Preface

The Oracle Solaris ZFS Administration Guide provides information about setting up and managing Oracle Solaris ZFS file systems.

This guide contains information for both SPARC based and x86 based systems.

Note – This Oracle Solaris release supports systems that use the SPARC and x86 families of processor architectures: UltraSPARC, SPARC64, AMD64, Pentium, and Xeon EM64T. The supported systems appear in the Solaris 10 Hardware Compatibility List at http://www.sun.com/bigadmin/hcl. This document cites any implementation differences between the platform types.

In this document these x86 terms mean the following:

- “x86” refers to the larger family of 64-bit and 32-bit x86 compatible products.
- “x64” points out specific 64-bit information about AMD64 or EM64T systems.
- “32-bit x86” points out specific 32-bit information about x86 based systems.

For supported systems, see the Solaris 10 Hardware Compatibility List.

Who Should Use This Book

This guide is intended for anyone who is interested in setting up and managing Oracle Solaris ZFS file systems. Experience using the Oracle Solaris operating system (OS) or another UNIX version is recommended.

How This Book Is Organized

The following table describes the chapters in this book.

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 1, &quot;Oracle Solaris ZFS File System (Introduction)&quot;</td>
<td>Provides an overview of ZFS and its features and benefits. It also covers some basic concepts and terminology.</td>
</tr>
</tbody>
</table>
### Related Books

Related information about general Oracle Solaris system administration topics can be found in the following books:

- *System Administration Guide: Basic Administration*
- *System Administration Guide: Advanced Administration*
- *System Administration Guide: Devices and File Systems*
- *System Administration Guide: Security Services*
Documentation, Support, and Training

See the following web sites for additional resources:

<td><code>machine_name#</code></td>
</tr>
</tbody>
</table>
This chapter provides an overview of the Oracle Solaris ZFS file system and its features and benefits. This chapter also covers some basic terminology used throughout the rest of this book.

The following sections are provided in this chapter:

- “What's New in ZFS?” on page 15
- “What Is ZFS?” on page 41
- “ZFS Terminology” on page 43
- “ZFS Component Naming Requirements” on page 45

What's New in ZFS?

This section summarizes new features in the ZFS file system.

- “Splitting a Mirrored ZFS Storage Pool (zpool split)” on page 16
- “New ZFS System Process” on page 17
- “Changes to the zpool list Command” on page 17
- “ZFS Storage Pool Recovery” on page 17
- “ZFS Log Device Enhancements” on page 17
- “Triple Parity RAIDZ (raidz3)” on page 18
- “Holding ZFS Snapshots” on page 18
- “ZFS Device Replacement Enhancements” on page 19
- “ZFS and Flash Installation Support” on page 20
- “ZFS User and Group Quotas” on page 20
- “ZFS ACL Pass Through Inheritance for Execute Permission” on page 21
- “ZFS Property Enhancements” on page 22
- “ZFS Log Device Recovery” on page 24
- “Using Cache Devices in Your ZFS Storage Pool” on page 25
- “Zone Migration in a ZFS Environment” on page 26
- “ZFS Installation and Boot Support” on page 26
- “Rolling Back a Dataset Without Unmounting” on page 26
Splitting a Mirrored ZFS Storage Pool (zpool split)

**Oracle Solaris 10 9/10 Release:** In this Solaris release, you can use the `zpool split` command to split a mirrored storage pool, which detaches a disk or disks in the original mirrored pool to create another identical pool.

For more information, see “Creating a New Pool By Splitting a Mirrored ZFS Storage Pool” on page 79.
New ZFS System Process

Oracle Solaris 10 9/10 Release: In this Solaris release, each ZFS storage pool has an associated process, `zpool -poolname`. The threads in this process are the pool’s I/O processing threads to handle I/O tasks, such as compression and checksumming, that are associated with the pool. The purpose of this process is to provide visibility into each storage pool’s CPU utilization. Information about these process can be reviewed by using the `ps` and `prstat` commands. These processes are only available in the global zone. For more information, see SDC(7).

Changes to the `zpool list` Command

Oracle Solaris 10 9/10 Release: In this Solaris release, the `zpool list` output has changed to provide better space allocation information. For example:

```
# zpool list tank
NAME SIZE ALLOC FREE CAP HEALTH ALTROOT
tank 136G 55.2G 80.8G 40% ONLINE -
```

The previous `USED` and `AVAIL` fields have been replaced with `ALLOC` and `FREE`.

The `ALLOC` field identifies the amount of physical space allocated to all datasets and internal metadata. The `FREE` field identifies the amount of unallocated space in the pool.

For more information, see “Displaying Information About ZFS Storage Pools” on page 95.

ZFS Storage Pool Recovery

Oracle Solaris 10 9/10 Release: A storage pool can become damaged if underlying devices become unavailable, a power failure occurs, or if more than the supported number of devices fail in a redundant ZFS configuration. This release provides new command features for recovering your damaged storage pool. However, using this recovery feature means that the last few transactions that occurred prior to the pool outage might be lost.

Both the `zpool clear` and `zpool import` commands support the `-F` option to possibly recover a damaged pool. In addition, running the `zpool status`, `zpool clear`, or `zpool import` command automatically report a damaged pool and these commands describe how to recover the pool.

For more information, see “Repairing ZFS Storage Pool-Wide Damage” on page 289.

ZFS Log Device Enhancements

Oracle Solaris 10 9/10 release: The following log device enhancements are available:
The logbias property – You can use this property to provide a hint to ZFS about handling synchronous requests for a specific dataset. If logbias is set to latency, ZFS uses the pool’s separate log devices, if any, to handle the requests at low latency. If logbias is set to throughput, ZFS does not use the pool’s separate log devices. Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources. The default value is latency. For most configurations, the default value is recommended. Using the logbias=throughput value might improve performance for writing database files.

Log device removal – You can now remove a log device from a ZFS storage pool by using the zpool remove command. A single log device can be removed by specifying the device name. A mirrored log device can be removed by specifying the top-level mirror for the log. When a separate log device is removed from the system, ZIL transaction records are written to the main pool.

Redundant top-level virtual devices are now identified with a numeric identifier. For example, in a mirrored storage pool of two disks, the top level virtual device is mirror-0.

For more information, see Example 4–3.

Triple Parity RAIDZ (raidz3)

Oracle Solaris 10 9/10 Release: In this Solaris release, a redundant RAID-Z configuration can now have either single-, double-, or triple-parity, which means that one, two, three device failures can be sustained respectively, without any data loss. You can specify the raidz3 keyword for a triple-parity RAID-Z configuration. For more information, see “Creating a RAID-Z Storage Pool” on page 65.

Holding ZFS Snapshots

Oracle Solaris 10 9/10 Release: If you implement different automatic snapshot policies so that older snapshots are being inadvertently destroyed by zfs receive because they no longer exist on the sending side, you might consider using the snapshots hold feature in this Solaris release.

Holding a snapshot prevents it from being destroyed. In addition, this feature allows a snapshot with clones to be deleted pending the removal of the last clone by using the zfs destroy -d command.

You can hold a snapshot or set of snapshots. For example, the following syntax puts a hold tag, keep, on tank/home/cindys/snap@1.

# zfs hold keep tank/home/cindys/snap@1

For more information, see “Holding ZFS Snapshots” on page 205.
ZFS Device Replacement Enhancements

Oracle Solaris 10 9/10 Release: In this Solaris release, a system event or sysevent is provided when an a disk is replaced with larger disk or the disks in the pool are replaced with larger disks. ZFS has been enhanced to recognize these events and adjusts the pool based on the new size of the disk, depending on the setting of the autoexpand property. You can use the autoexpand pool property to enable or disable automatic pool expansion when a larger disk replaces a smaller disk.

These features enable you to increase the pool size without having to export and import pool or reboot the system.

For example, the autoexpand property is enabled on the tank pool.

```
# zpool set autoexpand=on tank
```

Or, you can create the pool with the autoexpand property enabled.

```
# zpool create -o autoexpand=on tank c1t13d0
```

The autoexpand property is disabled by default so you can decide whether you want the pool size expanded when a larger disk replaces a smaller disk.

The pool size also be expanded by using the zpool online -e command. For example:

```
# zpool online -e tank c1t6d0
```

Or, you can reset the autoexpand property after the larger disk is attached or made available by using the zpool replace feature. For example, the following pool is created with one 8-GB disk (c0t0d0). The 8-GB disk is replaced with a 16-GB disk (c1t13d0), but the pool size is not expanded until the autoexpand property is enabled.

```
# zpool create pool c0t0d0
# zpool list
NAME SIZE ALLOC FREE CAP HEALTH ALTROOT
pool  8.44G  76.5K  8.44G  0% ONLINE -
# zpool replace pool c0t0d0 c1t13d0
# zpool list
NAME SIZE ALLOC FREE CAP HEALTH ALTROOT
pool  8.44G  91.5K  8.44G  0% ONLINE -
# zpool set autoexpand=on pool
# zpool list
NAME SIZE ALLOC FREE CAP HEALTH ALTROOT
pool  16.8G  91.5K  16.8G  0% ONLINE -
```

Another way to expand the LUN in the above example without enabling the autoexpand property, is to use the zpool online -e command even though the device is already online. For example:
### What's New in ZFS

```
# zpool create tank c0t0d0
# zpool list tank
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
tank  8.44G  76.5K  8.44G  0%  ONLINE -
# zpool replace tank c0t0d0 c1t13d0
# zpool list tank
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
tank  8.44G  91.5K  8.44G  0%  ONLINE -
# zpool online -e tank c1t13d0
# zpool list tank
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
tank  16.8G  90K  16.8G  0%  ONLINE -
```

Additional device replacement enhancements in this release include the following features:

- In previous releases, ZFS was not able to replace an existing disk with another disk or attach a disk if the replacement disk was a slightly different size. In this release, you can replace an existing disk with another disk or attach a new disk that is nominally the same size provided that the pool is not already full.

- In this release, you do not need to reboot the system or export and import a pool to expand the pool size. As described above, you can enable the autoexpand property or use the `zpool online -e` command to expand the pool size.

For more information about replacing devices, see “Replacing Devices in a Storage Pool” on page 85.

### ZFS and Flash Installation Support

**Solaris 10 10/09 Release:** In this Solaris release, you can set up a JumpStart profile to identify a flash archive of a ZFS root pool. For more information, see “Installing a ZFS Root File System (Oracle Solaris Flash Archive Installation)” on page 122.

### ZFS User and Group Quotas

**Solaris 10 10/09 Release:** In previous Solaris releases, you could apply quotas and reservations to ZFS file systems to manage and reserve disk space.

In this Solaris release, you can set a quota on the amount of disk space consumed by files that are owned by a particular user or group. You might consider setting user and group quotas in an environment with a large number of users or groups.

You can set a user quota by using the `zfs userquota` property. To set a group quota, use the `zfs groupquota` property. For example:

```
# zfs set userquota@user1=5G tank/data
# zfs set groupquota@staff=10G tank/staff/admins
```

You can display a user’s or a group’s current quota setting as follows:
Display general quota information as follows:

```
# zfs get userquota@user1 tank/data
NAME PROPERTY VALUE SOURCE
  tank/data userquota@user1 5G local
# zfs get groupquota@staff tank/staff/admins
NAME PROPERTY VALUE SOURCE
  tank/staff/admins groupquota@staff 10G local
```

You can display an individual user's disk space usage by viewing the userused@user property. A group's disk space usage can be viewed by using the groupused@group property. For example:

```
# zfs get userused@user1 tank/staff
NAME PROPERTY VALUE SOURCE
  tank/staff/userused@user1 213M local
# zfs get groupused@staff tank/staff
NAME PROPERTY VALUE SOURCE
  tank/staff/groupused@staff 213M local
```

For more information about setting user quotas, see “Setting ZFS Quotas and Reservations” on page 196.

---

**ZFS ACL Pass Through Inheritance for Execute Permission**

**Solaris 10 10/09 Release:** In previous Solaris releases, you could apply ACL inheritance so that all files are created with 0664 or 0666 permissions. In this release, if you want to optionally include the execute bit from the file creation mode into the inherited ACL, you can set the aclinherit mode to pass the execute permission to the inherited ACL.

If aclinherit=passthrough-x is enabled on a ZFS dataset, you can include execute permission for an output file that is generated from cc or gcc compiler tools. If the inherited ACL does not include execute permission, then the executable output from the compiler won't be executable until you use the chmod command to change the file's permissions.

For more information, see Example 8–12.
ZFS Property Enhancements

Solaris 10 10/09 and Oracle Solaris 10 9/10: The following ZFS file system enhancements are included in these releases.

- **ZFS Snapshot Stream Property Enhancements** – You can set a received property that is different from its local property setting. For example, you might receive a stream with the compression property disabled, but you want compression enabled in the receiving file system. This means that the received stream has a received compression value of off and a local compression value of on. Since the local value overrides the received value, you don’t have to worry about the setting on the sending side replacing the received side value. The `zfs get` command shows the effective value of the compression property under the `VALUE` column.

New ZFS command options and properties to support send and local property values are as follows:

- Use the `zfs inherit -S` to revert a local property value to the received value, if any. If a property does not have a received value, the behavior of the `zfs inherit -S` command is the same as the `zfs inherit` command without the `-S` option. If the property does have a received value, the `zfs inherit` command masks the received value with the inherited value until issuing a `zfs inherit -S` command reverts it to the received value.

- You can use the `zfs get -o` to include the new non-default `RECEIVED` column. Or, use the `zfs get -o all` command to include all columns, including `RECEIVED`.

- You can use the `zfs send -p` option to include properties in the send stream without the `-R` option.

In addition, you can use the `zfs send -e` option to use the last element of the sent snapshot name to determine the new snapshot name. The following example sends the `poola/bee/cee@1` snapshot to the `poold/eee` file system and only uses the last element (`cee@1`) of the snapshot name to create the received file system and snapshot.

```bash
# zfs list -rt all poola
NAME  USED  AVAIL  REFER  MOUNTPOINT
poola 134K  134G   23K   /poola
poola/bee 44K  134G   23K   /poola/bee
poola/bee/cee 21K  134G   21K   /poola/bee/cee
poola/bee/cee@1  0   -  21K   -
# zfs send -R poola/bee/cee@1 | zfs receive -e poold/eee

# zfs list -rt all poold
NAME  USED  AVAIL  REFER  MOUNTPOINT
poold 134K  134G   23K   /poold
poold/eee 44K  134G   23K   /poold/eee
poold/eee/cee 21K  134G   21K   /poold/eee/cee
poold/eee/cee@1  0   -  21K   -
```

- **Setting ZFS file system properties at pool creation time** – You can set ZFS file system properties when a storage pool is created. In the following example, compression is enabled on the ZFS file system that is created when the pool is created:

```bash
# zpool create -O compression=on pool mirror c0t1d0 c0t2d0
```
Setting cache properties on a ZFS file system – Two new ZFS file system properties enable you to control what is cached in the primary cache (ARC) and the secondary cache (L2ARC). The cache properties are set as follows:
- **primarycache** – Controls what is cached in the ARC.
- **secondarycache** – Controls what is cached in the L2ARC.

Possible values for both properties – *all*, *none*, and *metadata*. If set to *all*, both user data and metadata are cached. If set to *none*, neither user data nor metadata is cached. If set to *metadata*, only metadata is cached. The default is *all*.

You can set these properties on an existing file system or when a file system is created. For example:

```
# zfs set primarycache=metadata tank/datab
# zfs create -o primarycache=metadata tank/newdatab
```

When these properties are set on existing file systems, only new I/O is cache based on the values of these properties.

Some database environments might benefit from not caching user data. You must determine if setting cache properties is appropriate for your environment.

Viewing disk space accounting properties – New read-only file system properties help you identify disk space usage for clones, file systems, and volumes, and snapshots. The properties are as follows:
- **usedbychildren** – Identifies the amount of disk space that is used by children of this dataset, which would be freed if all the dataset’s children were destroyed. The property abbreviation is usedchild.
- **usedbydataset** – Identifies the amount of disk space that is used by this dataset itself, which would be freed if the dataset was destroyed, after first destroying any reservation. The property abbreviation is usedds.
- **usedbyrefreservation** – Identifies the amount of disk space that is used by a reservation set on this dataset, which would be freed if the reservation was removed. The property abbreviation is usedrefreserv.
- **usedbysnapshots** – Identifies the amount of disk space that is consumed by snapshots of this dataset, which would be freed if all of this dataset’s snapshots were destroyed. Note that this is not the sum of the snapshots’ *used* properties, because disk space can be shared by multiple snapshots. The property abbreviation is usedsnapshot.

These new properties break down the value of the *used* property into the various elements that consume disk space. In particular, the value of the *used* property breaks down as follows:

```
used property = usedbychildren + usedbydataset + usedbyrefreservation + usedbysnapshots
```

You can view these properties by using the `zfs list -o space` command. For example:
$ zfs list -o space

<table>
<thead>
<tr>
<th>NAME</th>
<th>AVAIL</th>
<th>USED</th>
<th>USEDSNAP</th>
<th>USEDDS</th>
<th>USEDFRESERV</th>
<th>USEDCHDIL</th>
<th>USECHIL</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpool</td>
<td>25.4G</td>
<td>7.79G</td>
<td>0</td>
<td>64K</td>
<td>0</td>
<td>7.79G</td>
<td></td>
</tr>
<tr>
<td>rpool/ROOT</td>
<td>25.4G</td>
<td>6.29G</td>
<td>0</td>
<td>18K</td>
<td>0</td>
<td>6.29G</td>
<td></td>
</tr>
<tr>
<td>rpool/ROOT/snv_98</td>
<td>25.4G</td>
<td>6.29G</td>
<td>0</td>
<td>6.29G</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>rpool/dump</td>
<td>25.4G</td>
<td>1.00G</td>
<td>0</td>

<td>25.4G</td>
<td>18K</td>
<td>0</td>
<td>18K</td>
<td>0</td>
<td>18K</td>
<td></td>
</tr>
<tr>
<td>rpool/export/home</td>
<td>25.4G</td>
<td>18K</td>
<td>0</td>
<td>18K</td>
<td>0</td>
<td>18K</td>
<td></td>
</tr>
<tr>
<td>rpool/swap</td>
<td>25.8G</td>
<td>512M</td>
<td>0</td>
<td>111M</td>
<td>401M</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

The preceding command is equivalent to the zfs list
-o name,avail,used,usedsnap,usedds,usedrefreserv,usedchild -t filesystem,volume
command.

- **Listing snapshots** – The listsnapshots pool property controls whether snapshot information is displayed by the zfs list command. The default value is on, which means snapshot information is displayed by default.

If your system has many ZFS snapshots and you wish to disable the display of snapshot information in the zfs list command, disable the listsnapshots property as follows:

```
# zpool get listsnapshots pool
NAME PROPRTY VALUE SOURCE
pool listsnaps on default
```

```
# zpool set listsnaps=off pool
```

If you disable the listsnapshots property, you can use the zfs list -t snapshots command to list snapshot information. For example:

```
# zfs list -t snapshot
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>

## ZFS Log Device Recovery

**Solaris 10 10/09 Release**: In this release, ZFS identifies intent log failures in the zpool status command output. Fault Management Architecture (FMA) reports these errors as well. Both ZFS and FMA describe how to recover from an intent log failure.

For example, if the system shuts down abruptly before synchronous write operations are committed to a pool with a separate log device, you see messages similar to the following:

```
# zpool status -x
pool: pool
state: FAULTED
status: One or more of the intent logs could not be read.
Waiting for administrator intervention to fix the faulted pool.
action: Either restore the affected device(s) and run 'zpool online',
or ignore the intent log records by running 'zpool clear'.
scrub: none requested
```
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool</td>
<td>FAULTED</td>
<td>0</td>
<td>0</td>
<td>0 bad intent log</td>
</tr>
<tr>
<td>mirror</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t4d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>logs</td>
<td>FAULTED</td>
<td>0</td>
<td>0</td>
<td>0 bad intent log</td>
</tr>
<tr>
<td>c0t5d0</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>0 cannot open</td>
</tr>
</tbody>
</table>

You can resolve the log device failure in the following ways:

- Replace or recover the log device. In this example, the log device is c0t5d0.
- Bring the log device back online.
  
  ```
  # zpool online pool c0t5d0
  ```
- Reset the failed log device error condition.
  
  ```
  # zpool clear pool
  ```

To recover from this error without replacing the failed log device, you can clear the error with the `zpool clear` command. In this scenario, the pool will operate in a degraded mode and the log records will be written to the main pool until the separate log device is replaced.

Consider using mirrored log devices to avoid the log device failure scenario.

### Using Cache Devices in Your ZFS Storage Pool

**Solaris 10 09/09 Release:** In this release, when you create a pool, you can specify `cache devices`, which are used to cache storage pool data.

Cache devices provide an additional layer of caching between main memory and disk. Using cache devices provides the greatest performance improvement for random-read workloads of mostly static content.

One or more cache devices can be specified when the pool is created. For example:

```
# zpool create pool mirror c0t2d0 c0t4d0 cache c0t0d0
# zpool status pool
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t2d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t4d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>cache</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors
After cache devices are added, they gradually fill with content from main memory. Depending on the size of your cache device, it could take over an hour for the device to fill. Capacity and reads can be monitored by using the `zpool iostat` command as follows:

```
# zpool iostat -v pool 5
```

Cache devices can be added or removed from a pool after the pool is created.

For more information, see “Creating a ZFS Storage Pool With Cache Devices” on page 67 and Example 4–4.

### Zone Migration in a ZFS Environment

**Solaris 10 5/09 Release**: This release extends support for migrating zones in a ZFS environment with Oracle Solaris Live Upgrade. For more information, see “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)” on page 139.

For a list of known issues with this release, see the Solaris 10 5/09 release notes.

### ZFS Installation and Boot Support

**Solaris 10 10/08 Release**: This release enables you to install and boot a ZFS root file system. You can use the initial installation option or the JumpStart feature to install a ZFS root file system. Or, you can use Oracle Solaris Live Upgrade to migrate a UFS root file system to a ZFS root file system. ZFS support for swap and dump devices is also provided. For more information, see Chapter 5, “Installing and Booting an Oracle Solaris ZFS Root File System.”

For a list of known issues with this release, go to the following site:

http://hub.opensolaris.org/bin/view/Community+Group+zfs/boot

Also, see the Solaris 10 10/08 release notes.

### Rolling Back a Dataset Without Unmounting

**Solaris 10 10/08 Release**: This release enables you to roll back a dataset without unmounting it first. Thus, the `zfs rollback -f` option is no longer needed to force an unmount operation. The `-f` option is no longer supported and is ignored, if specified.

### Enhancements to the `zfs send` Command

**Solaris 10 10/08 Release**: This release includes the following enhancements to the `zfs send` command. Using this command, you can now perform the following tasks:

- Send all incremental streams from one snapshot to a cumulative snapshot. For example:
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
pool 428K 16.5G 20K /pool
pool/fs 71K 16.5G 21K /pool/fs
pool/fs@snapA 16K - 18.5K -
pool/fs@snapB 17K - 20K -
pool/fs@snapC 17K - 20.5K -
pool/fs@snapD 0 - 21K -

# zfs send -I pool/fs@snapA pool/fs@snapD > /snaps/fs@combo

This syntax sends all incremental snapshots between fs@snapA to fs@snapD to fs@combo.

Send an incremental stream from the original snapshot to create a clone. The original snapshot must already exist on the receiving side to accept the incremental stream. For example:

# zfs send -I pool/fs@snap1 pool/clone@snapA > /snaps/fsclonesnap-I

# zfs receive -F pool/clone < /snaps/fsclonesnap-I

Send a replication stream of all descendent file systems, up to the named snapshots. When received, all properties, snapshots, descendent file systems, and clones are preserved. For example:

# zfs send -R pool/fs@snap > snaps/fs-R

For an extended example, see Example 7–1.

Send an incremental replication stream. For example:

# zfs send -R -[ii] @snapA pool/fs@snapD

For an extended example, see Example 7–1.

For more information, see “Sending and Receiving Complex ZFS Snapshot Streams” on page 214.

**ZFS Quotas and Reservations for File System Data Only**

**Solaris 10 10/08 Release**: In addition to the existing ZFS quota and reservation features, this release includes dataset quotas and reservations that do not include descendents, such as snapshots and clones, in the disk space accounting.

- The refquota property enforces a hard limit on the amount of disk space that a dataset can consume. This hard limit does not include disk space used by descendents, such as snapshots and clones.

- The refreservation property sets the minimum amount of disk space that is guaranteed for a dataset, not including its descendents.
For example, you can set a 10-GB refquota limit for studentA that sets a 10-GB hard limit of referenced disk space. For additional flexibility, you can set a 20-GB quota that enables you to manage studentA's snapshots.

```bash
# zfs set refquota=10g tank/studentA
# zfs set quota=20g tank/studentA
```

For more information, see “Setting ZFS Quotas and Reservations” on page 196.

---

**ZFS Storage Pool Properties**

**Solaris 10 10/08 Release:** ZFS storage pool properties were introduced in an earlier release. This release provides two properties, cachefile and failmode.

The following describes the new storage pool properties in this release:

- **The cachefile property** – This property controls where pool configuration information is cached. All pools in the cache are automatically imported when the system boots. However, installation and clustering environments might require this information to be cached in a different location so that pools are not automatically imported.

  You can set this property to cache pool configuration in a different location that can be imported later by using the `zpool import -c` command. For most ZFS configurations, this property would not be used.

  The cachefile property is not persistent and is not stored on disk. This property replaces the temporary property that was used to indicate that pool information should not be cached in previous Solaris releases.

- **The failmode property** – This property determines the behavior of a catastrophic pool failure due to a loss of device connectivity or the failure of all devices in the pool. The failmode property can be set to these values: wait, continue, or panic. The default value is wait, which means you must reconnect the device or replace a failed device, and then clear the error with the `zpool clear` command.

  The failmode property is set like other settable ZFS properties, which can be set either before or after the pool is created. For example:

  ```bash
  # zpool set failmode=continue tank
  # zpool get failmode tank
  NAME PROPERTY VALUE SOURCE
  tank failmode continue local
  # zpool create -o failmode=continue users mirror c0t1d0 c1t1d0
  ```

  For a description of pool properties, see Table 4-1.
ZFS Command History Enhancements (zpool history)

Solaris 10 10/08 Release: The zpool history command has been enhanced to provide the following new features:

- ZFS file system event information is now displayed. For example:

  ```
  # zpool history
  History for 'rpool':
  2010-06-23.09:30:12 zpool create -f -o failmode=continue -R /a -m legacy -o
cachefile=/tmp/root/etc/zfs/zpool.cach e rpool c1t0d0s0
  2010-06-23.09:30:13 zfs set canmount=noauto rpool
  2010-06-23.09:30:13 zfs set mountpoint=/rpool rpool
  2010-06-23.09:30:13 zfs create -o mountpoint=legacy rpool/ROOT
  2010-06-23.09:30:14 zfs create -b 8192 -V 2048m rpool/swap
  2010-06-23.09:30:14 zfs create -b 131072 -V 1024m rpool/dump
  2010-06-23.09:30:15 zfs create -o canmount=noauto rpool/ROOT/zfsBE
  2010-06-23.09:30:16 zpool set bootfs=rpool/ROOT/zfsBE rpool
  2010-06-23.09:30:16 zfs set mountpoint=/export rpool/export
  2010-06-23.09:30:17 zfs create rpool/export/home
  ```

- The -l option can be used to display a long format that includes the user name, the host name, and the zone in which the operation was performed. For example:

  ```
  # zpool history -l rpool
  History for 'tank':
  2010-06-24.13:07:58 zpool create tank mirror c2t2d0 c2t5d0 [user root on neo:global]
  2010-06-24.13:08:23 zpool scrub tank [user root on neo:global]
  2010-06-24.13:38:42 zpool clear tank [user root on neo:global]
  2010-06-29.11:44:18 zfs create tank/home [user root on neo:global]
  2010-06-29.13:28:51 zpool clear tank c2t5d0 [user root on neo:global]
  2010-06-30.14:07:40 zpool add tank spare c2t1d0 [user root on neo:global]
  ```

- The -i option can be used to display internal event information for diagnostic purposes. For example:

  ```
  # zpool history -i tank
  History for 'tank':
  2010-06-24.13:07:58 zpool create tank mirror c2t2d0 c2t5d0
  2010-06-24.13:08:23 zpool scrub tank
  2010-06-24.13:38:42 zpool clear tank
  2010-06-29.11:44:18 [internal create txg:14241] dataset = 34
  2010-06-29.11:44:18 zfs create tank/home
  2010-06-29.12:28:51 zpool clear tank c2t5d0
  2010-06-30.14:07:40 zpool add tank spare c2t1d0
  ```

For more information about using the zpool history command, see “Resolving Problems With ZFS” on page 271.
Upgrading ZFS File Systems (zfs upgrade)

Solaris 10 10/08 Release: The zfs upgrade command is included in this release to provide future ZFS file system enhancements to existing file systems. ZFS storage pools have a similar upgrade feature to provide pool enhancements to existing storage pools.

For example:

```
# zfs upgrade
This system is currently running ZFS filesystem version 3.
All filesystems are formatted with the current version.
```

**Note** – File systems that are upgraded and any streams created from those upgraded file systems by the zfs send command are not accessible on systems that are running older software releases.

ZFS Delegated Administration

Solaris 10 10/08 Release: In this release, you can grant fine-grained permissions to allow nonprivileged users to perform ZFS administration tasks.

You can use the zfs allow and zfs unallow commands to delegate and remove permissions.

You can modify delegated administration with the pool’s delegation property. For example:

```
# zpool get delegation users
NAME PROPERTY   VALUE SOURCE
users delegation on default
# zpool set delegation=off users
# zpool get delegation users
NAME PROPERTY   VALUE SOURCE
users delegation off local
```

By default, the delegation property is enabled.

For more information, see Chapter 9, “Oracle Solaris ZFS Delegated Administration,” and zfs(1M).

Setting Up Separate ZFS Log Devices

Solaris 10 10/08 Release: The ZFS intent log (ZIL) is provided to satisfy POSIX requirements for synchronous transactions. For example, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use fsync() to ensure data stability. By default, the ZIL is allocated from blocks within the main
storage pool. In this Solaris release, you can decide if you want the ZIL blocks to continue to be allocated from the main storage pool or from a separate log device. Better performance might be possible by using separate intent log devices in your ZFS storage pool, such as with NVRAM or a dedicated disk.

Log devices for the ZFS intent log are not related to database log files.

You can set up a ZFS log device when the storage pool is created or after the pool is created. For examples of setting up log devices, see “Creating a ZFS Storage Pool With Log Devices” on page 66 and “Adding Devices to a Storage Pool” on page 73.

You can attach a log device to an existing log device to create a mirrored log device. This operation is identical to attaching a device in a unmirrored storage pool.

Consider the following points when determining whether setting up a ZFS log device is appropriate for your environment:

- Any performance improvement seen by implementing a separate log device depends on the device type, the hardware configuration of the pool, and the application workload. For preliminary performance information, see this blog: [http://blogs.sun.com/perrin/entry/slog_blog_or_blogging_on](http://blogs.sun.com/perrin/entry/slog_blog_or_blogging_on)
- Log devices can be unreplicated or mirrored, but RAID-Z is not supported for log devices.
- If a separate log device is not mirrored and the device that contains the log fails, storing log blocks reverts to the storage pool.
- Log devices can be added, replaced, attached, detached, imported, and exported as part of the larger storage pool. Log devices can be removed starting in the Solaris 10 9/10 release.
- The minimum size of a log device is the same as the minimum size of each device in a pool, which is 64 MB. The amount of in-play data that might be stored on a log device is relatively small. Log blocks are freed when the log transaction (system call) is committed.
- The maximum size of a log device should be approximately 1/2 the size of physical memory because that is the maximum amount of potential in-play data that can be stored. For example, if a system has 16 GB of physical memory, consider a maximum log device size of 8 GB.

## Creating Intermediate ZFS Datasets

**Solaris 10 10/08 Release:** You can use the `-p` option with the `zfs create`, `zfs clone`, and `zfs rename` commands to quickly create a non-existent intermediate dataset, if it doesn’t already exist.

In the following example, ZFS datasets (`users/area51`) are created in the `datab` storage pool.
# zfs list
NAME    USED  AVAIL  REFER  MOUNTPOINT  
datab   106K  16.5G  18K   /datab

`# zfs create -p -o compression=on datab/users/area51`

If the intermediate dataset already exists during the create operation, the operation completes successfully.

Properties specified apply to the target dataset, not to the intermediate dataset. For example:

`# zfs get mountpoint,compression datab/users/area51`

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>datab/users/area51</td>
<td>mountpoint</td>
<td>/datab/users/area51</td>
<td>default</td>
</tr>
<tr>
<td>datab/users/area51</td>
<td>compression</td>
<td>on</td>
<td>local</td>
</tr>
</tbody>
</table>

The intermediate dataset is created with the default mount point. Any additional properties are disabled for the intermediate dataset. For example:

`# zfs get mountpoint,compression datab/users`

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>datab/users</td>
<td>mountpoint</td>
<td>/datab/users</td>
<td>default</td>
</tr>
<tr>
<td>datab/users</td>
<td>compression</td>
<td>off</td>
<td>default</td>
</tr>
</tbody>
</table>

For more information, see `zfs(1M)`.

### ZFS Hot-Plugging Enhancements

**Solaris 10 10/08 Release:** In this release, ZFS more effectively responds to devices that are removed and can now automatically identify devices that are inserted.

- You can replace an existing device with an equivalent device without having to use the `zpool replace` command.
  
The `autoreplace` property controls automatic device replacement. If set to `off`, device replacement must be initiated by the administrator by using the `zpool replace` command. If set to `on`, any new device that is found in the same physical location as a device that previously belonged to the pool is automatically formatted and replaced. The default behavior is `off`.

- The storage pool state `REMOVED` is provided when a device or hot spare has been physically removed while the system was running. A hot spare device is substituted for the removed device, if available.

- If a device is removed and then reinserted, the device is placed online. If a hot spare was activated when the device was reinserted, the hot spare is removed when the online operation completes.

- Automatic detection when devices are removed or inserted is hardware-dependent and might not be supported on all platforms. For example, USB devices are automatically configured upon insertion. However, you might have to use the `cfgadm -c configure` command to configure a SATA drive.
Hot spares are checked periodically to ensure that they are online and available.

For more information, see `zpool(1M)`.

**Recursively Renaming ZFS Snapshots (zfs rename -r)**

**Solaris 10 10/08 Release:** You can recursively rename all descendent ZFS snapshots by using the `zfs rename -r` command. For example:

First, a snapshot of a set of ZFS file systems is created.

```bash
# zfs snapshot -r users/home@today
# zfs list
NAME     USED  AVAIL REFER MOUNTPOINT
users     216K  16.5G  20K  /users
users/home 76K  16.5G  22K  /users/home
users/home@today 0    -  22K
users/home/markm 18K  16.5G  18K  /users/home/markm
users/home/markm@today 0    -  18K
users/home/marks 18K  16.5G  18K  /users/home/marks
users/home/marks@today 0    -  18K
users/home/neil 18K  16.5G  18K  /users/home/neil
users/home/neil@today 0    -  18K
```

Then, the snapshots are renamed the following day.

```bash
# zfs rename -r users/home@today @yesterday
# zfs list
NAME     USED  AVAIL REFER MOUNTPOINT
users     216K  16.5G  20K  /users
users/home 76K  16.5G  22K  /users/home
users/home/yesterday 0    -  22K
users/home/markm 18K  16.5G  18K  /users/home/markm
users/home/markm@yesterday 0    -  18K
users/home/marks 18K  16.5G  18K  /users/home/marks
users/home/marks@yesterday 0    -  18K
users/home/neil 18K  16.5G  18K  /users/home/neil
users/home/neil@yesterday 0    -  18K
```

A snapshot is the only type of dataset that can be renamed recursively.

For more information about snapshots, see “Overview of ZFS Snapshots” on page 203 and this blog entry that describes how to create rolling snapshots:

http://blogs.sun.com/mmusante/entry/rolling_snapshots_made_easy

**gzip Compression Is Available for ZFS**

**Solaris 10 10/08 Release:** In this Solaris release, you can set gzip compression on ZFS file systems, in addition to lzo/j compression. You can specify compression as `gzip`, or `gzip-N`, where `N` equals 1 through 9. For example:
Storing Multiple Copies of ZFS User Data

**Solaris 10 10/08 Release:** As a reliability feature, ZFS file system metadata is automatically stored multiple times across different disks, if possible. This feature is known as *ditto blocks*.

In this Solaris release, you can also store multiple copies of user data is also stored per file system by using the `zfs set copies` command. For example:

```
# zfs set copies=2 users/home
# zfs get copies users/home
NAME PROPERTY VALUE SOURCE
users/home copies 2 local
```

Available values are 1, 2, or 3. The default value is 1. These copies are in addition to any pool-level redundancy, such as in a mirrored or RAID-Z configuration.

The benefits of storing multiple copies of ZFS user data are as follows:

- Improves data retention by enabling recovery from unrecoverable block read faults, such as media faults (commonly known as *bit rot*) for all ZFS configurations.
- Provides data protection, even when only a single disk is available.
- Enables you to select data protection policies on a per-file system basis, beyond the capabilities of the storage pool.

**Note** – Depending on the allocation of the ditto blocks in the storage pool, multiple copies might be placed on a single disk. A subsequent full disk failure might cause all ditto blocks to be unavailable.

You might consider using ditto blocks when you accidentally create a non-redundant pool and when you need to set data retention policies.

For a detailed description of how storing multiple copies on a system with a single-disk pool or a multiple-disk pool might impact overall data protection, see this blog:

For more information about setting ZFS properties, see “Setting ZFS Properties” on page 185.

**Improved zpool status Output**

**Solaris 10 8/07 Release:** You can use the `zpool status -v` command to display a list of files with persistent errors. Previously, you had to use the `find -inum` command to identify the file names from the list of displayed inodes.

For more information about displaying a list of files with persistent errors, see “Repairing a Corrupted File or Directory” on page 288.

**ZFS and Solaris iSCSI Improvements**

**Solaris 10 8/07 Release:** In this Solaris release, you can create a ZFS volume as a Solaris iSCSI target device by setting the `shareiscsi` property on the ZFS volume. This method is a convenient way to quickly set up a Solaris iSCSI target. For example:

```
# zfs create -V 2g tank/volumes/v2
# zfs set shareiscsi=on tank/volumes/v2
# iscsitadm list target
Target: tank/volumes/v2
  iSCSI Name: iqn.1986-03.com.sun:02:984fe301-c412-ccc1-cc80-cf9a72aa062a
  Connections: 0
```

After the iSCSI target is created, you can set up the iSCSI initiator. For information about setting up a Solaris iSCSI initiator, see Chapter 14, “Configuring Oracle Solaris iSCSI Targets and Initiators (Tasks),” in *System Administration Guide: Devices and File Systems*.

For more information about managing a ZFS volume as an iSCSI target, see “Using a ZFS Volume as a Solaris iSCSI Target” on page 258.

**ZFS Command History (zpool history)**

**Solaris 10 8/07 Release:** In this Solaris release, ZFS automatically logs successful `zfs` and `zpool` commands that modify pool state information. For example:

```
# zpool history
History for 'newpool':
2007-04-25.11:37:31 zpool create newpool mirror c0t8d0 c0t10d0
2007-04-25.11:37:46 zpool replace newpool c0t10d0 c0t9d0
2007-04-25.11:38:04 zpool attach newpool c0t9d0 c0t11d0
2007-04-25.11:38:09 zfs create newpool/user1
2007-04-25.11:38:15 zfs destroy newpool/user1

History for 'tank':
2007-04-25.11:46:28 zpool create tank mirror c1t0d0 c2t0d0 mirror c3t0d0 c4t0d0
```
This feature enables you or Oracle support personnel to identify the actual ZFS commands that were executed to troubleshoot an error scenario.

You can identify a specific storage pool with the `zpool history` command. For example:

```
# zpool history newpool
History for 'newpool':
2007-04-25.11:37:31 zpool create newpool mirror c0t8d0 c0t10d0
2007-04-25.11:37:46 zpool replace newpool c0t10d0 c0t9d0
2007-04-25.11:38:04 zpool attach newpool c0t9d0 c0t11d0
2007-04-25.11:38:09 zfs create newpool/user1
2007-04-25.11:38:15 zfs destroy newpool/user1
```

In this Solaris release, the `zpool history` command does not record user-ID, hostname, or zone-name. However, this information is recorded starting in the Solaris 10 10/08 release. For more information, see “ZFS Command History Enhancements (`zpool history`)” on page 29.

For more information about troubleshooting ZFS problems, see “Resolving Problems With ZFS” on page 271.

**ZFS Property Improvements**

**ZFS xattr Property**

*Solaris 10 8/07 Release*: You can use the `xattr` property to disable or enable extended attributes for a specific ZFS file system. The default value is on. For a description of ZFS properties, see “Introducing ZFS Properties” on page 171.

**ZFS canmount Property**

*Solaris 10 8/07 Release*: The new `canmount` property enables you to specify whether a dataset can be mounted by using the `zfs mount` command. For more information, see “canmount Property” on page 180.

**ZFS User Properties**

*Solaris 10 8/07 Release*: In addition to the standard native properties that can be used to either export internal statistics or control ZFS file system behavior, ZFS provides user properties. User properties have no effect on ZFS behavior, but you can use them to annotate datasets with information that is meaningful in your environment.

For more information, see “ZFS User Properties” on page 182.

**Setting Properties When Creating ZFS File Systems**

*Solaris 10 8/07 Release*: In this Solaris release, you can set properties when you create a file system, not just after the file system is created.

The following examples illustrate equivalent syntax:
# zfs create tank/home
# zfs set mountpoint=/export/zfs tank/home
# zfs set sharenfs=on tank/home
# zfs set compression=on tank/home

# zfs create -o mountpoint=/export/zfs -o sharenfs=on -o compression=on tank/home

**Displaying All ZFS File System Information**

**Solaris 10 8/07 Release:** In this Solaris release, you can use various forms of the `zfs get` command to display information about all datasets if you do not specify a dataset or if you specify `all`. In previous releases, all dataset information was not retrievable with the `zfs get` command.

For example:

```
# zfs get -s local all
```

<table>
<thead>
<tr>
<th>Dataset</th>
<th>Atime</th>
<th>Off</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home</td>
<td></td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td>tank/home/bonwick</td>
<td></td>
<td>off</td>
<td>local</td>
</tr>
<tr>
<td>tank/home/marks</td>
<td></td>
<td>50G</td>
<td>local</td>
</tr>
</tbody>
</table>

**New zfs receive -F Option**

**Solaris 10 8/07 Release:** In this Solaris release, you can use the new `-F` option to the `zfs receive` command to force a rollback of the file system to the most recent snapshot before the receive is initiated. Using this option might be necessary when the file system is modified after a rollback occurs but before the receive is initiated.

For more information, see "Receiving a ZFS Snapshot" on page 213.

**Recursive ZFS Snapshots**

**Solaris 10 11/06 Release:** When you use the `zfs snapshot` command to create a file system snapshot, you can use the `-r` option to recursively create snapshots for all descendent file systems. In addition, you can use the `-r` option to recursively destroy all descendent snapshots when a snapshot is destroyed.

Recursive ZFS snapshots are created quickly as one atomic operation. The snapshots are created together (all at once) or not created at all. The benefit of such an operation is that the snapshot data is always taken at one consistent time, even across descendent file systems.

