | SUNWlpr_cmds       |
| Interface Stabilitly | Standard           |
| CSI                  | Enabled. See NOTES |

**See Also** [hostname\(1\)](#), [lp\(1\)](#), [lpc\(1B\)](#), [lpq\(1B\)](#), [lprm\(1B\)](#), [lpstat\(1\)](#), [mail\(1\)](#), [plot\(1B\)](#), [pr\(1\)](#), [troff\(1\)](#), [lpadmin\(1M\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Diagnostics** `lpr: destination | : unknown destination` *destination* was not found in the LP configuration database. Usually this is a typing mistake; however, it can indicate that the *destination* does not exist on the system. Use `lpstat -p` to display information about the status of the print service.

**Notes** `lpr` is CSI-enabled except for the *printer* name.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

**Name** lprm – remove print requests from the print queue

**Synopsis** /usr/ucb/lprm [-P *destination*] [-] [*request-ID*]...  
[*user*]...

**Description** The lprm utility removes print requests (*request-ID*) from the print queue.

Without arguments, lprm deletes the current print request. lprm reports the name of the file associated with print requests that it removes. lprm is silent if there are no applicable print requests to remove.

Users can only remove print requests associated with their user name. See [Notes](#). If a superuser executes lprm and specifies the *user* operand, lprm removes all print requests belonging to the specified user.

The print client commands locate destination information using the “printers” database in the name service switch. See [nsswitch.conf\(4\)](#), [printers\(4\)](#), and [printers.conf\(4\)](#) for details.

**Options** The following options are supported:

- P *destination* The name of the printer or class of printers (see [lpadmin\(1M\)](#)) from which to remove print requests. Specify destination using atomic, URI-style (*scheme://endpoint*), or POSIX-style (*server:destination*) names. See [printers.conf\(4\)](#) for information regarding the naming conventions for destination names.
- If a user specifies this option, removes all print requests owned by that user. If a superuser specifies this option, removes all requests in the print queue. Job ownership is determined by the user's login name and host name on the machine from which lpr was executed. See [Notes](#).

**Operands** The following operands are supported.

- request-ID* Removes a specific print request. Specify *request-ID* as the job number (Job) associated with a print request and reported by lpq. See [lpq\(1B\)](#).
- user* Removes print requests associated with a specific user. Specify *user* as a valid user name. This option can only be used by a superuser.

**Examples** **EXAMPLE 1** Removing a Print Request

The following example removes request-ID 385 from destination `killtree`:

```
example% lprm -P killtree 385
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

|              |                                   |                                                 |
|--------------|-----------------------------------|-------------------------------------------------|
| <b>Files</b> | <code>\$HOME/.printers</code>     | User-configurable printer database              |
|              | <code>/etc/printers.conf</code>   | System printer configuration database           |
|              | <code>printers.conf.byname</code> | NIS version of <code>/etc/printers.conf</code>  |
|              | <code>printers.org_dir</code>     | NIS+ version of <code>/etc/printers.conf</code> |
|              | <code>ou=printers</code>          | LDAP version of <code>/etc/printers.conf</code> |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlpr_cmds    |
| Interface Stability | Standard        |

**See Also** [lp\(1\)](#), [lpc\(1B\)](#), [lpq\(1B\)](#), [lpr\(1B\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

**Notes** Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a superuser has set `user-equivalence=true` in `/etc/printers.conf` on the print server, users can remove print requests associated with their user name on any host. Superusers can remove print requests on the host from which the print request was submitted. Superusers can also remove print requests from the print server.

Some print servers send cancelation notification to job owners when their print jobs have been cancelled. This notification usually comes in the form of an email message. Cancelation notices cannot be disabled on a Solaris server.

**Notes** When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

**Name** lpstat – print information about the status of the print service

**Synopsis** lpstat [-d] [-r] [-R] [-s] [-t] [-a *[list]*] [-c *[list]*]  
[-f *[list]*] [-o *[list]*] [-p *[list]*] [-D] [-S *[list]*]  
[-u *[login- ID -list]*] [-v *[list]*] [-l *level*]

**Description** The lpstat utility displays information about the current status of the LP print service to standard output.

If no options are given, lpstat prints the status of all the user's print requests made by lp. See [lp\(1\)](#). Any arguments that are not *options* are assumed to be *request-IDs* as returned by lp. The lpstat command prints the status of such requests. *options* appears in any order and can be repeated and intermixed with other arguments. Some key letters can be followed by an optional *list* that can be in one of two forms: a list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:

```
example% lpstat -u "user1 user2 user3"
```

Specifying all after any key letter that takes *list* as an argument causes all information relevant to the key letter to be printed. For example, the command:

```
example% lpstat -o all
```

prints the status of all output requests.

The omission of a *list* following such key letters causes all information relevant to the key letter to be printed. For example, the command:

```
example% lpstat -o
```

prints the status of all output requests.

The print client commands locate destination information using the “printers” database in the name service switch. See [nsswitch.conf\(4\)](#), [printers\(4\)](#), and [printers.conf\(4\)](#) for details.

**Options** The following options are supported:

-a *[list]* Reports whether print destinations are accepting requests. *list* is a list of intermixed printer names and class names.

If the print queue is remote and IPP is in use, the information provided is very close to that reported for local queues. If the print queue is remote and IPP is not in use (the print server is older than Solaris 9, Update 6 or another RFC-1179-based print service), this option does not report any useful information.

-c *[list]* Prints name of all classes and their members. *list* is a list of class names.

If the print queue is remote and IPP is in use, the information provided is very close to that reported for local queues. If the print queue is remote and IPP is not in use (the print server is older than Solaris 9, Update 6 or another RFC-1179–based print service), this option does not report any useful information.

**-d** Prints the default destination for output requests.

**-f [*list*] [-l]** Prints a verification that the forms in *list* are recognized by the LP print service. *list* is a list of forms; the default is all. The **-l** option lists the form descriptions.

If the print queue is remote and IPP is in use, the information provided is very close to that reported for local queues. If the print queue is remote and IPP is not in use (the print server is older than Solaris 9, Update 6 or another RFC-1179–based print service), this option does not report any useful information.

**-l [*level*]** specifies the verbosity level for extended reporting of printer or job objects (**-o**, **-p**, **-r**, **-u**). Without this option, a level of 0 is used, which reports summary information. When no level is specified, a level of 1 is used, which provides more information about the object. A level of 2 or more enumerates all of the object's attributes.

If the print queue is remote and IPP is in use, the information provided is very close to that reported for local queues. If the print queue is remote and IPP is not in use (the print server is older than Solaris 9, Update 6 or another RFC-1179–based print service), this option does not report any useful information.

**-o [*list*]** Prints the status of output requests. *list* is a list of intermixed printer names, class names, and request-IDs. The key letter **-o** can be omitted.

Specify printer and class names using atomic, URI-style (`scheme://endpoint`), or POSIX-style (`server:destination`) names. See [printers.conf\(4\)](#) for more information.

**-p [*list*] [-D]** Prints the status of printers. *list* is a list of printer names. If the **-D** option is given, a brief description is printed for each printer in *list*. If the **-l** option is given and the printer is on the local machine, a full description of each printer's configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.

**-r** Prints the status of the LP request scheduler.

**-R** Prints a number showing the position of each request in the print queue.

- s Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
- S [*list*] Prints a verification that the character sets or the print wheels specified in *list* are recognized by the LP print service. Items in *list* can be character sets or print wheels; the default for the list is `all`. If the `-l` option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps.
- If the print queue is remote and IPP is in use, the information provided is very close to that reported for local queues. If the print queue is remote and IPP is not in use (the print server is older than Solaris 9, Update 6 or another RFC-1179-based print service), this option does not report any useful information.
- t Prints all status information. This includes all the information obtained with the `-s` option, plus the acceptance and idle/busy status of all printers.
- u [*login-ID-list*] Prints the status of output requests for users. The *login-ID-list* argument can include any or all of the following constructs:
- |                                       |                                        |
|---------------------------------------|----------------------------------------|
| <i>login-ID</i>                       | a user on any system                   |
| <i>system_name</i> ! <i>login-ID</i>  | a user on system <i>system_name</i>    |
| <i>system_name</i> ! <code>all</code> | all users on system <i>system_name</i> |
| <code>all</code> ! <i>login-ID</i>    | a user on all systems                  |
| <code>all</code>                      | all users on all systems               |
- v [*list*] Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.

**Exit Status** The following exit values are returned:

- |          |                        |
|----------|------------------------|
| 0        | Successful completion. |
| non-zero | An error occurred.     |

- Files**
- |                                 |                                                 |
|---------------------------------|-------------------------------------------------|
| <code>/etc/printers.conf</code> | System printer configuration database           |
| <code>\$HOME/.printers</code>   | User-configurable printer database              |
| <code>ou=printers</code>        | LDAP version of <code>/etc/printers.conf</code> |

`printers.conf.byname`      NIS version of `/etc/printers.conf`  
`printers.org_dir`          NIS+ version of `/etc/printers.conf`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWlp-cmds     |
| Interface Stability | Standard        |

**See Also** [cancel\(1\)](#), [lp\(1\)](#), [lpq\(1B\)](#), [lpr\(1B\)](#), [lprm\(1B\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

**Notes** For remote print queues, the BSD print protocol provides a very limited set of information. The Internet Print Protocol (IPP) is preferred.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

**Name** lptest – generate line printer ripple pattern

**Synopsis** /usr/ucb/lptest [*length* [*count*]]

**Description** The lptest utility writes the traditional *ripple test* pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.

This command is obsolete.

**Options** *length* Specifies the length of the output line in characters. 79 characters is the default.

*count* Specifies the number of output lines. 200 lines is the default. If *count* is specified, *length* must also be specified.

**Exit Status** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscplp       |

**See Also** [attributes\(5\)](#)

**Name** ls – list contents of directory

**Synopsis** /usr/bin/ls [-aAbcCdEfFghHiLlmnopqrRstuvVx1@] [*file*]...  
 /usr/xpg4/bin/ls [-aAbcCdEfFghHiLlmnopqrRstuvVx1@]  
 [*file*]...  
 /usr/xpg6/bin/ls [-aAbcCdEfFghHiLlmnopqrRstuvVx1@]  
 [*file*]...

**Description** For each *file* that is a directory, ls lists the contents of the directory. For each *file* that is an ordinary file, ls repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory (.) is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.

There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The -1 option allows single column output and -m enables stream output format. In order to determine output formats for the -C, -x, and -m options, ls uses an environment variable, COLUMNS, to determine the number of character positions available on one output line. If this variable is not set, the [terminfo\(4\)](#) database is used to determine the number of columns, based on the environment variable, TERM. If this information cannot be obtained, 80 columns are assumed.

The mode printed when the -e, -E, -g, -l, -n, -o, -v, -V, or -@ option is in effect consists of eleven characters. The first character can be one of the following:

|   |                                                     |
|---|-----------------------------------------------------|
| d | The entry is a directory.                           |
| D | The entry is a door.                                |
| l | The entry is a symbolic link.                       |
| b | The entry is a block special file.                  |
| c | The entry is a character special file.              |
| p | The entry is a FIFO (or “named pipe”) special file. |
| P | The entry is an event port.                         |
| s | The entry is an AF_UNIX address family socket.      |
| – | The entry is an ordinary file.                      |

The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, execute permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is an ACL or extended attributes indicator. This character is an @ if extended attributes are

associated with the file and the `-@` option is in effect. Otherwise, this character is a plus sign (+) character if a non-trivial ACL is associated with the file or a space character if not.

`ls -l` (the long list) prints its output as follows for the POSIX locale:

```
-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2
```

Reading from right to left, you see that the current directory holds one file, named `part2`. Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group `dev` (perhaps indicating “development”), and his or her login name is `smith`. The number, in this case 1, indicates the number of links to file `part2` (see [cp\(1\)](#)). The plus sign indicates that there is an ACL associated with the file. If the `-@` option has been specified, the presence of extended attributes supersede the presence of an ACL and the plus sign is replaced with an ‘at’ sign (@). Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute `part2`.

The execute (x) symbol here occupies the third position of the three-character sequence. A `-` in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

|                                            |                                                                                                                                                                            |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| r                                          | The file is readable.                                                                                                                                                      |
| w                                          | The file is writable.                                                                                                                                                      |
| x                                          | The file is executable.                                                                                                                                                    |
| —                                          | The indicated permission is <i>not</i> granted.                                                                                                                            |
| s                                          | The set-user-ID or set-group-ID bit is on, and the corresponding user or group execution bit is also on.                                                                   |
| S                                          | Undefined bit-state (the set-user-ID or set-group-id bit is on and the user or group execution bit is off). For group permissions, this applies only to non-regular files. |
| t                                          | The 1000 (octal) bit, or sticky bit, is on (see <a href="#">chmod(1)</a> ), and execution is on.                                                                           |
| T                                          | The 1000 bit is turned on, and execution is off (undefined bit-state).                                                                                                     |
| /usr/bin/ls l                              | Mandatory locking occurs during access (on a regular file, the set-group-ID bit is on and the group execution bit is off).                                                 |
| /usr/xpg4/bin/ls and<br>/usr/xpg6/bin/ls L | Mandatory locking occurs during access (on a regular file, the set-group-ID bit is on and the group execution bit is off).                                                 |

For user and group permissions, the third position is sometimes occupied by a character other than x or -. s or S also can occupy this position, referring to the state of the set-ID bit, whether

it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.

In the case of the sequence of group permissions, `l` can occupy the third position. `l` refers to mandatory file and record locking. This permission describes a file's ability to allow other files to lock its reading or writing permissions during access.

For others permissions, the third position can be occupied by `t` or `T`. These refer to the state of the sticky bit and execution permissions.

**Options** The following options are supported:

/usr/bin/ls,  
/usr/xpg4/bin/ls, and  
/usr/xpg6/bin/ls

The following options are supported for all three versions:

- a Lists all entries, including those that begin with a dot (.), which are normally not listed.
- A Lists all entries, including those that begin with a dot (.), with the exception of the working directory (.) and the parent directory (..).
- b Forces printing of non-printable characters to be in the octal \ddd notation.
- c Uses time of last modification of the i-node (file created, mode changed, and so forth) for sorting (-t) or printing (-l or -n).
- C Multi-column output with entries sorted down the columns. This is the default output format.
- d If an argument is a directory, lists only its name (not its contents). Often used with -l to get the status of a directory.
- e The same as -l, except displays time to the second, and with one format for all files regardless of age: *mmm dd hh:mm:ss yyyy*.
- E The same as -l, except displays time to the nanosecond and with one format for all files regardless of age: *yyyy-mm-dd hh:mm:ss.nnnnnnnnnn* (ISO 8601:2000 format).  
  
In addition, this option displays the offset from UTC in ISO 8601:2000 standard format (*+hhmm* or *-hhmm*) or no characters if the offset is indeterminable. The offset reflects the appropriate standard or alternate offset in force at the file's displayed date and time, under the current timezone.
- f Forces each argument to be interpreted as a directory and list the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a. The order is the order in which entries appear in the directory.
- g The same as -l, except that the owner is not printed.

- h All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.
- H If an argument is a symbolic link that references a directory, this option evaluates the file information and file type of the directory that the link references, rather than those of the link itself. However, the name of the link is displayed, rather than the referenced directory.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year' for the POSIX locale. When the LC\_TIME locale category is not set to the POSIX locale, a different format of the time field can be used. Files modified within six months show 'month date time'. If the file is a symbolic link, the filename is printed followed by "→" and the path name of the referenced file.
- L If an argument is a symbolic link, this option evaluates the file information and file type of the file or directory that the link references, rather than those of the link itself. However, the name of the link is displayed, rather than the referenced file or directory.