For more information, see "Creating and Destroying ZFS Snapshots" on page 204.
Double-Parity RAID-Z (raidz2)

**Solaris 10 11/06 Release:** A redundant RAID-Z configuration can now have either a single- or double-parity configuration, which means that one or two device failures, respectively, can be sustained, without any data loss. You can specify the `raidz2` keyword for a double-parity RAID-Z configuration. Or, you can specify the `raidz` or `raidz1` keyword for a single-parity RAID-Z configuration.

For more information, see “Creating a RAID-Z Storage Pool” on page 65 or `zpool(1M)`.

Hot Spares for ZFS Storage Pool Devices

**Solaris 10 11/06 Release:** The ZFS hot spares feature enables you to identify disks that could be used to replace a failed or faulted device in one or more storage pools. Designating a device as a `hot spare` means that if an active device in the pool fails, the hot spare automatically replaces the failed device. Or, you can manually replace a device in a storage pool with a hot spare.

For more information, see “Designating Hot Spares in Your Storage Pool” on page 87 and `zpool(1M)`.

Replacing a ZFS File System With a ZFS Clone (zfs promote)

**Solaris 10 11/06 Release:** The `zfs promote` command enables you to replace an existing ZFS file system with a clone of that file system. This feature is helpful when you want to run tests on an alternative version of a file system and then make that alternative version the active file system.

For more information, see “Replacing a ZFS File System With a ZFS Clone” on page 210 and `zfs(1M)`.

Upgrading ZFS Storage Pools (zpool upgrade)

**Solaris 10 6/06 Release:** You can upgrade your storage pools to a newer version of ZFS to take advantage of the latest features by using the `zpool upgrade` command. In addition, the `zpool status` command has been modified to notify you when your pools are running older versions of ZFS.

For more information, see “Upgrading ZFS Storage Pools” on page 109 and `zpool(1M)`.

If you want to use the ZFS Administration console on a system with a pool from a previous Solaris release, ensure that you upgrade your pools before using the console. To determine if your pools need to be upgraded, use the `zpool status` command. For information about the ZFS Administration console, see “ZFS Web-Based Management” on page 40.
ZFS Backup and Restore Commands Are Renamed

**Solaris 10 6/06 Release**: In this Solaris release, the `zfs backup` and `zfs restore` commands are renamed to `zfs send` and `zfs receive` to more accurately describe their functions. These commands send and receive ZFS data stream representations.

For more information about these commands, see “Sending and Receiving ZFS Data” on page 211.

Recovering Destroyed Storage Pools

**Solaris 10 6/06 Release**: This release includes the `zpool import -D` command, which enables you to recover pools that were previously destroyed with the `zpool destroy` command.

For more information, see “Recovering Destroyed ZFS Storage Pools” on page 107.

ZFS Is Integrated With Fault Manager

**Solaris 10 6/06 Release**: This release includes a ZFS diagnostic engine that is capable of diagnosing and reporting pool failures and device failures. Checksum, I/O, device, and pool errors associated with pool or device failures are also reported.

The diagnostic engine does not include predictive analysis of checksum and I/O errors, nor does it include proactive actions based on fault analysis.

If a ZFS failure occurs, you might see a message similar to the following:

```
SUNW-MSG-ID: ZFS-8000-D3, TYPE: Fault, VER: 1, SEVERITY: Major
PLATFORM: SUNW,Sun-Fire-880, CSN: -, HOSTNAME: neo
SOURCE: zfs-diagnosis, REV: 1.0
EVENT-ID: 504a1188-b270-4ab0-af4e-8a77680576b8
AUTO-RESPONSE: No automated response will occur.
IMPACT: Fault tolerance of the pool may be compromised.
REC-ACTION: Run ‘zpool status -x’ and replace the bad device.
```

By reviewing the recommended action, which is to follow the more specific directions in the `zpool status` command, you can quickly identify and resolve the failure.

For an example of recovering from a reported ZFS problem, see “Resolving a Missing Device” on page 276.
The `zpool clear` Command

**Solaris 10 6/06 Release:** This release includes the `zpool clear` command for clearing error counts associated with a device or a pool. Previously, error counts were cleared when a device in a pool was brought online with the `zpool online` command. For more information, see “Clearing Storage Pool Device Errors” on page 84 and `zpool(1M)`.

Compact NFSv4 ACL Format

**Solaris 10 6/06 Release:** In this release, you can set and display NFSv4 ACLs in two formats: verbose and compact. You can use the `chmod` command to set either ACL formats. You can use the `ls -V` command to display the compact ACL format. You can use the `ls -v` command to display the verbose ACL format.

For more information, see “Setting and Displaying ACLs on ZFS Files in Compact Format” on page 239, `chmod(1)`, and `ls(1)`.

File System Monitoring Tool (`fsstat`)

**Solaris 10 6/06 Release:** A new file system monitoring tool, `fsstat`, reports file system operations. Activity can be reported by mount point or by file system type. The following example shows general ZFS file system activity:

```
$ fsstat zfs
new name name attr attr lookup rmdir read read write write
file remov chg get set ops ops bytes bytes
7.82M 5.92M 2.76M 1.02G 3.32M 5.60G 87.0M 363M 1.86T 20.9M 251G zfs
```

For more information, see `fsstat(1M)`.

ZFS Web-Based Management

**Solaris 10 6/06 Release:** A web-based ZFS management tool, the ZFS Administration console, enables you to perform the following administrative tasks:

- Create a new storage pool.
- Add capacity to an existing pool.
- Move (export) a storage pool to another system.
- Import a previously exported storage pool to make it available on another system.
- View information about storage pools.
- Create a file system.
What Is ZFS?

The ZFS file system is a revolutionary new file system that fundamentally changes the way file systems are administered, with features and benefits not found in any other file system available today. ZFS is robust, scalable, and easy to administer.

ZFS Pooled Storage

ZFS uses the concept of storage pools to manage physical storage. Historically, file systems were constructed on top of a single physical device. To address multiple devices and provide for data redundancy, the concept of a volume manager was introduced to provide a representation of a single device so that file systems would not need to be modified to take advantage of multiple devices. This design added another layer of complexity and ultimately prevented certain file system advances because the file system had no control over the physical placement of data on the virtualized volumes.

ZFS eliminates volume management altogether. Instead of forcing you to create virtualized volumes, ZFS aggregates devices into a storage pool. The storage pool describes the physical characteristics of the storage (device layout, data redundancy, and so on) and acts as an arbitrary data store from which file systems can be created. File systems are no longer constrained to individual devices, allowing them to share disk space with all file systems in the pool. You no longer need to predetermine the size of a file system, as file systems grow.
automatically within the disk space allocated to the storage pool. When new storage is added, all file systems within the pool can immediately use the additional disk space without additional work. In many ways, the storage pool works similarly to a virtual memory system: When a memory DIMM is added to a system, the operating system doesn’t force you to run commands to configure the memory and assign it to individual processes. All processes on the system automatically use the additional memory.

**Transactional Semantics**

ZFS is a transactional file system, which means that the file system state is always consistent on disk. Traditional file systems overwrite data in place, which means that if the system loses power, for example, between the time a data block is allocated and when it is linked into a directory, the file system will be left in an inconsistent state. Historically, this problem was solved through the use of the `fsck` command. This command was responsible for reviewing and verifying the file system state, and attempting to repair any inconsistencies during the process. This problem of inconsistent file systems caused great pain to administrators, and the `fsck` command was never guaranteed to fix all possible problems. More recently, file systems have introduced the concept of journaling. The journaling process records actions in a separate journal, which can then be replayed safely if a system crash occurs. This process introduces unnecessary overhead because the data needs to be written twice, often resulting in a new set of problems, such as when the journal cannot be replayed properly.

With a transactional file system, data is managed using *copy on write* semantics. Data is never overwritten, and any sequence of operations is either entirely committed or entirely ignored. Thus, the file system can never be corrupted through accidental loss of power or a system crash. Although the most recently written pieces of data might be lost, the file system itself will always be consistent. In addition, synchronous data (written using the `O_DSYNC` flag) is always guaranteed to be written before returning, so it is never lost.

**Checksums and Self-Healing Data**

With ZFS, all data and metadata is verified using a user-selectable checksum algorithm. Traditional file systems that do provide checksum verification have performed it on a per-block basis, out of necessity due to the volume management layer and traditional file system design. The traditional design means that certain failures, such as writing a complete block to an incorrect location, can result in data that is incorrect but has no checksum errors. ZFS checksums are stored in a way such that these failures are detected and can be recovered from gracefully. All checksum verification and data recovery are performed at the file system layer, and are transparent to applications.

In addition, ZFS provides for self-healing data. ZFS supports storage pools with varying levels of data redundancy. When a bad data block is detected, ZFS fetches the correct data from another redundant copy and repairs the bad data, replacing it with the correct data.
Unparalleled Scalability

A key design element of the ZFS file system is scalability. The file system itself is 128 bit, allowing for 256 quadrillion zettabytes of storage. All metadata is allocated dynamically, so no need exists to preallocate inodes or otherwise limit the scalability of the file system when it is first created. All the algorithms have been written with scalability in mind. Directories can have up to $2^{38}$ (256 trillion) entries, and no limit exists on the number of file systems or the number of files that can be contained within a file system.

ZFS Snapshots

A snapshot is a read-only copy of a file system or volume. Snapshots can be created quickly and easily. Initially, snapshots consume no additional disk space within the pool.

As data within the active dataset changes, the snapshot consumes disk space by continuing to reference the old data. As a result, the snapshot prevents the data from being freed back to the pool.

Simplified Administration

Most importantly, ZFS provides a greatly simplified administration model. Through the use of a hierarchical file system layout, property inheritance, and automatic management of mount points and NFS share semantics, ZFS makes it easy to create and manage file systems without requiring multiple commands or the editing configuration files. You can easily set quotas or reservations, turn compression on or off, or manage mount points for numerous file systems with a single command. You can examine or replace devices without learning a separate set of volume manager commands. You can send and receive file system snapshot streams.

ZFS manages file systems through a hierarchy that allows for this simplified management of properties such as quotas, reservations, compression, and mount points. In this model, file systems are the central point of control. File systems themselves are very cheap (equivalent to creating a new directory), so you are encouraged to create a file system for each user, project, workspace, and so on. This design enables you to define fine-grained management points.

ZFS Terminology

This section describes the basic terminology used throughout this book:

alternate boot environment  A boot environment that is created by the `lucreate` command and possibly updated by the `luupgrade` command, but it is not the active or primary boot environment. The alternate boot environment can become the primary boot environment by running the `luactivate` command.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>checksum</td>
<td>A 256-bit hash of the data in a file system block. The checksum capability can range from the simple and fast fletcher4 (the default) to cryptographically strong hashes such as SHA256.</td>
</tr>
<tr>
<td>clone</td>
<td>A file system whose initial contents are identical to the contents of a snapshot.</td>
</tr>
<tr>
<td>dataset</td>
<td>A generic name for the following ZFS components: clones, file systems, snapshots, and volumes. Each dataset is identified by a unique name in the ZFS namespace. Datasets are identified using the following format: <em>pool/path[@snapshot]</em></td>
</tr>
<tr>
<td>filesystem</td>
<td>A ZFS dataset of type <em>filesystem</em> that is mounted within the standard system namespace and behaves like other file systems.</td>
</tr>
<tr>

### ZFS Component Naming Requirements

Each ZFS component, such as datasets and pools, must be named according to the following rules:

- Each component can only contain alphanumeric characters in addition to the following four special characters:
  - Underscore (_)
  - Hyphen (-)
  - Colon (:)
  - Period (.)
Pool names must begin with a letter, except for the following restrictions:

- The beginning sequence `c[0-9]` is not allowed.
- The name `log` is reserved.
- A name that begins with `mirror`, `raidz`, `raidz1`, `raidz2`, `raidz3`, or `spare` is not allowed because these names are reserved.
- Pool names must not contain a percent sign (%).

Dataset names must begin with an alphanumeric character.

Dataset names must not contain a percent sign (%).

In addition, empty components are not allowed.
This chapter provides step-by-step instructions on setting up a basic Oracle Solaris ZFS configuration. By the end of this chapter, you will have a basic understanding of how the ZFS commands work, and should be able to create a basic pool and file systems. This chapter does not provide a comprehensive overview and refers to later chapters for more detailed information.

The following sections are provided in this chapter:

- “ZFS Hardware and Software Requirements and Recommendations” on page 47
- “Creating a Basic ZFS File System” on page 48
- “Creating a ZFS Storage Pool” on page 49
- “Creating a ZFS File System Hierarchy” on page 50

ZFS Hardware and Software Requirements and Recommendations

Ensure that you review the following hardware and software requirements and recommendations before attempting to use the ZFS software:

- Use a SPARC or x86 based system that is running at least the Solaris 10 6/06 release or later release.
- The minimum amount of disk space required for a storage pool is 64 MB. The minimum disk size is 128 MB.
- The minimum amount of memory needed to install a Solaris system is 768 MB. However, for good ZFS performance, use at least one GB or more of memory.
- If you create a mirrored disk configuration, use multiple controllers.
Creating a Basic ZFS File System

ZFS administration has been designed with simplicity in mind. Among the design goals is to reduce the number of commands needed to create a usable file system. For example, when you create a new pool, a new ZFS file system is created and mounted automatically.

The following example shows how to create a basic mirrored storage pool named tank and a ZFS file system named tank in one command. Assume that the whole disks /dev/dsk/c1t0d0 and /dev/dsk/c2t0d0 are available for use.

```
# zpool create tank mirror c1t0d0 c2t0d0
```

For more information about redundant ZFS pool configurations, see “Replication Features of a ZFS Storage Pool” on page 60.

The new ZFS file system, tank, can use available disk space as needed, and is automatically mounted at /tank.

```
# mkfile 100m /tank/foo
# df -h /tank
Filesystem size used avail capacity Mounted on
tank  80G  100M    80G    1% /tank
```

Within a pool, you probably want to create additional file systems. File systems provide points of administration that enable you to manage different sets of data within the same pool.

The following example shows how to create a file system named fs in the storage pool tank.

```
# zfs create tank/fs
```

The new ZFS file system, tank/fs, can use available disk space as needed, and is automatically mounted at /tank/fs.

```
# mkfile 100m /tank/fs/foo
# df -h /tank/fs
Filesystem size used avail capacity Mounted on
tank/fs  80G  100M    80G    1% /tank/fs
```

Typically, you want to create and organize a hierarchy of file systems that matches your organizational needs. For information about creating a hierarchy of ZFS file systems, see “Creating a ZFS File System Hierarchy” on page 50.
Creating a ZFS Storage Pool

The previous example illustrates the simplicity of ZFS. The remainder of this chapter provides a more complete example, similar to what you would encounter in your environment. The first tasks are to identify your storage requirements and create a storage pool. The pool describes the physical characteristics of the storage and must be created before any file systems are created.

▼ How to Identify Storage Requirements for Your ZFS Storage Pool

1 Determine available devices for your storage pool.
   Before creating a storage pool, you must determine which devices will store your data. These devices must be disks of at least 128 MB in size, and they must not be in use by other parts of the operating system. The devices can be individual slices on a preformatted disk, or they can be entire disks that ZFS formats as a single large slice.

   In the storage example in “How to Create a ZFS Storage Pool” on page 49, assume that the whole disks /dev/dsk/c1t0d0 and /dev/dsk/c2t0d0 are available for use.

   For more information about disks and how they are used and labeled, see “Using Disks in a ZFS Storage Pool” on page 57.

2 Choose data replication.
   ZFS supports multiple types of data replication, which determines the types of hardware failures the pool can withstand. ZFS supports nonredundant (striped) configurations, as well as mirroring and RAID-Z (a variation on RAID-5).

   In the storage example in “How to Create a ZFS Storage Pool” on page 49, basic mirroring of two available disks is used.

   For more information about ZFS replication features, see “Replication Features of a ZFS Storage Pool” on page 60.

▼ How to Create a ZFS Storage Pool

1 Become root or assume an equivalent role with the appropriate ZFS rights profile.
   For more information about the ZFS rights profiles, see “ZFS Rights Profiles” on page 266.
Pick a name for your storage pool.
This name is used to identify the storage pool when you are using the `zpool` and `zfs` commands. Most systems require only a single pool, so you can pick any name that you prefer, but it must satisfy the naming requirements in “ZFS Component Naming Requirements” on page 45.

Create the pool.
For example, the following command creates a mirrored pool that is named tank:

```
# zpool create tank mirror c1t0d0 c2t0d0
```

If one or more devices contains another file system or is otherwise in use, the command cannot create the pool.

For more information about creating storage pools, see “Creating a ZFS Storage Pool” on page 63. For more information about how device usage is determined, see “Detecting In-Use Devices” on page 69.

View the results.
You can determine if your pool was successfully created by using the `zpool list` command.

```
# zpool list
NAME     SIZE  ALLOC  FREE   CAP  HEALTH  ALTROOT
tank  80G  137K  80G  0%  ONLINE -
```

For more information about viewing pool status, see “Querying ZFS Storage Pool Status” on page 95.

Creating a ZFS File System Hierarchy

After creating a storage pool to store your data, you can create your file system hierarchy. Hierarchies are simple yet powerful mechanisms for organizing information. They are also very familiar to anyone who has used a file system.

ZFS allows file systems to be organized into hierarchies, where each file system has only a single parent. The root of the hierarchy is always the pool name. ZFS leverages this hierarchy by supporting property inheritance so that common properties can be set quickly and easily on entire trees of file systems.

How to Determine Your ZFS File System Hierarchy

1 Pick the file system granularity.
ZFS file systems are the central point of administration. They are lightweight and can be created easily. A good model to use is to establish one file system per user or project, as this model allows properties, snapshots, and backups to be controlled on a per-user or per-project basis.
Two ZFS file systems, bonwick and billm, are created in “How to Create ZFS File Systems” on page 51.

For more information about managing file systems, see Chapter 6, "Managing Oracle Solaris ZFS File Systems.”

2 **Group similar file systems.**

ZFS allows file systems to be organized into hierarchies so that similar file systems can be grouped. This model provides a central point of administration for controlling properties and administering file systems. Similar file systems should be created under a common name.

In the example in “How to Create ZFS File Systems” on page 51, the two file systems are placed under a file system named `home`.

3 **Choose the file system properties.**

Most file system characteristics are controlled by properties. These properties control a variety of behaviors, including where the file systems are mounted, how they are shared, if they use compression, and if any quotas are in effect.

In the example in “How to Create ZFS File Systems” on page 51, all home directories are mounted at `/export/zfs/user`, are shared by using NFS, and have compression enabled. In addition, a quota of 10 GB on user bonwick is enforced.

For more information about properties, see “Introducing ZFS Properties” on page 171.

▼ **How to Create ZFS File Systems**

1 **Become root or assume an equivalent role with the appropriate ZFS rights profile.**

For more information about the ZFS rights profiles, see “ZFS Rights Profiles” on page 266.

2 **Create the desired hierarchy.**

In this example, a file system that acts as a container for individual file systems is created.

```
# zfs create tank/home
```

3 **Set the inherited properties.**

After the file system hierarchy is established, set up any properties to be shared among all users:

```
# zfs set mountpoint=/export/zfs tank/home
# zfs set sharenfs=on tank/home
# zfs set compression=on tank/home
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home</td>
<td>compression</td>
<td>on</td>
<td>local</td>
</tr>
</tbody>
</table>

You can set file system properties when the file system is created. For example:

```
# zfs create -o mountpoint=/export/zfs -o sharenfs=on -o compression=on tank/home
```
For more information about properties and property inheritance, see "Introducing ZFS Properties" on page 171.

Next, individual file systems are grouped under the home file system in the pool tank.

4 Create the individual file systems.

File systems could have been created and then the properties could have been changed at the home level. All properties can be changed dynamically while file systems are in use.

```bash
# zfs create tank/home/bonwick
# zfs create tank/home/billm
```

These file systems inherit their property values from their parent, so they are automatically mounted at /export/zfs/user and are NFS shared. You do not need to edit the /etc/vfstab or /etc/dfs/dfstab file.

For more information about creating file systems, see “Creating a ZFS File System” on page 168.

For more information about mounting and sharing file systems, see “Mounting and Sharing ZFS File Systems” on page 190.

5 Set the file system-specific properties.

In this example, user bonwick is assigned a quota of 10 GBs. This property places a limit on the amount of space he can consume, regardless of how much space is available in the pool.

```bash
# zfs set quota=10G tank/home/bonwick
```

6 View the results.

View available file system information by using the `zfs list` command:

```bash
# zfs list

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>92.0K</td>
<td>67.0G</td>
<td>9.5K</td>
<td>/tank</td>
</tr>
<tr>
<td>tank/home</td>
<td>24.0K</td>
<td>67.0G</td>
<td>8K</td>
<td>/export/zfs</td>
</tr>
<tr>
<td>tank/home/billm</td>
<td>8K</td>
<td>67.0G</td>
<td>8K</td>
<td>/export/zfs/billm</td>
</tr>
<tr>
<td>tank/home/bonwick</td>
<td>8K</td>
<td>10.0G</td>
<td>8K</td>
<td>/export/zfs/bonwick</td>
</tr>
</tbody>
</table>
```

Note that user bonwick only has 10 GB of space available, while user billm can use the full pool (67 GB).

For more information about viewing file system status, see “Querying ZFS File System Information” on page 183.

For more information about how disk space is used and calculated, see “ZFS Disk Space Accounting” on page 54.
This chapter discusses some significant differences between Oracle Solaris ZFS and traditional file systems. Understanding these key differences can help reduce confusion when you use traditional tools to interact with ZFS.

The following sections are provided in this chapter:

- “ZFS File System Granularity” on page 53
- “ZFS Disk Space Accounting” on page 54
- “Out of Space Behavior” on page 54
- “Mounting ZFS File Systems” on page 55
- “Traditional Volume Management” on page 55
- “New Solaris ACL Model” on page 55

### ZFS File System Granularity

Historically, file systems have been constrained to one device and thus to the size of that device. Creating and re-creating traditional file systems because of size constraints are time-consuming and sometimes difficult. Traditional volume management products help manage this process.

Because ZFS file systems are not constrained to specific devices, they can be created easily and quickly, similar to the way directories are created. ZFS file systems grow automatically within the disk space allocated to the storage pool in which they reside.

Instead of creating one file system, such as `/export/home`, to manage many user subdirectories, you can create one file system per user. You can easily set up and manage many file systems by applying properties that can be inherited by the descendent file systems contained within the hierarchy.

For an example that shows how to create a file system hierarchy, see “Creating a ZFS File System Hierarchy” on page 50.
ZFS Disk Space Accounting

ZFS is based on the concept of pooled storage. Unlike typical file systems, which are mapped to physical storage, all ZFS file systems in a pool share the available storage in the pool. So, the available disk space reported by utilities such as `df` might change even when the file system is inactive, as other file systems in the pool consume or release disk space.

Note that the maximum file system size can be limited by using quotas. For information about quotas, see “Setting Quotas on ZFS File Systems” on page 196. A specified amount of disk space can be guaranteed to a file system by using reservations. For information about reservations, see “Setting Reservations on ZFS File Systems” on page 200. This model is very similar to the NFS model, where multiple directories are mounted from the same file system (consider `/home`).

All metadata in ZFS is allocated dynamically. Most other file systems preallocate much of their metadata. As a result, at file system creation time, an immediate space cost for this metadata is required. This behavior also means that the total number of files supported by the file systems is predetermined. Because ZFS allocates its metadata as it needs it, no initial space cost is required, and the number of files is limited only by the available disk space. The output from the `df -g` command must be interpreted differently for ZFS than other file systems. The `total files` reported is only an estimate based on the amount of storage that is available in the pool.

ZFS is a transactional file system. Most file system modifications are bundled into transaction groups and committed to disk asynchronously. Until these modifications are committed to disk, they are called pending changes. The amount of disk space used, available, and referenced by a file or file system does not consider pending changes. Pending changes are generally accounted for within a few seconds. Even committing a change to disk by using `fsync(3c)` or `O_SYNC` does not necessarily guarantee that the disk space usage information is updated immediately.

For additional details about ZFS disk space consumption as reported by the `du` and `df` commands, see:

http://hub.opensolaris.org/bin/view/Community+Group+zfs/faq/#whydsize

Out of Space Behavior

File system snapshots are inexpensive and easy to create in ZFS. Snapshots are common in most ZFS environments. For information about ZFS snapshots, see Chapter 7, “Working With Oracle Solaris ZFS Snapshots and Clones.”

The presence of snapshots can cause some unexpected behavior when you attempt to free disk space. Typically, given appropriate permissions, you can remove a file from a full file system, and this action results in more disk space becoming available in the file system. However, if the file to be removed exists in a snapshot of the file system, then no disk space is gained from the file deletion. The blocks used by the file continue to be referenced from the snapshot.
As a result, the file deletion can consume more disk space because a new version of the directory needs to be created to reflect the new state of the namespace. This behavior means that you can receive an unexpected ENOSPC or EDQUOT error when attempting to remove a file.

**Mounting ZFS File Systems**

ZFS reduces complexity and eases administration. For example, with traditional file systems, you must edit the /etc/vfstab file every time you add a new file system. ZFS has eliminated this requirement by automatically mounting and unmounting file systems according to the properties of the dataset. You do not need to manage ZFS entries in the /etc/vfstab file.

For more information about mounting and sharing ZFS file systems, see “Mounting and Sharing ZFS File Systems” on page 190.

**Traditional Volume Management**

As described in “ZFS Pooled Storage” on page 41, ZFS eliminates the need for a separate volume manager. ZFS operates on raw devices, so it is possible to create a storage pool comprised of logical volumes, either software or hardware. This configuration is not recommended, as ZFS works best when it uses raw physical devices. Using logical volumes might sacrifice performance, reliability, or both, and should be avoided.

**New Solaris ACL Model**

Previous versions of the Solaris OS supported an ACL implementation that was primarily based on the POSIX ACL draft specification. The POSIX-draft based ACLs are used to protect UFS files. A new Solaris ACL model that is based on the NFSv4 specification is used to protect ZFS files.

The main differences of the new Solaris ACL model are as follows:
- The model is based on the NFSv4 specification and is similar to NT-style ACLs.
- This model provides a much more granular set of access privileges.
- ACLs are set and displayed with the chmod and ls commands rather than the setfacl and getfacl commands.
- Richer inheritance semantics designate how access privileges are applied from directory to subdirectories, and so on.

For more information about using ACLs with ZFS files, see Chapter 8, “Using ACLs to Protect Oracle Solaris ZFS Files.”
This chapter describes how to create and administer storage pools in Oracle Solaris ZFS.

The following sections are provided in this chapter:

- “Components of a ZFS Storage Pool” on page 57
- “Replication Features of a ZFS Storage Pool” on page 60
- “Creating and Destroying ZFS Storage Pools” on page 63
- “Managing Devices in ZFS Storage Pools” on page 72
- “Managing ZFS Storage Pool Properties” on page 92
- “Querying ZFS Storage Pool Status” on page 95
- “Migrating ZFS Storage Pools” on page 103
- “Upgrading ZFS Storage Pools” on page 109

## Components of a ZFS Storage Pool

The following sections provide detailed information about the following storage pool components:

- “Using Disks in a ZFS Storage Pool” on page 57
- “Using Slices in a ZFS Storage Pool” on page 59
- “Using Files in a ZFS Storage Pool” on page 60

## Using Disks in a ZFS Storage Pool

The most basic element of a storage pool is physical storage. Physical storage can be any block device of at least 128 MB in size. Typically, this device is a hard drive that is visible to the system in the /dev/dsk directory.

A storage device can be a whole disk (c1t0d0) or an individual slice (c0t0d0s7). The recommended mode of operation is to use an entire disk, in which case the disk does not
require special formatting. ZFS formats the disk using an EFI label to contain a single, large slice. When used in this way, the partition table that is displayed by the \texttt{format} command appears similar to the following:

\begin{verbatim}
Current partition table (original):
Total disk sectors available: 286722878 + 16384 (reserved sectors)

Part  Tag  Flag  First Sector  Size    Last Sector
   0    usr  wvm    34    136.72GB  286729911
  1  unassigned  wvm    0    0       0
  2  unassigned  wvm    0    0       0
  3  unassigned  wvm    0    0       0
  4  unassigned  wvm    0    0       0
  5  unassigned  wvm    0    0       0
  6  unassigned  wvm    0    0       0
  8  reserved  wvm  286722912  8.00MB  286739295
\end{verbatim}

To use a whole disk, the disk must be named by using the \texttt{/dev/dsk/cNtNdN} naming convention. Some third-party drivers use a different naming convention or place disks in a location other than the \texttt{/dev/dsk} directory. To use these disks, you must manually label the disk and provide a slice to ZFS.

ZFS applies an EFI label when you create a storage pool with whole disks. For more information about EFI labels, see “EFI Disk Label” in \textit{System Administration Guide: Devices and File Systems}.

A disk that is intended for a ZFS root pool must be created with an SMI label, not an EFI label. You can relabel a disk with an SMI label by using the \texttt{format -e} command.

Disks can be specified by using either the full path, such as \texttt{/dev/dsk/c1t0d0}, or a shorthand name that consists of the device name within the \texttt{/dev/dsk} directory, such as \texttt{c1t0d0}. For example, the following are valid disk names:

- \texttt{c1t0d0}
- \texttt{/dev/dsk/c1t0d0}
- \texttt{/dev/foo/disk}

Using whole physical disks is the easiest way to create ZFS storage pools. ZFS configurations become progressively more complex, from management, reliability, and performance perspectives, when you build pools from disk slices, LUNs in hardware RAID arrays, or volumes presented by software-based volume managers. The following considerations might help you determine how to configure ZFS with other hardware or software storage solutions:

- If you construct a ZFS configuration on top of LUNs from hardware RAID arrays, you need to understand the relationship between ZFS redundancy features and the redundancy features offered by the array. Certain configurations might provide adequate redundancy and performance, but other configurations might not.

- You can construct logical devices for ZFS using volumes presented by software-based volume managers, such as Solaris Volume Manager (SVM) or Veritas Volume Manager (VxVM). However, these configurations are not recommended. Although ZFS functions properly on such devices, less-than-optimal performance might be the result.
For additional information about storage pool recommendations, see the ZFS best practices site:

Disks are identified both by their path and by their device ID, if available. On systems where device ID information is available, this identification method allows devices to be reconfigured without updating ZFS. Because device ID generation and management can vary by system, export the pool first before moving devices, such as moving a disk from one controller to another controller. A system event, such as a firmware update or other hardware change, might change the device IDs in your ZFS storage pool, which can cause the devices to become unavailable.

**Using Slices in a ZFS Storage Pool**

Disks can be labeled with a traditional Solaris VTOC (SMI) label when you create a storage pool with a disk slice.

For a bootable ZFS root pool, the disks in the pool must contain slices and the disks must be labeled with an SMI label. The simplest configuration would be to put the entire disk capacity in slice 0 and use that slice for the root pool.

On a SPARC based system, a 72-GB disk has 68 GB of usable space located in slice 0 as shown in the following `format` output:

```
# format
.
.
.
Specify disk (enter its number): 4
selecting c1t1d0

Using Files in a ZFS Storage Pool

ZFS also allows you to use UFS files as virtual devices in your storage pool. This feature is aimed primarily at testing and enabling simple experimentation, not for production use. The reason is that any use of files relies on the underlying file system for consistency. If you create a ZFS pool backed by files on a UFS file system, then you are implicitly relying on UFS to guarantee correctness and synchronous semantics.

However, files can be quite useful when you are first trying out ZFS or experimenting with more complicated configurations when insufficient physical devices are present. All files must be specified as complete paths and must be at least 64 MB in size.

Replication Features of a ZFS Storage Pool

ZFS provides data redundancy, as well as self-healing properties, in mirrored and RAID-Z configurations.

- “Mirrored Storage Pool Configuration” on page 61
- “RAID-Z Storage Pool Configuration” on page 61
- “Self-Healing Data in a Redundant Configuration” on page 62
- “Dynamic Striping in a Storage Pool” on page 62
- “ZFS Hybrid Storage Pool” on page 62
Mirrored Storage Pool Configuration

A mirrored storage pool configuration requires at least two disks, preferably on separate controllers. Many disks can be used in a mirrored configuration. In addition, you can create more than one mirror in each pool. Conceptually, a basic mirrored configuration would look similar to the following:

mirror c1t0d0 c2t0d0

Conceptually, a more complex mirrored configuration would look similar to the following:

mirror c1t0d0 c2t0d0 c3t0d0 mirror c4t0d0 c5t0d0 c6t0d0

For information about creating a mirrored storage pool, see “Creating a Mirrored Storage Pool” on page 64.

RAID-Z Storage Pool Configuration

In addition to a mirrored storage pool configuration, ZFS provides a RAID-Z configuration with either single-, double-, or triple-parity fault tolerance. Single-parity RAID-Z (raidz or raidz1) is similar to RAID-5. Double-parity RAID-Z (raidz2) is similar to RAID-6.

For more information about RAIDZ-3 (raidz3), see the following blog:

http://blogs.sun.com/ahl/entry/triple_parity_raid_z

All traditional RAID-5-like algorithms (RAID-4, RAID-6, RDP, and EVEN-ODD, for example) might experience a problem known as the “RAID-5 write hole.” If only part of a RAID-5 stripe is written, and power is lost before all blocks have been written to disk, the parity will remain unsynchronized with the data, and therefore forever useless, (unless a subsequent full-stripe write overwrites it). In RAID-Z, ZFS uses variable-width RAID stripes so that all writes are full-stripe writes. This design is only possible because ZFS integrates file system and device management in such a way that the file system’s metadata has enough information about the underlying data redundancy model to handle variable-width RAID stripes. RAID-Z is the world’s first software-only solution to the RAID-5 write hole.

A RAID-Z configuration with N disks of size X with P parity disks can hold approximately (N-P)*X bytes and can withstand P device(s) failing before data integrity is compromised. You need at least two disks for a single-parity RAID-Z configuration and at least three disks for a double-parity RAID-Z configuration. For example, if you have three disks in a single-parity RAID-Z configuration, parity data occupies disk space equal to one of the three disks. Otherwise, no special hardware is required to create a RAID-Z configuration.

Conceptually, a RAID-Z configuration with three disks would look similar to the following:

raidz c1t0d0 c2t0d0 c3t0d0
Conceptually, a more complex RAID-Z configuration would look similar to the following:

raidz c1t0d0 c2t0d0 c3t0d0 c4t0d0 c5t0d0 c6t0d0 c7t0d0
raidz c8t0d0 c9t0d0 c10t0d0 c11t0d0 c12t0d0 c13t0d0 c14t0d0

If you are creating a RAID-Z configuration with many disks, consider splitting the disks into multiple groupings. For example, a RAID-Z configuration with 14 disks is better split into two 7-disk groupings. RAID-Z configurations with single-digit groupings of disks should perform better.

For information about creating a RAID-Z storage pool, see “Creating a RAID-Z Storage Pool” on page 65.

For more information about choosing between a mirrored configuration or a RAID-Z configuration based on performance and disk space considerations, see the following blog entry:

http://blogs.sun.com/roch/entry/when_to_and_not_to

For additional information about RAID-Z storage pool recommendations, see the ZFS best practices site:

ZFS Hybrid Storage Pool

The ZFS hybrid storage pool, available in Oracle's Sun Storage 7000 product series, is a special storage pool that combines DRAM, SSDs, and HDDs, to improve performance and increase capacity, while reducing power consumption. With this product’s management interface, you can select the ZFS redundancy configuration of the storage pool and easily manage other configuration options.

For more information about this product, see the Sun Storage Unified Storage System Administration Guide.

Self-Healing Data in a Redundant Configuration

ZFS provides self-healing data in a mirrored or RAID-Z configuration.

When a bad data block is detected, not only does ZFS fetch the correct data from another redundant copy, but it also repairs the bad data by replacing it with the good copy.

Dynamic Striping in a Storage Pool

ZFS dynamically stripes data across all top-level virtual devices. The decision about where to place data is done at write time, so no fixed-width stripes are created at allocation time.
When new virtual devices are added to a pool, ZFS gradually allocates data to the new device in order to maintain performance and disk space allocation policies. Each virtual device can also be a mirror or a RAID-Z device that contains other disk devices or files. This configuration gives you flexibility in controlling the fault characteristics of your pool. For example, you could create the following configurations out of four disks:

- Four disks using dynamic striping
- One four-way RAID-Z configuration
- Two two-way mirrors using dynamic striping

Although ZFS supports combining different types of virtual devices within the same pool, avoid this practice. For example, you can create a pool with a two-way mirror and a three-way RAID-Z configuration. However, your fault tolerance is as good as your worst virtual device, RAID-Z in this case. A best practice is to use top-level virtual devices of the same type with the same redundancy level in each device.

Creating and Destroying ZFS Storage Pools

The following sections describe different scenarios for creating and destroying ZFS storage pools:

- “Creating a ZFS Storage Pool” on page 63
- “Displaying Storage Pool Virtual Device Information” on page 68
- “Handling ZFS Storage Pool Creation Errors” on page 69
- “Destroying ZFS Storage Pools” on page 71

Creating and destroying pools is fast and easy. However, be cautious when performing these operations. Although checks are performed to prevent using devices known to be in use in a new pool, ZFS cannot always know when a device is already in use. Destroying a pool is easier than creating one. Use `zpool destroy` with caution. This simple command has significant consequences.

Creating a ZFS Storage Pool

To create a storage pool, use the `zpool create` command. This command takes a pool name and any number of virtual devices as arguments. The pool name must satisfy the naming requirements in “ZFS Component Naming Requirements” on page 45.

Creating a Basic Storage Pool

The following command creates a new pool named tank that consists of the disks `c1t0d0` and `c1t1d0`:

```
# zpool create tank c1t0d0 c1t1d0
```
Device names representing the whole disks are found in the `/dev/dsk` directory and are labeled appropriately by ZFS to contain a single, large slice. Data is dynamically striped across both disks.

**Creating a Mirrored Storage Pool**

To create a mirrored pool, use the `mirror` keyword, followed by any number of storage devices that will comprise the mirror. Multiple mirrors can be specified by repeating the `mirror` keyword on the command line. The following command creates a pool with two, two-way mirrors:

```
# zpool create tank mirror c1d0 c2d0 mirror c3d0 c4d0
```

The second `mirror` keyword indicates that a new top-level virtual device is being specified. Data is dynamically striped across both mirrors, with data being redundant between each disk appropriately.

For more information about recommended mirrored configurations, see the following site:

Currently, the following operations are supported in a ZFS mirrored configuration:

- Adding another set of disks for an additional top-level virtual device (vdev) to an existing mirrored configuration. For more information, see “Adding Devices to a Storage Pool” on page 73.
- Attaching additional disks to an existing mirrored configuration. Or, attaching additional disks to a non-replicated configuration to create a mirrored configuration. For more information, see “Attaching and Detaching Devices in a Storage Pool” on page 77.
- Replacing a disk or disks in an existing mirrored configuration as long as the replacement disks are greater than or equal to the size of the device to be replaced. For more information, see “Replacing Devices in a Storage Pool” on page 85.
- Detaching a disk in a mirrored configuration as long as the remaining devices provide adequate redundancy for the configuration. For more information, see “Attaching and Detaching Devices in a Storage Pool” on page 77.
- Splitting a mirrored configuration by detaching one of the disks to create a new, identical pool. For more information, see “Creating a New Pool By Splitting a Mirrored ZFS Storage Pool” on page 79.

You cannot outright remove a device that is not a log or a cache device from a mirrored storage pool. An RFE is filed for this feature.

**Creating a ZFS Root Pool**

You can install and boot from a ZFS root file system. Review the following root pool configuration information:
Disks used for the root pool must have a VTOC (SMI) label, and the pool must be created with disk slices.

The root pool must be created as a mirrored configuration or as a single-disk configuration. You cannot add additional disks to create multiple mirrored top-level virtual devices by using the `zpool add` command, but you can expand a mirrored virtual device by using the `zpool attach` command.

A RAID-Z or a striped configuration is not supported.

The root pool cannot have a separate log device.

If you attempt to use an unsupported configuration for a root pool, you see messages similar to the following:

```
ERROR: ZFS pool <pool-name> does not support boot environments

# zpool add -f rpool log c0t6d0s0
cannot add to 'rpool': root pool can not have multiple vdevs or separate logs
```

For more information about installing and booting a ZFS root file system, see Chapter 5, "Installing and Booting an Oracle Solaris ZFS Root File System."

### Creating a RAID-Z Storage Pool

Creating a single-parity RAID-Z pool is identical to creating a mirrored pool, except that the `raidz` or `raidz1` keyword is used instead of `mirror`. The following example shows how to create a pool with a single RAID-Z device that consists of five disks:

```
# zpool create tank raidz c1t0d0 c2t0d0 c3t0d0 c4t0d0 /dev/dsk/c5t0d0
```

This example illustrates that disks can be specified by using their shorthand device names or their full device names. Both `/dev/dsk/c5t0d0` and `c5t0d0` refer to the same disk.

You can create a double-parity or triple-parity RAID-Z configuration by using the `raidz2` or `raidz3` keyword when creating the pool. For example:

```
# zpool create tank raidz2 c1t0d0 c2t0d0 c3t0d0 c4t0d0 c5t0d0
```

```
# zpool status -v tank
pool: tank
state: ONLINE
scrub: none requested

errors: No known data errors

Currently, the following operations are supported in a ZFS RAID-Z configuration:

- Adding another set of disks for an additional top-level virtual device to an existing RAID-Z configuration. For more information, see “Adding Devices to a Storage Pool” on page 73.
- Replacing a disk or disks in an existing RAID-Z configuration as long as the replacement disks are greater than or equal to the size of the device to be replaced. For more information, see “Replacing Devices in a Storage Pool” on page 85.

Currently, the following operations are not supported in a RAID-Z configuration:

- Attaching an additional disk to an existing RAID-Z configuration.
- Detaching a disk from a RAID-Z configuration, except when you are detaching a disk that is replaced by a spare disk.
- You cannot outright remove a device that is not a log or a cache device from a RAID-Z configuration. An RFE is filed for this feature.

For more information about a RAID-Z configuration, see “RAID-Z Storage Pool Configuration” on page 61.

Creating a ZFS Storage Pool With Log Devices

By default, the ZIL is allocated from blocks within the main pool. However, better performance might be possible by using separate intent log devices, such as NVRAM or a dedicated disk. For more information about ZFS log devices, see “Setting Up Separate ZFS Log Devices” on page 30.

You can set up a ZFS log device when the storage pool is created or after the pool is created.

The following example shows how to create a mirrored storage pool with mirrored log devices:
Creating a ZFS Storage Pool With Cache Devices

You can create a storage pool with cache devices to cache storage pool data. For example:

```bash
# zpool create datap mirror c1t1d0 c1t2d0 mirror c1t3d0 c1t4d0 log mirror c1t5d0 c1t8d0
# zpool status datap
pool: datap
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

errors: No known data errors

For information about recovering from a log device failure, see Example 11–2.

Consider the following points when determining whether to create a ZFS storage pool with cache devices:

- Using cache devices provides the greatest performance improvement for random-read workloads of mostly static content.
- Capacity and reads can be monitored by using the `zpool iostat` command.
- Single or multiple cache devices can be added when the pool is created. They can also be added and removed after the pool is created. For more information, see Example 4–4.
- Cache devices cannot be mirrored or be part of a RAID-Z configuration.
- If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or a RAID-Z configuration. The content of the cache devices is considered volatile, similar to other system caches.

### Displaying Storage Pool Virtual Device Information

Each storage pool contains one or more virtual devices. A virtual device is an internal representation of the storage pool that describes the layout of physical storage and the storage pool’s fault characteristics. As such, a virtual device represents the disk devices or files that are used to create the storage pool. A pool can have any number of virtual devices at the top of the configuration, known as a top-level vdev.