- m Streams output format. Files are listed across the page, separated by commas.
- n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- o The same as -l, except that the group is not printed.
- p Puts a slash (/) after each filename if the file is a directory.
- q Forces printing of non-printable characters in file names as the character question mark (?).
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Indicate the total number of file system blocks consumed by each file displayed.
- t Sorts by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
- u Uses time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
- v The same as -l, except that verbose ACL information is displayed as well as the -l output. ACL information is displayed even if the file or directory doesn't have an ACL.

-V      The same as -l, except that compact ACL information is displayed after the -l output.

The -V option is only applicable to file systems that support NFSv4 ACLs, such as the Solaris ZFS file system.

The format of the displayed ACL is as follows:

*entry\_type* : *permissions* : *inheritance\_flags* : *access\_type*

*entry\_type* is displayed as one of the following:

*user:username*

Additional user access for *username*.

*group:groupname*

Additional group access for group *groupname*.

*owner@*

File owner.

*group@*

File group owner.

*everyone@*

Everyone access, including file owner and file group owner. This is not equivalent to the POSIX other class.

The following permissions, supported by the NFSv4 ACL model, are displayed by using the -v or -V options:

|                      |                                                                                     |
|----------------------|-------------------------------------------------------------------------------------|
| read_data (r)        | Permission to read the data of a file.                                              |
| list_directory (r)   | Permission to list the contents of a directory.                                     |
| write_data (w)       | Permission to modify a file's data. anywhere in the file's offset range.            |
| add_file (w)         | Permission to add a new file to a directory.                                        |
| append_data (p)      | The ability to modify a file's data, but only starting at EOF.                      |
| add_subdirectory (p) | Permission to create a subdirectory to a directory.                                 |
| read_xattr (R)       | Ability to read the extended attributes of a file.                                  |
| write_xattr (A)      | Ability to create extended attributes or write to the extended attribute directory. |
| execute (x)          | Permission to execute a file.                                                       |

---

|                                   |                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------|
| <code>read_attributes (a)</code>  | The ability to read basic attributes (non-ACLs) of a file.                                |
| <code>write_attributes (w)</code> | Permission to change the times associated with a file or directory to an arbitrary value. |
| <code>delete (d)</code>           | Permission to delete a file.                                                              |
| <code>delete_child (D)</code>     | Permission to delete a file within a directory.                                           |
| <code>read_acl (c)</code>         | Permission to read the ACL of a file.                                                     |
| <code>write_acl (C)</code>        | Permission to write the ACL of a file.                                                    |
| <code>write_owner (o)</code>      | Permission to change the owner of a file.                                                 |
| <code>synchronize (s)</code>      | Permission to access file locally at server with synchronize reads and writes.            |
| <code>-</code>                    | No permission granted                                                                     |

The following inheritance flags, supported by the NFSv4 ACL model, are displayed by using the `-v` or `-V` options:

|                               |                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file_inherit (f)</code> | Inherit to all newly created files.                                                                                                                                                                                                                  |
| <code>dir_inherit (d)</code>  | Inherit to all newly created directories.                                                                                                                                                                                                            |
| <code>inherit_only (i)</code> | When placed on a directory, do not apply to the directory, only to newly created files and directories. This flag requires that either <code>file_inherit</code> and or <code>dir_inherit</code> is also specified.                                  |
| <code>no_propagate (n)</code> | Indicates that ACL entries should be inherited to objects in a directory, but inheritance should stop after descending one level. This flag is dependent upon either <code>file_inherit</code> and or <code>dir_inherit</code> also being specified. |
| <code>S</code>                | Successful access.                                                                                                                                                                                                                                   |
| <code>F</code>                | Failed access.                                                                                                                                                                                                                                       |
| <code>-</code>                | No permission granted.                                                                                                                                                                                                                               |

*access\_type* is displayed as one of the following types:

`allow`

Permission field that specifies allow permissions

`deny`

Permission field that specifies deny permissions

For example:

```
$ ls -dV /sandbox/dir.1
drwxr-xr-x+ 2 root root 2 Jan 17 15:09 dir.1
 user:marks:r-----:fd---:allow
 owner@:-----:-----:deny
 owner@:rwxp---A-W-Co:-----:allow
 group@:-w-p-----:-----:deny
 group@:r-x-----:-----:allow
 everyone@:-w-p---A-W-Co:-----:deny
 everyone@:r-x---a-R-C-s:-----:allow

$ |||||+ failed access
 |||||+--success access
 |||||+-- no propagate
 |||||+-- inherit only
 |||||+--- directory inherit
 |||||+----- file inherit
 |||||
 |||||+ sync
 |||||+-- change owner
 |||||+-- write ACL
 |||||+--- read ACL
 |||||+----- write extended attributes
 |||||+----- read extended attributes
 |||||+----- write attributes
 |||||+----- read attributes
 |||||+----- delete child
 |||||+----- delete
 |||||+----- append
 |||||+----- execute
 |||||+----- write data
 |||||+----- read data
```

- x      Multi-column output with entries sorted across rather than down the page.
- 1      Prints one entry per line of output.
- @      The same as -l, except that extended attribute information supersede ACL information. An @ is displayed after the file permission bits for files that have extended attributes.
- /usr/bin/ls -F      Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing “at” sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=). Follows symlinks named as operands.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The -l (ell) option overrides the other option specified in each pair.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each of these pairs determines the output format.

```
/usr/xpg4/bin/ls -F
```

Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing “at” sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=). Follows symlinks named as operands.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (ell), `-m` and `-l` (ell), `-x` and `-l` (ell), `-@` and `-l` (ell), `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each pair determines the output format.