If the top-level virtual device contains two or more physical devices, the configuration provides data redundancy as mirror or RAID-Z virtual devices. These virtual devices consist of disks, disk slices, or files. A spare is a special virtual dev that tracks available hot spares for a pool.

The following example shows how to create a pool that consists of two top-level virtual devices, each a mirror of two disks:

```
# zpool create tank mirror c1d0 c2d0 mirror c3d0 c4d0
```

The following example shows how to create a pool that consists of one top-level virtual device of four disks:

```
# zpool create mypool raidz2 c1d0 c2d0 c3d0 c4d0
```

You can add another top-level virtual device to this pool by using the `zpool add` command. For example:

```
# zpool add mypool raidz2 c2d1 c3d1 c4d1 c5d1
```

Disks, disk slices, or files that are used in nonredundant pools function as top-level virtual devices. Storage pools typically contain multiple top-level virtual devices. ZFS dynamically stripes data among all of the top-level virtual devices in a pool.

Virtual devices and the physical devices that are contained in a ZFS storage pool are displayed with the `zpool status` command. For example:

```
# zpool status tank
pool: tank
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```
Handling ZFS Storage Pool Creation Errors

Pool creation errors can occur for many reasons. Some reasons are obvious, such as when a specified device doesn’t exist, while other reasons are more subtle.

Detecting In-Use Devices

Before formatting a device, ZFS first determines if the disk is in-use by ZFS or some other part of the operating system. If the disk is in use, you might see errors such as the following:

```
# zpool create tank c1t0d0 c1t1d0
invalid vdev specification
use '-f' to override the following errors:
/dev/dsk/c1t0d0s0 is currently mounted on /. Please see umount(1M).
/dev/dsk/c1t0d0s1 is currently mounted on swap. Please see swap(1M).
/dev/dsk/c1t1d0s0 is part of active ZFS pool zeepool. Please see zpool(1M).
```

Some errors can be overridden by using the -f option, but most errors cannot. The following conditions cannot be overridden by using the -f option, and you must manually correct them:

- **Mounted file system**
  - The disk or one of its slices contains a file system that is currently mounted. To correct this error, use the `umount` command.

- **File system in /etc/vfstab**
  - The disk contains a file system that is listed in the `/etc/vfstab` file, but the file system is not currently mounted. To correct this error, remove or comment out the line in the `/etc/vfstab` file.

- **Dedicated dump device**
  - The disk is in use as the dedicated dump device for the system. To correct this error, use the `dumpadm` command.

- **Part of a ZFS pool**
  - The disk or file is part of an active ZFS storage pool. To correct this error, use the `zpool destroy` command to destroy the other pool, if it is no longer needed. Or, use the `zpool detach` command to detach the disk from the other pool. You can only detach a disk from a mirrored storage pool.

The following in-use checks serve as helpful warnings and can be overridden by using the -f option to create the pool.
Contains a file system  The disk contains a known file system, though it is not mounted and doesn’t appear to be in use.

Part of volume  The disk is part of a Solaris Volume Manager volume.

Live upgrade  The disk is in use as an alternate boot environment for Oracle Solaris Live Upgrade.

Part of exported ZFS pool  The disk is part of a storage pool that has been exported or manually removed from a system. In the latter case, the pool is reported as potentially active, as the disk might or might not be a network-attached drive in use by another system. Be cautious when overriding a potentially active pool.

The following example demonstrates how the -f option is used:

```
# zpool create tank c1t0d0
invalid vdev specification
use '-f' to override the following errors:
/dev/dsk/c1t0d0s0 contains a ufs filesystem.
# zpool create -f tank c1t0d0
```

Ideally, correct the errors rather than use the -f option to override them.

Mismatched Replication Levels
Creating pools with virtual devices of different replication levels is not recommended. The zpool command tries to prevent you from accidentally creating a pool with mismatched levels of redundancy. If you try to create a pool with such a configuration, you see errors similar to the following:

```
# zpool create tank c1t0d0 mirror c2t0d0 c3t0d0
invalid vdev specification
use '-f' to override the following errors:
mismatched replication level: both disk and mirror vdevs are present
# zpool create tank mirror c1t0d0 c2t0d0 mirror c3t0d0 c4t0d0 c5t0d0
invalid vdev specification
use '-f' to override the following errors:
mismatched replication level: 2-way mirror and 3-way mirror vdevs are present
```

You can override these errors with the -f option, but you should avoid this practice. The command also warns you about creating a mirrored or RAID-Z pool using devices of different sizes. Although this configuration is allowed, mismatched levels of redundancy result in unused disk space on the larger device. The -f option is required to override the warning.

Doing a Dry Run of Storage Pool Creation
Attempts to create a pool can fail unexpectedly in different ways, and formatting disks is a potentially harmful action. For these reasons, the zpool create command has an additional
option, -n, which simulates creating the pool without actually writing to the device. This dry run option performs the device in-use checking and replication-level validation, and reports any errors in the process. If no errors are found, you see output similar to the following:

```
# zpool create -n tank mirror c1t0d0 c1t1d0
```

would create ‘tank’ with the following layout:

```
  tank
    mirror
    c1t0d0
    c1t1d0
```

Some errors cannot be detected without actually creating the pool. The most common example is specifying the same device twice in the same configuration. This error cannot be reliably detected without actually writing the data, so the `zpool create -n` command can report success and yet fail to create the pool when the command is run without this option.

### Default Mount Point for Storage Pools

When a pool is created, the default mount point for the top-level dataset is `/pool-name`. This directory must either not exist or be empty. If the directory does not exist, it is automatically created. If the directory is empty, the root dataset is mounted on top of the existing directory.

To create a pool with a different default mount point, use the `-m` option of the `zpool create` command. For example:

```
# zpool create home c1t0d0
```

default mountpoint '/home' exists and is not empty
use `-m` option to provide a different default
# zpool create -m /export/zfs home c1t0d0
```

This command creates the new pool `home` and the `home` dataset with a mount point of `/export/zfs`.

For more information about mount points, see “Managing ZFS Mount Points” on page 190.

### Destroying ZFS Storage Pools

Pools are destroyed by using the `zpool destroy` command. This command destroys the pool even if it contains mounted datasets.

```
# zpool destroy tank
```
Caution – Be very careful when you destroy a pool. Ensure that you are destroying the right pool and you always have copies of your data. If you accidentally destroy the wrong pool, you can attempt to recover the pool. For more information, see “Recovering Destroyed ZFS Storage Pools” on page 107.

Destroying a Pool With Faulted Devices

The act of destroying a pool requires data to be written to disk to indicate that the pool is no longer valid. This state information prevents the devices from showing up as a potential pool when you perform an import. If one or more devices are unavailable, the pool can still be destroyed. However, the necessary state information won’t be written to these unavailable devices.

These devices, when suitably repaired, are reported as potentially active when you create a new pool. They appear as valid devices when you search for pools to import. If a pool has enough faulted devices such that the pool itself is faulted (meaning that a top-level virtual device is faulted), then the command prints a warning and cannot complete without the -f option. This option is necessary because the pool cannot be opened, so whether data is stored there is unknown. For example:

```
# zpool destroy tank
cannot destroy ‘tank’: pool is faulted
use ‘-f’ to force destruction anyway
# zpool destroy -f tank
```

For more information about pool and device health, see “Determining the Health Status of ZFS Storage Pools” on page 100.

For more information about importing pools, see “Importing ZFS Storage Pools” on page 106.

Managing Devices in ZFS Storage Pools

Most of the basic information regarding devices is covered in “Components of a ZFS Storage Pool” on page 57. After a pool has been created, you can perform several tasks to manage the physical devices within the pool.

- “Adding Devices to a Storage Pool” on page 73
- “ Attaching and Detaching Devices in a Storage Pool” on page 77
- “Creating a New Pool By Splitting a Mirrored ZFS Storage Pool” on page 79
- “Onlineing and Offlining Devices in a Storage Pool” on page 82
- “Clearing Storage Pool Device Errors” on page 84
- “Replacing Devices in a Storage Pool” on page 85
- “Designating Hot Spares in Your Storage Pool” on page 87
Adding Devices to a Storage Pool

You can dynamically add disk space to a pool by adding a new top-level virtual device. This disk space is immediately available to all datasets in the pool. To add a new virtual device to a pool, use the `zpool add` command. For example:

```
# zpool add zeepool mirror c2t1d0 c2t2d0
```

The format for specifying the virtual devices is the same as for the `zpool create` command. Devices are checked to determine if they are in use, and the command cannot change the level of redundancy without the `-f` option. The command also supports the `-n` option so that you can perform a dry run. For example:

```
# zpool add -n zeepool mirror c3t1d0 c3t2d0
```

would update `zeepool` to the following configuration:

```
zeepool
  mirror
    c1t0d0
    c1t1d0
  mirror
    c2t1d0
    c2t2d0
  mirror
    c3t1d0
    c3t2d0
```

This command syntax would add mirrored devices `c3t1d0` and `c3t2d0` to the `zeepool` pool's existing configuration.

For more information about how virtual device validation is done, see "Detecting In-Use Devices" on page 69.

**EXAMPLE 4-1  Adding Disks to a Mirrored ZFS Configuration**

In the following example, another mirror is added to an existing mirrored ZFS configuration on Oracle's Sun Fire x4500 system.

```
# zpool status tank
pool: tank
  state: ONLINE
  scrub: none requested
config:
  NAME  STATE  READ  WRITE  CKSUM
  tank  ONLINE  0     0     0
  mirror-0 ONLINE  0     0     0
c0t1d0 ONLINE  0     0     0
c1t1d0 ONLINE  0     0     0
  mirror-1 ONLINE  0     0     0
c0t2d0 ONLINE  0     0     0
c1t2d0 ONLINE  0     0     0
```
EXAMPLE 4–1  Adding Disks to a Mirrored ZFS Configuration  

(Continued)

errors: No known data errors
# zpool add tank mirror c0t3d0 c1t3d0
# zpool status tank
  pool: tank
  state: ONLINE
  scrub: none requested
  config:

  NAME   STATE  READ  WRITE  CKSUM
  tank   ONLINE  0 0 0
  mirror-0 ONLINE  0 0 0
  c0t1d0  ONLINE  0 0 0
  c1t1d0  ONLINE  0 0 0
  mirror-1 ONLINE  0 0 0
  c0t2d0  ONLINE  0 0 0
  c1t2d0  ONLINE  0 0 0
  mirror-2 ONLINE  0 0 0
  c0t3d0  ONLINE  0 0 0
  c1t3d0  ONLINE  0 0 0

errors: No known data errors

EXAMPLE 4–2  Adding Disks to a RAID-Z Configuration

Additional disks can be added similarly to a RAID-Z configuration. The following example
shows how to convert a storage pool with one RAID-Z device that contains three disks to a
storage pool with two RAID-Z devices that contains three disks each.

# zpool status rzpool
  pool: rzpool
  state: ONLINE
  scrub: none requested
  config:

  NAME   STATE  READ  WRITE  CKSUM
  rzpool ONLINE  0 0 0
  raidz1-0 ONLINE  0 0 0
  c1t0d0  ONLINE  0 0 0
  c1t3d0  ONLINE  0 0 0
  c1t4d0  ONLINE  0 0 0

errors: No known data errors
# zpool add rzpool raidz c2t2d0 c2t3d0 c2t4d0
# zpool status rzpool
  pool: rzpool
  state: ONLINE
  scrub: none requested
  config:

  NAME   STATE  READ  WRITE  CKSUM
  rzpool ONLINE  0 0 0
  raidz1-0 ONLINE  0 0 0
  c1t0d0  ONLINE  0 0 0
  c1t2d0  ONLINE  0 0 0
EXAMPLE 4–2  Adding Disks to a RAID-Z Configuration

(Continued)

c1t3d0 ONLINE 0 0 0
raidz1-1 ONLINE 0 0 0
c2t2d0 ONLINE 0 0 0
c2t3d0 ONLINE 0 0 0
c2t4d0 ONLINE 0 0 0

errors: No known data errors

EXAMPLE 4–3  Adding and Removing a Mirrored Log Device

The following examples show how to add a mirrored log device to mirrored storage pool. For more information about using log devices in your storage pool, see “Setting Up Separate ZFS Log Devices” on page 30.

# zpool status newpool
pool: newpool
state: ONLINE
scrub: none requested
cfg:

NAME   STATE  READ  WRITE  CKSUM
newpool ONLINE 0 0 0
mirror-0 ONLINE 0 0 0
c0t4d0 ONLINE 0 0 0
c0t5d0 ONLINE 0 0 0

errors: No known data errors

# zpool add newpool log mirror c0t6d0 c0t7d0

# zpool status newpool
pool: newpool
state: ONLINE
scrub: none requested
cfg:

NAME   STATE  READ  WRITE  CKSUM
newpool ONLINE 0 0 0
mirror-0 ONLINE 0 0 0
c0t4d0 ONLINE 0 0 0
c0t5d0 ONLINE 0 0 0
logs
mirror-1 ONLINE 0 0 0
c0t6d0 ONLINE 0 0 0
c0t7d0 ONLINE 0 0 0

errors: No known data errors

You can attach a log device to an existing log device to create a mirrored log device. This operation is identical to attaching a device in a unmirrored storage pool.

Log devices can be removed by using the zpool remove command. The mirrored log device in the previous example can be removed by specifying the mirror-1 argument. For example:
EXAMPLE 4-3  Adding and Removing a Mirrored Log Device  (Continued)

# zpool remove newpool mirror-1
# zpool status newpool
  pool: newpool
  state: ONLINE
  scrub: none requested
  config:
  
<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>newpool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t4d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t5d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors

If your pool configuration only contains one log device, you would remove the log device by specifying the device name. For example:

# zpool status pool
  pool: pool
  state: ONLINE
  scrub: none requested
  config:
  
<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>raidz1-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t8d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t9d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>logs</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c0t10d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors
# zpool remove pool c0t10d0

EXAMPLE 4-4  Adding and Removing Cache Devices

You can add to your ZFS storage pool and remove them if they are no longer required.

Use the zpool add command to add cache devices. For example:

# zpool add tank cache c2t5d0 c2t8d0
# zpool status tank
  pool: tank
  state: ONLINE
  scrub: none requested
  config:
  
<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c2t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c2t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
Adding and Removing Cache Devices

(Continued)

errors: No known data errors

Cache devices cannot be mirrored or be part of a RAID-Z configuration.

Use the `zpool remove` command to remove cache devices. For example:

```
# zpool remove tank c2t5d0 c2t8d0
# zpool status tank
pool: tank
  state: ONLINE
  scrub: none requested
  config:
    NAME     STATE  READ  WRITE  CKSUM
    tank    ONLINE   0     0      0
    mirror-0 ONLINE   0     0      0
    c2t3d0  ONLINE   0     0      0
    c2t8d0  ONLINE   0     0      0
errors: No known data errors
```

Currently, the `zpool remove` command only supports removing hot spares, log devices, and cache devices. Devices that are part of the main mirrored pool configuration can be removed by using the `zpool detach` command. Nonredundant and RAID-Z devices cannot be removed from a pool.

For more information about using cache devices in a ZFS storage pool, see “Creating a ZFS Storage Pool With Cache Devices” on page 67.

Attaching and Detaching Devices in a Storage Pool

In addition to the `zpool add` command, you can use the `zpool attach` command to add a new device to an existing mirrored or nonmirrored device.

If you are attaching a disk to create a mirrored root pool, see “How to Create a Mirrored Root Pool (Post Installation)” on page 121.

If you are replacing a disk in a ZFS root pool, see "How to Replace a Disk in the ZFS Root Pool" on page 159.
Converting a Two-Way Mirrored Storage Pool to a Three-way Mirrored Storage Pool

In this example, zeepool is an existing two-way mirror that is converted to a three-way mirror by attaching c2t1d0, the new device, to the existing device, c1t1d0.

```bash
# zpool status zeepool
pool: zeepool
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>zeepool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors
```

```bash
# zpool attach zeepool c1t1d0 c2t1d0
# zpool status zeepool
pool: zeepool
state: ONLINE
scrub: resilver completed after 0h0m with 0 errors on Fri Jan 8 12:59:20 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>zeepool</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c2t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>592K resilvered</td>
</tr>
</tbody>
</table>

errors: No known data errors
```

If the existing device is part of a three-way mirror, attaching the new device creates a four-way mirror, and so on. Whatever the case, the new device begins to resilver immediately.

Converting a Nonredundant ZFS Storage Pool to a Mirrored ZFS Storage Pool

In addition, you can convert a nonredundant storage pool to a redundant storage pool by using the `zpool attach` command. For example:

```bash
# zpool create tank c0t1d0
# zpool status tank
pool: tank
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors
```

```bash
# zpool attach tank c0t1d0 c1t1d0
# zpool status tank
```

Managing Devices in ZFS Storage Pools
Converting a Nonredundant ZFS Storage Pool to a Mirrored ZFS Storage Pool  
(Continued)

pool: tank  
state: ONLINE  
scrub: resilver completed after 0h0m with 0 errors on Fri Jan 8 14:28:23 2010  
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>73.5K resilvered</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

effects: No known data errors

You can use the `zpool detach` command to detach a device from a mirrored storage pool. For example:

```
# zpool detach zeepool c2t1d0
```

However, this operation fails if no other valid replicas of the data exist. For example:

```
# zpool detach newpool c1t2d0  
cannot detach c1t2d0: only applicable to mirror and replacing vdevs
```

### Creating a New Pool By Splitting a Mirrored ZFS Storage Pool

A mirrored ZFS storage pool can be quickly cloned as a backup pool by using the `zpool split` command.

Currently, this feature cannot be used to split a mirrored root pool.

You can use the `zpool split` command to detach disks from a mirrored ZFS storage pool to create a new pool with one of the detached disks. The new pool will have identical contents to the original mirrored ZFS storage pool.

By default, a `zpool split` operation on a mirrored pool detaches the last disk for the newly created pool. After the split operation, import the new pool. For example:

```
# zpool status tank  
--pool: tank  
state: ONLINE  
scrub: none requested  
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
</table>
```

---

Managing Devices in ZFS Storage Pools

Chapter 4 • Managing Oracle Solaris ZFS Storage Pools

79
errors: No known data errors

# zpool split tank tank2
# zpool import tank2
# zpool status tank tank2

You can identify which disk should be used for the newly created pool by specifying it with the `zpool split` command. For example:

```
# zpool split tank tank2 c1t0d0
```

Before the actual split operation occurs, data in memory is flushed to the mirrored disks. After the data is flushed, the disk is detached from the pool and given a new pool GUID. A new pool GUID is generated so that the pool can be imported on the same system on which it was split.

If the pool to be split has non-default dataset mount points and the new pool is created on the same system, then you will need to use the `zpool split -R` option to identify an alternate root directory for the new pool so that any existing mount points do not conflict. For example:

```
# zpool split -R /tank2 tank tank2
```

If you don’t use the `zpool split -R` option and you can see that mount points conflict when you attempt to import the new pool, import the new pool with the `-R` option. If the new pool is created on a different system, then specifying an alternate root directory should not be necessary unless mount point conflicts occur.
Review the following considerations before using the `zpool split` feature:

- This feature is not available for a RAIDZ configuration or a non-redundant pool of multiple disks.
- Data and application operations should be quiesced before attempting a `zpool split` operation.
- Having disks that honor, rather than ignore, the disk's flush write cache command is important.
- A pool cannot be split if resilvering is in process.
- Splitting a mirrored pool is optimal when composed of two to three disks, where the last disk in the original pool is used for the newly created pool. Then, you can use the `zpool attach` command to recreate your original mirrored storage pool or convert your newly created pool into a mirrored storage pool. No way currently exists to create a new mirrored pool from an *existing* mirrored pool by using this feature.
- If the existing pool is a three-way mirror, then the new pool will contain one disk after the split operation. If the existing pool is a two-way mirror of two disks, then the outcome is two non-redundant pools of two disks. You will need to attach two additional disks to convert the non-redundant pools to mirrored pools.
- A good way to keep your data redundant during a split operation is to split a mirrored storage pool that is composed of three disks so that the original pool is comprised of two mirrored disks after the split operation.

**EXAMPLE 4-7  Splitting a Mirrored ZFS Pool**

In the following example, a mirrored storage pool called `trinity`, with three disks, `c1t0d0`, `c1t2d0` and `c1t3d0` is split. The two resulting pools are the mirrored pool `trinity`, with disks `c1t0d0` and `c1t2d0`, and the new pool, `neo`, with disk `c1t3d0`. Each pool has identical content.

```bash
# zpool status trinity
pool: trinity
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>trinity</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t2d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors
# zpool split trinity neo
# zpool import neo
# zpool status trinity neo
pool: neo
state: ONLINE
```
### Onlining and Offlining Devices in a Storage Pool

ZFS allows individual devices to be taken offline or brought online. When hardware is unreliable or not functioning properly, ZFS continues to read data from or write data to the device, assuming the condition is only temporary. If the condition is not temporary, you can instruct ZFS to ignore the device by taking it offline. ZFS does not send any requests to an offline device.

**Note** – Devices do not need to be taken offline in order to replace them.

You can use the `zpool offline` command when you need to temporarily disconnect storage. For example, if you need to physically disconnect an array from one set of Fibre Channel switches and connect the array to a different set, you can take offline the LUNs from the array that is used in the ZFS storage pools. After the array is reconnected and operational on the new set of switches, you can then bring the same LUNs online. Data that had been added to the storage pools while the LUNs were offline would resilver to the LUNs after they are brought back online.

This scenario is possible assuming that the systems in question can detect the storage after it is attached to the new switches, possibly through different controllers than before, and your pools are set up as RAID-Z or mirrored configurations.
Taking a Device Offline

You can take a device offline by using the `zpool offline` command. The device can be specified by path or by short name, if the device is a disk. For example:

```
# zpool offline tank clt0d0
bringing device clt0d0 offline
```

Consider the following points when taking a device offline:

- You cannot take a pool offline to the point where it becomes faulted. For example, you cannot take offline two devices in a raidz1 configuration, nor can you take offline a top-level virtual device.

```
# zpool offline tank clt0d0
cannot offline clt0d0: no valid replicas
```

- By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted.

To temporarily take a device offline, use the `zpool offline -t` option. For example:

```
# zpool offline -t tank clt0d0
bringing device 'clt0d0' offline
```

When the system is rebooted, this device is automatically returned to the ONLINE state.

- When a device is taken offline, it is not detached from the storage pool. If you attempt to use the offline device in another pool, even after the original pool is destroyed, you see a message similar to the following:

```
device is part of exported or potentially active ZFS pool. Please see zpool(1M)
```

If you want to use the offline device in another storage pool after destroying the original storage pool, first bring the device online, then destroy the original storage pool.

Another way to use a device from another storage pool, while keeping the original storage pool, is to replace the existing device in the original storage pool with another comparable device. For information about replacing devices, see "Replacing Devices in a Storage Pool" on page 85.

Offline devices are in the OFFLINE state when you query pool status. For information about querying pool status, see "Querying ZFS Storage Pool Status" on page 95.

For more information on device health, see "Determining the Health Status of ZFS Storage Pools" on page 100.

Bringing a Device Online

After a device is taken offline, it can be brought online again by using the `zpool online` command. For example:
# zpool online tank c1t0d0

When a device is brought online, any data that has been written to the pool is resynchronized with the newly available device. Note that you cannot use bring a device online to replace a disk. If you take a device offline, replace the device, and try to bring it online, it remains in the faulted state.

If you attempt to bring online a faulted device, a message similar to the following is displayed:

# zpool online tank c1t0d0

warning: device 'c1t0d0' onlined, but remains in faulted state
use 'zpool replace' to replace devices that are no longer present

You might also see the faulted disk message displayed on the console or written to the /var/adm/messages file. For example:

SUNW-MSG-ID: ZFS-8000-D3, TYPE: Fault, VER: 1, SEVERITY: Major
PLATFORM: SUNW,Sun-Fire-880, CSN: -, HOSTNAME: neo
SOURCE: zfs-diagnosis, REV: 1.0
EVENT-ID: 504a1188-b270-4ab0-af4e-8a77600576b8
AUTO-RESPONSE: No automated response will occur.
IMPACT: Fault tolerance of the pool may be compromised.
REC-ACTION: Run 'zpool status -x' and replace the bad device.

For more information about replacing a faulted device, see "Resolving a Missing Device" on page 276.

You can use the zpool online -e command to expand the pool's size when a smaller disk is replaced by a larger disk. By default, pool size is not expanded to its full size unless the autoexpand pool property is enabled. You can expand the pool size automatically when a smaller disk is replaced by a larger disk by using the zpool online -e command even if the disk is already online or if the disk is currently offline. For example:

# zpool online -e tank c1t13d0

Clearing Storage Pool Device Errors

If a device is taken offline due to a failure that causes errors to be listed in the zpool status output, you can clear the error counts with the zpool clear command.

If specified with no arguments, this command clears all device errors within the pool. For example:

# zpool clear tank
If one or more devices are specified, this command only clear errors associated with the specified devices. For example:

```
# zpool clear tank c1t0d0
```

For more information about clearing zpool errors, see “Clearing Transient Errors” on page 279.

---

**Replacing Devices in a Storage Pool**

You can replace a device in a storage pool by using the `zpool replace` command.

If you are physically replacing a device with another device in the same location in a redundant pool, then you might only need to identify the replaced device. ZFS recognizes that the device is a different disk in the same location on some hardware. For example, to replace a failed disk (`c1t1d0`) by removing the disk and replacing it in the same location, use the following syntax:

```
# zpool replace tank c1t1d0
```

If you are replacing a device in a storage pool with a disk in a different physical location, you will need to specify both devices. For example:

```
# zpool replace tank c1t0d0 c1t2d0
```

If you are replacing a disk in the ZFS root pool, see “How to Replace a Disk in the ZFS Root Pool” on page 159.

The following are the basic steps for replacing a disk:

- Offline the disk, if necessary, with the `zpool offline` command.
- Remove the disk to be replaced.
- Insert the replacement disk.
- Run the `zpool replace` command. For example:

  ```
  # zpool replace tank c1t1d0
  ```

- Bring the disk online with the `zpool online` command.

On some systems, such as the Sun Fire x4500, you must unconfigure a disk before you can take it offline. If you are replacing a disk in the same slot position on this system, then you can just run the `zpool replace` command as described in the first example in this section.

For an example of replacing a disk on a Sun Fire X4500 system, see Example 11–1.
Consider the following when replacing devices in a ZFS storage pool:

- If you set the `autoreplace` pool property to on, then any new device found in the same physical location as a device that previously belonged to the pool is automatically formatted and replaced. You are not required to use the `zpool replace` command when this property is enabled. This feature might not be available on all hardware types.

- The size of the replacement device must be equal to or larger than the smallest disk in a mirrored or RAID-Z configuration.

- When a replacement device that is greater in size than the device it is replacing is added to a pool, is not automatically expanded to its full size. The `autoexpand` pool property value determines whether a pool is expanded to its full size when the disk is added to the pool. By default, the `autoexpand` property is disabled. You can enable this property to expand a pool's size before or after the larger disk is added to the pool.

In the following example, two 16-GB disks in a mirrored pool are replaced with two 72-GB disks. The `autoexpand` property is enabled after the disk replacements to expand the full disk sizes.

```bash
# zpool create pool mirror c1t16d0 c1t17d0
# zpool status
pool: pool
  state: ONLINE
  scrub: none requested
cfg:

  NAME  STATE  READ  WRITE  CKSUM
  pool   ONLINE  0    0      0
  mirror ONLINE  0    0      0
  c1t16d0 ONLINE  0    0      0
  c1t17d0 ONLINE  0    0      0

zpool list pool
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
pool  16.8G  76.5K  16.7G  0%  ONLINE -

# zpool replace pool c1t16d0 c1t1d0
# zpool replace pool c1t17d0 c1t2d0
# zpool list pool
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
pool  16.8G  88.5K  16.7G  0%  ONLINE -

# zpool set autoexpand=on pool
# zpool list pool
NAME  SIZE  ALLOC  FREE  CAP  HEALTH  ALTROOT
pool  68.2G 117K  68.2G  0%  ONLINE -
```

- Replacing many disks in a large pool is time-consuming due to resilvering the data onto the new disks. In addition, you might consider running the `zpool scrub` command between disk replacements to ensure that the replacement devices are operational and that the data is written correctly.

- If a failed disk has been replaced automatically with a hot spare, then you might need to detach the spare after the failed disk is replaced. For information about detaching a hot spare, see “Activating and Deactivating Hot Spares in Your Storage Pool” on page 88.
For more information about replacing devices, see "Resolving a Missing Device" on page 276 and "Replacing or Repairing a Damaged Device" on page 278.

**Designating Hot Spares in Your Storage Pool**

The hot spares feature enables you to identify disks that could be used to replace a failed or faulted device in one or more storage pools. Designating a device as a *hot spare* means that the device is not an active device in the pool, but if an active device in the pool fails, the hot spare automatically replaces the failed device.

Devices can be designated as hot spares in the following ways:

- When the pool is created with the `zpool create` command.
- After the pool is created with the `zpool add` command.

The following example shows how to designate devices as hot spares when the pool is created:

```
# zpool create trinity mirror c1t1d0 c2t1d0 spare c1t2d0 c2t2d0
# zpool status trinity
pool: trinity
  state: ONLINE
  scrub: none requested
config:

  NAME   STATE        READ  WRITE CKSUM
  trinity ONLINE      0      0     0
  mirror-0 ONLINE      0      0     0
  c1t1d0  ONLINE      0      0     0
  c2t1d0  ONLINE      0      0     0
  spares
  c1t2d0  AVAIL
  c2t2d0  AVAIL

errors: No known data errors
```

The following example shows how to designate hot spares by adding them to a pool after the pool is created:

```
# zpool add neo spare c5t3d0 c6t3d0
# zpool status neo
pool: neo
  state: ONLINE
  scrub: none requested
config:

  NAME   STATE        READ  WRITE CKSUM
  neo     ONLINE      0      0     0
  mirror-0 ONLINE      0      0     0
  c3t3d0  ONLINE      0      0     0
  c4t3d0  ONLINE      0      0     0
  spares
```
Hot spares can be removed from a storage pool by using the `zpool remove` command. For example:

```
# zpool remove zeepool c2t3d0
# zpool status zeepool
pool: zeepool
  state: ONLINE
  scrub: none requested
config:
  NAME    STATE  READ  WRITE CKSUM
  zeepool ONLINE 0 0 0
  mirror-0 ONLINE 0 0 0
  c1t1d0  ONLINE 0 0 0
  c2t1d0  ONLINE 0 0 0
  spares
    c1t3d0  AVAIL
errors: No known data errors
```

A hot spare cannot be removed if it is currently used by a storage pool.

Consider the following when using ZFS hot spares:

- Currently, the `zpool remove` command can only be used to remove hot spares, cache devices, and log devices.
- To add a disk as a hot spare, the hot spare must be equal to or larger than the size of the largest disk in the pool. Adding a smaller disk as a spare to a pool is allowed. However, when the smaller spare disk is activated, either automatically or with the `zpool replace` command, the operation fails with an error similar to the following:

```
cannot replace disk3 with disk4: device is too small
```

### Activating and Deactivating Hot Spares in Your Storage Pool

Hot spares are activated in the following ways:

- Manual replacement – You replace a failed device in a storage pool with a hot spare by using the `zpool replace` command.
- Automatic replacement – When a fault is detected, an FMA agent examines the pool to determine if it has any available hot spares. If so, it replaces the faulted device with an available spare.
If a hot spare that is currently in use fails, the FMA agent detaches the spare and thereby cancels the replacement. The agent then attempts to replace the device with another hot spare, if one is available. This feature is currently limited by the fact that the ZFS diagnostic engine only generates faults when a device disappears from the system.

If you physically replace a failed device with an active spare, you can reactivate the original device by using the `zpool detach` command to detach the spare. If you set the `autoreplace` pool property to `on`, the spare is automatically detached and returned to the spare pool when the new device is inserted and the online operation completes.

You can manually replace a device with a hot spare by using the `zpool replace` command. See Example 4–8.

A faulted device is automatically replaced if a hot spare is available. For example:

```
# zpool status -x
pool: zeepool
state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
scrub: resilver completed after 0h0m with 0 errors on Mon Jan 11 10:20:35 2010
config:
  NAME    STATE   READ  WRITE CKSUM
  zeepool DEGRADED 0 0 0
  mirror-0 DEGRADED 0 0 0
c1t2d0  ONLINE 0 0 0
  spare-1 DEGRADED 0 0 0
c2t1d0  UNAVAIL 0 0 0 cannot open
c2t3d0  ONLINE 0 0 0 88.5K resilvered
  spares
c2t3d0  INUSE currently in use
errors: No known data errors
```

Currently, you can deactivate a hot spare in the following ways:

- By removing the hot spare from the storage pool.
- By detaching a hot spare after a failed disk is physically replaced. See Example 4–9.
- By temporarily or permanently swapping in the hot spare. See Example 4–10.

**EXAMPLE 4–8  Manually Replacing a Disk With a Hot Spare**

In this example, the `zpool replace` command is used to replace disk `c2t1d0` with the hot spare `c2t3d0`.

```
# zpool replace zeepool c2t1d0 c2t3d0
# zpool status zeepool
  pool: zeepool
  state: ONLINE
```
EXAMPLE 4–8  Manually Replacing a Disk With a Hot Spare  (Continued)

scrub: resilver completed after 0h0m with 0 errors on Wed Jan 20 10:00:50 2010

Managing Devices in ZFS Storage Pools
Detaching a Hot Spare After the Failed Disk Is Replaced (Continued)

Then, you can use the `zpool detach` command to return the hot spare back to the spare pool. For example:

```
# zpool detach zeepool c2t3d0
# zpool status zeepool
  pool: zeepool
  state: ONLINE
  scrub: resilver completed with 0 errors on Wed Jan 20 10:08:44 2010
  config:

  NAME     STATE  READ  WRITE CKSUM
  zeepool  ONLINE 0    0    0
  mirror   ONLINE 0    0    0
  c1t2d0   ONLINE 0    0    0
  c2t1d0   ONLINE 0    0    0
  spares
  c2t3d0   AVAIL

errors: No known data errors
```

Detaching a Failed Disk and Using the Hot Spare

If you want to replace a failed disk by temporarily or permanently swap in the hot spare that is currently replacing it, then detach the original (failed) disk. If the failed disk is eventually replaced, then you can add it back to the storage pool as a spare. For example:

```
# zpool status zeepool
  pool: zeepool
  state: DEGRADED
  status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state.
  action: Attach the missing device and online it using ‘zpool online’.

Managing ZFS Storage Pool Properties

You can use the `zpool get` command to display pool property information. For example:

# zpool get all mpool

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool</td>
<td>size</td>
<td>68G</td>
<td>-</td>
</tr>
<tr>
<td>pool</td>
<td>capacity</td>
<td>%</td>
<td>-</td>
</tr>
<tr>
<td>pool</td>
<td>altroot</td>
<td>-</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>health</td>
<td>ONLINE</td>
<td>-</td>
</tr>
<tr>
<td>pool</td>
<td>guid</td>
<td>601891032394735745</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>version</td>
<td>22</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>bootfs</td>
<td>-</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>delegation</td>
<td>on</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>autoreplace</td>
<td>off</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>cachefile</td>
<td>-</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>failmode</td>
<td>wait</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>listsnapshots</td>
<td>on</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>autoexpand</td>
<td>off</td>
<td>default</td>
</tr>
<tr>
<td>pool</td>
<td>free</td>
<td>68.0G</td>
<td>-</td>
</tr>
<tr>
<td>pool</td>
<td>allocated</td>
<td>76.5K</td>
<td>-</td>
</tr>
</tbody>
</table>
Storage pool properties can be set with the `zpool set` command. For example:

```
# zpool set autoreplace=on mpool
# zpool get autoreplace mpool
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpool</td>
<td>autoreplace</td>
<td>on</td>
<td>default</td>
</tr>
</tbody>
</table>

**TABLE 4-1 ZFS Pool Property Descriptions**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allocated</td>
<td>String</td>
<td>N/A</td>
<td>Read-only value that identifies the amount of storage space within the pool that has been physically allocated.</td>
</tr>
<tr>
<td>altroot</td>
<td>String</td>
<td>off</td>
<td>Identifies an alternate root directory. If set, this directory is prepended to any mount points within the pool. This property can be used when you are examining an unknown pool, if the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid.</td>
</tr>
<tr>
<td>autoreplace</td>
<td>Boolean</td>
<td>off</td>
<td>Controls automatic device replacement. If set to off, device replacement must be initiated by using the <code>zpool replace</code> command. If set to on, any new device found in the same physical location as a device that previously belonged to the pool is automatically formatted and replaced. The property abbreviation is <code>replace</code>.</td>
</tr>
<tr>
<td>bootfs</td>
<td>Boolean</td>
<td>N/A</td>
<td>Identifies the default bootable dataset for the root pool. This property is typically set by the installation and upgrade programs.</td>
</tr>
<tr>
<td>cachefile</td>
<td>String</td>
<td>N/A</td>
<td>Controls where pool configuration information is cached. All pools in the cache are automatically imported when the system boots. However, installation and clustering environments might require this information to be cached in a different location so that pools are not automatically imported. You can set this property to cache pool configuration information in a different location. This information can be imported later by using the <code>zpool import -c</code> command. For most ZFS configurations, this property is not used.</td>
</tr>
<tr>
<td>capacity</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only value that identifies the percentage of pool space used. The property abbreviation is <code>cap</code>.</td>
</tr>
<tr>
<td>delegation</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether a nonprivileged user can be granted access permissions that are defined for a dataset. For more information, see Chapter 9, &quot;Oracle Solaris ZFS Delegated Administration.&quot;</td>
</tr>
</tbody>
</table>
### TABLE 4–1  ZFS Pool Property Descriptions (Continued)

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>failmode</td>
<td>String</td>
<td>wait</td>
<td>Controls the system behavior if a catastrophic pool failure occurs. This condition is typically a result of a loss of connectivity to the underlying storage device or devices or a failure of all devices within the pool. The behavior of such an event is determined by one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>■ wait – Blocks all I/O requests to the pool until device connectivity is restored, and the errors are cleared by using the <code>zpool clear</code> command. In this state, I/O operations to the pool are blocked, but read operations might succeed. A pool remains in the wait state until the device issue is resolved.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>■ continue – Returns an EIO error to any new write I/O requests, but allows reads to any of the remaining healthy devices. Any write requests that have yet to be committed to disk are blocked. After the device is reconnected or replaced, the errors must be cleared with the <code>zpool clear</code> command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>■ panic – Prints a message to the console and generates a system crash dump.</td>
</tr>
<tr>
<td>free</td>
<td>String</td>
<td>N/A</td>
<td>Read-only value that identifies the number of blocks within the pool that are not allocated.</td>
</tr>
<tr>
<td>guid</td>
<td>String</td>
<td>N/A</td>
<td>Read-only property that identifies the unique identifier for the pool.</td>
</tr>
<tr>
<td>health</td>
<td>String</td>
<td>N/A</td>
<td>Read-only property that identifies the current health of the pool, as either ONLINE, DEGRADED, FAULTED, OFFLINE, REMOVED, or UNAVAIL.</td>
</tr>
<tr>
<td>listsnapshots</td>
<td>String</td>
<td>on</td>
<td>Controls whether snapshot information that is associated with this pool is displayed with the <code>zfs list</code> command. If this property is disabled, snapshot information can be displayed with the <code>zfs list -t snapshot</code> command.</td>
</tr>
<tr>
<td>size</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only property that identifies the total size of the storage pool.</td>
</tr>
<tr>
<td>version</td>
<td>Number</td>
<td>N/A</td>
<td>Identifies the current on-disk version of the pool. The preferred method of updating pools is with the <code>zpool upgrade</code> command, although this property can be used when a specific version is needed for backwards compatibility. This property can be set to any number between 1 and the current version reported by the <code>zpool upgrade -v</code> command.</td>
</tr>
</tbody>
</table>
The *zpool list* command provides several ways to request information regarding pool status. The information available generally falls into three categories: basic usage information, I/O statistics, and health status. All three types of storage pool information are covered in this section.

- “Displaying Information About ZFS Storage Pools” on page 95
- “Viewing I/O Statistics for ZFS Storage Pools” on page 98
- “Determining the Health Status of ZFS Storage Pools” on page 100

## Displaying Information About ZFS Storage Pools

You can use the `zpool list` command to display basic information about pools.

### Listing Information About All Storage Pools or a Specific Pool

With no arguments, the *zpool list* command displays the following information for all pools on the system:

```
# zpool list
NAME  SIZE  ALLOC  FREE  CAP   HEALTH  ALTROOT
tank   80.0G  22.3G  47.7G  28%  ONLINE
dozer  1.2T   384G   816G  32%  ONLINE
```

This command output displays the following information:

- **NAME**: The name of the pool.
- **SIZE**: The total size of the pool, equal to the sum of the sizes of all top-level virtual devices.
- **ALLOC**: The amount of physical space allocated to all datasets and internal metadata. Note that this amount differs from the amount of disk space as reported at the file system level.
  
  For more information about determining available file system space, see “ZFS Disk Space Accounting” on page 54.
- **FREE**: The amount of unallocated space in the pool.
- **CAP (CAPACITY)**: The amount of disk space used, expressed as a percentage of the total disk space.
- **HEALTH**: The current health status of the pool.
  
  For more information about pool health, see “Determining the Health Status of ZFS Storage Pools” on page 100.
- **ALTROOT**: The alternate root of the pool, if one exists.
For more information about alternate root pools, see “Using ZFS Alternate Root Pools” on page 265.

You can also gather statistics for a specific pool by specifying the pool name. For example:

```
# zpool list tank
NAME    SIZE   ALLOC   FREE   CAP   HEALTH  ALTROOT
tank  80.0G  22.3G   47.7G  28%   ONLINE   -
```

### Listing Specific Storage Pool Statistics

Specific statistics can be requested by using the `-o` option. This option provides custom reports or a quick way to list pertinent information. For example, to list only the name and size of each pool, you use the following syntax:

```
# zpool list -o name,size
NAME    SIZE
tank  80.0G
dozer  1.2T
```

The column names correspond to the properties that are listed in “Listing Information About All Storage Pools or a Specific Pool” on page 95.

### Scripting ZFS Storage Pool Output

The default output for the `zpool list` command is designed for readability and is not easy to use as part of a shell script. To aid programmatic uses of the command, the `-H` option can be used to suppress the column headings and separate fields by tabs, rather than by spaces. For example, to request a list of all pool names on the system, you would use the following syntax:

```
# zpool list -Ho name
name
  tank
  dozer
```

Here is another example:

```
# zpool list -H -o name,size
name
  tank  80.0G
  dozer  1.2T
```

### Displaying ZFS Storage Pool Command History

ZFS automatically logs successful `zfs` and `zpool` commands that modify pool state information. This information can be displayed by using the `zpool history` command.

For example, the following syntax displays the command output for the root pool:

```
# zpool history
History for 'rpool':
```
2010-05-11.10:18:54 zpool create -f -o failmode=continue -R /a -m legacy -o 
cachefile=/tmp/root/etc/zfs/zpool.cache rpool mirror c1t0d0s0 c1t1d0s0
2010-05-11.10:18:55 zfs set canmount=noauto rpool
2010-05-11.10:18:55 zfs set mountpoint=/rpool rpool
2010-05-11.10:18:56 zfs create -o mountpoint=legacy rpool/ROOT
2010-05-11.10:18:57 zfs create -b 8192 -V 2048m rpool/swap
2010-05-11.10:18:58 zfs create -b 131072 -V 1536m rpool/dump
2010-05-11.10:19:01 zfs create -o canmount=noauto rpool/ROOT/zfsBE rpool
2010-05-11.10:19:02 zfs set mountpoint=/ rpool/ROOT/zfsBE
2010-05-11.10:19:03 zfs set mountpoint=/export rpool/export
2010-05-11.10:19:04 zfs create -o mountpoint=/export rpool/export
2010-05-11.10:19:05 zfs create rpool/export/home
2010-05-11.11:10 zpool set bootfs=rpool/ROOT/zfsBE rpool
2010-05-11.11:10 zpool set bootfs=rpool rpool
2010-05-11.11:10 zpool set bootfs=rpool/ROOT/zfsBE rpool

You can use similar output on your system to identify the actual ZFS commands that were 
executed to troubleshoot an error condition.

The features of the history log are as follows:

- The log cannot be disabled.
- The log is saved persistently on disk, which means that the log is saved across system 
  reboots.
- The log is implemented as a ring buffer. The minimum size is 128 KB. The maximum size is 
  32 MB.
- For smaller pools, the maximum size is capped at 1 percent of the pool size, where the size 
  is determined at pool creation time.
- The log requires no administration, which means that tuning the size of the log or changing 
  the location of the log is unnecessary.

To identify the command history of a specific storage pool, use syntax similar to the following:

```
# zpool history tank
History for 'tank':
2010-05-13.14:13:15 zpool create tank mirror c1t2d0 c1t3d0
2010-05-14.08:10:29 zfs create tank/ws01
2010-05-14.08:10:54 zfs snapshot tank/ws01@now
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix
```

Use the -l option to display a long format that includes the user name, the host name, and the 
zone in which the operation was performed. For example:

```
# zpool history -l tank
History for 'tank':
2010-05-13.14:13:15 zpool create tank mirror c1t2d0 c1t3d0 [user root on neo]
2010-05-14.08:10:29 zfs create tank/ws01 [user root on neo]
2010-05-14.08:10:54 zfs snapshot tank/ws01@now [user root on neo]
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix [user root on neo]
```
Use the `-i` option to display internal event information that can be used for diagnostic purposes. For example:

```
# zpool history -i tank
2010-05-13.14:13:15 zpool create -f tank mirror c1t2d0 c1t23d0
2010-05-14.08:10:29 zfs create tank/ws01
2010-05-14.08:10:54 [internal snapshot txg:53992] dataset = 42
2010-05-14.08:10:54 zfs snapshot tank/ws01@now
2010-05-14.08:11:04 [internal create txg:53994] dataset = 58
2010-05-14.08:11:04 [internal create txg:53994] dataset = 58
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix
```

**Viewing I/O Statistics for ZFS Storage Pools**

To request I/O statistics for a pool or specific virtual devices, use the `zpool iostat` command. Similar to the `iostat` command, this command can display a static snapshot of all I/O activity, as well as updated statistics for every specified interval. The following statistics are reported:

- **alloc capacity**: The amount of data currently stored in the pool or device. This amount differs from the amount of disk space available to actual file systems by a small margin due to internal implementation details.

  For more information about the differences between pool space and dataset space, see “ZFS Disk Space Accounting” on page 54.

- **free capacity**: The amount of disk space available in the pool or device. As with the used statistic, this amount differs from the amount of disk space available to datasets by a small margin.

- **read operations**: The number of read I/O operations sent to the pool or device, including metadata requests.

- **write operations**: The number of write I/O operations sent to the pool or device.

- **read bandwidth**: The bandwidth of all read operations (including metadata), expressed as units per second.

- **write bandwidth**: The bandwidth of all write operations, expressed as units per second.

**Listing Pool-Wide I/O Statistics**

With no options, the `zpool iostat` command displays the accumulated statistics since boot for all pools on the system. For example:
Because these statistics are cumulative since boot, bandwidth might appear low if the pool is relatively idle. You can request a more accurate view of current bandwidth usage by specifying an interval. For example:

```
# zpool iostat tank 2
```

In this example, the command displays usage statistics for the pool tank every two seconds until you type Control-C. Alternatively, you can specify an additional count argument, which causes the command to terminate after the specified number of iterations. For example, `zpool iostat 23` would print a summary every two seconds for three iterations, for a total of six seconds. If there is only a single pool, then the statistics are displayed on consecutive lines. If more than one pool exists, then an additional dashed line delineates each iteration to provide visual separation.

**Listing Virtual Device I/O Statistics**

In addition to pool-wide I/O statistics, the `zpool iostat` command can display I/O statistics for virtual devices. This command can be used to identify abnormally slow devices or to observe the distribution of I/O generated by ZFS. To request the complete virtual device layout as well as all I/O statistics, use the `zpool iostat -v` command. For example:

```
# zpool iostat -v
```

Note two important points when viewing I/O statistics for virtual devices:
First, disk space usage statistics are only available for top-level virtual devices. The way in which disk space is allocated among mirror and RAID-Z virtual devices is particular to the implementation and not easily expressed as a single number.

Second, the numbers might not add up exactly as you would expect them to. In particular, operations across RAID-Z and mirrored devices will not be exactly equal. This difference is particularly noticeable immediately after a pool is created, as a significant amount of I/O is done directly to the disks as part of pool creation, which is not accounted for at the mirror level. Over time, these numbers gradually equalize. However, broken, unresponsive, or offline devices can affect this symmetry as well.

You can use the same set of options (interval and count) when examining virtual device statistics.

**Determining the Health Status of ZFS Storage Pools**

ZFS provides an integrated method of examining pool and device health. The health of a pool is determined from the state of all its devices. This state information is displayed by using the `zpool status` command. In addition, potential pool and device failures are reported by `fmd`, displayed on the system console, and logged in the `/var/adm/messages` file.

This section describes how to determine pool and device health. This chapter does not document how to repair or recover from unhealthy pools. For more information about troubleshooting and data recovery, see Chapter 11, "Oracle Solaris ZFS Troubleshooting and Pool Recovery."

Each device can fall into one of the following states:

- **ONLINE** The device or virtual device is in normal working order. Although some transient errors might still occur, the device is otherwise in working order.
- **DEGRADED** The virtual device has experienced a failure but can still function. This state is most common when a mirror or RAID-Z device has lost one or more constituent devices. The fault tolerance of the pool might be compromised, as a subsequent fault in another device might be unrecoverable.
- **FAULTED** The device or virtual device is completely inaccessible. This status typically indicates total failure of the device, such that ZFS is incapable of sending data to it or receiving data from it. If a top-level virtual device is in this state, then the pool is completely inaccessible.
- **OFFLINE** The device has been explicitly taken offline by the administrator.
- **UNAVAIL** The device or virtual device cannot be opened. In some cases, pools with UNAVAIL devices appear in DEGRADED mode. If a top-level virtual device is UNAVAIL, then nothing in the pool can be accessed.
The device was physically removed while the system was running. Device removal detection is hardware-dependent and might not be supported on all platforms.

The health of a pool is determined from the health of all its top-level virtual devices. If all virtual devices are ONLINE, then the pool is also ONLINE. If any one of the virtual devices is DEGRADED or UNAVAIL, then the pool is also DEGRADED. If a top-level virtual device is FAULTED or OFFLINE, then the pool is also FAULTED. A pool in the FAULTED state is completely inaccessible. No data can be recovered until the necessary devices are attached or repaired. A pool in the DEGRADED state continues to run, but you might not achieve the same level of data redundancy or data throughput than if the pool were online.

**Basic Storage Pool Health Status**

You can quickly review pool health status by using the `zpool status` command as follows:

```
# zpool status -x
all pools are healthy
```

Specific pools can be examined by specifying a pool name in the command syntax. Any pool that is not in the ONLINE state should be investigated for potential problems, as described in the next section.

**Detailed Health Status**

You can request a more detailed health summary status by using the `-v` option. For example:

```
# zpool status -v tank
pool: tank
  state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
  see: http://www.sun.com/msg/ZFS-8000-2Q
scrub: scrub completed after 0h0m with 0 errors on Wed Jan 20 15:13:59 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>DEGRADED</td>

<td>0</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>cannot open</td>
</tr>
</tbody>
</table>
```

errors: No known data errors

This output displays a complete description of why the pool is in its current state, including a readable description of the problem and a link to a knowledge article for more information.
Each knowledge article provides up-to-date information about the best way to recover from your current problem. Using the detailed configuration information, you can determine which device is damaged and how to repair the pool.

In the preceding example, the faulted device should be replaced. After the device is replaced, use the `zpool online` command to bring the device online. For example:

```
# zpool online tank c1t0d0
Bringing device c1t0d0 online
# zpool status -x
all pools are healthy
```

If the `autoreplace` property is on, you might not have to online the replaced device.

If a pool has an offline device, the command output identifies the problem pool. For example:

```
# zpool status -x
pool: tank
  state: DEGRADED
  status: One or more devices has been taken offline by the administrator.
          Sufficient replicas exist for the pool to continue functioning in a
          degraded state.
  action: Online the device using 'zpool online' or replace the device with
          'zpool replace'.
  scrub: resilver completed after 0h0m with 0 errors on Wed Jan 20 15:15:09 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>DEGRADED</td>

<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>DEGRADED</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>OFFLINE</td>
<td>0</td>
<td>0</td>
<td>48K</td>
</tr>
</tbody>
</table>
```

errors: No known data errors

The READ and WRITE columns provide a count of I/O errors that occurred on the device, while the CKSUM column provides a count of uncorrectable checksum errors that occurred on the device. Both error counts indicate a potential device failure, and some corrective action is needed. If non-zero errors are reported for a top-level virtual device, portions of your data might have become inaccessible.

The `errors:` field identifies any known data errors.

In the preceding example output, the offline device is not causing data errors.

For more information about diagnosing and repairing faulted pools and data, see Chapter 11, “Oracle Solaris ZFS Troubleshooting and Pool Recovery.”
Migrating ZFS Storage Pools

Occasionally, you might need to move a storage pool between systems. To do so, the storage devices must be disconnected from the original system and reconnected to the destination system. This task can be accomplished by physically recabling the devices, or by using multiported devices such as the devices on a SAN. ZFS enables you to export the pool from one machine and import it on the destination system, even if the system are of different architectural endianness. For information about replicating or migrating file systems between different storage pools, which might reside on different machines, see "Sending and Receiving ZFS Data" on page 211.

- “Preparing for ZFS Storage Pool Migration” on page 103
- “Exporting a ZFS Storage Pool” on page 103
- “Determining Available Storage Pools to Import” on page 104
- “Importing ZFS Storage Pools From Alternate Directories” on page 106
- “Importing ZFS Storage Pools” on page 106
- “Recovering Destroyed ZFS Storage Pools” on page 107

Preparing for ZFS Storage Pool Migration

Storage pools should be explicitly exported to indicate that they are ready to be migrated. This operation flushes any unwritten data to disk, writes data to the disk indicating that the export was done, and removes all information about the pool from the system.

If you do not explicitly export the pool, but instead remove the disks manually, you can still import the resulting pool on another system. However, you might lose the last few seconds of data transactions, and the pool will appear faulted on the original system because the devices are no longer present. By default, the destination system cannot import a pool that has not been explicitly exported. This condition is necessary to prevent you from accidentally importing an active pool that consists of network-attached storage that is still in use on another system.

Exporting a ZFS Storage Pool

To export a pool, use the `zpool export` command. For example:

```
# zpool export tank
```

The command attempts to unmount any mounted file systems within the pool before continuing. If any of the file systems fail to unmount, you can forcefully unmount them by using the `-f` option. For example:
Determining Available Storage Pools to Import

After the pool has been removed from the system (either through an explicit export or by forcefully removing the devices), you can attach the devices to the target system. ZFS can handle some situations in which only some of the devices are available, but a successful pool migration depends on the overall health of the devices. In addition, the devices do not necessarily have to be attached under the same device name. ZFS detects any moved or renamed devices, and adjusts the configuration appropriately. To discover available pools, run the `zpool import` command with no options. For example:

```bash
# zpool import
pool: tank
id: 11809215114195894163
state: ONLINE
action: The pool can be imported using its name or numeric identifier.

config:

<table>
<thead>
<tr>
<th>tank</th>
<th>ONLINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>
```

In this example, the pool `tank` is available to be imported on the target system. Each pool is identified by a name as well as a unique numeric identifier. If multiple pools with the same name are available to import, you can use the numeric identifier to distinguish between them.

Similar to the `zpool status` command output, the `zpool import` output includes a link to a knowledge article with the most up-to-date information regarding repair procedures for the problem that is preventing a pool from being imported. In this case, the user can force the pool to be imported. However, importing a pool that is currently in use by another system over a storage network can result in data corruption and panics as both systems attempt to write to the
same storage. If some devices in the pool are not available but sufficient redundant data exists to provide a usable pool, the pool appears in the DEGRADED state. For example:

```
# zpool import
pool: tank
    id: 11809215114195894163
state: DEGRADED
status: One or more devices are missing from the system.
action: The pool can be imported despite missing or damaged devices. The fault tolerance of the pool may be compromised if imported.
    see: http://www.sun.com/msg/ZFS-8000-20
config:

    NAME    STATE    READ  WRITE  CKSUM
    tank    DEGRADE  D000   D000   D000
    mirror-0 DEGRADE  D000   D000   D000
c1t0d0 UNAVAIL  0 0 0 cannot open
c1t3d0 ONLINE  0 0 0
```

In this example, the first disk is damaged or missing, though you can still import the pool because the mirrored data is still accessible. If too many faulted or missing devices are present, the pool cannot be imported. For example:

```
# zpool import
pool: dozer
    id: 978448658935214634
state: FAULTED
status: One or more devices are missing from the system.
action: The pool cannot be imported. Attach the missing devices and try again.
    see: http://www.sun.com/msg/ZFS-8000-6X
config:

    NAME    STATE    READ WRITE CKSUM
    raidz1-0 FAULTED
    c1t0d0 ONLINE
    c1t1d0 FAULTED
    c1t2d0 ONLINE
```

In this example, two disks are missing from a RAID-Z virtual device, which means that sufficient redundant data is not available to reconstruct the pool. In some cases, not enough devices are present to determine the complete configuration. In this case, ZFS cannot determine what other devices were part of the pool, though ZFS does report as much information as possible about the situation. For example:

```
# zpool import
pool: dozer
    id: 978448658935214634
state: FAULTED
status: One or more devices are missing from the system.
action: The pool cannot be imported. Attach the missing devices and try again.
    see: http://www.sun.com/msg/ZFS-8000-6X
config:

    dozer    FAULTED  missing device
    raidz1-0 ONLINE
```
Additional devices are known to be part of this pool, though their exact configuration cannot be determined.

**Importing ZFS Storage Pools From Alternate Directories**

By default, the `zpool import` command only searches devices within the `/dev/dsk` directory. If devices exist in another directory, or you are using pools backed by files, you must use the `-d` option to search alternate directories. For example:

```bash
# zpool create dozer mirror /file/a /file/b
# zpool export dozer
# zpool import -d /file
    pool: dozer
    id: 7318363136755146
    state: ONLINE
    action: The pool can be imported using its name or numeric identifier.
    config:
    
    dozer ONLINE
    mirror-0 ONLINE
    /file/a ONLINE
    /file/b ONLINE
# zpool import -d /file dozer
```

If devices exist in multiple directories, you can specify multiple `-d` options.

**Importing ZFS Storage Pools**

After a pool has been identified for import, you can import it by specifying the name of the pool or its numeric identifier as an argument to the `zpool import` command. For example:

```bash
# zpool import tank
```

If multiple available pools have the same name, you must specify which pool to import by using the numeric identifier. For example:

```bash
# zpool import
    pool: dozer
    id: 270447562219377801
    state: ONLINE
    action: The pool can be imported using its name or numeric identifier.
    config:
```
The pool can be imported using its name or numeric identifier. For example:

```
# zpool import dozer
```

cannot import `dozer`: more than one matching pool
import by numeric ID instead
```
# zpool import 6223921996155991199
```

If the pool name conflicts with an existing pool name, you can import the pool under a different name. For example:

```
# zpool import dozer zeepool
```

This command imports the exported pool dozer using the new name zeepool.

If the pool was not cleanly exported, ZFS requires the `-f` flag to prevent users from accidentally importing a pool that is still in use on another system. For example:

```
# zpool import dozer
```

cannot import `dozer`: pool may be in use on another system
use `-f` to import anyway
```
# zpool import -f dozer
```

**Note** - Do not attempt to import a pool that is active on one system to another system. ZFS is not a native cluster, distributed, or parallel file system and cannot provide concurrent access from multiple, different hosts.

Pools can also be imported under an alternate root by using the `-R` option. For more information on alternate root pools, see “Using ZFS Alternate Root Pools” on page 265.

### Recovering Destroyed ZFS Storage Pools

You can use the `zpool import -D` command to recover a storage pool that has been destroyed. For example:

```
# zpool destroy tank
# zpool import -D
dozer ONLINE
c1t9d0 ONLINE

pool: dozer
id: 6223921996155991199
state: ONLINE
action: The pool can be imported using its name or numeric identifier.
config:

    dozer ONLINE
c1t8d0 ONLINE

# zpool import dozer
```

cannot import `dozer`: more than one matching pool
import by numeric ID instead
```
# zpool import 6223921996155991199
```

```
# zpool import zeepool
```

`zeepool` is imported using the new name `zeepool`.

If the pool was not cleanly exported, ZFS requires the `-f` flag to prevent users from accidentally importing a pool that is still in use on another system. For example:

```
# zpool import dozer
```

cannot import `dozer`: pool may be in use on another system
use `-f` to import anyway
```
# zpool import -f dozer
```

**Note** - Do not attempt to import a pool that is active on one system to another system. ZFS is not a native cluster, distributed, or parallel file system and cannot provide concurrent access from multiple, different hosts.

Pools can also be imported under an alternate root by using the `-R` option. For more information on alternate root pools, see “Using ZFS Alternate Root Pools” on page 265.
action: The pool can be imported using its name or numeric identifier.

config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this zpool import output, you can identify the tank pool as the destroyed pool because of the following state information:

state: ONLINE (DESTROYED)

To recover the destroyed pool, run the zpool import -D command again with the pool to be recovered. For example:

```
# zpool import -D tank
# zpool status tank
pool: tank
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

errors: No known data errors

If one of the devices in the destroyed pool is faulted or unavailable, you might be able to recover the destroyed pool anyway by including the -f option. In this scenario, you would import the degraded pool and then attempt to fix the device failure. For example:

```
# zpool destroy dozer
# zpool import -D
pool: dozer
  id: 13643595538644303788
state: DEGRADED (DESTROYED)
status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
see: http://www.sun.com/msg/ZFS-8000-2Q
config:

## Upgrading ZFS Storage Pools

If you have ZFS storage pools from a previous Solaris release, such as the Solaris 10 10/09 release, you can upgrade your pools with the zpool upgrade command to take advantage of the pool features in the current release. In addition, the zpool status command has been modified to notify you when your pools are running older versions. For example:

# zpool status
pool: tank
state: ONLINE
status: The pool is formatted using an older on-disk format. The pool can still be used, but some features are unavailable.
action: Upgrade the pool using 'zpool upgrade'. Once this is done, the pool will no longer be accessible on older software versions.
scrub: none requested

errors: No known data errors

You can use the following syntax to identify additional information about a particular version and supported releases:
```
# zpool upgrade -v
This system is currently running ZFS pool version 22.

The following versions are supported:

<table>
<thead>
<tr>
<th>VER</th>

</tbody>
</table>

For more information on a particular version, including supported releases, see the ZFS Administration Guide.

Then, you can run the `zpool upgrade` command to upgrade all of your pools. For example:

```
# zpool upgrade -a
```

**Note** – If you upgrade your pool to a later ZFS version, the pool will not be accessible on a system that runs an older ZFS version.
This chapter describes how to install and boot a Oracle Solaris ZFS file system. Migrating a UFS root file system to a ZFS file system by using Oracle Solaris Live Upgrade is also covered.

The following sections are provided in this chapter:

“Installing and Booting an Oracle Solaris ZFS Root File System (Overview)” on page 111
“Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support” on page 113
“Installing a ZFS Root File System (Initial Installation)” on page 115
“Installing a ZFS Root File System (Oracle Solaris Flash Archive Installation)” on page 122
“Installing a ZFS Root File System (Oracle Solaris JumpStart Installation)” on page 124
“Migrating a UFS Root File System to a ZFS Root File System (Oracle Solaris Live Upgrade)” on page 128
“ZFS Support for Swap and Dump Devices” on page 148
“Booting From a ZFS Root File System” on page 152
“Recovering the ZFS Root Pool or Root Pool Snapshots” on page 159

For a list of known issues in this release, see Oracle Solaris 10 9/10 Release Notes.

For up-to-date troubleshooting information, go to the following site:

Installing and Booting an Oracle Solaris ZFS Root File System (Overview)

Starting in the Solaris 10 10/08 release, you can install and boot from a ZFS root file system in the following ways:

- You can perform an initial installation during which ZFS is selected as the root file system.
You can use Oracle Solaris Live Upgrade to migrate a UFS root file system to a ZFS root file system. In addition, you can use Oracle Solaris Live Upgrade to perform the following tasks:

- Create a new boot environment within an existing ZFS root pool.
- Create a new boot environment in a new ZFS root pool.

You can use an Oracle Solaris JumpStart profile to automatically install a system with a ZFS root file system.

Starting in the Solaris 10 10/09 release, you can use a JumpStart profile to automatically install a system with a ZFS Flash archive.

After a SPARC based or an x86 based system is installed with or migrated to a ZFS root file system, the system boots automatically from the ZFS root file system. For more information about boot changes, see “Booting From a ZFS Root File System” on page 152.

ZFS Installation Features

The following ZFS installation features are provided in this Solaris release:

- Using the Solaris interactive text installer, you can install a UFS or a ZFS root file system. The default file system is still UFS for this Solaris release. You can access the interactive text installer option in the following ways:
  - SPARC: Use the following syntax from the Solaris Installation DVD:
    ```
    ok boot cdrom - text
    ```
  - SPARC: Use the following syntax when booting from the network:
    ```
    ok boot net - text
    ```
  - x86: Select the text-mode installation option.

- A Custom JumpStart profile provides the following features:
  - You can set up a profile to create a ZFS storage pool and designate a bootable ZFS file system.
  - You can set up a profile to identify a flash archive of a ZFS root pool.

- Using Oracle Solaris Live Upgrade, you can migrate a UFS root file system to a ZFS root file system. The `lucreate` and `luactivate` commands have been enhanced to support ZFS pools and file systems.

- You can set up a mirrored ZFS root pool by selecting two disks during installation. Or, you can attach additional disks after installation to create a mirrored ZFS root pool.

- Swap and dump devices are automatically created on ZFS volumes in the ZFS root pool.
The following installation features are not provided in this release:

- The GUI installation feature for installing a ZFS root file system is not currently available.
- The Oracle Solaris Flash installation feature for installing a ZFS root file system is not available by selecting the flash installation option from the initial installation option. However, you can create a JumpStart profile to identify a flash archive of a ZFS root pool. For more information, see “Installing a ZFS File System (Oracle Solaris Flash Archive Installation)” on page 122.
- You cannot use the standard upgrade program to upgrade your UFS root file system to a ZFS root file system.

Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support

Ensure that the following requirements are met before attempting to install a system with a ZFS root file system or attempting to migrate a UFS root file system to a ZFS root file system.

Oracle Solaris Release Requirements

You can install and boot a ZFS root file system or migrate to a ZFS root file system in the following ways:

- Install a ZFS root file system – Available starting in the Solaris 10 10/08 release.
- Migrate from a UFS root file system to a ZFS root file system with Oracle Solaris Live Upgrade – You must have installed at least the Solaris 10 10/08 release or you must have upgraded to at least the Solaris 10 10/08 release.

General ZFS Storage Pool Requirements

The following sections describe ZFS root pool space and configuration requirements.

Disk Space Requirements for ZFS Storage Pools

The required minimum amount of available pool space for a ZFS root file system is larger than for a UFS root file system because swap and dump devices must be separate devices in a ZFS root environment. By default, swap and dump devices are the same device in a UFS root file system.

When a system is installed or upgraded with a ZFS root file system, the size of the swap area and the dump device are dependent upon the amount of physical memory. The minimum amount of available pool space for a bootable ZFS root file system depends upon the amount of physical memory, the disk space available, and the number of boot environments (BEs) to be created.

Review the following disk space requirements for ZFS storage pools:
768 MB is the minimum amount of memory required to install a ZFS root file system.
1 GB of memory is recommended for better overall ZFS performance.
At least 16 GB of disk space is recommended. The disk space is consumed as follows:

- **Swap area and dump device** – The default sizes of the swap and dump volumes that are created by the Solaris installation programs are as follows:
  - **Solaris initial installation** – In the new ZFS boot environment, the default swap volume size is calculated as half the size of physical memory, generally in the 512 MB to 2 GB range. You can adjust the swap size during an initial installation.
  - The default dump volume size is calculated by the kernel based on `dumpadm` information and the size of physical memory. You can adjust the dump size during an initial installation.

- **Oracle Solaris Live Upgrade** – When a UFS root file system is migrated to a ZFS root file system, the default swap volume size for the ZFS BE is calculated as the size of the swap device of the UFS BE. The default swap volume size calculation adds the sizes of all the swap devices in the UFS BE, and creates a ZFS volume of that size in the ZFS BE. If no swap devices are defined in the UFS BE, then the default swap volume size is set to 512 MB.
  - In the ZFS BE, the default dump volume size is set to half the size of physical memory, between 512 MB and 2 GB.

You can adjust the sizes of your swap and dump volumes to sizes of your choosing as long as the new sizes support system operations. For more information, see “Adjusting the Sizes of Your ZFS Swap Device and Dump Device” on page 149.

- **Boot environment (BE)** – In addition to either new swap and dump space requirements or adjusted swap and dump device sizes, a ZFS BE that is migrated from a UFS BE requires approximately 6 GB. Each ZFS BE that is cloned from another ZFS BE doesn’t require additional disk space, but consider that the BE size will increase when patches are applied. All ZFS BEs in the same root pool use the same swap and dump devices.

- **Solaris OS Components** – All subdirectories of the root file system that are part of the OS image, with the exception of `/var`, must be in the same dataset as the root file system. In addition, all Solaris OS components must reside in the root pool, with the exception of the swap and dump devices.

  Another restriction is that the `/var` directory or dataset must be a single dataset. For example, you cannot create a descendant `/var` dataset, such as `/var/tmp`, if you want to also use Oracle Solaris Live Upgrade to migrate or patch a ZFS BE or create a ZFS flash archive of this pool.

For example, a system with 12 GB of disk space might be too small for a bootable ZFS environment because 2 GB of disk space is required for each swap and dump device and approximately 6 GB of disk space is required for the ZFS BE that is migrated from the UFS BE.
ZFS Storage Pool Configuration Requirements

Review the following ZFS storage pool configuration requirements:

- The pool that is intended to be the root pool must have an SMI label. This requirement is met if the pool is created with disk slices.
- The pool must exist either on a disk slice or on disk slices that are mirrored. If you attempt to use an unsupported pool configuration during an Oracle Solaris Live Upgrade migration, you see a message similar to the following:

```
ERROR: ZFS pool name does not support boot environments
```

For a detailed description of supported ZFS root pool configurations, see “Creating a ZFS Root Pool” on page 64.

- x86: The disk must contain a Solaris `fdisk` partition. A Solaris `fdisk` partition is created automatically when the x86 based system is installed. For more information about Solaris `fdisk` partitions, see “Guidelines for Creating an fdisk Partition” in System Administration Guide: Devices and File Systems.
- Disks that are designated for booting in a ZFS root pool must be limited to 1 TB in size on both SPARC based and x86 based systems.
- Compression can be enabled on the root pool but only after the root pool is installed. No way exists to enable compression on a root pool during installation. The gzip compression algorithm is not supported on root pools.
- Do not rename the root pool after it is created by an initial installation or after Solaris Live Upgrade migration to a ZFS root file system. Renaming the root pool might cause an unbootable system.

Installing a ZFS Root File System (Initial Installation)

In this Solaris release, you can perform an initial installation by using the Solaris interactive text installer to create a ZFS storage pool that contains a bootable ZFS root file system. If you have an existing ZFS storage pool that you want to use for your ZFS root file system, then you must use Oracle Solaris Live Upgrade to migrate your existing UFS root file system to a ZFS root file system in an existing ZFS storage pool. For more information, see “Migrating a UFS Root File System to a ZFS Root File System (Oracle Solaris Live Upgrade)” on page 128.

If you will be configuring zones after the initial installation of a ZFS root file system and you plan on patching or upgrading the system, see “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)” on page 134 or “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)” on page 139.

If you already have ZFS storage pools on the system, they are acknowledged by the following message. However, these pools remain untouched, unless you select the disks in the existing pools to create the new storage pool.
There are existing ZFS pools available on this system. However, they can only be upgraded using the Live Upgrade tools. The following screens will only allow you to install a ZFS root system, not upgrade one.

**Caution**– Existing pools will be destroyed if any of their disks are selected for the new pool.

Before you begin the initial installation to create a ZFS storage pool, see “Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support” on page 113.

**EXAMPLE 5-1**  Initial Installation of a Bootable ZFS Root FileSystem

The Solaris interactive text installation process is basically the same as in previous Solaris releases, except that you are prompted to create a UFS or a ZFS root file system. UFS is the still the default file system in this release. If you select a ZFS root file system, you are prompted to create a ZFS storage pool. The steps for installing a ZFS root file system follow:

1. Select the Solaris interactive installation method because a Solaris Flash installation is not available to create a bootable ZFS root file system. However, you can create a ZFS flash archive to be used during a JumpStart installation. For more information, see “Installing a ZFS Root File System (Oracle Solaris Flash Archive Installation)” on page 122.

   Starting in the Solaris 10 10/08 release, you can migrate a UFS root file system to a ZFS root file system as long as at least the Solaris 10 10/08 release is already installed. For more information about migrating to a ZFS root file system, see “Migrating a UFS Root File System to a ZFS Root File System (Oracle Solaris Live Upgrade)” on page 128.

2. To create a ZFS root file system, select the ZFS option. For example:

   Choose Filesystem Type

   Select the filesystem to use for your Solaris installation

   [ ] UFS
   [X] ZFS

3. After you select the software to be installed, you are prompted to select the disks to create your ZFS storage pool. This screen is similar as in previous Solaris releases.

   Select Disks

   On this screen you must select the disks for installing Solaris software.

   Start by looking at the Suggested Minimum field; this value is the approximate space needed to install the software you’ve selected. For ZFS, multiple disks will be configured as mirrors, so the disk you choose, or the slice within the disk must exceed the Suggested Minimum value.

   **NOTE:** ** denotes current boot disk

<table>
<thead>
<tr>
<th>Disk Device</th>
<th>Available Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>[X] c1t0d0</td>
<td>69994 MB (F4 to edit)</td>
</tr>
<tr>
<td>[ ] c1t1d0</td>
<td>69994 MB</td>
</tr>
<tr>
<td>[-] c1t2d0</td>
<td>0 MB</td>
</tr>
</tbody>
</table>
EXAMPLE 5–1  Initial Installation of a Bootable ZFS Root FileSystem  (Continued)

You can select the disk or disks to be used for your ZFS root pool. If you select two disks, a mirrored two-disk configuration is set up for your root pool. Either a two-disk or a three-disk mirrored pool is optimal. If you have eight disks and you select all of them, those eight disks are used for the root pool as one big mirror. This configuration is not optimal. Another option is to create a mirrored root pool after the initial installation is complete. A RAID-Z pool configuration for the root pool is not supported. For more information about configuring ZFS storage pools, see “Replication Features of a ZFS Storage Pool” on page 60.

4. To select two disks to create a mirrored root pool, use the cursor control keys to select the second disk. In the following example, both c1t1d0 and c1t2d0 are selected as the root pool disks. Both disks must have an SMI label and a slice 0. If the disks are not labeled with an SMI label or they don't contain slices, then you must exit the installation program, use the format utility to relabel and repartition the disks, and then restart the installation program.

Select Disks

On this screen you must select the disks for installing Solaris software. Start by looking at the Suggested Minimum field; this value is the approximate space needed to install the software you've selected. For ZFS, multiple disks will be configured as mirrors, so the disk you choose, or the slice within the disk must exceed the Suggested Minimum value.

NOTE: ** denotes current boot disk

<table>
<thead>
<tr>
<th>Disk Device</th>
<th>Available Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>[X] c1t0d0</td>
<td>69994 MB</td>
</tr>
<tr>
<td>[X] c1t1d0</td>
<td>69994 MB (F4 to edit)</td>
</tr>
<tr>
<td>[-] c1t2d0</td>
<td>0 MB</td>
</tr>
<tr>
<td>[-] c1t3d0</td>
<td>0 MB</td>
</tr>
</tbody>
</table>

Maximum Root Size: 69994 MB
Suggested Minimum: 8279 MB

If the Available Space column identifies 0 MB, the disk most likely has an EFI label. If you want to use a disk with an EFI label, you will need to exit the installation program, relabel the disk with an SMI label by using the format -e command, then restart the installation program.

If you do not create a mirrored root pool during installation, you can easily create one after the installation. For information, see “How to Create a Mirrored Root Pool (Post Installation)” on page 121.

5. After you have selected a disk or disks for your ZFS storage pool, a screen similar to the following is displayed:

Configure ZFS Settings
Specify the name of the pool to be created from the disk(s) you have chosen. Also specify the name of the dataset to be created within the pool that is to be used as the root directory for the filesystem.

ZFS Pool Name: rpool
ZFS Root Dataset Name: s10s_u9wos_08
ZFS Pool Size (in MB): 69995
Size of Swap Area (in MB): 2048
Size of Dump Area (in MB): 1536
(Pool size must be between 6231 MB and 69995 MB)

[X] Keep / and /var combined
[ ] Put /var on a separate dataset

From this screen, you can change the name of the ZFS pool, the dataset name, the pool size, and the swap and dump device sizes by moving the cursor control keys through the entries and replacing the default value with new values. Or, you can accept the default values. In addition, you can modify how the /var file system is created and mounted.

In this example, the root dataset name is changed to zfsBE.

ZFS Pool Name: rpool
ZFS Root Dataset Name: zfsBE
ZFS Pool Size (in MB): 69995
Size of Swap Area (in MB): 2048
Size of Dump Area (in MB): 1536
(Pool size must be between 6231 MB and 69995 MB)

[X] Keep / and /var combined
[ ] Put /var on a separate dataset

6. You can change the installation profile at this final installation screen. For example:

Profile

The information shown below is your profile for installing Solaris software. It reflects the choices you’ve made on previous screens.

***************************************************************************************

Installation Option: Initial
Boot Device: c1t0d0
Root File System Type: ZFS
Client Services: None

Regions: North America
System Locale: C ( C )

Software: Solaris 10, Entire Distribution
Pool Name: rpool
Boot Environment Name: zfsBE
Pool Size: 69995 MB
Devices in Pool: c1t0d0 c1t1d0

***************************************************************************************

7. After the installation is completed, review the resulting ZFS storage pool and file system information. For example:
EXAMPLE 5-1 Initial Installation of a Bootable ZFS Root FileSystem  

(Continued)

```
# zpool status
pool: rpool
  state: ONLINE
scrub: none requested
config:

    NAME    STATE READ WRITE CKSUM
    rpool   ONLINE 0 0 0
    mirror-0 ONLINE 0 0 0
    c1t0d0s0 ONLINE 0 0 0
    c1t1d0s0 ONLINE 0 0 0

errors: No known data errors
```

```
# zfs list
NAME    USED  AVAIL REFER  MOUNTPOINT
rpool   8.03G 58.9G  96K /rpool
rpool/ROOT 4.47G 58.9G  21K legacy
rpool/ROOT/zfsBE 4.47G 58.9G  4.47G /
rpool/dump 1.50G 58.9G 1.50G -
rpool/export 44K 58.9G  23K /export
rpool/export/home 21K 58.9G  21K /export/home
rpool/swap 2.06G 61.0G  16K -
```

The sample `zfs list` output identifies the root pool components, such as the `rpool/ROOT` directory, which is not accessible by default.

8. To create another ZFS boot environment (BE) in the same storage pool, you can use the `lucreate` command. In the following example, a new BE named `zfs2BE` is created. The current BE is named `zfsBE`, as shown in the `zfs list` output. However, the current BE is not acknowledged in the `lустatus` output until the new BE is created.

```
# lустatus
ERROR: No boot environments are configured on this system
ERROR: cannot determine list of all boot environment names
```

If you create a new ZFS BE in the same pool, use syntax similar to the following:

```
# lucreate -n zfs2BE
INFORMATION: The current boot environment is not named - assigning name <zfsBE>.
Current boot environment is named <zfsBE>.
Creating initial configuration for primary boot environment <zfsBE>.
The device </dev/dsk/c1t0d0s0> is not a root device for any boot environment; cannot get BE ID.
PBE configuration successful: PBE name <zfsBE> PBE Boot Device </dev/dsk/c1t0d0s0>.
Comparing source boot environment <zfsBE> file systems with the file system(s) you specified for the new boot environment. Determining which file systems should be in the new boot environment.
Updating boot environment description database on all BEs.
Updating system configuration files.
Creating configuration for boot environment <zfs2BE>.
Source boot environment is <zfsBE>.
Creating boot environment <zfs2BE>.
Cloning file systems from boot environment <zfsBE> to create boot environment <zfs2BE>.
Creating snapshot for <rpool/ROOT/zfsBE> on <rpool/ROOT/zfsBE@zfs2BE>.
Creating clone for <rpool/ROOT/zfsBE@zfs2BE> on <rpool/ROOT/zfs2BE>.
Setting canmount=noauto for </> in zone <global> on <rpool/ROOT/zfs2BE>.
```
Population of boot environment <zfs2BE> successful.
Creation of boot environment <zfs2BE> successful.

Creating a ZFS BE within the same pool uses ZFS clone and snapshot features to instantly create the BE. For more details about using Oracle Solaris Live Upgrade for a ZFS root migration, see "Migrating a UFS Root File System to a ZFS Root File System (Oracle Solaris Live Upgrade)" on page 128.

9. Next, verify the new boot environments. For example:

```bash
# lustatus
Name        Is Active Active Can Copy
------------ ----------- -------- ------- -------
  zfsBE  yes    yes    yes    no     -
  zfs2BE yes   no      no    yes    -
```

```bash
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
rpool 8.03G 58.9G 97K /rpool
rpool/ROOT 4.47G 58.9G 21K legacy
rpool/ROOT/zfs2BE 116K 58.9G 4.47G /
rpool/ROOT/zfsBE 4.47G 58.9G 4.47G /
... 
rpool/swap 2.06G 61.0G 16K -
```

10. To boot from an alternate BE, use the `luactivate` command. After you activate the BE on a SPARC based system, use the `boot -L` command to identify the available BEs when the boot device contains a ZFS storage pool. When booting from an x86 based system, identify the BE to be booted from the GRUB menu.

For example, on a SPARC based system, use the `boot -L` command to display a list of available BEs. To boot from the new BE, zfs2BE, select option 2. Then, type the displayed `boot -Z` command.

```bash
ok boot -L
Executing last command: boot -L
Boot device: /pci@7c0/pci@0/pci@1/pci@0,2/LSILogic,sas@2/disk@0 File and args: -L
1 zfsBE
2 zfs2BE
Select environment to boot: [ 1 - 2 ]: 2

To boot the selected entry, invoke:
boot [-root-device] -Z rpool/ROOT/zfs2BE
ok boot -Z rpool/ROOT/zfs2BE
```

For more information about booting a ZFS file system, see "Booting From a ZFS Root File System" on page 152.
How to Create a Mirrored Root Pool (Post Installation)

If you did not create a mirrored ZFS root pool during installation, you can easily create one after the installation.

For information about replacing a disk in root pool, see "How to Replace a Disk in the ZFS Root Pool" on page 159.

1 Display your current root pool status.

```bash
# zpool status rpool
pool: rpool
    state: ONLINE
    scrub: none requested
config:

    NAME     STATE READ WRITE CKSUM
    rpool    ONLINE 0 0 0
    c1t0d0s0 ONLINE 0 0 0

errors: No known data errors
```

2 Attach a second disk to configure a mirrored root pool.

```bash
# zpool attach rpool c1t0d0s0 c1t1d0s0
```

Please be sure to invoke installboot(1M) to make 'c1t1d0s0' bootable. Make sure to wait until resilver is done before rebooting.

3 View the root pool status to confirm that resilvering is complete.

```bash
# zpool status rpool
pool: rpool
    state: ONLINE
status: One or more devices is currently being resilvered. The pool will continue to function, possibly in a degraded state.
action: Wait for the resilver to complete.
    scrub: resilver in progress for 0h1m, 24.26% done, 0h3m to go
config:

    NAME     STATE READ WRITE CKSUM
    rpool    ONLINE 0 0 0
    mirror-0 ONLINE 0 0 0
    c1t0d0s0 ONLINE 0 0 0
    c1t1d0s0 ONLINE 0 0 0 3.18G resilvered

errors: No known data errors
```

In the above output, the resilvering process is not complete. Resilvering is complete when you see messages similar to the following:

```bash
scrub: resilver completed after 0h10m with 0 errors on Thu Mar 11 11:27:22 2010
```
4 Apply boot blocks to the second disk after resilvering is complete.

sparc# installboot -F zfs /usr/platform/'uname -i'/lib/fs/zfs/bootblk /dev/rdsk/c1t1d0s0

x86# installgrub /boot/grub/stage1 /boot/grub/stage2 /dev/rdsk/c1t1d0s0

5 Verify that you can boot successfully from the second disk.

6 Set up the system to boot automatically from the new disk, either by using the `EEPROM` command, the `setenv` command from the SPARC boot PROM. Or, reconfigure the PC BIOS.

Installing a ZFS Root File System (Oracle Solaris Flash Archive Installation)

Starting in the Solaris 10 10/09 release, you can create a flash archive on a system that is running a UFS root file system or a ZFS root file system. A flash archive of a ZFS root pool contains the entire pool hierarchy, except for the swap and dump volumes, and any excluded datasets. The swap and dump volumes are created when the flash archive is installed. You can use the flash archive installation method as follows:

- Generate a flash archive that can be used to install and boot a system with a ZFS root file system.
- Perform a JumpStart installation of a system by using a ZFS flash archive. Creating a ZFS flash archive clones an entire root pool, not individual boot environments. Individual datasets within the pool can be excluded by using the `flarc create` and `flarc` commands' `-D` option.

Review the following limitations before you consider installing a system with a ZFS flash archive:

- Only a JumpStart installation of a ZFS flash archive is supported. You cannot use the interactive installation option of a flash archive to install a system with a ZFS root file system. Nor can you use a flash archive to install a ZFS BE with Oracle Solaris Live Upgrade.
- You can only install a flash archive on a system that has the same architecture as the system on which you created the ZFS flash archive. For example, an archive that is created on a sun4u system cannot be installed on a sun4v system.
- Only a full initial installation of a ZFS flash archive is supported. You cannot install differential flash archive of a ZFS root file system nor can you install a hybrid UFS/ZFS archive.
- Existing UFS flash archives can still only be used to install a UFS root file system. The ZFS Flash archive can only be used to install a ZFS root file system.
Although the entire root pool, minus any explicitly excluded datasets, is archived and installed, only the ZFS BE that is booted when the archive is created is usable after the flash archive is installed. However, pools that are archived with the `flar create` or the `flar` commands’ `-R rootdir` option can be used to archive a root pool other than the one that is currently booted.

A ZFS root pool name that is created with a flash archive must match the master root pool name. The root pool name that is used to create the flash archive is the name that is assigned to the new pool created. Changing the pool name is not supported.

The `flar create` and `flar` command options used to include and exclude individual files are not supported in a ZFS flash archive. You can only exclude entire datasets from a ZFS flash archive.

The `flar info` command is not supported for a ZFS flash archive. For example:

```bash
# flar info -l zfs10u8flar
ERROR: archive content listing not supported for zfs archives.
```

After a master system is installed with or upgraded to at least the Solaris 10 10/09 release, you can create a ZFS flash archive to be used to install a target system. The basic process follows:

- Install or upgrade to at least the Solaris 10 10/09 release on the master system. Add any customizations that you want.
- Create the ZFS flash archive with the `flar create` command on the master system. All datasets in the root pool, except for the swap and dump volumes, are included in the ZFS flash archive.
- Create a JumpStart profile to include the flash archive information on the installation server.
- Install the ZFS flash archive on the target system.

The following archive options are supported for installing a ZFS root pool with a flash archive:

- Use the `flar create` or `flar` command to create a flash archive from the specified ZFS root pool. If not specified, a flash archive of the default root pool is created.
- Use `flar create -D dataset` to exclude the specified datasets from the flash archive. This option can be used multiple times to exclude multiple datasets.

After a ZFS flash archive is installed, the system is configured as follows:

- The entire dataset hierarchy that existed on the system where the flash archive was created is recreated on the target system, minus any datasets that were specifically excluded at the time of archive creation. The swap and dump volumes are not included in the flash archive.
- The root pool has the same name as the pool that was used to create the archive.
- The boot environment that was active when the flash archive was created is the active and default BE on the deployed systems.
EXAMPLE 5-2  Installing a System with a ZFS Flash Archive

After the master system is installed or upgraded to at least the Solaris 10 10/09 release, create a flash archive of the ZFS root pool. For example:

```
# flarcreate -n zfsBE zfs10upflar
Full Flash
Checking integrity...  
Integrity OK.
Running precreation scripts...  
Precreation scripts done. 
Determining the size of the archive...  
The archive will be approximately 4.94GB. 
Creating the archive...  
Archive creation complete. 
Running postcreation scripts...  
Postcreation scripts done. 
Running pre-exit scripts...  
Pre-exit scripts done. 
```

On the system that will be used as the installation server, create a JumpStart profile as you would to install any system. For example, the following profile is used to install the zfs10upflar archive.