```
/usr/xpg6/bin/ls -F
```

Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing “at” sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=). Does not follow symlinks named as operands unless the `-H` or `-L` option is specified.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (ell), `-m` and `-l` (ell), `-x` and `-l` (ell), `-@` and `-l` (ell), `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each pair determines the output format.

**Operands** The following operand is supported:

*file* A path name of a file to be written. If the file specified is not found, a diagnostic message is output on standard error.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

### Examples **EXAMPLE 1** Viewing File Permissions

The following example shows how to display detailed information about a file.

```
% ls -l file.1
-rw-r--r-- 1 gozer staff 206663 Mar 14 10:15 file.1
```

The permissions string above (`-rw-r--r--`) describes that the file owner has read and write permissions, the owning group has read permissions, and others have read permissions.

The following example shows how to display detailed information about a directory.

```
% ls -ld test.dir
drwxr-xr-x 2 gozer staff 2 Mar 14 10:17 test.dir
```

**EXAMPLE 1** Viewing File Permissions (Continued)

The permissions string above (`drwxr-xr-x`) describes that the directory owner has read, write, and execute permissions, the owning group has read and execute permissions, and others have read and execute permissions.

Another example of listing file permissions is as follows:

```
% ls -l file.2
-rw-rwl--- 1 gozer staff 206663 Mar 14 10:47 file.2
```

The permissions string above (`-rw-rwl---`) describes that the file owner has read and write permissions, the owning group has read and write permissions, and the file can be locked during access.

**EXAMPLE 2** Displaying ACL Information on Files and Directories

The following example shows how to display verbose ACL information on a ZFS file.

```
% ls -v file.1
-rw-r--r-- 1 marks staff 206663 Mar 14 10:15 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
 /write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
 /write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
 :allow
```

The following example shows how to display compact ACL information on a ZFS directory.

```
% ls -dV test.dir
drwxr-xr-x 2 marks staff 2 Mar 14 10:17 test.dir
owner@:-----:-----:deny
owner@:rwxp---A-W-Co:-----:allow
group@:-w-p-----:-----:deny
group@:r-x-----:-----:allow
everyone@:-w-p---A-W-Co:-----:deny
everyone@:r-x---a-R-c--s:-----:allow
```

The following example illustrates the `ls -v` behavior when listing ACL information on a UFS file.

```
$ ls -v file.3
-rw-r--r-- 1 root root 2703 Mar 14 10:59 file.3
0:user::rw-
1:group::r-- #effective:r--
```

EXAMPLE 2    Displaying ACL Information on Files and Directories        (Continued)

```
2:mask:r--
3:other:r--
```

EXAMPLE 3    Printing the Names of All Files

This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print:

```
example% ls -a
```

EXAMPLE 4    Providing File Information

Another example of a command line is:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (a), the i-number—the memory address of the i-node associated with the file—printed in the left-hand column (i); the size (in blocks) of the files, printed in the column to the right of the i-numbers (s); finally, the report is displayed in the numeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**Environment Variables**    See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ls`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TZ`.

**COLUMNS**                Determines the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the `ls` utility calculates how many path name text columns to write (see `-C`) based on the width provided. If `COLUMNS` is not set or is invalid, 80 is used. The column width chosen to write the names of files in any given directory is constant. File names are not be truncated to fit into the multiple text-column output.

**Exit Status**    0                All information was written successfully.  
                 >0            An error occurred.

**Files**            /etc/group                    group IDs for `ls -l` and `ls -g`  
                 /etc/passwd                user IDs for `ls -l` and `ls -o`  
                 /usr/share/lib/terminfo/?/\*        terminal information database

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| /usr/bin/ls | ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|-------------|---------------------|-----------------|
|             | Availability        | SUNWcsu         |
|             | CSI                 | Enabled         |
|             | Interface Stability | Stable          |

| /usr/xpg4/bin/ls | ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|------------------|---------------------|-----------------|
|                  | Availability        | SUNWxcu4        |
|                  | CSI                 | Enabled         |
|                  | Interface Stability | Standard        |

| /usr/xpg6/bin/ls | ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|------------------|---------------------|-----------------|
|                  | Availability        | SUNWxcu6        |
|                  | CSI                 | Enabled         |
|                  | Interface Stability | Standard        |

**See Also** [chmod\(1\)](#), [cp\(1\)](#), [setfacl\(1\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Notes** Unprintable characters in file names can confuse the columnar output options.