```
install_type flash install
archive_location nfs system:/export/jump/zfs10upflar
partitioning explicit
pool rpool auto auto auto mirror c0t1d0s0 c0t0d0s0
```

Installing a ZFS Root File System (Oracle Solaris JumpStart Installation)

You can create a JumpStart profile to install a ZFS root file system or a UFS root file system.

A ZFS specific profile must contain the new pool keyword. The pool keyword installs a new root pool, and a new boot environment is created by default. You can provide the name of the boot environment as well as create a separate /var dataset with the bootenv installbe keywords and the bename and dataset options.

For general information about using JumpStart features, see Oracle Solaris 10 9/10 Installation Guide: Custom JumpStart and Advanced Installations.

If you will be configuring zones after the JumpStart installation of a ZFS root file system and you plan on patching or upgrading the system, see "Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)" on page 134 or "Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)" on page 139.
JumpStart Keywords for ZFS

The following keywords are permitted in a ZFS specific profile:

auto

Automatically specifies the size of the slices for the pool, swap volume, or dump volume. The size of the disk is checked to verify that the minimum size can be accommodated. If the minimum size can be accommodated, the largest possible pool size is allocated, given the constraints, such as the size of the disks, preserved slices, and so on.

For example, if you specify c0t0d0s0, the root pool slice is created as large as possible if you specify either the all or auto keywords. Or, you can specify a particular size for the slice, swap volume, or dump volume.

The auto keyword works similarly to the all keyword when used with a ZFS root pool because pools don't have unused disk space.

bootenv

Identifies the boot environment characteristics.

Use the following bootenv keyword syntax to create a bootable ZFS root environment:

```
bootenv installbe bename BE-name [dataset mount-point]
```

installbe

Creates a new BE that is identified by the bename option and BE-name entry and installs it.

bename BE-name

Identifies the BE-name to install.

If bename is not used with the pool keyword, then a default BE is created.

dataset mount-point

Use the optional dataset keyword to identify a /var dataset that is separate from the root dataset. The mount-point value is currently limited to /var. For example, a bootenv syntax line for a separate /var dataset would be similar to the following:

```
bootenv installbe bename zfsroot dataset /var
```

pool

Defines the new root pool to be created. The following keyword syntax must be provided:

```
pool poolname poolsize swapsize dumpsize vdevlist
```

poolname

Identifies the name of the pool to be created. The pool is created with the specified pool size and with the specified physical devices (vdevs). The poolname value should not identify the name of an existing pool or the existing pool is overwritten.
poolsize

Specifies the size of the pool to be created. The value can be auto or existing. The auto value allocates the largest possible pool size, given the constraints, such as size of the disks, preserved slices, and so on. The existing value means the boundaries of existing slices by that name are preserved and not overwritten. The size is assumed to be in MB, unless specified by g (GB).

swapsize

Specifies the size of the swap volume to be created. The auto value means that the default swap size is used. You can specify a size with a size value. The size is in MB, unless specified by g (GB).

dumpsize

Specifies the size of the dump volume to be created. The auto value means that the default swap size is used. You can specify a size with a size value. The size is assumed to be in MB, unless specified by g (GB).

vdevlist

Specifies one or more devices that are used to create the pool. The format of vdevlist is the same as the format of the zpool create command. At this time, only mirrored configurations are supported when multiple devices are specified. Devices in vdevlist must be slices for the root pool. The any value means that the installation software selects a suitable device.

You can mirror as many disks as you like, but the size of the pool that is created is determined by the smallest of the specified disks. For more information about creating mirrored storage pools, see “Mirrored Storage Pool Configuration” on page 61.

JumpStart Profile Examples for ZFS

This section provides examples of ZFS specific JumpStart profiles.

The following profile performs an initial installation specified with install_type initial_install in a new pool, identified with pool newpool, whose size is automatically sized with the auto keyword to the size of the specified disks. The swap area and dump device are automatically sized with the auto keyword in a mirrored configuration of disks (with the mirror keyword and disks specified as c0t0d0s0 and c0t1d0s0). Boot environment characteristics are set with the bootenv keyword to install a new BE with the keyword installbe and a bename named s10-xx is created.

install_type initial install
pool newpool auto auto auto mirror c0t0d0s0 c0t1d0s0
bootenv installbe bename s10-xx
The following profile performs an initial installation with the keyword `install_type initial_install` of the SUNWCall metaclass in a new pool called `newpool`, which is 80 GBs in size. This pool is created with a 2-GB swap volume and a 2-GB dump volume, in a mirrored configuration of any two available devices that are large enough to create an 80-GB pool. If two such devices aren’t available, the installation fails. Boot environment characteristics are set with the `bootenv` keyword to install a new BE with the keyword `installbe` and a `bename` named `s10-xx` is created.

```plaintext
install_type initial_install
cluster SUNWCall
pool newpool 80g 2g 2g mirror any any
bootenv installbe bename s10-xx
```

JumpStart installation syntax enables you to preserve or create a UFS file system on a disk that also includes a ZFS root pool. This configuration is not recommended for production systems, but could be used for migration needs on a small system, such as a laptop.

### JumpStart Issues for ZFS

Consider the following issues before starting a JumpStart installation of a bootable ZFS root file system:

- You cannot use an existing ZFS storage pool for a JumpStart installation to create a bootable ZFS root file system. You must create a new ZFS storage pool with syntax similar to the following:
  ```plaintext
  pool rpool 20G 4G 4G c0t0d0s0
  ```

- You must create your pool with disk slices rather than with whole disks as described in “Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support” on page 113. For example, the bold syntax in the following example is not acceptable:
  ```plaintext
  install_type initial_install
  cluster SUNWCall
  pool rpool all auto auto mirror c0t0d0 c0t1d0
  bootenv installbe bename newBE
  ```

The bold syntax in the following example is acceptable:

```plaintext
install_type initial_install
cluster SUNWCall
pool rpool all auto auto mirror c0t0d0s0 c0t1d0s0
bootenv installbe bename newBE
```
Migrating a UFS Root File System to a ZFS Root File System
(Oracle Solaris Live Upgrade)

Oracle Solaris Live Upgrade features related to UFS components are still available, and they work as in previous Solaris releases.

The following features are also available:

■ When you migrate your UFS root file system to a ZFS root file system, you must designate an existing ZFS storage pool with the \(-p\) option.
■ If the UFS root file system has components on different slices, they are migrated to the ZFS root pool.
■ You can migrate a system with zones but the supported configurations are limited in the Solaris 10 10/08 release. More zone configurations are supported starting in the Solaris 10 5/09 release. For more information, see the following sections:
  ▪ “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)” on page 134
  ▪ “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)” on page 139

If you are migrating a system without zones, see “Using Oracle Solaris Live Upgrade to Migrate to a ZFS Root File System (Without Zones)” on page 129.

■ Oracle Solaris Live Upgrade can use the ZFS snapshot and clone features when you create a new ZFS BE in the same pool. So, BE creation is much faster than previous Solaris releases.

For detailed information about Oracle Solaris installation and Oracle Solaris Live Upgrade features, see the Oracle Solaris 10 9/10 Installation Guide: Solaris Live Upgrade and Upgrade Planning.

The basic process for migrating a UFS root file system to a ZFS root file system follows:

■ Install the Solaris 10 10/08, Solaris 10 5/09, Solaris 10 10/09, or Oracle Solaris 10 9/10 release or use the standard upgrade program to upgrade from a previous Solaris 10 release on any supported SPARC based or x86 based system.
■ When you are running at least the Solaris 10 10/08 release, create a ZFS storage pool for your ZFS root file system.
■ Use Oracle Solaris Live Upgrade to migrate your UFS root file system to a ZFS root file system.
■ Activate your ZFS BE with the \(luactivate\) command.

For information about ZFS and Oracle Solaris Live Upgrade requirements, see “Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support” on page 113.
ZFS Migration Issues With Oracle Solaris Live Upgrade

Review the following issues before you use Oracle Solaris Live Upgrade to migrate your UFS root file system to a ZFS root file system:

- The Oracle Solaris installation GUI's standard upgrade option is not available for migrating from a UFS to a ZFS root file system. To migrate from a UFS file system, you must use Oracle Solaris Live Upgrade.

- You must create the ZFS storage pool that will be used for booting before the Oracle Solaris Live Upgrade operation. In addition, due to current boot limitations, the ZFS root pool must be created with slices instead of whole disks. For example:

  ```
  # zpool create rpool mirror c1t0d0s0 c1t1d0s0
  ```

  Before you create the new pool, ensure that the disks to be used in the pool have an SMI (VTOC) label instead of an EFI label. If the disk is relabeled with an SMI label, ensure that the labeling process did not change the partitioning scheme. In most cases, all of the disk's capacity should be in the slices that are intended for the root pool.

- You cannot use Oracle Solaris Live Upgrade to create a UFS BE from a ZFS BE. If you migrate your UFS BE to a ZFS BE and you retain your UFS BE, you can boot from either your UFS BE or your ZFS BE.

- Do not rename your ZFS BEs with the `zfs rename` command because Oracle Solaris Live Upgrade feature cannot detect the name change. Subsequent commands, such as `ludelete`, will fail. In fact, do not rename your ZFS pools or file systems if you have existing BEs that you want to continue to use.

- When creating an alternative BE that is a clone of the primary BE, you cannot use the `-f`, `-x`, `-y`, `-Y`, and `-z` options to include or exclude files from the primary BE. You can still use the inclusion and exclusion option set in the following cases:

  ```
  UFS -> UFS
  UFS -> ZFS
  ZFS -> ZFS (different pool)
  ```

- Although you can use Oracle Solaris Live Upgrade to upgrade your UFS root file system to a ZFS root file system, you cannot use Oracle Solaris Live Upgrade to upgrade non-root or shared file systems.

- You cannot use the `lu` command to create or migrate a ZFS root file system.

Using Oracle Solaris Live Upgrade to Migrate to a ZFS Root File System (Without Zones)

The following examples show how to migrate a UFS root file system to a ZFS root file system.

If you are migrating or updating a system with zones, see the following sections:
EXAMPLE 5–3 Using Oracle Solaris Live Upgrade to Migrate a UFS Root File System to a ZFS Root File System

The following example shows how to create a BE of a ZFS root file system from a UFS root file system. The current BE, ufsBE, which contains a UFS root file system, is identified by the -c option. If you do not include the optional -c option, the current BE name defaults to the device name. The new BE, zfsBE, is identified by the -n option. A ZFS storage pool must exist before the lucreate operation.

The ZFS storage pool must be created with slices rather than with whole disks to be upgradeable and bootable. Before you create the new pool, ensure that the disks to be used in the pool have an SMI (VTOC) label instead of an EFI label. If the disk is relabeled with an SMI label, ensure that the labeling process did not change the partitioning scheme. In most cases, all of the disk’s capacity should be in the slice that is intended for the root pool.

```
# zpool create rpool mirror c1t2d0s0 c2t1d0s0
# lucreate -c ufsBE -n zfsBE -p rpool
Analyzing system configuration.
No name for current boot environment.
Current boot environment is named <ufsBE>.
Creating initial configuration for primary boot environment <ufsBE>.
The device </dev/dsk/c1t0d0s0> is not a root device for any boot environment; cannot get BE ID.
PBE configuration successful: PBE name <ufsBE> PBE Boot Device </dev/dsk/c1t0d0s0>.
Comparing source boot environment <ufsBE> file systems with the file system(s) you specified for the new boot environment. Determining which file systems should be in the new boot environment.
Updating boot environment description database on all BEs.
Updating system configuration files.
The device </dev/dsk/c1t2d0s0> is not a root device for any boot environment; cannot get BE ID.
Creating configuration for boot environment <zfsBE>.
Source boot environment is <ufsBE>.
Creating boot environment <zfsBE>.
Creating file systems on boot environment <zfsBE>.
Creating <zfs> file system for </> in zone <global> on <rpool/ROOT/zfsBE>.
Populating file systems on boot environment <zfsBE>.
Checking selection integrity.
Integrity check OK.
Populating contents of mount point </>.
Copying.
Creating shared file system mount points.
Creating compare databases for boot environment <zfsBE>.
Creating compare database for file system </rpool/ROOT>.
Creating compare database for file system </>.
Updating compare databases on boot environments <zfsBE>.
Making boot environment <zfsBE> bootable.
Creating boot archive for /.alt.tmp.b-qD.mnt
updating /.alt.tmp.b-qD.mnt/platform/sun4u/boot_archive
```
Population of boot environment <zfsBE> successful.
Creation of boot environment <zfsBE> successful.

After the `lucreate` operation completes, use the `lustatus` command to view the BE status. For example:

```
# lustatus
Boot Environment Is Complete Active Active Can Copy
Name Complete Now On Reboot Delete Status
---------- -------- ------ --------- ------ ----------
ufsBE yes yes yes no -
zfsBE yes no no yes -
```

Then, review the list of ZFS components. For example:

```
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
rpool 7.17G 59.8G 95.5K /rpool
rpool/ROOT 4.66G 59.8G 21K /rpool/ROOT
rpool/ROOT/zfsBE 4.66G 59.8G 4.66G /
rpool/dump 2G 61.8G 16K -
rpool/swap 517M 60.3G 16K -
```

Next, use the `luactivate` command to activate the new ZFS BE. For example:

```
# luactivate zfsBE
A Live Upgrade Sync operation will be performed on startup of boot environment <zfsBE>.

******************************************************************************
The target boot environment has been activated. It will be used when you reboot. NOTE: You MUST NOT USE the reboot, halt, or uadmin commands. You MUST use either the init or the shutdown command when you reboot. If you do not use either init or shutdown, the system will not boot using the target BE.

******************************************************************************
```

Modifying boot archive service
Activation of boot environment <zfsBE> successful.

Next, reboot the system to the ZFS BE.

```
# init 6
```

Confirm that the ZFS BE is active.

```
# lustatus
Boot Environment Is Active Active Can Copy
Name Complete Now On Reboot Delete Status
---------- -------- ------ --------- ------ ----------
```
Using Oracle Solaris Live Upgrade to Migrate a UFS Root File System to a ZFS Root File System (Continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Complete</th>
<th>Now</th>
<th>On Reboot</th>
<th>Delete</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>ufsBE</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>-</td>
</tr>
<tr>
<td>zfsBE</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>-</td>
</tr>
</tbody>
</table>

If you switch back to the UFS BE, you must re-import any ZFS storage pools that were created while the ZFS BE was booted because they are not automatically available in the UFS BE.

If the UFS BE is no longer required, you can remove it with the `ludclete` command.

Creating a ZFS BE from a ZFS BE in the same pool is very quick because this operation uses ZFS snapshot and clone features. If the current BE resides on the same ZFS pool, the `-p` option is omitted.

If you have multiple ZFS BES, do the following to select which BE to boot from:

- **SPARC:** You can use the `boot -L` command to identify the available BES and select a BE from which to boot by using the `boot -Z` command.
- **x86:** You can select a BE from the GRUB menu.

For more information, see Example 5–9.

```
# lucreate -n zfs2BE
Analyzing system configuration.
No name for current boot environment.
INFORMATION: The current boot environment is not named - assigning name <zfsBE>.
Current boot environment is named <zfsBE>.
Creating initial configuration for primary boot environment <zfsBE>.
The device </dev/dsk/c1t0d0s0> is not a root device for any boot environment; cannot get BE ID.
PBE configuration successful: PBE name <zfsBE> PBE Boot Device </dev/dsk/c1t0d0s0>.
Comparing source boot environment <zfsBE> file systems with the file system(s) you specified for the new boot environment. Determining which file systems should be in the new boot environment. Updating boot environment description database on all BES. Updating system configuration files. Creating configuration for boot environment <zfs2BE>. Source boot environment is <zfsBE>.
```
Upgrading Your ZFS BE (\texttt{luupgrade})

You can upgrade your ZFS BE with additional packages or patches.

The basic process follows:

- Create an alternate BE with the \texttt{lucreate} command.
- Activate and boot from the alternate BE.
- Upgrade your primary ZFS BE with the \texttt{luupgrade} command to add packages or patches.

\begin{verbatim}
# lstatus
Boot Environment Is Active Active Can Copy
Name Complete Now On Reboot Delete Status
-------------------------- -------- ------ --------- ------ ----------
zfsBE yes no no yes -
zfs2BE yes yes yes no -
# luupgrade -p -n zfsBE -s /net/system/export/s10up/Solaris_10/Product SUNWchxge
Validating the contents of the media </net/install/export/s10up/Solaris_10/Product>.  
Mounting the BE <zfsBE>.  
Adding packages to the BE <zfsBE>.  
Processing package instance <SUNWchxge> from </net/install/export/s10up/Solaris_10/Product>.
Chelsio N110 10GE NIC Driver (sparc) 11.10.0, REV=2006.02.15.20.41
This appears to be an attempt to install the same architecture and  
version of a package which is already installed. This installation  
will attempt to overwrite this package.
Using </a> as the package base directory.
## Processing package information.
## Processing system information.
## Verifying package dependencies.
## Verifying disk space requirements.
## Checking for conflicts with packages already installed.
## Checking for setuid/setgid programs.

This package contains scripts which will be executed with super-user  
permission during the process of installing this package.

Do you want to continue with the installation of <SUNWchxge> [y,n,?] y
Installing Chelsio N110 10GE NIC Driver as <SUNWchxge>
## Installing part 1 of 1.
## Executing postinstall script.
Installation of <SUNWchxge> was successful.
Unmounting the BE <zfsBE>.
The package add to the BE <zfsBE> completed.
\end{verbatim}
Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)

You can use Oracle Solaris Live Upgrade to migrate a system with zones, but the supported configurations are limited in the Solaris 10 10/08 release. If you are installing or upgrading to at least the Solaris 10 5/09 release, more zone configurations are supported. For more information, see “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)” on page 139.

This section describes how to configure and install a system with zones so that it can be upgraded and patched with Oracle Solaris Live Upgrade. If you are migrating to a ZFS root file system without zones, see “Using Oracle Solaris Live Upgrade to Migrate to a ZFS Root File System (Without Zones)” on page 129.

If you are migrating a system with zones or if you are configuring a system with zones in the Solaris 10 10/08 release, review the following procedures:

- “How to Migrate a UFS Root FileSystem With Zone Roots on UFS to a ZFS Root FileSystem (Solaris 10 10/08)” on page 134
- “How to Configure a ZFS Root FileSystem With Zone Roots on ZFS (Solaris 10 10/08)” on page 136
- “How to Upgrade or Patch a ZFS Root FileSystem With Zone Roots on ZFS (Solaris 10 10/08)” on page 137
- “Resolving ZFS Mount-Point Problems That Prevent Successful Booting (Solaris 10 10/08)” on page 156

Follow these recommended procedures to set up zones on a system with a ZFS root file system to ensure that you can use Oracle Solaris Live Upgrade on that system.

How to Migrate a UFS Root FileSystem With Zone Roots on UFS to a ZFS Root FileSystem (Solaris 10 10/08)

This procedure explains how to migrate a UFS root file system with zones installed to a ZFS root file system and ZFS zone root configuration that can be upgraded or patched.

In the steps that follow the example pool name is rpool, and the example name of the active boot environment is s10BE*.

1 Upgrade the system to the Solaris 10 10/08 release if it is running a previous Solaris 10 release.

For more information about upgrading a system is running the Solaris 10 release, see Oracle Solaris 10 9/10 Installation Guide: Solaris Upgrade and Upgrade Planning.

2 Create the root pool.

```bash
# zpool create rpool mirror c0t1d0 c1t1d0
```
For information about the root pool requirements, see “Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support” on page 113.

3 Confirm that the zones from the UFS environment are booted.

4 Create the new ZFS boot environment.
   
   # lucreate -n s10BE2 -p rpool
   
   This command establishes datasets in the root pool for the new boot environment and copies the current boot environment (including the zones) to those datasets.

5 Activate the new ZFS boot environment.
   
   # luactivate s10BE2
   
   Now, the system is running a ZFS root file system, but the zone roots on UFS are still in the UFS root file system. The next steps are required to fully migrate the UFS zones to a supported ZFS configuration.

6 Reboot the system.
   
   # init 6

7 Migrate the zones to a ZFS BE.

   a. Boot the zones.

   b. Create another ZFS BE within the pool.
      
      # lucreate s10BE3

   c. Activate the new boot environment.
      
      # luactivate s10BE3

   d. Reboot the system.
      
      # init 6
      
      This step verifies that the ZFS BE and the zones are booted.

8 Resolve any potential mount-point problems.
   Due to a bug in Oracle Solaris Live Upgrade, the inactive boot environment might fail to boot because a ZFS dataset or a zone’s ZFS dataset in the boot environment has an invalid mount point.

   a. Review the zfs list output.
      
      Look for incorrect temporary mount points. For example:
      
      # zfs list -r -o name,mountpoint rpool/ROOT/s10u6
b. Reset the mount points for the ZFS BE and its datasets.

For example:

```
# zfs inherit -r mountpoint rpool/ROOT/s10u6
# zfs set mountpoint=/ rpool/ROOT/s10u6
```

c. Reboot the system.

When the option to boot a specific boot environment is presented, either in the GRUB menu or at the OpenBoot PROM prompt, select the boot environment whose mount points were just corrected.

How to Configure a ZFS Root File System With Zone Roots on ZFS (Solaris 10 10/08)

This procedure explains how to set up a ZFS root file system and ZFS zone root configuration that can be upgraded or patched. In this configuration, the ZFS zone roots are created as ZFS datasets.

In the steps that follow the example pool name is rpool and the example name of the active boot environment is s10BE. The name for the zones dataset can be any legal dataset name. In the following example, the zones dataset name is zones.

1. **Install the system with a ZFS root, either by using the Solaris interactive text installer or the Solaris JumpStart installation method.**

   For information about installing a ZFS root file system by using the initial installation method or the Solaris JumpStart method, see “Installing a ZFS Root File System (Initial Installation)” on page 115 or “Installing a ZFS Root File System (Oracle Solaris JumpStart Installation)” on page 124.

2. **Boot the system from the newly created root pool.**

3. **Create a dataset for grouping the zone roots.**

   For example:

   ```
   # zfs create -o canmount=noauto rpool/ROOT/s10BE/zones
   ```

   Setting the noauto value for the canmount property prevents the dataset from being mounted other than by the explicit action of Oracle Solaris Live Upgrade and system startup code.
4 Mount the newly created zones dataset.
   # zfs mount rpool/ROOT/s10BE/zones
   The dataset is mounted at /zones.

5 Create and mount a dataset for each zone root.
   # zfs create -o canmount=noauto rpool/ROOT/s10BE/zones/zonerootA
   # zfs mount rpool/ROOT/s10BE/zones/zonerootA

6 Set the appropriate permissions on the zone root directory.
   # chmod 700 /zones/zonerootA

7 Configure the zone, setting the zone path as follows:
   # zonecfg -z zoneA
      zoneA: No such zone configured
      Use 'create' to begin configuring a new zone.
      zonecfg:zoneA> create
      zonecfg:zoneA> set zonepath=/zones/zonerootA
   You can enable the zones to boot automatically when the system is booted by using the
   following syntax:

      zonecfg:zoneA> set autoboote=true

8 Install the zone.
   # zoneadm -z zoneA install

9 Boot the zone.
   # zoneadm -z zoneA boot

▼ How to Upgrade or Patch a ZFS Root File System With Zone Roots on
    ZFS (Solaris 10 10/08)

Use this procedure when you need to upgrade or patch a ZFS root file system with zone roots on
ZFS. These updates can either be a system upgrade or the application of patches.

In the steps that follow, newBE is the example name of the boot environment that is upgraded or
patched.

1 Create the boot environment to upgrade or patch.
   # lucreate -n newBE
   The existing boot environment, including all the zones, is cloned. A dataset is created for each
dataset in the original boot environment. The new datasets are created in the same pool as the
current root pool.
2 Select one of the following to upgrade the system or apply patches to the new boot environment:
   ■ Upgrade the system.
     
     # luupgrade -u -n newBE -s /net/install/export/s10u7/latest
     where the -s option specifies the location of the Solaris installation medium.
   ■ Apply patches to the new boot environment.
     
     # luupgrade -t -n newBE -t -s /patchdir 139147-02 157347-14

3 Activate the new boot environment.
   
   # luactivate newBE

4 Boot from the newly activated boot environment.
   
   # init 6

5 Resolve any potential mount-point problems.
   Due to a bug in Oracle Solaris Live Upgrade feature, the inactive boot environment might fail to boot because a ZFS dataset or a zone's ZFS dataset in the boot environment has an invalid mount point.

   a. Review the zfs list output.
      Look for incorrect temporary mount points. For example:
      
      # zfs list -r -o name,mountpoint rpool/ROOT/newBE
      
      NAME MOUNTPOINT
      rpool/ROOT/newBE / .alt.tmp.b-VP.mnt/
      rpool/ROOT/newBE/zones / .alt.tmp.b-VP.mnt/zones
      rpool/ROOT/newBE/zones/zonerootA / .alt.tmp.b-VP.mnt/zones/zonerootA
      
      The mount point for the root ZFS BE (rpool/ROOT/newBE) should be /.

   b. Reset the mount points for the ZFS BE and its datasets.
      
      For example:
      
      # zfs inherit -r mountpoint rpool/ROOT/newBE
      # zfs set mountpoint=/ rpool/ROOT/newBE

   c. Reboot the system.
      When the option to boot a specific boot environment is presented, either in the GRUB menu or at the OpenBoot PROM prompt, select the boot environment whose mount points were just corrected.
Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)

You can use the Oracle Solaris Live Upgrade feature to migrate or upgrade a system with zones starting in the Solaris 10 10/08 release. Additional sparse—root and whole—root zone configurations are supported by Live Upgrade starting in the Solaris 10 5/09 release.

This section describes how to configure a system with zones so that it can be upgraded and patched with Oracle Solaris Live Upgrade starting in the Solaris 10 5/09 release. If you are migrating to a ZFS root file system without zones, see “Using Oracle Solaris Live Upgrade to Migrate to a ZFS Root File System (Without Zones)” on page 129.

Consider the following points when using Oracle Solaris Live Upgrade with ZFS and zones starting in at least the Solaris 10 5/09 release:

- To use Oracle Solaris Live Upgrade with zone configurations that are supported starting in at least the Solaris 10 5/09 release, you must first upgrade your system to at least the Solaris 10 5/09 release by using the standard upgrade program.
- Then, with Oracle Solaris Live Upgrade, you can either migrate your UFS root file system with zone roots to a ZFS root file system or you can upgrade or patch your ZFS root file system and zone roots.
- You cannot directly migrate unsupported zone configurations from a previous Solaris 10 release to at least the Solaris 10 5/09 release.

If you are migrating or configuring a system with zones starting in the Solaris 10 5/09 release, review the following information:

- “Supported ZFS with Zone Root Configuration Information (at Least Solaris 10 5/09)” on page 139
- “How to Create a ZFS BE With a ZFS Root File System and a Zone Root (at Least Solaris 10 5/09)” on page 141
- “How to Upgrade or Patch a ZFS Root File System With Zone Roots (at Least Solaris 10 5/09)” on page 142
- “How to Migrate a UFS Root File System With a Zone Root to a ZFS Root File System (at Least Solaris 10 5/09)” on page 146

Supported ZFS with Zone Root Configuration Information (at Least Solaris 10 5/09)

Review the supported zone configurations before using Oracle Solaris Live Upgrade to migrate or upgrade a system with zones.

- **Migrate a UFS root file system to a ZFS root file system** – The following configurations of zone roots are supported:
- In a directory in the UFS root file system
- In a subdirectory of a mount point in the UFS root file system
- UFS root file system with a zone root in a UFS root file system directory or in a subdirectory of a UFS root file system mount point and a ZFS non-root pool with a zone root

The following UFS/zone configuration is not supported: UFS root file system that has a zone root as a mount point.

- **Migrate or upgrade a ZFS root file system** – The following configurations of zone roots are supported:
  - In a dataset in the ZFS root pool. In some cases, if a dataset for the zone root is not provided before the Oracle Solaris Live Upgrade operation, a dataset for the zone root (zoneds) will be created by Oracle Solaris Live Upgrade.
  - In a subdirectory of the ZFS root file system
  - In a dataset outside of the ZFS root file system
  - In a subdirectory of a dataset outside of the ZFS root file system
  - In a dataset in a non root pool. In the following example, `zonepool/zones` is a dataset that contains the zone roots, and `rpool` contains the ZFS BE:

```
zonepool
zonepool/zones
zonepool/zones/myzone
rpool
rpool/ROOT
rpool/ROOT/myBE
```

Oracle Solaris Live Upgrade snapshots and clones the zones in `zonepool` and the `rpool` BE if you use this syntax:

```
# lucreate -n newBE
```

The `newBE` BE in `rpool/ROOT/newBE` is created. When activated, `newBE` provides access to the `zonepool` components.

In the proceeding example, if `/zonepool/zones` was a subdirectory and not a separate dataset, then Live Upgrade would migrate it as components of the root pool, `rpool`.

- **Zones Migration or upgrade information with zones for both UFS and ZFS** – Review the following considerations that might affect a migration or an upgrade of either a UFS and ZFS environment:

  - If you configured your zones as described in “Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)” on page 134 in the Solaris 10 10/08 release and have upgraded to at least the Solaris 10 5/09, you should be able to migrate to a ZFS root file system or use Solaris Live Upgrade to upgrade to at least the Solaris 10 5/09 release.
Do not create zone roots in nested directories, for example, zones/zone1 and zones/zone1/zone2. Otherwise, mounting might fail at boot time.

How to Create a ZFS BE With a ZFS Root File System and a Zone Root (at Least Solaris 10 5/09)

Use this procedure after you have performed an initial installation of at least the Solaris 10 5/09 release to create a ZFS root file system. Also use this procedure after you have used the \upgrade feature to upgrade a ZFS root file system to at least the Solaris 10 5/09 release. A ZFS BE that is created using this procedure can then be upgraded or patched.

In the steps that follow, the example Oracle Solaris 10 9/10 system has a ZFS root file system and a zone root dataset in /rpool/zones. A ZFS BE named zfs2BE is created and can then be upgraded or patched.

1 Review the existing ZFS file systems.

```
# zfs list
NAME    USED   AVAIL   REFER  MOUNTPOINT
rpool   7.26G  59.7G   98K    /rpool
rpool/ROOT 4.64G  59.7G   21K    /zone1
rpool/ROOT/zfsBE 4.64G  59.7G  4.64G   /
```

2 Ensure that the zones are installed and booted.

```
# zoneadm list -cv
ID    NAME    STATUS PATH BRAND   IP
0     global  running / native   shared
2     zfszone running /rpool/zones native shared
```

3 Create the ZFS BE.

```
# lucreate -n zfs2BE
Analyzing system configuration.
No name for current boot environment.
INFORMATION: The current boot environment is not named - assigning name <zfs2BE>. Current boot environment is named <zfs2BE>. Creating initial configuration for primary boot environment <zfs2BE>. The device /dev/dsk/c1t0d0s0 is not a root device for any boot environment; cannot get BE ID. PBE configuration successful: PBE name <zfs2BE> PBE Boot Device /dev/dsk/c1t0d0s0. Comparing source boot environment <zfs2BE> file systems with the file system(s) you specified for the new boot environment. Determining which file systems should be in the new boot environment. Updating boot environment description database on all BEs. Updating system configuration files. Creating configuration for boot environment <zfs2BE>. Source boot environment is <zfs2BE>. Creating boot environment <zfs2BE>.
```
Cloning file systems from boot environment <zfsBE> to create boot environment <zfs2BE>.
Creating snapshot for <rpool/ROOT/zfsBE> on <rpool/ROOT/zfsBE@zfs2BE>.
Creating clone for <rpool/ROOT/zfsBE@zfs2BE> on <rpool/ROOT/zfs2BE>.
Population of boot environment <zfs2BE> successful.
Creation of boot environment <zfs2BE> successful.

4 Activate the ZFS BE.

# lstatus

How to Upgrade or Patch a ZFS Root File System With Zone Roots (at Least Solaris 10 5/09)

Use this procedure when you need to upgrade or patch a ZFS root file system with zone roots in at least the Solaris 10 5/09 release. These updates can either be a system upgrade or the application of patches.

In the steps that follow, zfs2BE, is the example name of the boot environment that is upgraded or patched.
1 Review the existing ZFS file systems.

   # zfs list
   NAME     USED  AVAIL  REFER MOUNTPOINT
   rpool    7.38G  59.6G  100K /rpool
   rpool/ROOT 4.72G  59.6G   21K legacy
   rpool/ROOT/zfs2BE 4.72G  59.6G   4.64G /
   rpool/ROOT/zfs2BE@zfs2BE 75.0M - 4.64G -
   rpool/zfsBE 5.46M  59.6G    4.64G /
   rpool/dump 1.00G  59.6G   1.00G -
   rpool/export 44K  59.6G    23K /export
   rpool/export/home 21K  59.6G    21K /export/home
   rpool/swap    1G  68.6G    16K -
   rpool/zones 22.9M  59.6G  637M /rpool/zones
   rpool/zones-zfsBE 653M  59.6G  633M /rpool/zones-zfsBE
   rpool/zones-zfsBE@zfs2BE 20.0M - 633M -

2 Ensure that the zones are installed and booted.

   # zoneadm list -cv
   ID NAME STATUS PATH BRAND IP
   0 global running / native shared
   5 zfszone running /rpool/zones native shared

3 Create the ZFS BE to upgrade or patch.

   # lucreate -n zfs2BE
   Analyzing system configuration.
   Comparing source boot environment <zfsBE> file systems with the file
   system(s) you specified for the new boot environment. Determining which
   file systems should be in the new boot environment.
   Updating boot environment description database on all BEs.
   Updating system configuration files.
   Creating configuration for boot environment <zfs2BE>.
   Source boot environment is <zfsBE>.
   Creating boot environment <zfs2BE>.
   Cloning file systems from boot environment <zfsBE> to create boot environment <zfs2BE>.
   Creating snapshot for <rpool/ROOT/zfsBE> on <rpool/ROOT/zfs2BE>.
   Creating clone for <rpool/ROOT/zfsBE@zfs2BE> on <rpool/ROOT/zfs2BE>.
   Setting canmount=noauto for </> in zone <global> on <rpool/ROOT/zfs2BE>.
   Creating snapshot for <rpool/zones> on <rpool/zones@zfs10092BE>.
   Creating clone for <rpool/zones@zfsBE> on <rpool/zones-zfs2BE>.
   Population of boot environment <zfs2BE> successful.
   Creation of boot environment <zfs2BE> successful.

4 Select one of the following to upgrade the system or apply patches to the new boot environment:

   - Upgrade the system.
     
     # luupgrade -u -n zfs2BE -s /net/install/export/sl0up/latest
     
     where the -s option specifies the location of the Solaris installation medium.
     
     This process can take a very long time.
     
     For a complete example of the `luupgrade` process, see Example 5–6.
Apply patches to the new boot environment.

```
# luupgrade -t -n zfs2BE -t -s /patchdir patch-id-02 patch-id-04
```

5 Activate the new boot environment.

```
# lstatus

<table>
<thead>
<tr>
<th>Boot Environment</th>
<th>Is Complete</th>
<th>Active</th>
<th>Active</th>
<th>Can Copy</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>zfsBE</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>-</td>
</tr>
<tr>
<td>zfs2BE</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>-</td>
</tr>
</tbody>
</table>
```

```
# luactivate zfs2BE
```

A Live Upgrade Sync operation will be performed on startup of boot environment <zfs2BE>.

6 Boot from the newly activated boot environment.

```
# init 6
```

Example 5–6 Upgrading a ZFS Root File System With a Zone Root to a Oracle Solaris 10 9/10 ZFS Root File System

In this example, a ZFS BE (zfsBE), which was created on a Solaris 10 10/09 system with a ZFS root file system and zone root in a non root pool, is upgraded to the Oracle Solaris 10 9/10 release. This process can take a long time. Then, the upgraded BE (zfs2BE) is activated. Ensure that the zones are installed and booted before attempting the upgrade.

In this example, the zonepool pool, the /zonepool/zones dataset, and the zfszone zone are created as follows:

```
# zpool create zonepool mirror c2t1d0 c2t5d0
# zfs create zonepool/zones
# chmod 700 zonepool/zones
# zonectf -z zfszone
zfszone: No such zone configured
Use 'create' to begin configuring a new zone.
zoneconfig:zfszone> create
zoneconfig:zfszone> set zonepath=/zonepool/zones
zoneconfig:zfszone> verify
zoneconfig:zfszone> exit
# zoneadm -z zfszone install
cannot create ZFS dataset zonepool/zones: dataset already exists
Preparing to install zone <zfszone>.
Creating list of files to copy from the global zone.
Copying <8960> files to the zone.
```

How to Migrate a UFS Root File System With a Zone Root to a ZFS Root File System (at Least Solaris 10 5/09)

Use this procedure to migrate a system with a UFS root file system and a zone root to at least the Solaris 10 5/09 release. Then, use Oracle Solaris Live Upgrade to create a ZFS BE.

In the steps that follow, the example UFS BE name is c0t1d0s0, the UFS zone root is zonepool/zfszone, and the ZFS root BE is zfsBE.

1 Upgrade the system to at least the Solaris 10 5/09 release if it is running a previous Solaris 10 release.

For information about upgrading a system that is running the Solaris 10 release, see Oracle Solaris 10 9/10 Installation Guide: Solaris Live Upgrade and Upgrade Planning.

2 Create the root pool.

For information about the root pool requirements, see "Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support" on page 113.

3 Confirm that the zones from the UFS environment are booted.

```
# zoneadm list -cv

<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
<th>STATUS</th>
<th>PATH</th>
<th>BRAND</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>global</td>
<td>running</td>
<td>/</td>
<td>native</td>
<td>shared</td>
</tr>
<tr>
<td>2</td>
<td>zfszone</td>
<td>running</td>
<td>/zonepool/zones</td>
<td>native</td>
<td>shared</td>
</tr>
</tbody>
</table>
```

4 Create the new ZFS boot environment.

```
# l ucreate -c c1t1d0s0 -n zfsBE -p rpool
```

This command establishes datasets in the root pool for the new boot environment and copies the current boot environment (including the zones) to those datasets.

5 Activate the new ZFS boot environment.

```
# l ustatus

Boot Environment Name | Is Complete | Active | Active On Reboot | Can Delete | Copy Status
-----------------------|-------------|--------|------------------|------------|---------------
clt1d0s0              | yes         | no     | no               | yes        | -             |
zfsBE                  | yes         | yes    | yes              | no         | -             |
```

```
# l uactivate zfsBE
```

A Live Upgrade Sync operation will be performed on startup of boot environment <zfsBE>.

6 Reboot the system.

```
# init 6
```
Confirm that the ZFS file systems and zones are created in the new BE.

```
# zfs list
NAME | USED  | AVAIL | REFER | MOUNTPOINT
--- | --- | --- | --- | ---
rpool | 6.17G | 60.8G | 98K | /rpool
rpool/ROOT | 4.67G | 60.8G | 21K | /rpool/ROOT
rpool/ROOT/zfsBE | 4.67G | 60.8G | 4.67G | /

zonепool/zones-c1t1d0s0@zfsBE | 262K | - | 633M | -
```

```
# zoneadm list -cv
ID | NAME | STATUS | PATH | BRAND | IP
--- | --- | --- | --- | --- | ---
0 | global | running | / | native | shared
- | zfszone | installed | /zonепool/zones | native | shared
```

Example 5–7 Migrating a UFS Root File System With a Zone Root to a ZFS Root File System

In this example, a Oracle Solaris 10 9/10 system with a UFS root file system and a zone root (/uzone/ufszone), as well as a ZFS non-root pool (pool) and a zone root (/pool/zfszone), is migrated to a ZFS root file system. Ensure that the ZFS root pool is created and that the zones are installed and booted before attempting the migration.

```
# zoneadm list -cv
ID | NAME | STATUS | PATH | BRAND | IP
--- | --- | --- | --- | --- | ---
0 | global | running | / | native | shared
2 | ufszone | running | /uzone/ufszone | native | shared
3 | zfszone | running | /pool/zones/zfszone | native | shared
```

```
# lucreate -c ufsBE -n zfsBE -P rpool
Analyzing system configuration.
No name for current boot environment.
Current boot environment is named <zfsBE>.

Creating shared file system mount points.
```
ZFS Support for Swap and Dump Devices

During an initial Solaris OS installation or after performing an Oracle Solaris Live Upgrade migration from a UFS file system, a swap area is created on a ZFS volume in the ZFS root pool. For example:

```
# swap -l
swapfile      dev swaplo blocks free
/dev/zvol/dsk/rpool/swap 256,1 16 4194288 4194288
```
During an initial Solaris OS installation or a Oracle Solaris Live Upgrade from a UFS file system, a dump device is created on a ZFS volume in the ZFS root pool. In general, a dump device requires no administration because it is setup automatically at installation time. For example:

```
# dumpadm
Dump content: kernel pages
   Dump device: /dev/zvol/dsk/rpool/dump (dedicated)
Savecore directory: /var/crash/t2000
   Savecore enabled: yes
   Save compressed: on
```

If you disable and remove the dump device, then you will need to enable it with the `dumpadm` command after it is recreated. In most cases, you will only have to adjust the size of the dump device by using the `zfs` command.

For information about the swap and dump volume sizes that are created by the installation programs, see "Oracle Solaris Installation and Oracle Solaris Live Upgrade Requirements for ZFS Support" on page 113.

Both the swap volume size and the dump volume size can be adjusted during and after installation. For more information, see "Adjusting the Sizes of Your ZFS Swap Device and Dump Device" on page 149.

Consider the following issues when working with your ZFS swap and dump devices:

- Separate ZFS volumes must be used for the swap area and the dump device.
- Currently, using a swap file on a ZFS file system is not supported.
- If you need to change your swap area or dump device after the system is installed or upgraded, use the `swap` and `dumpadm` commands as in previous Solaris releases. For more information, see Chapter 20, “Configuring Additional Swap Space (Tasks),” in System Administration Guide: Devices and File Systems and Chapter 17, “Managing System Crash Information (Tasks),” in System Administration Guide: Advanced Administration.

See the following sections for more information:

- “Adjusting the Sizes of Your ZFS Swap Device and Dump Device” on page 149
- “Troubleshooting ZFS Dump Device Issues” on page 151

### Adjusting the Sizes of Your ZFS Swap Device and Dump Device

Because of the differences in the way a ZFS root installation determines the size of swap and dump devices, you might need to adjust their size before, during, or after installation.
You can adjust the size of your swap and dump volumes during an initial installation. For more information, see Example 5–1.

You can create and size your swap and dump volumes before you perform an Oracle Solaris Live Upgrade operation. For example:

1. Create your storage pool.
   
   ```
   # zpool create rpool mirror c0t0d0s0 c0t1d0s0
   ```

2. Create your dump device.
   
   ```
   # zfs create -V 2G rpool/dump
   ```

3. Enable the dump device.
   
   ```
   # dumpadm -d /dev/zvol/dsk/rpool/dump
   
   Dump content: kernel pages
   Dump device: /dev/zvol/dsk/rpool/dump (dedicated)
   Savecore directory: /var/crash/t2000
   Savecore enabled: yes
   Save compressed: on
   ```

4. Select one of the following to create your swap area:
   
   - SPARC: Create your swap area. Set the block size to 8 KB.
     ```
     # zfs create -V 2G -b 8k rpool/swap
     ```
   - x86: Create your swap area. Set the block size to 4 KB.
     ```
     # zfs create -V 2G -b 4k rpool/swap
     ```

5. You must enable the swap volume when a new swap device is added or changed.
6. Add an entry for the swap volume to the /etc/vfstab file.

Oracle Solaris Live Upgrade does not resize existing swap and dump volumes.

You can reset the volsize property of the dump device after a system is installed. For example:

```
# zfs set volsize=2G rpool/dump
# zfs get volsize rpool/dump
```

```
NAME  PROPERTY  VALUE  SOURCE
rpool/dump  volsize  2G  -
```

You can resize the swap volume but until CR 6765386 is integrated, it is best to remove the swap device first. Then, recreate it. For example:

```
# swap -d /dev/zvol/dsk/rpool/swap
# zfs volsize=2G rpool/swap
# swap -a /dev/zvol/dsk/rpool/swap
```

For information about removing a swap device on an active system, see this site:

You can adjust the size of the swap and dump volumes in a JumpStart profile by using profile syntax similar to the following:
install_type initial_install
cluster SUNWCXall
pool rpool 16g 2g 2g c0t0d0s0

In this profile, two 2g entries set the size of the swap volume and dump volume as 2 GB each.

- If you need more swap space on a system that is already installed, just add another swap volume. For example:

  # zfs create -V 2G rpool/swap2

Then, activate the new swap volume. For example:

  # swap -a /dev/zvol/dsk/rpool/swap2

  # swap -l

  swapfile    dev    swaplo    blocks    free
  /dev/zvol/dsk/rpool/swap 256,1       16 1058800 1058800
  /dev/zvol/dsk/rpool/swap2 256,3      16 4194288 4194288

Finally, add an entry for the second swap volume to the /etc/vfstab file.

Troubleshooting ZFS Dump Device Issues

Review the following items if you have problems either capturing a system crash dump or resizing the dump device.

- If a crash dump was not created automatically, you can use the savecore command to save the crash dump.

- A dump volume is created automatically when you initially install a ZFS root file system or migrate to a ZFS root file system. In most cases, you will only need to adjust the size of the dump volume if the default dump volume size is too small. For example, on a large-memory system, the dump volume size is increased to 40 GB as follows:

  # zfs set volsize=40G rpool/dump

Resizing a large dump volume can be a time-consuming process.

If, for any reason, you need to enable a dump device after you create a dump device manually, use syntax similar to the following:

  # dumpadm -d /dev/zvol/dsk/rpool/dump

  Dump content: kernel pages
  Dump device: /dev/zvol/dsk/rpool/dump (dedicated)
  Savecore directory: /var/crash/t2000
  Savecore enabled: yes

- A system with 128 GB or greater memory will need a larger dump device than the dump device that is created by default. If the dump device is too small to capture an existing crash dump, a message similar to the following is displayed:

  # dumpadm -d /dev/zvol/dsk/rpool/dump
dumpadm: dump device /dev/zvol/dsk/rpool/dump is too small to hold a system dump
dump size 36255432704 bytes, device size 34359738368 bytes

For information about sizing the swap and dump devices, see “Planning for Swap Space” in System Administration Guide: Devices and File Systems.

- You cannot currently add a dump device to a pool with multiple top level-devices. You will see a message similar to the following:

```
# dumpadm -d /dev/zvol/dsk/datapool/dump
dump is not supported on device '/dev/zvol/dsk/datapool/dump': 'datapool' has multiple top level vdevs
```

Add the dump device to the root pool, which cannot have multiple top-level devices.

Booting From a ZFS Root File System

Both SPARC based and x86 based systems use the new style of booting with a boot archive, which is a file system image that contains the files required for booting. When a system is booted from a ZFS root file system, the path names of both the boot archive and the kernel file are resolved in the root file system that is selected for booting.

When a system is booted for installation, a RAM disk is used for the root file system during the entire installation process.

Booting from a ZFS file system differs from booting from a UFS file system because with ZFS, the boot device specifier identifies a storage pool, not a single root file system. A storage pool can contain multiple bootable datasets or ZFS root file systems. When booting from ZFS, you must specify a boot device and a root file system within the pool that was identified by the boot device.

By default, the dataset selected for booting is identified by the pool’s boot fs property. This default selection can be overridden by specifying an alternate bootable dataset in the boot -Z command.

Booting From an Alternate Disk in a Mirrored ZFS Root Pool

You can create a mirrored ZFS root pool when the system is installed, or you can attach a disk to create a mirrored ZFS root pool after installation. For more information see:

- “Installing a ZFS Root File System (Initial Installation)” on page 115
- “How to Create a Mirrored Root Pool (Post Installation)” on page 121

Review the following known issues regarding mirrored ZFS root pools:
You must install the boot information on the additionally attached disks by using the `installboot` or `installgrub` commands to enable booting on the other disks in the mirror. If you create a mirrored ZFS root pool with the initial installation method, then this step is unnecessary. For example, if `c0t1d0s0` was the second disk added to the mirror, then the `installboot` or `installgrub` command syntax would be as follows:

**SPARC:**
```
sparc# installboot -F zfs /usr/platform/`uname -i`/lib/fs/zfs/bootblk /dev/rdsk/c0t1d0s0
```

**x86:**
```
x86# installgrub /boot/grub/stage1 /boot/grub/stage2 /dev/rdsk/c0t1d0s0
```

You can boot from different devices in a mirrored ZFS root pool. Depending on the hardware configuration, you might need to update the PROM or the BIOS to specify a different boot device.

For example, you can boot from either disk (`c1t0d0s0` or `c1t1d0s0`) in the following pool.

```
# zpool status
pool: rpool
  state: ONLINE
  scrub: none requested
  config:

  NAME    STATE  READ  WRITE  CKSUM
  rpool   ONLINE  0    0      0
  mirror-0 ONLINE  0    0      0
  c1t0d0s0 ONLINE  0    0      0
  c1t1d0s0 ONLINE  0    0      0
```

**SPARC:** Enter the alternate disk at the `ok` prompt.
```
ok boot /pci@7c0/pci@0/pci@1/pci@0,2/LSILogic,sas@2/disk@0
```

After the system is rebooted, confirm the active boot device. For example:

```
SPARC# prtconf -vp | grep bootpath
bootpath: /pci@7c0/pci@0/pci@1/pci@0,2/LSILogic,sas@2/disk@0,0:a'
```

**x86:** Select an alternate disk in the mirrored ZFS root pool from the appropriate BIOS menu. Then, use syntax similar to the following to confirm that you are booted from the alternate disk:

```
x86# prtconf -v|sed -n '/bootpath/,'value/p'
  name='bootpath' type=string items=1
  value='/pci@0,0/pci8086,25f8@4/pci108e,286@0/disk@0,0:a'
```

---

**SPARC: Booting From a ZFS Root File System**

On a SPARC based system with multiple ZFS BEs, you can boot from any BE by using the `luactivate` command.
During the Solaris OS installation and Oracle Solaris Live Upgrade process, the ZFS root file system is automatically designated with the `bootfs` property.

Multiple bootable datasets can exist within a pool. By default, the bootable dataset entry in the `/pool-name/boot/menu.lst` file is identified by the pool’s `bootfs` property. However, a `menu.lst` entry can contain a `bootfs` command, which specifies an alternate dataset in the pool. In this way, the `menu.lst` file can contain entries for multiple root file systems within the pool.

When a system is installed with a ZFS root file system or migrated to a ZFS root file system, an entry similar to the following is added to the `menu.lst` file:

```
title zfsBE
bootfs rpool/ROOT/zfsBE

title zfs2BE
bootfs rpool/ROOT/zfs2BE
```

When a new BE is created, the `menu.lst` file is updated automatically.

On a SPARC based system, two new boot options are available:

- After the BE is activated, you can use the `boot -L` command to display a list of bootable datasets within a ZFS pool. Then, you can select one of the bootable datasets in the list. Detailed instructions for booting that dataset are displayed. You can boot the selected dataset by following the instructions.
- You can use the `boot -Z dataset` command to boot a specific ZFS dataset.

**EXAMPLE 5-8  SPARC: Booting From a Specific ZFS Boot Environment**

If you have multiple ZFS BEs in a ZFS storage pool on your system’s boot device, you can use the `luactivate` command to specify a default BE.

For example, the following ZFS BEs are available as described by the `lustatus` output:

```
# lustatus
Boot Environment Name  Is Complete  Active Now  Active On Reboot  Can Delete  Copy Status
-------------------------- -------- ------ ----------- ----------- --------- --------
zfsBE                     yes     no      no          yes         -
zfs2BE                    yes     yes     yes         no         -
```

If you have multiple ZFS BEs on your SPARC based system, you can use the `boot -L` command to boot from a BE that is different from the default BE. However, a BE that is booted from a `boot -L` session is not reset as the default BE nor is the `bootfs` property updated. If you want to make the BE booted from a `boot -L` session the default BE, then you must activate it with the `luactivate` command.

For example:
EXAMPLE 5–8  SPARC: Booting From a Specific ZFS Boot Environment  (Continued)

ok boot -L
Rebooting with command: boot -L
Boot device: /pci@7c0/pci@0/pci@1/pci@0,2/LSILogic,sas@2/disk@0
File and args: -L

1 zfsBE
2 zfs2BE
Select environment to boot: [ 1 - 2 ]; 1
To boot the selected entry, invoke:
boot [<root-device>] -Z rpool/ROOT/zfsBE

Program terminated
ok boot -Z rpool/ROOT/zfsBE

EXAMPLE 5–9  SPARC: Booting a ZFS File System in Failsafe Mode

On a SPARC based system, you can boot from the failsafe archive located in /platform/'uname -i'/failsafe as follows:

ok boot -F failsafe

To boot a failsafe archive from a particular ZFS bootable dataset, use syntax similar to the following:

ok boot -Z rpool/ROOT/zfsBE -F failsafe

x86: Booting From a ZFS Root File System

The following entries are added to the /pool-name/boot/grub/menu.lst file during the Solaris OS installation process or Oracle Solaris Live Upgrade operation to boot ZFS automatically:

title Solaris 10 9/10 X86
findroot (rootfs0,0,a)
kernels /platform/i86pc/multiboot -B $ZFS-BOOTFS
module /platform/i86pc/boot_archive

title Solaris failsafe
findroot (rootfs0,0,a)
kernels /boot/multiboot kernel/unix -s -B console=ttya
module /boot/x86.miniroot-safe

If the device identified by GRUB as the boot device contains a ZFS storage pool, the menu.lst file is used to create the GRUB menu.

On an x86 based system with multiple ZFS BEs, you can select a BE from the GRUB menu. If the root file system corresponding to this menu entry is a ZFS dataset, the following option is added:

- B $ZFS-BOOTFS
When a system boots from a ZFS file system, the root device is specified by the boot
-B $ZFS\_BOOTFS parameter on either the kernel or module line in the GRUB menu entry. This
parameter value, similar to all parameters specified by the -B option, is passed by GRUB to the
kernel. For example:

```
title Solaris 10 9/10 X86
findroot (rootfs0,0,a)
kernelf /platform/i86pc/multiboot -B $ZFS\_BOOTFS
module /platform/i86pc/boot_archive

```  

```
title Solaris failsafe
findroot (rootfs0,0,a)
kernelf /boot/multiboot kernel/unix -s -B console=ttya
module /boot/x86.miniroot-safe
```

The x86 failsafe archive is /boot/x86.miniroot-safe and can be booted by selecting the Solaris
failsafe entry from the GRUB menu. For example:

```
title Solaris failsafe
findroot (rootfs0,0,a)
kernelf /boot/multiboot kernel/unix -s -B console=ttya
module /boot/x86.miniroot-safe
```

**Resolving ZFS Mount-Point Problems That Prevent Successful Booting (Solaris 10 10/08)**

The best way to change the active boot environment is to use the `luactivate` command. If
booting the active environment fails due to a bad patch or a configuration error, the only way to
boot from a different environment is to select that environment at boot time. You can select an
alternate BE from the GRUB menu on an x86 based system or by booting it explicitly from the
PROM on a SPARC based system.

Due to a bug in Oracle Solaris Live Upgrade in the Solaris 10 10/08 release, the inactive boot
environment might fail to boot because a ZFS dataset or a zone's ZFS dataset in the boot
environment has an invalid mount point. The same bug also prevents the BE from mounting if
it has a separate /var dataset.

If a zone dataset has an invalid mount point, the mount point can be corrected by performing
the following steps.
How to Resolve ZFS Mount-Point Problems

1. Boot the system from a failsafe archive.

2. Import the pool.
   For example:
   ```
   # zpool import rpool
   ```

3. Look for incorrect temporary mount points.
   For example:
   ```
   # zfs list -r -o name,mountpoint rpool/ROOT/s10u6
   ```
<table>
<thead>
<tr>
<th>NAME</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpool/ROOT/s10u6</td>
<td>/.alt.tmp.b-VP.mnt/</td>
</tr>
<tr>
<td>rpool/ROOT/s10u6/zones</td>
<td>/.alt.tmp.b-VP.mnt//zones</td>
</tr>
<tr>
<td>rpool/ROOT/s10u6/zones/zonerootA</td>
<td>/.alt.tmp.b-VP.mnt//zones/zonerootA</td>
</tr>
</tbody>
</table>

   The mount point for the root BE (rpool/ROOT/s10u6) should be `/`.

   If the boot is failing because of `/var` mounting problems, look for a similar incorrect temporary mount point for the `/var` dataset.

4. Reset the mount points for the ZFS BE and its datasets.
   For example:
   ```
   # zfs inherit -r mountpoint rpool/ROOT/s10u6
   # zfs set mountpoint=/ rpool/ROOT/s10u6
   ```

5. Reboot the system.
   When the option to boot a specific boot environment is presented, either in the GRUB menu or at the OpenBoot PROM prompt, select the boot environment whose mount points were just corrected.

Booting For Recovery Purposes in a ZFS Root Environment

Use the following procedure if you need to boot the system so that you can recover from a lost root password or similar problem.

You will need to boot failsafe mode or boot from alternate media, depending on the severity of the error. In general, you can boot failsafe mode to recover a lost or unknown root password.

- “How to Boot ZFS Failsafe Mode” on page 158
- “How to Boot ZFS From Alternate Media” on page 158
If you need to recover a root pool or root pool snapshot, see “Recovering the ZFS Root Pool or Root Pool Snapshots” on page 159.

▼ How to Boot ZFS Failsafe Mode

1 Boot failsafe mode.
   On a SPARC system:
   ok boot -F failsafe
   On an x86 system, select failsafe mode from the GRUB prompt.

2 Mount the ZFS BE on /a when prompted:
   .
   .
   ROOT/zfsBE was found on rpool.
   Do you wish to have it mounted read-write on /a? [y,n,?] y
   mounting rpool on /a
   Starting shell.

3 Change to the /a/etc directory.
   # cd /a/etc

4 If necessary, set the TERM type.
   # TERM=vt100
   # export TERM

5 Correct the passwd or shadow file.
   # vi shadow

6 Reboot the system.
   # init 6

▼ How to Boot ZFS From Alternate Media

If a problem prevents the system from booting successfully or some other severe problem occurs, you will need to boot from a network install server or from a Solaris installation CD, import the root pool, mount the ZFS BE, and attempt to resolve the issue.

1 Boot from an installation CD or from the network.
   - SPARC:
     ok boot cdrom -s
     ok boot net -s
     If you don’t use the -s option, you will need to exit the installation program.
Recovering the ZFS Root Pool or Root Pool Snapshots

The following sections describe how to perform the following tasks:

- "How to Replace a Disk in the ZFS Root Pool" on page 159
- "How to Create Root Pool Snapshots" on page 161
- "How to Recreate a ZFS Root Pool and Restore Root Pool Snapshots" on page 162
- "How to Roll Back Root Pool Snapshots From a Failsafe Boot" on page 164

▼ How to Replace a Disk in the ZFS Root Pool

You might need to replace a disk in the root pool for the following reasons:

- The root pool is too small and you want to replace a smaller disk with a larger disk.
- A root pool disk is failing. In a non-redundant pool, if the disk is failing such that the system
  won’t boot, you must boot from an alternate media, such as a CD or the network, before you
  replace the root pool disk.

In a mirrored root pool configuration, you can attempt a disk replacement without booting
from alternate media. You can replace a failed disk by using the zpool replace command. Or,
if you have an additional disk, you can use the zpool attach command. See the procedure in
this section for an example of attaching an additional disk and detaching a root pool disk.

Some hardware requires that you take a disk offline and unconfigure it before attempting the
zpool replace operation to replace a failed disk. For example:

```
# zpool offline rpool clt0d0s0
# cfgadm -c unconfigure cl::disk/clt0d0
<Physically remove failed disk clt0d0>
```
<Physically insert replacement disk c1t0d0>
# cfgadm -c configure c1::dsk/c1t0d0
# zpool replace rpool c1t0d0s0
# zpool online rpool c1t0d0s0
# zpool status rpool

<Let disk resilver before installing the boot blocks>

On some hardware, you do not have to online or reconfigure the replacement disk after it is inserted.

You must identify the boot device pathnames of the current disk and the new disk so that you can test booting from the replacement disk and also manually boot from the existing disk, if the replacement disk fails. In the example in the following procedure, the path name for current root pool disk (c1t10d0s0) is:

```
/pci@8,700000/pci@3/scsi@5/sd@a,0
```

The path name for the replacement boot disk (c1t9d0s0) is:

```
/pci@8,700000/pci@3/scsi@5/sd@9,0
```

1  Physically connect the replacement (or new) disk.

2  Confirm that the new disk has an SMI label and a slice 0.
For information about relabeling a disk that is intended for the root pool, see the following site:

3  Attach the new disk to the root pool.
For example:

```
# zpool attach rpool c1t10d0s0 c1t9d0s0
```

4  Confirm the root pool status.
For example:

```
# zpool status rpool
pool: rpool
  state: ONLINE
  status: One or more devices is currently being resilvered. The pool will continue to function, possibly in a degraded state.
  action: Wait for the resilver to complete.
  scrub: resilver in progress, 25.47% done, 0h4m to go
  config:

   NAME     STATE   READ  WRITE  CKSUM
   rpool    ONLINE  0     0      0
   mirror-0 ONLINE  0     0      0
   c1t10d0s0 ONLINE  0     0      0
   c1t9d0s0  ONLINE  0     0      0
```
After the resilvering is completed, apply the boot blocks to the new disk.

Using syntax similar to the following:

- **SPARC:**
  ```
  # installboot -F zfs /usr/platform/`uname -i`/lib/fs/zfs/bootblk /dev/rdsk/c1t9d0s0
  ```

- **x86:**
  ```
  # installgrub /boot/grub/stage1 /boot/grub/stage2 /dev/rdsk/c1t9d0s0
  ```

Verify that you can boot from the new disk.

For example, on a SPARC based system, you would use syntax similar to the following:

```
ok boot /pci@8,700000/pci@3/scsi@5/sd@9,0
```

If the system boots from the new disk, detach the old disk.

For example:

```
# zpool detach rpool c1t10d0s0
```

Set up the system to boot automatically from the new disk, either by using the `eeprom` command, the `setenv` command from the SPARC boot PROM, or reconfigure the PC BIOS.

### How to Create Root Pool Snapshots

You can create root pool snapshots for recovery purposes. The best way to create root pool snapshots is to perform a recursive snapshot of the root pool.

The following procedure creates a recursive root pool snapshot and stores the snapshot as a file in a pool on a remote system. If a root pool fails, the remote dataset can be mounted by using NFS and the snapshot file can be received into the recreated pool. You can instead store root pool snapshots as the actual snapshots in a pool on a remote system. Sending and receiving the snapshots from a remote system is a bit more complicated because you must configure `ssh` or use `rsh` while the system to be repaired is booted from the Solaris OS miniroot.

For information about remotely storing and recovering root pool snapshots, for the most up-to-date information about root pool recovery, go to this site:

Validating remotely stored snapshots as files or snapshots is an important step in root pool recovery. With either method, snapshots should be recreated on a routine basis, such as when the pool configuration changes or when the Solaris OS is upgraded.
In the following procedure, the system is booted from the zfsBE boot environment.

1. Create a pool and file system on a remote system to store the snapshots.
   For example:
   ```
   remote# zfs create rpool/snaps
   ```

2. Share the file system with the local system.
   For example:
   ```
   remote# zfs set sharenfs='rw=local-system,root=local-system' rpool/snaps
   # share
   -@rpool/snaps /rpool/snaps sec=sys,rw=local-system,root=local-system ""
   ```

3. Create a recursive snapshot of the root pool.
   ```
   local# zfs snapshot -r rpool@0804
   local# zfs list
   NAME       USED   AVAIL  REFER MOUNTPOINT
   rpool      6.17G   60.8G  98K   /rpool
   rpool@0804 0      -     98K   -
   rpool/ROOT 4.67G   60.8G  21K   /rpool/ROOT
   rpool/ROOT@0804 0     -   21K   -
   rpool/ROOT/zfsBE 4.67G   60.8G  4.67G  /
   rpool/ROOT/zfsBE@0804 386K    -   4.67G  -
   rpool/dump 1.00G   60.8G  1.00G  -
   rpool/dump@0804 0      -   1.00G  -
   rpool/swap 517M   61.3G  16K   -
   rpool/swap@0804 0      -   16K   -
   ```

4. Send the root pool snapshots to the remote system.
   For example:
   ```
   local# zfs send -Rv rpool@0804 > /net/remote-system/rpool/snaps/rpool.0804
   sending from @ to rpool@0804
   sending from @ to rpool/swap@0804
   sending from @ to rpool/ROOT@0804
   sending from @ to rpool/ROOT/zfsBE@0804
   sending from @ to rpool/dump@0804
   ```

## How to Recreate a ZFS Root Pool and Restore Root Pool Snapshots

In this procedure, assume the following conditions:

- The ZFS root pool cannot be recovered.
- The ZFS root pool snapshots are stored on a remote system and are shared over NFS.

All the steps are performed on the local system.
1 **Boot from a CD/DVD or the network.**

   - **SPARC:** Select one of the following boot methods:
     
     ok boot net -s
     ok boot cdrom -s

     If you don’t use -s option, you'll need to exit the installation program.

   - **x86:** Select the option for booting from the DVD or the network. Then, exit the installation program.

2 **Mount the remote snapshot dataset.**

   For example:
   
   ```
   # mount -F nfs remote-system:/rpool/snaps /mnt
   ```

   If your network services are not configured, you might need to specify the `remote-system`'s IP address.

3 **If the root pool disk is replaced and does not contain a disk label that is usable by ZFS, you must relabel the disk.**

   For more information about relabeling the disk, go to the following site:

4 **Recreate the root pool.**

   For example:
   
   ```
   # zpool create -f -o failmode=continue -R /a -m legacy -o cachefile=/etc/zfs/zpool.cache rpool cltl0s0
   ```

5 **Restore the root pool snapshots.**

   This step might take some time. For example:
   
   ```
   # cat /mnt/rpool.0804 | zfs receive -Fdu rpool
   ```

   Using the -u option means that the restored archive is not mounted when the `zfs receive` operation completes.

6 **Verify that the root pool datasets are restored.**

   For example:
   
   ```
   # zfs list
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpool</td>
<td>6.17G</td>
<td>60.8G</td>
<td>98K</td>
<td>/a/rpool</td>
</tr>
<tr>
<td>rpool@004</td>
<td>0</td>
<td>-</td>
<td>98K</td>
<td>-</td>
</tr>
<tr>
<td>rpool/ROOT</td>
<td>4.67G</td>
<td>60.8G</td>
<td>21K</td>
<td>/legacy</td>

<td>60.8G</td>
<td>1.00G</td>
<td>-</td>
</tr>
</tbody>
</table>
7 Set the bootfs property on the root pool BE.
   For example:
   
   # zpool set bootfs=rpool/ROOT/zfsBE rpool

8 Install the boot blocks on the new disk.
   SPARC:
   
   # installboot -F zfs /usr/platform/`uname -i`/lib/fs/zfs/bootblk /dev/rdsk/c1t1d0s0
   
   x86:
   
   # installgrub /boot/grub/stage1 /boot/grub/stage2 /dev/rdsk/c1t1d0s0

9 Reboot the system.
   
   # init 6

-how to roll back root pool snapshots from a failsafe boot-

This procedure assumes that existing root pool snapshots are available. In the example, they are
available on the local system.

# zfs snapshot -r rpool@0804
# zfs list

    NAME  USED  AVAIL  REFER  MOUNTPOINT
    rpool  6.17G  60.8G  98K   /rpool
    rpool/0804  0   -     98K   
    rpool/ROOT 4.67G  60.8G  21K   /rpool/ROOT
    rpool/ROOT/0804  0   -     21K   
    rpool/ROOT/zfsBE  4.67G  60.8G  4.67G   /
    rpool/ROOT/zfsBE@0804 398K   -     4.67G   
    rpool/dump  1.00G  60.8G  1.00G   
    rpool/dump@0804  0   -     1.00G   
    rpool/swap  517M  61.3G  16K   
    rpool/swap@0804  0   -     16K   

1 Shut down the system and boot failsafe mode.
   ok boot -F failsafe
   ROOT/zfsBE was found on rpool.
   Do you wish to have it mounted read-write on /a? [y,n,?] y
   mounting rpool on /a
   Starting shell.
2 Roll back each root pool snapshot.
   # zfs rollback rpool@0804
   # zfs rollback rpool/ROOT@0804
   # zfs rollback rpool/ROOT/zfsBE@0804

3 Reboot to multiuser mode.
   # init 6
Managing Oracle Solaris ZFS File Systems

This chapter provides detailed information about managing Oracle Solaris ZFS file systems. Concepts such as the hierarchical file system layout, property inheritance, and automatic mount point management and share interactions are included.

The following sections are provided in this chapter:
- “Managing ZFS File Systems (Overview)” on page 167
- “Creating, Destroying, and Renaming ZFS File Systems” on page 168
- “Introducing ZFS Properties” on page 171
- “Querying ZFS File System Information” on page 183
- “Managing ZFS Properties” on page 185
- “Mounting and Sharing ZFS File Systems” on page 190
- “Setting ZFS Quotas and Reservations” on page 196

Managing ZFS File Systems (Overview)

A ZFS file system is built on top of a storage pool. File systems can be dynamically created and destroyed without requiring you to allocate or format any underlying disk space. Because file systems are so lightweight and because they are the central point of administration in ZFS, you are likely to create many of them.

ZFS file systems are administered by using the `zfs` command. The `zfs` command provides a set of subcommands that perform specific operations on file systems. This chapter describes these subcommands in detail. Snapshots, volumes, and clones are also managed by using this command, but these features are only covered briefly in this chapter. For detailed information about snapshots and clones, see Chapter 7, “Working With Oracle Solaris ZFS Snapshots and Clones.” For detailed information about ZFS volumes, see “ZFS Volumes” on page 257.
Note – The term *dataset* is used in this chapter as a generic term to refer to a file system, snapshot, clone, or volume.

Creating, Destroying, and Renaming ZFS File Systems

ZFS file systems can be created and destroyed by using the `zfs create` and `zfs destroy` commands. ZFS file systems can be renamed by using the `zfs rename` command.

- “Creating a ZFS File System” on page 168
- “Destroying a ZFS File System” on page 169
- “Renaming a ZFS File System” on page 170

Creating a ZFS File System

ZFS file systems are created by using the `zfs create` command. The `create` subcommand takes a single argument: the name of the file system to be created. The file system name is specified as a path name starting from the name of the pool as follows:

`pool-name/[filesystem-name/]filesystem-name`

The pool name and initial file system names in the path identify the location in the hierarchy where the new file system will be created. The last name in the path identifies the name of the file system to be created. The file system name must satisfy the naming requirements in “ZFS Component Naming Requirements” on page 45.

In the following example, a file system named bonwick is created in the `tank/home` file system.

```
# zfs create tank/home/bonwick
```

ZFS automatically mounts the newly created file system if it is created successfully. By default, file systems are mounted as `dataset`, using the path provided for the file system name in the `create` subcommand. In this example, the newly created bonwick file system is mounted at `/tank/home/bonwick`. For more information about automatically managed mount points, see “Managing ZFS Mount Points” on page 190.

For more information about the `zfs create` command, see `zfs(1M)`.

You can set file system properties when the file system is created.

In the following example, a mount point of `/export/zfs` is created for the `tank/home` file system:

```
# zfs create -o mountpoint=/export/zfs tank/home
```
For more information about file system properties, see "Introducing ZFS Properties" on page 171.

**Destroying a ZFS File System**

To destroy a ZFS file system, use the `zfs destroy` command. The destroyed file system is automatically unmounted and unshared. For more information about automatically managed mounts or automatically managed shares, see “Automatic Mount Points” on page 191.

In the following example, the `tabriz` file system is destroyed:

```bash
# zfs destroy tank/home/tabriz
```

**Caution** – No confirmation prompt appears with the `destroy` subcommand. Use it with extreme caution.

If the file system to be destroyed is busy and cannot be unmounted, the `zfs destroy` command fails. To destroy an active file system, use the `-f` option. Use this option with caution as it can unmount, unshare, and destroy active file systems, causing unexpected application behavior.

```bash
# zfs destroy tank/home/ahrens
```

```bash
cannot unmount 'tank/home/ahrens': Device busy
```

```bash
# zfs destroy -f tank/home/ahrens
```

The `zfs destroy` command also fails if a file system has descendents. To recursively destroy a file system and all its descendents, use the `-r` option. Note that a recursive destroy also destroys snapshots, so use this option with caution.

```bash
# zfs destroy tank/ws
```

```bash
cannot destroy 'tank/ws': filesystem has children
```

```bash
use '-r' to destroy the following datasets:
tank/ws/billm
tank/ws/bonwick
tank/ws/maybee
```

```bash
# zfs destroy -r tank/ws
```

If the file system to be destroyed has indirect dependents, even the recursive destroy command fails. To force the destruction of all dependents, including cloned file systems outside the target hierarchy, the `-R` option must be used. Use extreme caution with this option.

```bash
# zfs destroy -r tank/home/schrock
```

```bash
cannot destroy 'tank/home/schrock': filesystem has dependent clones
```

```bash
use '-R' to destroy the following datasets:
tank/clones/schrock-clone
```

```bash
# zfs destroy -R tank/home/schrock
```
Creating, Destroying, and Renaming ZFS File Systems

Caution – No confirmation prompt appears with the -f, -r, or -R options to the zfs destroy command, so use these options carefully.

For more information about snapshots and clones, see Chapter 7, “Working With Oracle Solaris ZFS Snapshots and Clones.”

Renaming a ZFS File System

File systems can be renamed by using the zfs rename command. With the rename subcommand, you can perform the following operations:

- Change the name of a file system.
- Relocate the file system within the ZFS hierarchy.
- Change the name of a file system and relocate it within the ZFS hierarchy.

The following example uses the rename subcommand to rename a file system from kustarz to kustarz_old:

```
# zfs rename tank/home/kustarz tank/home/kustarz_old
```

The following example shows how to use zfs rename to relocate a file system:

```
# zfs rename tank/home/maybee tank/ws/maybee
```

In this example, the maybee file system is relocated from tank/home to tank/ws. When you relocate a file system through rename, the new location must be within the same pool and it must have enough disk space to hold this new file system. If the new location does not have enough disk space, possibly because it has reached its quota, rename operation fails.

For more information about quotas, see “Setting ZFS Quotas and Reservations” on page 196.

The rename operation attempts an unmount/remount sequence for the file system and any descendent file systems. The rename command fails if the operation is unable to unmount an active file system. If this problem occurs, you must forcibly unmount the file system.

For information about renaming snapshots, see “Renaming ZFS Snapshots” on page 206.
Introducing ZFS Properties

Properties are the main mechanism that you use to control the behavior of file systems, volumes, snapshots, and clones. Unless stated otherwise, the properties defined in this section apply to all the dataset types.

- "ZFS Read-Only Native Properties" on page 178
- "Settable ZFS Native Properties" on page 179
- "ZFS User Properties" on page 182

Properties are divided into two types, native properties and user-defined properties. Native properties either export internal statistics or control ZFS file system behavior. In addition, native properties are either settable or read-only. User properties have no effect on ZFS file system behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see "ZFS User Properties" on page 182.

Most settable properties are also inheritable. An inheritable property is a property that, when set on a parent dataset, is propagated down to all of its descendents.

All inheritable properties have an associated source that indicates how a property was obtained. The source of a property can have the following values:

- `local` - Indicates that the property was explicitly set on the dataset by using the `zfs set` command as described in "Setting ZFS Properties" on page 185.
- `inherited from dataset-name` - Indicates that the property was inherited from the named ancestor.
- `default` - Indicates that the property value was not inherited or set locally. This source is a result of no ancestor having the property set as source `local`.

The following table identifies both read-only and settable native ZFS file system properties. Read-only native properties are identified as such. All other native properties listed in this table are settable. For information about user properties, see "ZFS User Properties" on page 182.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aclinherit</td>
<td>String</td>
<td>secure</td>
<td>Controls how ACL entries are inherited when files and directories are created. The values are discard, nallow, secure, and pass through. For a description of these values, see &quot;ACL Properties&quot; on page 224.</td>
</tr>
</tbody>
</table>

TABLE 6-1 ZFS Native Property Descriptions
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aclmode</td>
<td>String</td>
<td>groupmask</td>
<td>Controls how an ACL entry is modified during a chmod operation. The values are discard, groupmask, and passthrough. For a description of these values, see “ACL Properties” on page 224.</td>
</tr>
<tr>
<td>atime</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and similar utilities.</td>
</tr>
<tr>
<td>available</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only property that identifies the amount of disk space available to a dataset and all its children, assuming no other activity in the pool. Because disk space is shared within a pool, available space can be limited by various factors including physical pool size, quotas, reservations, and other datasets within the pool. The property abbreviation is avail. For more information about disk space accounting, see “ZFS Disk Space Accounting” on page 54.</td>
</tr>
<tr>
<td>canmount</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether a file system can be mounted with the zfs mount command. This property can be set on any file system, and the property itself is not inheritable. However, when this property is set to off, a mount point can be inherited to descendent file systems, but the file system itself is never mounted. When the noauto option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the zfs mount -a command or unmounted by the zfs unmount -a command. For more information, see “canmount Property” on page 180.</td>
</tr>
<tr>
<td>checksum</td>
<td>String</td>
<td>on</td>
<td>Controls the checksum used to verify data integrity. The default value is on, which automatically selects an appropriate algorithm, currently fletcher4. The values are on, off, fletcher2, fletcher4, and sha256. A value of off disables integrity checking on user data. A value of off is not recommended.</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Default Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>compression</td>
<td>String</td>
<td>off</td>
<td>Enables or disables compression for a dataset. The values are on, off, lzjb, gzip, and gzip.-N. Currently, setting this property to lzjb, gzip, or gzip.-N has the same effect as setting this property to on. Enabling compression on a file system with existing data only compresses new data. Existing data remains uncompressed. The property abbreviation is compress.</td>
</tr>
<tr>
<td>compressratio</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only property that identifies the compression ratio achieved for a dataset, expressed as a multiplier. Compression can be enabled by the zfs set compression=on dataset command. The value is calculated from the logical size of all files and the amount of referenced physical data. It includes explicit savings through the use of the compression property.</td>
</tr>
<tr>
<td>copies</td>
<td>Number</td>
<td>1</td>
<td>Sets the number of copies of user data per file system. Available values are 1, 2, or 3. These copies are in addition to any pool-level redundancy. Disk space used by multiple copies of user data is charged to the corresponding file and dataset, and counts against quotas and reservations. In addition, the used property is updated when multiple copies are enabled. Consider setting this property when the file system is created because changing this property on an existing file system only affects newly written data.</td>
</tr>
<tr>
<td>creation</td>
<td>String</td>
<td>N/A</td>
<td>Read-only property that identifies the date and time that a dataset was created.</td>
</tr>
<tr>
<td>devices</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether device files in a filesystem can be opened.</td>
</tr>
<tr>
<td>exec</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether programs in a filesystem are allowed to be executed. Also, when set to off, mmap(2) calls with PROT_EXEC are disallowed.</td>
</tr>
<tr>
<td>mounted</td>
<td>Boolean</td>
<td>N/A</td>
<td>Read-only property that indicates whether a filesystem, clone, or snapshot is currently mounted. This property does not apply to volumes. The value can be either yes or no.</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Default Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------</td>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mountpoint</td>
<td>String</td>
<td>N/A</td>
<td>Controls the mount point used for this file system. When the mountpoint property is changed for a file system, the file system and any descendents that inherit the mount point are unmounted. If the new value is legacy, then they remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously legacy or none, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location. For more information about using this property, see &quot;Managing ZFS Mount Points&quot; on page 190.</td>
</tr>
<tr>
<td>primarycache</td>
<td>String</td>
<td>all</td>
<td>Controls what is cached in the primary cache (ARC). Possible values are all, none, and metadata. If set to all, both user data and metadata are cached. If set to none, neither user data nor metadata is cached. If set to metadata, only metadata is cached.</td>
</tr>
<tr>
<td>origin</td>
<td>String</td>
<td>N/A</td>
<td>Read-only property for cloned file systems or volumes that identifies the snapshot from which the clone was created. The origin cannot be destroyed (even with the -r or -f option) as long as a clone exists. Non-cloned file systems have an origin of none.</td>
</tr>
<tr>
<td>quota</td>
<td>Number (or none)</td>
<td>none</td>
<td>Limits the amount of disk space a dataset and its descendents can consume. This property enforces a hard limit on the amount of disk space used, including all space consumed by descendents, such as file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor's quota, but rather imposes an additional limit. Quotas cannot be set on volumes, as the volsize property acts as an implicit quota. For information about setting quotas, see &quot;Setting Quotas on ZFS File Systems&quot; on page 196.</td>
</tr>
<tr>
<td>readonly</td>
<td>Boolean</td>
<td>off</td>
<td>Controls whether a dataset can be modified. When set to on, no modifications can be made. The property abbreviation is rdonly.</td>
</tr>
<tr>
<td>recordsize</td>
<td>Number</td>
<td>128K</td>
<td>Specifies a suggested block size for files in a file system. The property abbreviation is recsize. For a detailed description, see &quot;recordsize Property&quot; on page 181.</td>
</tr>
</tbody>
</table>
### TABLE 6–1 ZFS Native Property Descriptions (Continued)

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>referenced</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only property that identifies the amount of data accessible by a dataset, which might or might not be shared with other datasets in the pool. When a snapshot or clone is created, it initially references the same amount of disk space as the file system or snapshot it was created from, because its contents are identical. The property abbreviation is refer.</td>
</tr>
<tr>
<td>refquota</td>
<td>Number (or none)</td>
<td>none</td>
<td>Sets the amount of disk space that a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include disk space used by descendents, such as snapshots and clones.</td>
</tr>
<tr>
<td>refreservation</td>
<td>Number (or none)</td>
<td>none</td>
<td>Sets the minimum amount of disk space that is guaranteed to a dataset, not including descendents, such as snapshots and clones. When the amount of disk space used is below this value, the dataset is treated as if it were taking up the amount of space specified by refreservation. The refreservation reservation is accounted for in the parent dataset's disk space used, and counts against the parent dataset's quotas and reservations. If refreservation is set, a snapshot is only allowed if enough free pool space is available outside of this reservation to accommodate the current number of referenced bytes in the dataset. The property abbreviation is refreserv.</td>
</tr>
<tr>
<td>reservation</td>
<td>Number (or none)</td>
<td>none</td>
<td>Sets the minimum amount of disk space guaranteed to a dataset and its descendents. When the amount of disk space used is below this value, the dataset is treated as if it were using the amount of space specified by its reservation. Reservations are accounted for in the parent dataset's disk space used, and count against the parent dataset's quotas and reservations. The property abbreviation is reserv. For more information, see “Setting Reservations on ZFS File Systems” on page 200.</td>
</tr>
</tbody>
</table>

Introducing ZFS Properties
## Introducing ZFS Properties

### TABLE 6–1  ZFS Native Property Descriptions (Continued)

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>secondarycache</td>
<td>String</td>
<td>all</td>
<td>Controls what is cached in the secondary cache (L2ARC). Possible values are all, none, and metadata. If set to all, both user data and metadata are cached. If set to none, neither user data nor metadata is cached. If set to metadata, only metadata is cached.</td>
</tr>
<tr>
<td>setuid</td>
<td>Boolean</td>
<td>on</td>
<td>Controls whether the setuid bit is honored in a file system.</td>
</tr>
<tr>
<td>shareiscsi</td>
<td>String</td>
<td>off</td>
<td>Controls whether a ZFS volume is shared as an iSCSI target. The property values are on, off, and type=disk. You might want to set shareiscsi=on for a file system so that all ZFS volumes within the file system are shared by default. However, setting this property on a file system has no direct effect.</td>
</tr>
<tr>
<td>sharenfs</td>
<td>String</td>
<td>off</td>
<td>Controls whether a file system is available over NFS and what options are used. If set to on, the zfs share command is invoked with no options. Otherwise, the zfs share command is invoked with options equivalent to the contents of this property. If set to off, the file system is managed by using the legacy share and unshare commands and the dfstab file. For more information about sharing ZFS file systems, see “Sharing and Unsharing ZFS File Systems” on page 194.</td>
</tr>
<tr>
<td>snapdir</td>
<td>String</td>
<td>hidden</td>
<td>Controls whether the .zfs directory is hidden or visible in the root of the file system. For more information about using snapshots, see “Overview of ZFS Snapshots” on page 203.</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>N/A</td>
<td>Read-only property that identifies the dataset type as filesystem (file system or clone), volume, or snapshot.</td>
</tr>
<tr>
<td>used</td>
<td>Number</td>
<td>N/A</td>
<td>Read-only property that identifies the amount of disk space consumed by a dataset and all its descendents. For a detailed description, see “The used Property” on page 179.</td>
</tr>
<tr>
<td>usedbychildren</td>
<td>Number</td>
<td>off</td>
<td>Read-only property that identifies the amount of disk space that is used by children of this dataset, which would be freed if all the dataset’s children were destroyed. The property abbreviation is usedchild.</td>
</tr>
</tbody>
</table>
### TABLE 6–1 ZFS Native Property Descriptions (Continued)

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usedbydataset</td>
<td>Number</td>
<td>off</td>
<td>Read-only property that identifies the amount of disk space that is used by a dataset itself, which would be freed if the dataset was destroyed, after first destroying any snapshots and removing any reservation. The property abbreviation is usedds.</td>
</tr>
<tr>
<td>usedbyrefreservation</td>
<td>Number</td>
<td>off</td>
<td>Read-only property that identifies the amount of disk space that is used by a reservation set on a dataset, which would be freed if the reservation was removed. The property abbreviation is usedrefreserv.</td>
</tr>
<tr>
<td>usedbysnapshots</td>
<td>Number</td>
<td>off</td>
<td>Read-only property that identifies the amount of disk space that is consumed by snapshots of a dataset. In particular, it is the amount of disk space that would be freed if all of this dataset’s snapshots were destroyed. Note that this value is not simply the sum of the snapshots’ used properties, because space can be shared by multiple snapshots. The property abbreviation is usedsnap.</td>
</tr>
<tr>
<td>version</td>
<td>Number</td>
<td>N/A</td>
<td>Identifies the on-disk version of a file system, which is independent of the pool version. This property can only be set to a later version that is available from the supported software release. For more information, see the zfs upgrade command.</td>
</tr>
<tr>
<td>volsize</td>
<td>Number</td>
<td>N/A</td>
<td>For volumes, specifies the logical size of the volume. For a detailed description, see “volsize Property” on page 181.</td>
</tr>
<tr>
<td>volblocksize</td>
<td>Number</td>
<td>8 KB</td>
<td>For volumes, specifies the block size of the volume. The block size cannot be changed after the volume has been written, so set the block size at volume creation time. The default block size for volumes is 8 KB. Any power of 2 from 512 bytes to 128 KB is valid. The property abbreviation is volblock.</td>
</tr>
</tbody>
</table>
**TABLE 6–1  ZFS Native Property Descriptions (Continued)**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>zoned</td>
<td>Boolean</td>
<td>N/A</td>
<td>Indicates whether a dataset has been added to a non-global zone. If this property is set, then the mount point is not honored in the global zone, and ZFS cannot mount such a file system when requested. When a zone is first installed, this property is set for any added file systems. For more information about using ZFS with zones installed, see “Using ZFS on a Solaris System With Zones Installed” on page 259.</td>
</tr>
<tr>
<td>xattr</td>
<td>Boolean</td>
<td>on</td>
<td>Indicates whether extended attributes are enabled (on) or disabled (off) for this file system.</td>
</tr>
</tbody>
</table>

**ZFS Read-Only Native Properties**

Read-only native properties can be retrieved but not set. Read-only native properties are not inherited. Some native properties are specific to a particular type of dataset. In such cases, the dataset type is mentioned in the description in Table 6–1.

The read-only native properties are listed here and described in Table 6–1.

- available
- compressratio
- creation
- mounted
- origin
- referenced
- type
- used

For detailed information, see “The used Property” on page 179.

- usedbychildren
- usedbydataset
- usedbyrefreservation
- usedbysnapshots

For more information about disk space accounting, including the used, referenced, and available properties, see “ZFS Disk Space Accounting” on page 54.
The used Property

The used property is a read-only property that identifies the amount of disk space consumed by this dataset and all its descendents. This value is checked against the dataset’s quota and reservation. The disk space used does not include the dataset’s reservation, but does consider the reservation of any descendent datasets. The amount of disk space that a dataset consumes from its parent, as well as the amount of disk space that is freed if the dataset is recursively destroyed, is the greater of its space used and its reservation.

When snapshots are created, their disk space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, disk space that was previously shared becomes unique to the snapshot and is counted in the snapshot’s space used. The disk space that is used by a snapshot accounts for its unique data. Additionally, deleting snapshots can increase the amount of disk space unique to (and used by) other snapshots. For more information about snapshots and space issues, see "Out of Space Behavior" on page 54.

The amount of disk space used, available, and referenced does not include pending changes. Pending changes are generally accounted for within a few seconds. Committing a change to a disk using the `fsync(3c)` or `O_SYNC` function does not necessarily guarantee that the disk space usage information will be updated immediately.

The `usedbychildren`, `usedbydataset`, `usedbyrefreservation`, and `usedbysnapshots` property information can be displayed with the `zfs list -o space` command. These properties identify the used property into disk space that is consumed by descendents. For more information, see Table 6–1.

Settable ZFS Native Properties

Settable native properties are properties whose values can be both retrieved and set. Settable native properties are set by using the `zfs set` command, as described in “Setting ZFS Properties” on page 185 or by using the `zfs create` command as described in “Creating a ZFS File System” on page 168. With the exceptions of quotas and reservations, settable native properties are inherited. For more information about quotas and reservations, see “Setting ZFS Quotas and Reservations” on page 196.

Some settable native properties are specific to a particular type of dataset. In such cases, the dataset type is mentioned in the description in Table 6–1. If not specifically mentioned, a property applies to all dataset types: file systems, volumes, clones, and snapshots.

The settable properties are listed here and described in Table 6–1.

- `aclinherit`
  For a detailed description, see "ACL Properties” on page 224.
- `aclmode`
  For a detailed description, see "ACL Properties” on page 224.
Introducing ZFS Properties

- atime
- canmount
- checksum
- compression
- copies
- devices
- exec
- mountpoint

- readonly
- recordsize
  For a detailed description, see “recordsize Property” on page 181.
- refquota
- refreservation
- reservation
- secondarycache
- shareiscsi
- shar enf
- setuid
- snapdir
- version
- volsize
  For a detailed description, see “volsize Property” on page 181.
- volblocksize
- zoned
- xattr

**canmount Property**

If the canmount property is set to off, the file system cannot be mounted by using the `zfs mount` or `zfs mount -a` commands. Setting this property to off is similar to setting the mountpoint property to none, except that the dataset still has a normal mountpoint property that can be inherited. For example, you can set this property to off, establish inheritable properties for descendent file systems, but the parent file system itself is never mounted nor is it accessible to
users. In this case, the parent file system is serving as a container so that you can set properties on the container, but the container itself is never accessible.

In the following example, userpool is created, and its canmount property is set to off. Mount points for descendent user file systems are set to one common mount point, /export/home. Properties that are set on the parent file system are inherited by descendent file systems, but the parent file system itself is never mounted.

```
# zpool create userpool mirror c0t5d0 c1t6d0
# zfs set canmount=off userpool
# zfs set mountpoints=/export/home userpool
# zfs set compression=on userpool
# zfs create userpool/user1
# zfs create userpool/user2
# zfs mount
userpool/user1 /export/home/user1
userpool/user2 /export/home/user2
```

Setting the canmount property to noauto means that the dataset can only be mounted explicitly, not automatically. This value setting is used by the Oracle Solaris upgrade software so that only those datasets belonging to the active boot environment are mounted at boot time.

**recordsize Property**

The recordsize property specifies a suggested block size for files in the file system.

This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically adjust block sizes according to internal algorithms optimized for typical access patterns. For databases that create very large files but access the files in small random chunks, these algorithms might be suboptimal. Specifying a recordsize value greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged and might adversely affect performance. The size specified must be a power of 2 greater than or equal to 512 bytes and less than or equal to 128 KB. Changing the file system’s recordsize value only affects files created afterward. Existing files are unaffected.

The property abbreviation is recsize.

**volsize Property**

The volsize property specifies the logical size of the volume. By default, creating a volume establishes a reservation for the same amount. Any changes to volsize are reflected in an equivalent change to the reservation. These checks are used to prevent unexpected behavior for users. A volume that contains less space than it claims is available can result in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while the volume is in use, particularly when you shrink the size. Use extreme care when adjusting the volume size.
Though not recommended, you can create a sparse volume by specifying the -s flag to `zfs create -V` or by changing the reservation after the volume has been created. A *sparse volume* is a volume whose reservation is not equal to the volume size. For a sparse volume, changes to `volsize` are not reflected in the reservation.

For more information about using volumes, see “ZFS Volumes” on page 257.

### ZFS User Properties

In addition to the native properties, ZFS supports arbitrary user properties. User properties have no effect on ZFS behavior, but you can use them to annotate datasets with information that is meaningful in your environment.

User property names must conform to the following conventions:

- They must contain a colon (`:`) character to distinguish them from native properties.
- They must contain lowercase letters, numbers, or the following punctuation characters: `:`, `+`, `*`, `_`.
- The maximum length of a user property name is 256 characters.

The expected convention is that the property name is divided into the following two components but this namespace is not enforced by ZFS:

```
module:property
```

When making programmatic use of user properties, use a reversed DNS domain name for the `module` component of property names to reduce the chance that two independently developed packages will use the same property name for different purposes. Property names that begin with `com.sun` are reserved for use by Oracle Corporation.

The values of user properties must conform to the following conventions:

- They must consist of arbitrary strings that are always inherited and are never validated.
- The maximum length of the user property value is 1024 characters.

For example:

```
# zfs set dept:users=finance userpool/user1
# zfs set dept:users=general userpool/user2
# zfs set dept:users=itops userpool/user3
```

All of the commands that operate on properties, such as `zfs list`, `zfs get`, `zfs set`, and so on, can be used to manipulate both native properties and user properties.

For example:
Querying ZFS File System Information

The `zfs list` command provides an extensible mechanism for viewing and querying dataset information. Both basic and complex queries are explained in this section.

Listing Basic ZFS Information

You can list basic dataset information by using the `zfs list` command with no options. This command displays the names of all datasets on the system and the values of their used, available, referenced, and mountpoint properties. For more information about these properties, see "Introducing ZFS Properties" on page 171.

For example:

```
# zfs list
NAME    USED  AVAIL  REFER  MOUNTPOINT
pool    476K   16.5G  21K   /pool
pool/clone 18K   16.5G  18K   /pool/clone
pool/home 296K   16.5G  19K   /pool/home
pool/home/marks 277K   16.5G  277K   /pool/home/marks
pool/home/marks@snap 0    -      277K   -
pool/test 18K   16.5G  18K   /test
```

You can also use this command to display specific datasets by providing the dataset name on the command line. Additionally, use the `-r` option to recursively display all descendents of that dataset. For example:

```
# zfs list -r pool/home/marks
NAME    USED  AVAIL  REFER  MOUNTPOINT
pool/home/marks 277K   16.5G  277K   /pool/home/marks
pool/home/marks@snap 0    -      277K   -
```

You can use the `zfs list` command with the mount point of a file system. For example:

```
# zfs list /pool/home/marks
NAME    USED  AVAIL  REFER  MOUNTPOINT
pool/home/marks 277K   16.5G  277K   /pool/home/marks
```
The following example shows how to display basic information about `tank/home/chua` and all of its descendant datasets:

```
# zfs list -r tank/home/chua
NAME   USED   AVAIL  REFER  MOUNTPOINT
tank/home/chua  26.0K  4.81G  10.0K /tank/home/chua
tank/home/chua/projects 16K  4.81G  9.0K /tank/home/chua/projects
tank/home/chua/projects/fs1  8K  4.81G  8K /tank/home/chua/projects/fs1
tank/home/chua/projects/fs2  8K  4.81G  8K /tank/home/chua/projects/fs2
```

For additional information about the `zfs list` command, see `zfs(1M)`.

## Creating Complex ZFS Queries

The `zfs list` output can be customized by using the `-o`, `-t`, and `-H` options.

You can customize property value output by using the `-o` option and a comma-separated list of desired properties. You can supply any dataset property as a valid argument. For a list of all supported dataset properties, see "Introducing ZFS Properties" on page 171. In addition to the properties defined, the `-o` option list can also contain the literal name to indicate that the output should include the name of the dataset.

The following example uses `zfs list` to display the dataset name, along with the `sharenfs` and `mountpoint` property values.

```
# zfs list -o name,sharenfs,mountpoint
NAME     SHARENFS MOUNTPOINT
tank     off /tank
tank/home on /tank/home
tank/home/ahrens on /tank/home/ahrens
tank/home/bonwick on /tank/home/bonwick
tank/home/chua on /tank/home/chua
tank/home/eschrock on /tank/home/chua
```

You can use the `-t` option to specify the types of datasets to display. The valid types are described in the following table.

### TABLE 6–2 Types of ZFS Datasets

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filesystem</td>
<td>File systems and clones</td>
</tr>
<tr>
<td>volume</td>
<td>Volumes</td>
</tr>
<tr>
<td>snapshot</td>
<td>Snapshots</td>
</tr>
</tbody>
</table>
The -t option takes a comma-separated list of the types of datasets to be displayed. The following example uses the -t and -o options simultaneously to show the name and used property for all file systems:

```
# zfs list -t filesystem -o name,used
<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool</td>
<td>476K</td>
</tr>
<tr>
<td>pool/clone</td>
<td>18K</td>
</tr>
<tr>
<td>pool/home</td>
<td>296K</td>
</tr>
<tr>
<td>pool/home/marks</td>
<td>277K</td>
</tr>
<tr>
<td>pool/test</td>
<td>18K</td>
</tr>
</tbody>
</table>
```

You can use the -H option to omit the zfs list header from the generated output. With the -H option, all white space is replaced by the Tab character. This option can be useful when you need parseable output, for example, when scripting. The following example shows the output generated from using the zfs list command with the -H option:

```
# zfs list -H -o name
pool
pool/clone
pool/home
pool/home/marks
pool/home/marks@snap
pool/test
```

Managing ZFS Properties

Dataset properties are managed through the zfs command's set, inherit, and get subcommands.

- “Setting ZFS Properties” on page 185
- “Inheriting ZFS Properties” on page 186
- “Querying ZFS Properties” on page 187

Setting ZFS Properties

You can use the zfs set command to modify any settable dataset property. Or, you can use the zfs create command to set properties when a dataset is created. For a list of settable dataset properties, see “Settable ZFS Native Properties” on page 179.

The zfs set command takes a property/value sequence in the format of property=value followed by a dataset name. Only one property can be set or modified during each zfs set invocation.

The following example sets the atime property to off for tank/home.

```
# zfs set atime=off tank/home
```
In addition, any file system property can be set when a file system is created. For example:

```
# zfs create -o atime=off tank/home
```

You can specify numeric property values by using the following easy-to-understand suffixes (in increasing order of magnitude): BKMGTPEZ. Any of these suffixes can be followed by an optional `b`, indicating bytes, with the exception of the `B` suffix, which already indicates bytes. The following four invocations of `zfs set` are equivalent numeric expressions that set the `quota` property to be set to the value of 50 GB on the `tank/home/marks` file system:

```
# zfs set quota=50G tank/home/marks
# zfs set quota=50g tank/home/marks
# zfs set quota=50GB tank/home/marks
# zfs set quota=50gb tank/home/marks
```

The values of non-numeric properties are case-sensitive and must be in lowercase letters, with the exception of `mountpoint` and `share nfs`. The values of these properties can have mixed upper and lower case letters.

For more information about the `zfs set` command, see `zfs(1M)`.

### Inheriting ZFS Properties

All settable properties, with the exception of quotas and reservations, inherit their value from the parent dataset, unless a quota or reservation is explicitly set on the descendent dataset. If no ancestor has an explicit value set for an inherited property, the default value for the property is used. You can use the `zfs inherit` command to clear a property value, thus causing the value to be inherited from the parent dataset.

The following example uses the `zfs set` command to turn on compression for the `tank/home/bonwick` file system. Then, `zfs inherit` is used to clear the compression property, thus causing the property to inherit the default value of `off`. Because neither `home` nor `tank` has the `compression` property set locally, the default value is used. If both had compression enabled, the value set in the most immediate ancestor would be used (`home` in this example).

```
# zfs set compression=on tank/home/bonwick
# zfs get -r compression tank
NAME    PROPERTY    VALUE    SOURCE
---      ----------  -------   ------
tank     compression off     default
tank/home compression off     default
tank/home/bonwick compression on    local
# zfs inherit compression tank/home/bonwick
# zfs get -r compression tank
NAME    PROPERTY    VALUE    SOURCE
---      ----------  -------   ------
tank     compression off     default
tank/home compression off     default
tank/home/bonwick compression off     default
```
The `inherit` subcommand is applied recursively when the `-r` option is specified. In the following example, the command causes the value for the `compression` property to be inherited by `tank/home` and any descendents it might have:

```
# zfs inherit -r compression tank/home
```

**Note** – Be aware that the use of the `-r` option clears the current property setting for all descendent datasets.

For more information about the `zfs inherit` command, see `zfs(1M)`.

**Querying ZFS Properties**

The simplest way to query property values is by using the `zfs list` command. For more information, see “Listing Basic ZFS Information” on page 183. However, for complicated queries and for scripting, use the `zfs get` command to provide more detailed information in a customized format.

You can use the `zfs get` command to retrieve any dataset property. The following example shows how to retrieve a single property value on a dataset:

```
# zfs get checksum tank/ws
NAME PROPERTY VALUE SOURCE
tank/ws checksum on default
```

The fourth column, `SOURCE`, indicates the origin of this property value. The following table defines the possible source values.

**TABLE 6-3 Possible SOURCE Values (zfs get Command)**

<table>
<thead>
<tr>
<th>Source Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>default</code></td>
<td>This property value was never explicitly set for this dataset or any of its ancestors. The default value for this property is being used.</td>
</tr>
<tr>
<td><code>inherited from dataset-name</code></td>
<td>This property value is inherited from the parent dataset specified in <code>dataset-name</code>.</td>
</tr>
<tr>
<td><code>local</code></td>
<td>This property value was explicitly set for this dataset by using <code>zfs set</code>.</td>
</tr>
<tr>
<td><code>temporary</code></td>
<td>This property value was set by using the <code>zfs mount -o</code> option and is only valid for the duration of the mount. For more information about temporary mount point properties, see “Using Temporary Mount Properties” on page 193.</td>
</tr>
<tr>
<td><code>- (none)</code></td>
<td>This property is read-only. Its value is generated by ZFS.</td>
</tr>
</tbody>
</table>
You can use the special keyword `all` to retrieve all dataset property values. The following examples use the `all` keyword:

```
# zfs get all tank/home
NAME     PROPERTY  VALUE          SOURCE
tank/home type       filesystem -
tank/home creation   Tue Jun 29 11:44 2010 -
tank/home used       21K  -
tank/home available  66.9G -
tank/home referenced 21K -
tank/home compressratio 1.00x -
tank/home mounted yes -
tank/home quota none default
tank/home reservation none default
tank/home recordsize 128K default
tank/home mountpoint /tank/home default
tank/home sharefs off default
tank/home checksum on default
tank/home compression off default
tank/home atime on default
tank/home devices on default
tank/home exec on default
tank/home setuid on default
tank/home readonly off default
tank/home zoned off default
tank/home snapdir hidden default
tank/home aclmode groupmask default
tank/home aclinherit restricted default
tank/home cammount on default
tank/home sharesiscsi off default
tank/home xattr on default
tank/home copies 1 default
tank/home version 4 -
tank/home utf8only off -
tank/home normalization none -
tank/home casesensitivity sensitive -
tank/home vscan off default
tank/home nbmand off default
tank/home sharesmb off default
tank/home refquota none default
tank/home refreservation none default
tank/home primarycache all default
tank/home secondarycache all default
tank/home usedbysnapshots 0 -
tank/home usedbydataset 21K -
tank/home usedbychildren 0 -
tank/home usedbysnapshots 0 -
tank/home logbias latency default
```

**Note** — The `casesensitivity`, `nbmand`, `normalization`, `sharesmb`, `utf8only`, and `vscan` properties are not fully operational in the Oracle Solaris 10 release because the Oracle Solaris SMB service is not supported in the Oracle Solaris 10 release.

The `-s` option to `zfs get` enables you to specify, by source type, the properties to display. This option takes a comma-separated list indicating the desired source types. Only properties with
the specified source type are displayed. The valid source types are local, default, inherited, temporary, and none. The following example shows all properties that have been locally set on pool.

```
# zfs get -s local all pool
NAME   PROPERTY     VALUE     SOURCE
pool   compression  on        local
```

Any of the above options can be combined with the -r option to recursively display the specified properties on all children of the specified dataset. In the following example, all temporary properties on all datasets within tank are recursively displayed:

```
# zfs get -r -s temporary all tank
NAME                PROPERTY     VALUE     SOURCE
tank/home            atime       off       temporary
tank/home/bonwick    atime       off       temporary
tank/home/marks      atime       off       temporary
```

You can query property values by using the zfs get command without specifying a target file system, which means the command operates on all pools or file systems. For example:

```
# zfs get -s local all
tank/home             atime       off       local
tank/home/bonwick     atime       off       local
tank/home/marks       quota       50G       local
```

For more information about the zfs get command, see zfs(1M).

### Querying ZFS Properties for Scripting

The zfs get command supports the -H and -o options, which are designed for scripting. You can use the -H option to omit header information and to replace white space with the Tab character. Uniform white space allows for easily parseable data. You can use the -o option to customize the output in the following ways:

- The literal name can be used with a comma-separated list of properties as defined in the "Introducing ZFS Properties" on page 171 section.
- A comma-separated list of literal fields, name, value, property, and source, to be output followed by a space and an argument, which is a comma-separated list of properties.

The following example shows how to retrieve a single value by using the -H and -o options of zfs get:

```
# zfs get -H -o value compression tank/home
on
```

The -p option reports numeric values as their exact values. For example, 1 MB would be reported as 1000000. This option can be used as follows:

```
# zfs get -H -o -p used tank/home
182983742
```
Mounting and Sharing ZFS File Systems

This section describes how mount points and shared file systems are managed in ZFS.

- “Managing ZFS Mount Points” on page 190
- “Mounting ZFS File Systems” on page 192
- “Using Temporary Mount Properties” on page 193
- “Unmounting ZFS File Systems” on page 194
- “Sharing and Unsharing ZFS File Systems” on page 194

Managing ZFS Mount Points

By default, a ZFS file system is automatically mounted when it is created. You can determine specific mount-point behavior for a file system as described in this section.

You can also set the default mount point for a pool's dataset at creation time by using zpool create's -m option. For more information about creating pools, see “Creating a ZFS Storage Pool” on page 63.

All ZFS file systems are mounted by ZFS at boot time by using the Service Management Facility's (SMF) svc://system/filesystem/local service. File systems are mounted under /path, where path is the name of the file system.

You can override the default mount point by using the zfs set command to set the mountpoint property to a specific path. ZFS automatically creates the specified mount point, if needed, and automatically mounts the associated file system when the zfs mount -a command is invoked, without requiring you to edit the /etc/vfstab file.

The mountpoint property is inherited. For example, if pool/home has the mountpoint property set to /export/stuff, then pool/home/user inherits /export/stuff/user for its mountpoint property value.

To prevent a file system from being mounted, set the mountpoint property to none. In addition, the canmount property can be used to control whether a file system can be mounted. For more information about the canmount property, see “canmount Property” on page 180.
File systems can also be explicitly managed through legacy mount interfaces by using `zfs set` to set the `mountpoint` property to `legacy`. Doing so prevents ZFS from automatically mounting and managing a file system. Legacy tools including the `mount` and `umount` commands, and the `/etc/vfstab` file must be used instead. For more information about legacy mounts, see “Legacy Mount Points” on page 191.

**Automatic Mount Points**

- When you change the `mountpoint` property from `legacy` or `none` to a specific path, ZFS automatically mounts the file system.
- If ZFS is managing a file system but it is currently unmounted, and the `mountpoint` property is changed, the file system remains unmounted.

Any dataset whose `mountpoint` property is not `legacy` is managed by ZFS. In the following example, a dataset is created whose mount point is automatically managed by ZFS:

```
# zfs create pool/filesystem
# zfs get mountpoint pool/filesystem
NAME    PROPERTY    VALUE     SOURCE
pool/filesystem mountpoint   /pool/filesystem default
# zfs get mounted pool/filesystem
NAME    PROPERTY    VALUE     SOURCE
pool/filesystem mounted yes -
```

You can also explicitly set the `mountpoint` property as shown in the following example:

```
# zfs set mountpoints=mnt pool/filesystem
# zfs get mountpoint pool/filesystem
NAME    PROPERTY    VALUE     SOURCE
pool/filesystem mountpoint /mnt local
# zfs get mounted pool/filesystem
NAME    PROPERTY    VALUE     SOURCE
pool/filesystem mounted yes -
```

When the `mountpoint` property is changed, the file system is automatically unmounted from the old mount point and remounted to the new mount point. Mount-point directories are created as needed. If ZFS is unable to unmount a file system due to it being active, an error is reported, and a forced manual unmount is necessary.

**Legacy Mount Points**

You can manage ZFS file systems with legacy tools by setting the `mountpoint` property to `legacy`. Legacy file systems must be managed through the `mount` and `umount` commands and the `/etc/vfstab` file. ZFS does not automatically mount legacy file systems at boot time, and the ZFS `mount` and `umount` commands do not operate on datasets of this type. The following examples show how to set up and manage a ZFS dataset in legacy mode:

```
# zfs set mountpoint=legacy tank/home/eschrock
# mount -F zfs tank/home/eschrock /mnt
```
To automatically mount a legacy file system at boot time, you must add an entry to the 
/etc/vfstab file. The following example shows what the entry in the /etc/vfstab file might look like:

```
#device device mount FS fsck mount mount
#to mount to fsck point type pass at boot options
#
tank/home/eschrock - /mnt zfs - yes -
```

The device to fsck and fsck pass entries are set to - because the fsck command is not applicable to ZFS file systems. For more information about ZFS data integrity, see “Transactional Semantics” on page 42.

## Mounting ZFS File Systems

ZFS automatically mounts file systems when file systems are created or when the system boots. Use of the zfs mount command is necessary only when you need to change mount options, or explicitly mount or unmount file systems.

The `zfs mount` command with no arguments shows all currently mounted file systems that are managed by ZFS. Legacy managed mount points are not displayed. For example:

```
# zfs mount
tank
 tank/home
 tank/home/bonwick
 tank/ws
```

You can use the `-a` option to mount all ZFS managed file systems. Legacy managed file systems are not mounted. For example:

```
# zfs mount -a
```

By default, ZFS does not allow mounting on top of a nonempty directory. To force a mount on top of a nonempty directory, you must use the `-O` option. For example:

```
# zfs mount tank/home/lalt
cannot mount '/export/home/lalt': directory is not empty
use legacy mountpoint to allow this behavior, or use the -O flag
# zfs mount -O tank/home/lalt
```

Legacy mount points must be managed through legacy tools. An attempt to use ZFS tools results in an error. For example:

```
# zfs mount pool/home/billm
cannot mount 'pool/home/billm': legacy mountpoint
use mount(1M) to mount this filesystem
# mount -F zfs tank/home/billm
```
When a file system is mounted, it uses a set of mount options based on the property values associated with the dataset. The correlation between properties and mount options is as follows:

### TABLE 6-4  ZFS Mount-Related Properties and Mount Options

<table>
<thead>
<tr>
<th>Property</th>
<th>Mount Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>atime</td>
<td>atime/noatime</td>
</tr>
<tr>
<td>devices</td>
<td>devices/nodevices</td>
</tr>
<tr>
<td>exec</td>
<td>exec/noexec</td>
</tr>
<tr>
<td>nbmand</td>
<td>nbmand/nonbmand</td>
</tr>
<tr>
<td>readonly</td>
<td>ro/rw</td>
</tr>
<tr>
<td>setuid</td>
<td>setuid/nosetuid</td>
</tr>
<tr>
<td>xattr</td>
<td>xattr/noxattr</td>
</tr>
</tbody>
</table>

The mount option nosuid is an alias for nodevices, nosetuid.

### Using Temporary Mount Properties

If any of the mount options described in the preceding section are set explicitly by using the -o option with the zfs mount command, the associated property value is temporarily overridden. These property values are reported as temporary by the zfs get command and revert back to their original values when the file system is unmounted. If a property value is changed while the dataset is mounted, the change takes effect immediately, overriding any temporary setting.

In the following example, the read-only mount option is temporarily set on the tank/home/perrin file system. The file system is assumed to be unmounted.

```
# zfs mount -o ro tank/home/perrin
```

To temporarily change a property value on a file system that is currently mounted, you must use the special remount option. In the following example, the atime property is temporarily changed to off for a file system that is currently mounted:

```
# zfs mount -o remount,noatime tank/home/perrin
# zfs get atime tank/home/perrin
NAME PROPERTY VALUE SOURCE
tank/home/perrin atime off temporary
```

For more information about the zfs mount command, see zfs(1M).
Unmounting ZFS File Systems

You can unmount ZFS file systems by using the `zfs unmount` subcommand. The `unmount` command can take either the mount point or the file system name as an argument.

In the following example, a file system is unmounted by its file system name:

```bash
# zfs unmount tank/home/tabriz
```

In the following example, the file system is unmounted by its mount point:

```bash
# zfs unmount /export/home/tabriz
```

The `unmount` command fails if the file system is busy. To forcibly unmount a file system, you can use the `-f` option. Be cautious when forcibly unmounting a file system if its contents are actively being used. Unpredictable application behavior can result.

```bash
# zfs unmount tank/home/eschrock
```

```bash
cannot unmount '/export/home/eschrock': Device busy
```

```bash
# zfs unmount -f tank/home/eschrock
```

To provide for backward compatibility, the legacy `umount` command can be used to unmount ZFS file systems. For example:

```bash
# umount /export/home/bob
```

For more information about the `zfs unmount` command, see `zfs(1M)`.

Sharing and Unsharing ZFS File Systems

ZFS can automatically share file systems by setting the `sharenfs` property. Using this property, you do not have to modify the `/etc/dfs/dfstab` file when a new file system is shared. The `sharenfs` property is a comma-separated list of options to pass to the `share` command. The value `on` is an alias for the default share options, which provides read/write permissions to anyone. The value `off` indicates that the file system is not managed by ZFS and can be shared through traditional means, such as the `/etc/dfs/dfstab` file. All file systems whose `sharenfs` property is not `off` are shared during boot.

Controlling Share Semantics

By default, all file systems are unshared. To share a new file system, use `zfs set` syntax similar to the following:

```bash
# zfs set sharenfs=on tank/home/eschrock
```

The `sharenfs` property is inherited, and file systems are automatically shared on creation if their inherited property is not `off`. For example:
Both tank/home/bricker and tank/home/tabriz are initially shared as writable because they inherit the sharenfs property from tank/home. After the property is set to ro (read only), tank/home/tabriz is shared as read-only regardless of the sharenfs property that is set for tank/home.

### Unsharing ZFS File Systems

Although most filesystems are automatically shared or unshared during boot, creation, and destruction, filesystems sometimes need to be explicitly unshared. To do so, use the `zfs unshare` command. For example:

```bash
# zfs unshare tank/home/tabriz
```

This command unshares the tank/home/tabriz filesystem. To unshare all ZFS filesystems on the system, you need to use the `-a` option.

```bash
# zfs unshare -a
```

### Sharing ZFS File Systems

Most of the time, the automatic behavior of ZFS with respect to sharing filesystem on boot and creation is sufficient for normal operations. If, for some reason, you unshare a filesystem, you can share it again by using the `zfs share` command. For example:

```bash
# zfs share tank/home/tabriz
```

You can also share all ZFS filesystems on the system by using the `-a` option.

```bash
# zfs share -a
```

### Legacy Share Behavior

If the sharenfs property is set to off, then ZFS does not attempt to share or unshare the filesystem at any time. This value enables you to administer filesystem sharing through traditional means, such as the `/etc/dfs/dfstab` file.

Unlike the legacy `mount` command, the legacy `share` and `unshare` commands can still function on ZFS filesystems. As a result, you can manually share a filesystem with options that differ from the options of the sharenfs property. This administrative model is discouraged. Choose to manage NFS shares either completely through ZFS or completely through the `/etc/dfs/dfstab` file. The ZFS administrative model is designed to be simpler and less work than the traditional model.
Setting ZFS Quotas and Reservations

You can use the quota property to set a limit on the amount of disk space a file system can use. In addition, you can use the reservation property to guarantee that a specified amount of disk space is available to a file system. Both properties apply to the dataset on which they are set and all descendents of that dataset.

That is, if a quota is set on the tank/home dataset, the total amount of disk space used by tank/home and all of its descendents cannot exceed the quota. Similarly, if tank/home is given a reservation, tank/home and all of its descendents draw from that reservation. The amount of disk space used by a dataset and all of its descendents is reported by the used property.

The refquota and refreservation properties are used to manage file system space without accounting for disk space consumed by descendents, such as snapshots and clones.

In this Solaris release, you can set a user or a group quota on the amount of disk space consumed by files that are owned by a particular user or group. The user and group quota properties cannot be set on a volume, on a file system before file system version 4, or on a pool before pool version 15.

Consider the following points to determine which quota and reservation features might best help you manage your file systems:

- The quota and reservation properties are convenient for managing disk space consumed by datasets and their descendents.
- The refquota and refreservation properties are appropriate for managing disk space consumed by datasets.
- Setting the refquota or refreservation property higher than the quota or reservation property has no effect. If you set the quota or refquota property, operations that try to exceed either value fail. It is possible to exceed a quota that is greater than the refquota. For example, if some snapshot blocks are modified, you might actually exceed the quota before you exceed the refquota.
- User and group quotas provide a way to more easily manage disk space with many user accounts, such as in a university environment.

For more information about setting quotas and reservations, see “Setting Quotas on ZFS File Systems” on page 196 and “Setting Reservations on ZFS File Systems” on page 200.

Setting Quotas on ZFS File Systems

Quotas on ZFS file systems can be set and displayed by using the zfs set and zfs get commands. In the following example, a quota of 10 GB is set on tank/home/bonwick:
# zfs set quota=10G tank/home/bonwick
# zfs get quota tank/home/bonwick

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROPERTY</th>
<th>VALUE</th>
<th>SOURCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home/bonwick</td>
<td>quota</td>
<td>10.0G</td>
<td>local</td>
</tr>
</tbody>
</table>

Quotas also affect the output of the zfs list and df commands. For example:

# zfs list

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/home</td>
<td>16.5K</td>
<td>33.5G</td>
<td>8.50K</td>
<td>/export/home</td>
</tr>
<tr>
<td>tank/home/bonwick</td>
<td>15.0K</td>
<td>10.0G</td>
<td>8.50K</td>
<td>/export/home/bonwick</td>
</tr>
<tr>
<td>tank/home/bonwick/ws</td>
<td>6.50K</td>
<td>10.0G</td>
<td>8.50K</td>
<td>/export/home/bonwick/ws</td>
</tr>
</tbody>
</table>

# df -h /export/home/bonwick

Filesystem size used avail capacity Mounted on

tank/home/bonwick 10G 8K 10G 1% /export/home/bonwick

Note that although tank/home has 33.5 GB of disk space available, tank/home/bonwick and tank/home/bonwick/ws each have only 10 GB of disk space available, due to the quota on tank/home/bonwick.

You cannot set a quota to an amount less than is currently being used by a dataset. For example:

# zfs set quota=10K tank/home/bonwick
cannot set quota for 'tank/home/bonwick': size is less than current used or reserved space

You can set a refquota on a dataset that limits the amount of disk space that the dataset can consume. This hard limit does not include disk space that is consumed by descendents. For example:

# zfs set refquota=10g students/studentA

# zfs list

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>profs</td>
<td>106K</td>
<td>33.2G</td>
<td>18K</td>
<td>/profs</td>
</tr>
<tr>
<td>students</td>
<td>57.7M</td>
<td>33.2G</td>
<td>19K</td>
<td>/students</td>
</tr>
<tr>
<td>students/studentA</td>
<td>57.5M</td>
<td>9.94G</td>
<td>57.5M</td>
<td>/students/studentA</td>
</tr>
</tbody>
</table>

# zfs snapshot students/studentA@today

# zfs list

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>profs</td>
<td>106K</td>
<td>33.2G</td>
<td>18K</td>
<td>/profs</td>
</tr>
<tr>
<td>students</td>
<td>57.7M</td>
<td>33.2G</td>
<td>19K</td>
<td>/students</td>
</tr>
<tr>
<td>students/studentA</td>
<td>57.5M</td>
<td>9.94G</td>
<td>57.5M</td>
<td>/students/studentA</td>
</tr>
<tr>
<td>students/studentA@today</td>
<td>0</td>
<td>-</td>
<td>57.5M</td>
<td>-</td>
</tr>
</tbody>
</table>

For additional convenience, you can set another quota on a dataset to help manage the disk space that is consumed by snapshots. For example:

# zfs set quota=20g students/studentA

# zfs list

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>profs</td>
<td>106K</td>
<td>33.2G</td>
<td>18K</td>
<td>/profs</td>
</tr>
<tr>
<td>students</td>
<td>57.7M</td>
<td>33.2G</td>
<td>19K</td>
<td>/students</td>
</tr>
<tr>
<td>students/studentA</td>
<td>57.5M</td>
<td>9.94G</td>
<td>57.5M</td>
<td>/students/studentA</td>
</tr>
<tr>
<td>students/studentA@today</td>
<td>0</td>
<td>-</td>
<td>57.5M</td>
<td>-</td>
</tr>
</tbody>
</table>
In this scenario, studentA might reach the refquota (10 GB) hard limit, but studentA can remove files to recover, even if snapshots exist.

In the preceding example, the smaller of the two quotas (10 GB as compared to 20 GB) is displayed in the `zfs list` output. To view the value of both quotas, use the `zfs get` command. For example:

```
# zfs get refquota,quota students/studentA
NAME PROPERTY VALUE SOURCE
students/studentA refquota 10G local
students/studentA quota 20G local
```

### Setting User and Group Quotas on a ZFS File System

You can set a user quota or a group quota by using the `zfs userquota` or `zfs groupquota` commands, respectively. For example:

```
# zfs create students/compsci
# zfs set userquota@student1=10G students/compsci
# zfs create students/labstaff
# zfs set groupquota@staff=20GB students/labstaff
```

Display the current user quota or group quota as follows:

```
# zfs get userquota@student1 students/compsci
NAME PROPERTY VALUE SOURCE
students/compsci userquota@student1 10G local

# zfs get groupquota@staff students/labstaff
NAME PROPERTY VALUE SOURCE
students/labstaff groupquota@staff 20G local
```

You can display general user or group disk space usage by querying the following properties:

```
# zfs userspace students/compsci
TYPE NAME USED QUOTA
POSIX User root 227M none
POSIX User student1 455M 10G

# zfs groupspace students/labstaff
TYPE NAME USED QUOTA
POSIX Group root 217M none
POSIX Group staff 217M 20G
```

To identify individual user or group disk space usage, query the following properties:

```
# zfs get userused@student1 students/compsci
NAME PROPERTY VALUE SOURCE
students/compsci userused@student1 455M local

# zfs get groupused@staff students/labstaff
NAME PROPERTY VALUE SOURCE
students/labstaff groupused@staff 217M local
```

The user and group quota properties are not displayed by using the `zfs get all dataset` command, which displays a list of all of the other file system properties.
You can remove a user quota or group quota as follows:

```
# zfs set userquota@user1=none students/compsci
# zfs set groupquota@staff=none students/labstaff
```

User and group quotas on ZFS file systems provide the following features:

- A user quota or group quota that is set on a parent file system is not automatically inherited by a descendent file system.
- However, the user or group quota is applied when a clone or a snapshot is created from a file system that has a user or group quota. Likewise, a user or group quota is included with the file system when a stream is created by using the `zfs send` command, even without the `-R` option.
- Unprivileged users can only access their own disk space usage. The root user or a user who has been granted the `userused` or `groupused` privilege, can access everyone's user or group disk space accounting information.
- The `userquota` and `groupquota` properties cannot be set on ZFS volumes, on a file system prior to file system version 4, or on a pool prior to pool version 15.

Enforcement of user and group quotas might be delayed by several seconds. This delay means that users might exceed their quota before the system notices that they are over quota and refuses additional writes with the `EDQUOT` error message.

You can use the legacy `quota` command to review user quotas in an NFS environment, for example, where a ZFS file system is mounted. Without any options, the `quota` command only displays output if the user's quota is exceeded. For example:

```
# zfs set userquota@student1=10m students/compsci
# zfs userspace students/compsci
<table>
<thead>
<tr>
<th>TYPE</th>
<th>NAME</th>
<th>USED</th>
<th>QUOTA</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX</td>
<td>User root</td>
<td>227M</td>
<td>none</td>
</tr>
<tr>
<td>POSIX</td>
<td>User student1</td>
<td>455M</td>
<td>10m</td>
</tr>
</tbody>
</table>
```

```
# quota student1
Block limit reached on /students/compsci
```

If you reset the user quota and the quota limit is no longer exceeded, you can use the `quota -v` command to review the user's quota. For example:

```
# zfs set userquota@student1=10GB students/compsci
# zfs userspace students/compsci
<table>
<thead>
<tr>
<th>TYPE</th>
<th>NAME</th>
<th>USED</th>
<th>QUOTA</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX</td>
<td>User root</td>
<td>227M</td>
<td>none</td>
</tr>
<tr>
<td>POSIX</td>
<td>User student1</td>
<td>455M</td>
<td>10G</td>
</tr>
</tbody>
</table>
```

```
# quota student1
# quota -v student1
Disk quotas for student1 (uid 201):
Filesystem  usage quota limit  timeleft files quota limit  timeleft
/students/compsci  466029  10485760  10485760
```
Setting Reservations on ZFS File Systems

A ZFS reservation is an allocation of disk space from the pool that is guaranteed to be available to a dataset. As such, you cannot reserve disk space for a dataset if that space is not currently available in the pool. The total amount of all outstanding, unconsumed reservations cannot exceed the amount of unused disk space in the pool. ZFS reservations can be set and displayed by using the `zfs set` and `zfs get` commands. For example:

```
# zfs set reservation=5G tank/home/moore
# zfs get reservation tank/home/moore
NAME PROPERTY VALUE SOURCE
tank/home/moore reservation 5G local
```

Reservations can affect the output of the `zfs list` command. For example:

```
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
tank/home 5.00G 33.5G 8.50K /export/home
tank/home/moore 15.0K 33.5G 8.50K /export/home/moore
```

Note that `tank/home` is using 5 GB of disk space, although the total amount of space referred to by `tank/home` and its descendents is much less than 5 GB. The used space reflects the space reserved for `tank/home/moore`. Reservations are considered in the used disk space calculation of the parent dataset and do count against its quota, reservation, or both.

```
# zfs set quota=5G pool/filesystem
# zfs set reservation=10G pool/filesystem/user1
cannot set reservation for 'pool/filesystem/user1': size is greater than available space
```

A dataset can use more disk space than its reservation, as long as unreserved space is available in the pool, and the dataset’s current usage is below its quota. A dataset cannot consume disk space that has been reserved for another dataset.

Reservations are not cumulative. That is, a second invocation of `zfs set` to set a reservation does not add its reservation to the existing reservation. Rather, the second reservation replaces the first reservation. For example:

```
# zfs set reservation=10G tank/home/moore
# zfs set reservation=5G tank/home/moore
# zfs get reservation tank/home/moore
NAME PROPERTY VALUE SOURCE
tank/home/moore reservation 5.00G local
```

You can set a reservation reservation to guarantee disk space for a dataset that does not include disk space consumed by snapshots and clones. This reservation is accounted for in the parent dataset’s space used calculation, and counts against the parent dataset’s quotas and reservations. For example:
# zfs set refreservation=10g profs/prof1
# zfs list
NAME                  USED  AVAIL  REFER MOUNTPOINT
profs                10.0G  23.2G  19K    /profs
profs/prof1          10G   33.2G  18K    /profs/prof1

You can also set a reservation on the same dataset to guarantee dataset space and snapshot space. For example:

# zfs set reservation=20g profs/prof1
# zfs list
NAME                  USED  AVAIL  REFER MOUNTPOINT
profs                20.0G  13.2G  19K    /profs
profs/prof1          10G   33.2G  18K    /profs/prof1

Regular reservations are accounted for in the parent's used space calculation.

In the preceding example, the smaller of the two quotas (10 GB as compared to 20 GB) is displayed in the zfs list output. To view the value of both quotas, use the zfs get command. For example:

# zfs get reservation,refreserv profs/prof1
NAME      PROPERTY  VALUE  SOURCE
profs/prof1 reservation  20G  local
profs/prof1 refreservation  10G  local

If refreservation is set, a snapshot is only allowed if sufficient unreserved pool space exists outside of this reservation to accommodate the current number of referenced bytes in the dataset.
This chapter describes how to create and manage Oracle Solaris ZFS snapshots and clones. Information about saving snapshots is also provided.

The following sections are provided in this chapter:

- “Overview of ZFS Snapshots” on page 203
- “Creating and Destroying ZFS Snapshots” on page 204
- “Displaying and Accessing ZFS Snapshots” on page 207
- “Rolling Back a ZFS Snapshot” on page 208
- “Overview of ZFS Clones” on page 209
- “Creating a ZFS Clone” on page 210
- “Destroying a ZFS Clone” on page 210
- “Replacing a ZFS File System With a ZFS Clone” on page 210
- “Sending and Receiving ZFS Data” on page 211

Overview of ZFS Snapshots

A snapshot is a read-only copy of a file system or volume. Snapshots can be created almost instantly, and they initially consume no additional disk space within the pool. However, as data within the active dataset changes, the snapshot consumes disk space by continuing to reference the old data, thus preventing the disk space from being freed.

ZFS snapshots include the following features:

- The persist across system reboots.
- The theoretical maximum number of snapshots is $2^{64}$.
- Snapshots use no separate backing store. Snapshots consume disk space directly from the same storage pool as the file system or volume from which they were created.
- Recursive snapshots are created quickly as one atomic operation. The snapshots are created together (all at once) or not created at all. The benefit of atomic snapshot operations is that the snapshot data is always taken at one consistent time, even across descendent file systems.
Snapshots of volumes cannot be accessed directly, but they can be cloned, backed up, rolled back to, and so on. For information about backing up a ZFS snapshot, see “Sending and Receiving ZFS Data” on page 211.

- “Creating and Destroying ZFS Snapshots” on page 204
- “Displaying and Accessing ZFS Snapshots” on page 207
- “Rolling Back a ZFS Snapshot” on page 208

Creating and Destroying ZFS Snapshots

Snapshots are created by using the `zfs snapshot` command, which takes as its only argument the name of the snapshot to create. The snapshot name is specified as follows:

`filesystem@snapname`
`volume@snapname`

The snapshot name must satisfy the naming requirements in “ZFS Component Naming Requirements” on page 45.

In the following example, a snapshot of `tank/home/ahrens` that is named `friday` is created.

```
# zfs snapshot tank/home/ahrens@friday
```

You can create snapshots for all descendent file systems by using the `-r` option. For example:

```
# zfs snapshot -r tank/home@now
```

```
# zfs list -t snapshot
NAME USED AVAIL REFER MOUNTPOINT
rpool/ROOT/zfs2BE@zfs2BE 78.3M - 4.53G -
tank/home@now 0 - 26K -
tank/home/ahrens@now 0 - 250M -
tank/home/anne@now 0 - 156M -
tank/home/bob@now 0 - 156M -
tank/home/cindys@now 0 - 156M -
```

Snapshots have no modifiable properties. Nor can dataset properties be applied to a snapshot. For example:

```
# zfs set compression=on tank/home/ahrens@now
```

```
cannot set compression property for 'tank/home/ahrens@now': snapshot properties cannot be modified
```

Snapshots are destroyed by using the `zfs destroy` command. For example:

```
# zfs destroy tank/home/ahrens@now
```

A dataset cannot be destroyed if snapshots of the dataset exist. For example:

```
# zfs destroy tank/home/ahrens
```

```
cannot destroy 'tank/home/ahrens': filesystem has children use '-r' to destroy the following datasets:
```
In addition, if clones have been created from a snapshot, then they must be destroyed before the snapshot can be destroyed.

For more information about the `destroy` subcommand, see “Destroying a ZFS File System” on page 169.

**Holding ZFS Snapshots**

If you have different automatic snapshot policies such that older snapshots are being inadvertantly destroyed by `zfs receive` because they no longer exist on the sending side, you might consider using the snapshots hold feature.

`Holding` a snapshot prevents it from being destroyed. In addition, this feature allows a snapshot with clones to be deleted pending the removal of the last clone by using the `zfs destroy -d` command. Each snapshot has an associated user-reference count, which is initialized to zero. This count increases by one whenever a hold is put on a snapshot and decreases by one whenever a hold is released.

In the previous Solaris release, a snapshot could only be destroyed by using the `zfs destroy` command if it had no clones. In this Solaris release, the snapshot must also have a zero user-reference count.

You can hold a snapshot or set of snapshots. For example, the following syntax puts a hold tag, `keep`, on `tank/home/cindys/snap@1`.

```
# zfs hold keep tank/home/cindys@snap1
```

You can use the `-r` option to recursively hold the snapshots of all descendent file systems. For example:

```
# zfs snapshot -r tank/home@now
# zfs hold -r keep tank/home@now
```

This syntax adds a single reference, `keep`, to the given snapshot or set of snapshots. Each snapshot has its own tag namespace and hold tags must be unique within that space. If a hold exists on a snapshot, attempts to destroy that held snapshot by using the `zfs destroy` command will fail. For example:

```
# zfs destroy tank/home/cindys@snap1
cannot destroy `tank/home/cindys@snap1': dataset is busy
```

If you want to destroy a held snapshot, use the `-d` option. For example:

```
# zfs destroy -d tank/home/cindys@snap1
```

Use the `zfs holds` command to display a list of held snapshots. For example:
ZFS Holds

```bash
# zfs holds tank/home@now
NAME     TAG     TIMESTAMP
tank/home@now  keep  Thu Jul 15 11:25:39 2010
```

```bash
# zfs holds -r tank/home@now
NAME     TAG     TIMESTAMP
tank/home/cindys@now  keep  Thu Jul 15 11:25:39 2010
tank/home/mark@now  keep  Thu Jul 15 11:25:39 2010
tank/home@now  keep  Thu Jul 15 11:25:39 2010
```

You can use the `zfs release` command to release a hold on a snapshot or set of snapshots. For example:

```bash
# zfs release -r keep tank/home@now
```

If the snapshot is released, the snapshot can be destroyed by using the `zfs destroy` command. For example:

```bash
# zfs destroy -r tank/home@now
```

Two new properties identify snapshot hold information:

- The `defer_destroy` property is on if the snapshot has been marked for deferred destruction by using the `zfs destroy -d` command. Otherwise, the property is off.
- The `userrefs` property is set to the number of holds on this snapshot, also referred to as the user-reference count.

### Renaming ZFS Snapshots

You can rename snapshots, but they must be renamed within the same pool and dataset from which they were created. For example:

```bash
# zfs rename tank/home/cindys@083006 tank/home/cindys@today
```

In addition, the following shortcut syntax is equivalent to the preceding syntax:

```bash
# zfs rename tank/home/cindys@083006 today
```

The following snapshot rename operation is not supported because the target pool and file system name are different from the pool and file system where the snapshot was created:

```bash
# zfs rename tank/home/cindys@today pool/home/cindys@saturday
```

You can recursively rename snapshots by using the `zfs rename -r` command. For example:

```bash
# zfs list
NAME     USED      AVAIL       REFER  MOUNTPOINT
users     270K      16.5G     22K     /users
users/home 76K      16.5G     22K     /users/home
```
Displaying and Accessing ZFS Snapshots

You can enable or disable the display of snapshot listings in the zfs list output by using the listsnapshots pool property. This property is enabled by default.

If you disable this property, you can use the zfs list -t snapshot command to display snapshot information. Or, enable the listsnapshots pool property. For example:

```bash
# zpool get listsnapshots tank
NAME PROPERTY VALUE SOURCE
tank listsnapshots on default
# zpool set listsnapshots=off tank
# zpool get listsnapshots tank
NAME PROPERTY VALUE SOURCE
tank listsnapshots off local
```

Snapshots of file systems are accessible in the .zfs/snapshot directory within the root of the file system. For example, if tank/home/ahrens is mounted on /home/ahrens, then the tank/home/ahrens@thursday snapshot data is accessible in the /home/ahrens/.zfs/snapshot/thursday directory.

```bash
# ls /tank/home/ahrens/.zfs/snapshot
tuesday wednesday thursday
```

You can list snapshots as follows:

```bash
# zfs list -t snapshot
NAME USED AVAIL REFER MOUNTPOINT
pool/home/anne@monday 0 - 780K -
pool/home/bob@monday 0 - 1.01M -
tank/home/ahrens@tuesday 8.50K - 780K -
tank/home/ahrens@wednesday 8.50K - 1.01M -
tank/home/ahrens@thursday 0 - 1.77M -
tank/home/cindys@today 8.50K - 524K -
```
You can list snapshots that were created for a particular file system as follows:

```
# zfs list -r -t snapshot -o name,creation tank/home
NAME CREATION
tank/home@now Wed Jun 30 16:16 2010
tank/home/ahrens@now Wed Jun 30 16:16 2010
tank/home/anne@now Wed Jun 30 16:16 2010
tank/home/bob@now Wed Jun 30 16:16 2010
```

**Disk Space Accounting for ZFS Snapshots**

When a snapshot is created, its disk space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, disk space that was previously shared becomes unique to the snapshot, and thus is counted in the snapshot's used property. Additionally, deleting snapshots can increase the amount of disk space unique to (and thus used by) other snapshots.

A snapshot's space referenced property value is the same as the file system's was when the snapshot was created.

You can identify additional information about how the values of the used property are consumed. New read-only file system properties describe disk space usage for clones, file systems, and volumes. For example:

```
$ zfs list -o space
# zfs list -ro space tank/home
NAME AVAIL USED USEDSNAP USEDDEDS USEDREFRESERV USEDCHILD
tank/home 66.3G 675M 0 26K 0 675M
tank/home@now - - - - - -
tank/home/ahrens 66.3G 259M 0 259M 0 0
```

For a description of these properties, see Table 6–1.

**Rolling Back a ZFS Snapshot**

You can use the `zfs rollback` command to discard all changes made to a file system since a specific snapshot was created. The file system reverts to its state at the time the snapshot was taken. By default, the command cannot roll back to a snapshot other than the most recent snapshot.

To roll back to an earlier snapshot, all intermediate snapshots must be destroyed. You can destroy earlier snapshots by specifying the `-r` option.
If clones of any intermediate snapshots exist, the `-R` option must be specified to destroy the clones as well.

**Note** – The file system that you want to roll back is unmounted and remounted, if it is currently mounted. If the file system cannot be unmounted, the rollback fails. The `-f` option forces the file system to be unmounted, if necessary.

In the following example, the `tank/home/ahrens` file system is rolled back to the `tuesday` snapshot:

```bash
# zfs rollback tank/home/ahrens@tuesday
cannot rollback to 'tank/home/ahrens@tuesday': more recent snapshots exist
use '-r' to force deletion of the following snapshots:
tank/home/ahrens@wednesday
tank/home/ahrens@thursday
# zfs rollback -r tank/home/ahrens@tuesday
```

In this example, the `wednesday` and `thursday` snapshots are destroyed because you rolled back to the earlier `tuesday` snapshot.

```bash
# zfs list -r -t snapshot -o name,creation tank/home/ahrens
NAME CREATION
tank/home/ahrens@now Wed Jun 30 16:16 2010
```

**Overview of ZFS Clones**

A clone is a writable volume or file system whose initial contents are the same as the dataset from which it was created. As with snapshots, creating a clone is nearly instantaneous and initially consumes no additional disk space. In addition, you can snapshot a clone.

Clones can only be created from a snapshot. When a snapshot is cloned, an implicit dependency is created between the clone and snapshot. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as the clone exists. The origin property exposes this dependency, and the `zfs destroy` command lists any such dependencies, if they exist.

Clones do not inherit the properties of the dataset from which it was created. Use the `zfs get` and `zfs set` commands to view and change the properties of a cloned dataset. For more information about setting ZFS dataset properties, see “Setting ZFS Properties” on page 185.

Because a clone initially shares all its disk space with the original snapshot, its used property value is initially zero. As changes are made to the clone, it uses more disk space. The used property of the original snapshot does not include the disk space consumed by the clone.

- “Creating a ZFS Clone” on page 210
- “Destroying a ZFS Clone” on page 210
Creating a ZFS Clone

To create a clone, use the `zfs clone` command, specifying the snapshot from which to create the clone, and the name of the new file system or volume. The new file system or volume can be located anywhere in the ZFS hierarchy. The new dataset is the same type (for example, file system or volume) as the snapshot from which the clone was created. You cannot create a clone of a file system in a pool that is different from where the original file system snapshot resides.

In the following example, a new clone named `tank/home/ahrens/bug123` with the same initial contents as the snapshot `tank/ws/gate@yesterday` is created:

```
# zfs snapshot tank/ws/gate@yesterday
# zfs clone tank/ws/gate@yesterday tank/home/ahrens/bug123
```

In the following example, a cloned workspace is created from the `projects/newproject@today` snapshot for a temporary user as `projects/teamA/tempuser`. Then, properties are set on the cloned workspace.

```
# zfs snapshot projects/newproject@today
# zfs clone projects/newproject@today projects/teamA/tempuser
# zfs set sharenfs=on projects/teamA/tempuser
# zfs set quota=5G projects/teamA/tempuser
```

Destroying a ZFS Clone

ZFS clones are destroyed by using the `zfs destroy` command. For example:

```
# zfs destroy tank/home/ahrens/bug123
```

Clones must be destroyed before the parent snapshot can be destroyed.

Replacing a ZFS File System With a ZFS Clone

You can use the `zfs promote` command to replace an active ZFS file system with a clone of that file system. This feature enables you to clone and replace file systems so that the original file system becomes the clone of the specified file system. In addition, this feature makes it possible to destroy the file system from which the clone was originally created. Without clone promotion, you cannot destroy an original file system of active clones. For more information about destroying clones, see "Destroying a ZFS Clone" on page 210.

In the following example, the `tank/test/productA` file system is cloned and then the clone file system, `tank/test/productAbeta`, becomes the original `tank/test/productA` file system.
# zfs create tank/test
# zfs create tank/test/productA
# zfs snapshot tank/test/productA@today
# zfs clone tank/test/productA@today tank/test/productAbeta
# zfs list -r tank/test

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/test</td>
<td>104M</td>
<td>66.2G</td>
<td>23K</td>
<td>/tank/test</td>
</tr>
<tr>
<td>tank/test/productA</td>
<td>104M</td>
<td>66.2G</td>
<td>104M</td>
<td>/tank/test/productA</td>
</tr>
<tr>
<td>tank/test/productA@today</td>
<td>0</td>
<td>-</td>
<td>104M</td>
<td>-</td>
</tr>
<tr>
<td>tank/test/productAbeta</td>
<td>0</td>
<td>66.2G</td>
<td>104M</td>
<td>/tank/test/productAbeta</td>
</tr>
</tbody>
</table>

# zfs promote tank/test/productAbeta
# zfs list -r tank/test

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank/test</td>
<td>104M</td>
<td>66.2G</td>
<td>24K</td>
<td>/tank/test</td>
</tr>
<tr>
<td>tank/test/productA</td>
<td>0</td>
<td>66.2G</td>
<td>104M</td>
<td>/tank/test/productA</td>
</tr>
<tr>
<td>tank/test/productAbeta</td>
<td>104M</td>
<td>66.2G</td>
<td>104M</td>
<td>/tank/test/productAbeta</td>
</tr>
<tr>
<td>tank/test/productAbeta@today</td>
<td>0</td>
<td>-</td>
<td>104M</td>
<td>-</td>
</tr>
</tbody>
</table>

In this zfs list output, note that the disk space accounting information for the original productA file system has been replaced with the productAbeta file system.

You can complete the clone replacement process by renaming the file systems. For example:

# zfs rename tank/test/productA tank/test/productAlegacy
# zfs rename tank/test/productAbeta tank/test/productA
# zfs list -r tank/test

Optionaly, you can remove the legacy file system. For example:

# zfs destroy tank/test/productAlegacy

## Sending and Receiving ZFS Data

The zfs send command creates a stream representation of a snapshot that is written to standard output. By default, a full stream is generated. You can redirect the output to a file or to a different system. The zfs receive command creates a snapshot whose contents are specified in the stream that is provided on standard input. If a full stream is received, a new file system is created as well. You can send ZFS snapshot data and receive ZFS snapshot data and file systems with these commands. See the examples in the next section.

- “Sending a ZFS Snapshot” on page 212
- "Receiving a ZFS Snapshot" on page 213
- “Sending and Receiving Complex ZFS Snapshot Streams” on page 214
- “Saving ZFS Data With Other Backup Products” on page 212

The following backup solutions for saving ZFS data are available:

- **Enterprise backup products** – If you need the following features, then consider an enterprise backup solution:
  - Per-file restoration
Backup media verification

Media management

File system snapshots and rolling back snapshots – Use the zfs snapshot and zfs rollback commands if you want to easily create a copy of a file system and revert to a previous file system version, if necessary. For example, to restore a file or files from a previous version of a file system, you could use this solution.

For more information about creating and rolling back to a snapshot, see “Overview of ZFS Snapshots” on page 203.

Saving snapshots – Use the zfs send and zfs receive commands to send and receive a ZFS snapshot. You can save incremental changes between snapshots, but you cannot restore files individually. You must restore the entire file system snapshot. These commands do not provide a complete backup solution for saving your ZFS data.

Remote replication – Use the zfs send and zfs receive commands to copy a file system from one system to another system. This process is different from a traditional volume management product that might mirror devices across a WAN. No special configuration or hardware is required. The advantage of replicating a ZFS file system is that you can re-create a file system on a storage pool on another system, and specify different levels of configuration for the newly created pool, such as RAID-Z, but with identical file system data.

Archive utilities – Save ZFS data with archive utilities such as tar, cpio, and pax or third-party backup products. Currently, both tar and cpio translate NFSv4-style ACLs correctly, but pax does not.

Saving ZFS Data With Other Backup Products

In addition to the zfs send and zfs receive commands, you can also use archive utilities, such as the tar and cpio commands, to save ZFS files. These utilities save and restore ZFS file attributes and ACLs. Check the appropriate options for both the tar and cpio commands.

For up-to-date information about issues with ZFS and third-party backup products, see the Solaris 10 Release Notes or the ZFS FAQ, available here:

http://hub.opensolaris.org/bin/view/Community+Group+zfs/faq/#backupsoftware

Sending a ZFS Snapshot

You can use the zfs send command to send a copy of a snapshot stream and receive the snapshot stream in another pool on the same system or in another pool on a different system that is used to store backup data. For example, to send the snapshot stream on a different pool to the same system, use syntax similar to the following:

# zfs send tank/data@snap1 | zfs recv spool/ds01
You can use `zfs recv` as an alias for the `zfs receive` command.

If you are sending the snapshot stream to a different system, pipe the `zfs send` output through the `ssh` command. For example:

```
host1# zfs send tank/dana@snap1 | ssh host2 zfs recv newtank/dana
```

When you send a full stream, the destination file system must not exist.

You can send incremental data by using the `zfs send -i` option. For example:

```
host1# zfs send -i tank/dana@snap1 tank/dana@snap2 | ssh host2 zfs recv newtank/dana
```

Note that the first argument (`snap1`) is the earlier snapshot and the second argument (`snap2`) is the later snapshot. In this case, the `newtank/dana` file system must already exist for the incremental receive to be successful.

The incremental `snap1` source can be specified as the last component of the snapshot name. This shortcut means you only have to specify the name after the `@` sign for `snap1`, which is assumed to be from the same file system as `snap2`. For example:

```
host1# zfs send -i snap1 tank/dana@snap2 > ssh host2 zfs recv newtank/dana
```

This shortcut syntax is equivalent to the incremental syntax in the preceding example.

The following message is displayed if you attempt to generate an incremental stream from a different file system `snap1`:

```
cannot send 'pool/fs@name': not an earlier snapshot from the same fs
```

If you need to store many copies, consider compressing a ZFS snapshot stream representation with the `gzip` command. For example:

```
# zfs send pool/fs@snap | gzip > backupfile.gz
```

### Receiving a ZFS Snapshot

Keep the following key points in mind when you receive a file system snapshot:

- Both the snapshot and the file system are received.
- The file system and all descendent file systems are unmounted.
- The file systems are inaccessible while they are being received.
- The original file system to be received must not exist while it is being transferred.
- If the file system name already exists, you can use `zfs rename` command to rename the file system.

For example:
# zfs send tank/gozer@0830 > /bkups/gozer.083006
# zfs receive tank/gozer2@today < /bkups/gozer.083006
# zfs rename tank/gozer tank/gozer.old
# zfs rename tank/gozer2 tank/gozer

If you make a change to the destination file system and you want to perform another incremental send of a snapshot, you must first roll back the receiving file system.

Consider the following example. First, make a change to the file system as follows:

host2# rm newtank/dana/file.1

Then, perform an incremental send of tank/dana@snap3. However, you must first roll back the receiving file system to receive the new incremental snapshot. Or, you can eliminate the rollback step by using the -F option. For example:

host1# zfs send -i tank/dana@snap2 tank/dana@snap3 | ssh host2 zfs recv -F newtank/dana

When you receive an incremental snapshot, the destination file system must already exist.

If you make changes to the file system and you do not roll back the receiving file system to receive the new incremental snapshot or you do not use the -F option, you see a message similar to the following:

host1# zfs send -i tank/dana@snap4 tank/dana@snap5 | ssh host2 zfs recv newtank/dana
cannot receive: destination has been modified since most recent snapshot

The following checks are performed before the -F option is successful:

- If the most recent snapshot doesn’t match the incremental source, neither the roll back nor the receive is completed, and an error message is returned.
- If you accidentally provide the name of different file system that doesn't match the incremental source specified in the zfs receive command, neither the rollback nor the receive is completed, and the following error message is returned:
  
cannot send 'pool/fs@name': not an earlier snapshot from the same fs

Sending and Receiving Complex ZFS Snapshot Streams

This section describes how to use the zfs send -I and -R options to send and receive more complex snapshot streams.
Keep the following points in mind when sending and receiving complex ZFS snapshot streams:

- Use the `zfs send -I` option to send all incremental streams from one snapshot to a cumulative snapshot. Or, use this option to send an incremental stream from the original snapshot to create a clone. The original snapshot must already exist on the receiving side to accept the incremental stream.
- Use the `zfs send -R` option to send a replication stream of all descendent file systems. When the replication stream is received, all properties, snapshots, descendent file systems, and clones are preserved.
- Use both options to send an incremental replication stream.
  - Changes to properties are preserved, as are snapshot and file system `rename` and `destroy` operations are preserved.
  - If `zfs recv -F` is not specified when receiving the replication stream, dataset `destroy` operations are ignored. The `zfs recv -F` syntax in this case also retains its `rollback if necessary` meaning.
  - As with other (non `zfs send -R`) -i or -I cases, if -i is used, all snapshots between snapA and snapD are sent. If -I is used, only snapD (for all descendents) are sent.
  - To receive any of these new types of `zfs send` streams, the receiving system must be running a software version capable of sending them. The stream version is incremented. However, you can access streams from older pool versions by using a newer software version. For example, you can send and receive streams created with the newer options to and from a version 3 pool. But, you must be running recent software to receive a stream sent with the newer options.

**EXAMPLE 7-1  Sending and Receiving Complex ZFS Snapshot Streams**

A group of incremental snapshots can be combined into one snapshot by using the `zfs send -I` option. For example:

```bash
# zfs send -I pool/fs@snapA pool/fs@snapD > /snaps/fs@all-I
```

Then, you would remove snapB, snapC, and snapD.

```bash
# zfs destroy pool/fs@snapB
# zfs destroy pool/fs@snapC
# zfs destroy pool/fs@snapD
```

To receive the combined snapshot, you would use the following command.

```bash
# zfs receive -d -F pool/fs < /snaps/fs@all-I
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>USED</th>
<th>AVAIL</th>
<th>REFER</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>pool/fs</td>
<td>428K</td>
<td>16.5G</td>
<td>20K</td>
<td>/pool</td>
</tr>
<tr>
<td>pool/fs@snapA</td>
<td>16K</td>
<td>-</td>
<td>18.5K</td>
<td>-</td>
</tr>
<tr>
<td>pool/fs@snapB</td>
<td>17K</td>
<td>-</td>
<td>20K</td>
<td>-</td>
</tr>
</tbody>
</table>
You can also use the `zfs send -I` command to combine a snapshot and a clone snapshot to create a combined dataset. For example:

```
# zfs create pool/fs
# zfs snapshot pool/fs@snap1
# zfs clone pool/fs@snap1 pool/clone
# zfs snapshot pool/clone@snapA
# zfs send -I pool/fs@snap1 pool/clone@snapA > /snaps/fsclonesnap-I
# zfs destroy pool/clone@snapA
# zfs destroy pool/clone
# zfs receive -F pool/clone < /snaps/fsclonesnap-I
```

You can use the `zfs send -R` command to replicate a ZFS file system and all descendent file systems, up to the named snapshot. When this stream is received, all properties, snapshots, descendent file systems, and clones are preserved.

In the following example, snapshots are created for user filesystems. One replication stream is created for all usersnapshots. Next, the original file systems and snapshots are destroyed and then recovered.

```
# zfs snapshot -r users@today
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
users 187K 33.2G 22K /users
users@today 0 - 22K -
users/user1 18K 33.2G 18K /users/user1
users/user1@today 0 - 18K -
users/user2 18K 33.2G 18K /users/user2
users/user2@today 0 - 18K -
users/user3 18K 33.2G 18K /users/user3
users/user3@today 0 - 18K -
# zfs send -R users@today > /snaps/users-R
# zfs destroy -r users
# zfs receive -F -d users < /snaps/users-R
# zfs list
NAME USED AVAIL REFER MOUNTPOINT
users 196K 33.2G 22K /users
users@today 0 - 22K -
users/user1 18K 33.2G 18K /users/user1
users/user1@today 0 - 18K -
users/user2 18K 33.2G 18K /users/user2
users/user2@today 0 - 18K -
users/user3 18K 33.2G 18K /users/user3
users/user3@today 0 - 18K -
```

In the following example, the `zfs send -R` command was used to replicate the `users` dataset and its descendents, and to send the replicated stream to another pool, `users2`.

```
# zfs create users2 mirror c0t1d0 c1t1d0
# zfs receive -F -d users2 < /snaps/users-R
```
EXAMPLE 7–1  Sending and Receiving Complex ZFS Snapshot Streams  (Continued)

**Remote Replication of ZFS Data**

You can use the `zfs send` and `zfs recv` commands to remotely copy a snapshot stream representation from one system to another system. For example:

```
# zfs send tank/cindy@today | ssh newsys zfs recv sandbox/restfs@today
```

This command sends the `tank/cindy@today` snapshot data and receives it into the `sandbox/restfs` file system. The command also creates a `restfs@today` snapshot on the `newsys` system. In this example, the user has been configured to use `ssh` on the remote system.
Using ACLs to Protect Oracle Solaris ZFS Files

This chapter provides information about using access control lists (ACLs) to protect your ZFS files. ACLs provide more granular permissions than the standard UNIX permissions.

The following sections are provided in this chapter:

- “New Solaris ACL Model” on page 219
- “Setting ACLs on ZFS Files” on page 225
- “Setting and Displaying ACLs on ZFS Files in Verbose Format” on page 228
- “Setting and Displaying ACLs on ZFS Files in Compact Format” on page 239

New Solaris ACL Model

Previous versions of the Solaris OS supported an ACL implementation that was primarily based on the POSIX-draft ACL specification. The POSIX-draft based ACLs are used to protect UFS files and are translated by versions of NFS prior to NFSv4.

With the introduction of NFSv4, a new ACL model fully supports the interoperability that NFSv4 offers between UNIX and non-UNIX clients. The new ACL implementation, as defined in the NFSv4 specification, provides much richer semantics that are based on NT-style ACLs.

The main differences of the new ACL model follow:

- The new ACL model is based on the NFSv4 specification and is similar to NT-style ACLs.
- The new model provides a much more granular set of access privileges. For more information, see Table 8-2.
- ACLs are set and displayed with the chmod and ls commands rather than the setfacl and getfacl commands.
- The new model provides richer inheritance semantics for designating how access privileges are applied from a directory to subdirectories, and so on. For more information, see “ACL Inheritance” on page 223.
Both ACL models provide more fine-grained access control than is available with the standard file permissions. Much like POSIX-draft ACLs, the new ACLs are composed of multiple Access Control Entries (ACEs).

POSIX-draft based ACLs use a single entry to define which permissions are allowed and which permissions are denied. The new ACL model has two types of ACEs that affect access checking: ALLOW and DENY. As such, you cannot infer from any single ACE that defines a set of permissions whether the permissions that weren’t defined in that ACE are allowed or denied.

Translation between NFSv4 ACLs and POSIX-draft ACLs is as follows:

- If you use an ACL-aware utility, such as the `cp`, `mv`, `tar`, `cpio`, or `rcp` command, to transfer UFS files with ACLs to a ZFS file system, the POSIX-draft ACLs are translated into the equivalent NFSv4 ACLs.
- Some NFSv4 ACLs are translated into POSIX-draft ACLs. You see a message similar to the following if an NFSv4 ACL isn’t translated into a POSIX-draft ACL:
  ```
  # cp -p filea /var/tmp
  cp: failed to set acl entries on /var/tmp/filea
  ```
- If you create a UFS `tar` or `cpio` archive with the preserve ACL option (`tar -p` or `cpio -P`) on a system that runs a current Solaris release, you will lose the ACLs when the archive is extracted on a system that runs a previous Solaris release.
  All of the files are extracted with the correct file modes, but the ACL entries are ignored.
- You can use the `ufsrestore` command to restore data into a ZFS file system. If the original data includes POSIX-draft ACLs, they are translated into NFSv4 ACLs.
- If you attempt to set an NFSv4 ACL on a UFS file, you see a message similar to the following:
  ```
  chmod: ERROR: ACL type’s are different
  ```
- If you attempt to set a POSIX-draft ACL on a ZFS file, you see messages similar to the following:
  ```
  # getfacl filea
  File system doesn’t support aclent_t style ACL’s.
  See acl(5) for more information on Solaris ACL support.
  ```

For information about other limitations with ACLs and backup products, see “Saving ZFS Data With Other Backup Products” on page 212.

**Syntax Descriptions for Setting ACLs**

Two basic ACL formats follow:

**Syntax for Setting Trivial ACLs**

An ACL is *trivial* in that it only represents the traditional UNIX owner/group/other entries.
Syntax for Setting Non-Trivial ACLs

chmod [options] A[index]{{+|=}owner@ |group@ |everyone@:access-permissions/...:[inheritance-flags]:deny | allow file

chmod [options] A-owner@, group@, everyone@:access-permissions/...:[inheritance-flags]:deny | allow file ...

chmod [options] A[index]- file

Identifies the ACL-entry-type for trivial ACL syntax. For a description of ACL entry types, see Table 8–1.

user or group:ACL-entry-ID=username or groupname

Identifies the ACL-entry-type for explicit ACL syntax. The user and group ACL-entry-type must also contain the ACL-entry-ID, username or groupname. For a description of ACL entry types, see Table 8–1.

access-permissions/...

Identifies the access permissions that are granted or denied. For a description of ACL access privileges, see Table 8–2.

inheritance-flags

Identifies an optional list of ACL inheritance flags. For a description of the ACL inheritance flags, see Table 8–3.

deny | allow

Identifies whether the access permissions are granted or denied.

In the following example, the ACL-entry-ID value is not relevant:

group@:write_data/append_data/execute:deny

The following example includes an ACL-entry-ID because a specific user (ACL-entry-type) is included in the ACL.

0:user:gozer:list_directory/read_data/execute:allow

When an ACL entry is displayed, it looks similar to the following:

2:group@:write_data/append_data/execute:deny
In this example, the 2, known as the index-ID designation, identifies the ACL entry in the larger ACL, which might have multiple entries for owner, specific UIDs, group, and everyone. You can specify the index-ID with the chmod command to identify which part of the ACL you want to modify. For example, you can identify index ID 3 as A3 in the chmod command syntax, similar to the following:

```bash
chmod A3=user:venkman:read_acl:allow filename
```

ACL entry types, which are the ACL representations of owner, group, and other, are described in the following table.

**TABLE 8-1  ACL Entry Types**

<table>
<thead>
<tr>
<th>ACL Entry Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner@</td>
<td>Specifies the access granted to the owner of the object.</td>
</tr>
<tr>
<td>group@</td>
<td>Specifies the access granted to the owning group of the object.</td>
</tr>
<tr>
<td>everyone@</td>
<td>Specifies the access granted to any user or group that does not match any other ACL entry.</td>
</tr>
<tr>
<td>user</td>
<td>With a user name, specifies the access granted to an additional user of the object. This entry must include the ACL-entry-ID, which contains a username or userID. If the value is not a valid numeric UID or username, the ACL entry type is invalid.</td>
</tr>
<tr>
<td>group</td>
<td>With a group name, specifies the access granted to an additional group of the object. This entry must include the ACL-entry-ID, which contains a groupname or groupID. If the value is not a valid numeric GID or groupname, the ACL entry type is invalid.</td>
</tr>
</tbody>
</table>

ACL access privileges are described in the following table.

**TABLE 8-2  ACL Access Privileges**

<table>
<thead>
<tr>
<th>Access Privilege</th>
<th>Compact Access Privilege</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_file</td>
<td>w</td>
<td>Permission to add a new file to a directory.</td>
</tr>
<tr>
<td>add_subdirectory</td>
<td>p</td>
<td>On a directory, permission to create a subdirectory.</td>
</tr>
<tr>
<td>append_data</td>
<td>p</td>
<td>Placeholder. Not currently implemented.</td>
</tr>
<tr>
<td>delete</td>
<td>d</td>
<td>Permission to delete a file.</td>
</tr>
<tr>
<td>delete_child</td>
<td>D</td>
<td>Permission to delete a file or a directory within a directory.</td>
</tr>
<tr>
<td>execute</td>
<td>x</td>
<td>Permission to execute a file or search the contents of a directory.</td>
</tr>
<tr>
<td>list_directory</td>
<td>r</td>
<td>Permission to list the contents of a directory.</td>
</tr>
</tbody>
</table>
TABLE 8–2  ACL Access Privileges  (Continued)

<table>
<thead>
<tr>
<th>Access Privilege</th>
<th>Compact Access Privilege</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read_acl</td>
<td>c</td>
<td>Permission to read the ACL (ls).</td>
</tr>
<tr>
<td>read_attributes</td>
<td>a</td>
<td>Permission to read the basic attributes (non-ACLs) of a file. Think of basic attributes as the stat-level attributes. Allowing this access mask bit means that the entity can execute ls(1) and stat(2).</td>
</tr>
<tr>
<td>read_data</td>
<td>r</td>
<td>Permission to read the contents of a file.</td>
</tr>
<tr>
<td>read_xattr</td>
<td>R</td>
<td>Permission to read the extended attributes of a file or to perform a lookup in the file’s extended attributes directory.</td>
</tr>
<tr>
<td>synchronize</td>
<td>s</td>
<td>Placeholder. Not currently implemented.</td>
</tr>
<tr>
<td>write_xattr</td>
<td>W</td>
<td>Permission to create extended attributes or write to the extended attributes directory. Granting this permission to a user means that the user can create an extended attribute directory for a file. The attribute file’s permissions control the user’s access to the attribute.</td>
</tr>
<tr>
<td>write_data</td>
<td>w</td>
<td>Permission to modify or replace the contents of a file.</td>
</tr>
<tr>
<td>write_attributes</td>
<td>A</td>
<td>Permission to change the time stamps associated with a file or directory to an arbitrary value.</td>
</tr>
<tr>
<td>write_acl</td>
<td>C</td>
<td>Permission to write the ACL or to modify the ACL by using the chmod command.</td>
</tr>
<tr>
<td>write_owner</td>
<td>o</td>
<td>Permission to change the file’s owner or group. Or, the ability to execute the chown or chgrp command on the file. Permission to take ownership of a file or permission to change the group ownership of a file to a group of which the user is a member. If you want to change the file or group ownership to an arbitrary user or group, then the PRIV_FILE_CHOWN privilege is required.</td>
</tr>
</tbody>
</table>

**ACL Inheritance**

The purpose of using ACL inheritance is so that a newly created file or directory can inherit the ACLs they are intended to inherit, but without disregarding the existing permissions on the parent directory.

By default, ACLs are not propagated. If you set a non-trivial ACL on a directory, it is not inherited by any subsequent directory. You must specify the inheritance of an ACL on a file or directory.

The optional inheritance flags are described in the following table.
TABLE 8–3  ACL Inheritance Flags

<table>
<thead>
<tr>
<th>Inheritance Flag</th>
<th>Compact Inheritance Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_inherit</td>
<td>f</td>
<td>Inherit the ACL from the parent directory but only applies to the directory's files.</td>
</tr>
<tr>
<td>dir_inherit</td>
<td>d</td>
<td>Inherit the ACL from the parent directory but only applies to the directory's subdirectories.</td>
</tr>
<tr>
<td>inherit_only</td>
<td>i</td>
<td>Inherit the ACL from the parent directory but applies only to newly created files or subdirectories and not the directory itself. This flag requires the file_inherit flag, the dir_inherit flag, or both, to indicate what to inherit.</td>
</tr>
<tr>
<td>no_propagate</td>
<td>n</td>
<td>Only inherit the ACL from the parent directory to the first-level contents of the directory, not the second-level or subsequent contents. This flag requires the file_inherit flag, the dir_inherit flag, or both, to indicate what to inherit.</td>
</tr>
<tr>
<td>-</td>
<td>N/A</td>
<td>No permission granted.</td>
</tr>
</tbody>
</table>

In addition, you can set a default ACL inheritance policy on a file system that is more strict or less strict by using the aclinherit file system property. For more information, see the next section.

### ACL Properties

A ZFS file system has two properties related to ACLs.

- **aclinherit** – This property determines the behavior of ACL inheritance. Values include the following:
  - **discard** – For new objects, no ACL entries are inherited when a file or directory is created. The ACL on the new file or directory is equal to the permissions of the file or directory.
  - **noallow** – For new objects, only inheritable ACL entries that have an access type of deny are inherited.
  - **restricted** – For new objects, the write_owner and write_acl permissions are removed when an ACL entry is inherited.
  - **passthrough** – When the property value is set to passthrough, files are created with permissions determined by the inheritable ACEs. If no inheritable ACEs exist that affect the permissions, then the permissions are set in accordance to the requested permissions from the application.
• **passthrough-x** – This property value has the same semantics as passthrough, except that when passthrough-x is enabled, files are created with the execute (x) permission, but only if the execute permission is set in the file creation mode and in an inheritable ACE that affects the mode.

The default value for the aclinherit property is restricted.

• **aclmode** – This property modifies ACL behavior when a file is initially created or whenever a file or directory's permissions are modified by the chmod command. Values include the following:
  - **discard** – All ACL entries are removed except for the entries needed to define the mode of the file or directory.
  - **groupmask** – User or group ACL permissions are reduced so that they are no greater than the group permissions, unless it is a user entry that has the same UID as the owner of the file or directory. Then, the ACL permissions are reduced so that they are no greater than the owner permissions.
  - **passthrough** – During a chmod operation, ACEs other than owner@, group@, or everyone@ are not modified in any way. ACEs with owner@, group@, or everyone@ are disabled to set the file mode as requested by the chmod operation.

The default value for the aclmode property is groupmask.

### Setting ACLs on ZFS Files

As implemented with ZFS, ACLs are composed of ACL entries. ZFS provides a *pure ACL* model, where all files have an ACL. Typically, the ACL is *trivial* in that it only represents the traditional UNIX owner/group/other entries.

If you change the permissions of the file, a file's ACL is updated accordingly. In addition, if you remove a non-trivial ACL that granted a user access to a file or directory, that user could still have access to the file or directory because of the file or directory's permission bits that grant access to a group or to everyone. All access control decisions are governed by the permissions represented in a file or directory's ACL.

The primary rules of ACL access on a ZFS file follow:

- ZFS processes ACL entries in the order they are listed in the ACL, from the top down.
- Only ACL entries that have a "who" that matches the requester of the access are processed.
- After an allow permission has been granted, it cannot be denied by a subsequent ACL deny entry in the same ACL permission set.
- The owner of a file is granted the write_acl permission unconditionally, even if the permission is explicitly denied. Otherwise, any permission left unspecified is denied.
In cases of deny permissions or when an access permission for a file is missing, the privilege subsystem determines what access request is granted for the owner of the file or for superuser. This mechanism prevents owners of files from getting locked out of their files and enables superuser to modify files for recovery purposes.

If you set a non-trivial ACL on a directory, the ACL is not automatically inherited by the directory's children. If you set a non-trivial ACL and you want it to be inherited by the directory's children, you have to use the ACL inheritance flags. For more information, see Table 8–3 and “Setting ACL Inheritance on ZFS Files in Verbose Format” on page 233.

When you create a new file and depending on the umask value, a default trivial ACL, similar to the following, is applied:

```bash
$ ls -v file.1
-rw-r--r-- 1 root root 206663 May 20 14:09 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
/write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
/write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
:allow
```

Note that each user category (owner@, group@, everyone@) has two ACL entries in this example. One entry is for deny permissions, and one entry is for allow permissions.

A description of this file ACL follows:

0:owner@ The owner is denied execute permission on the file (execute:deny).

1:owner@ The owner can read and modify the contents of the file (read_data/write_data/append_data). The owner can also modify the file's attributes such as time stamps, extended attributes, and ACLs (write_xattr/write_attributes/write_acl). In addition, the owner can modify the ownership of the file (write_owner:allow).

2:group@ The group is denied modify and execute permissions on the file (write_data/append_data/execute:deny).

3:group@ The group is granted read permissions to the file (read_data:allow).

4:everyone@ Everyone who is not the owner of the file or a member of the owning group of the file is denied permission to execute or modify the contents of the file and to modify any attributes of the file (write_data/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:deny).

5:everyone@ Everyone who is not the owner of the file or a member of the owning group of the file is granted read permissions on the file and the file's attributes.
When you create a new directory and depending on the umask value, a default directory ACL, similar to the following is applied:

```
$ ls -dv dir.1
drwxr-xr-x 2 root root 2 May 20 14:11 dir.1
```

0:owner@::deny
1:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
append_data/write_xattr/execute/write_attributes/write_acl
/write_owner:allow
2:group@:add_file/write_data/add_subdirectory/append_data:deny
3:group@:list_directory/read_data/execute:allow
4:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
/write_attributes/write_acl/write_owner:deny
5:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
/write_acl/synchronize:allow
```

A description of this directory ACL follows:

0:owner@ The owner deny list is empty for the directory (::deny).

1:owner@ The owner can read and modify the directory contents
(list_directory/read_data/add_file/write_data/
add_subdirectory/append_data), search the contents (execute), and
modify the directory’s attributes such as time stamps, extended attributes,
and ACLs (write_xattr/write_attributes/write_acl). In addition, the
owner can modify the ownership of the directory (write_owner:allow).

2:group@ The group cannot add to or modify the directory contents
(add_file/write_data/add_subdirectory/append_data
:deny).

3:group@ The group can list and read the directory contents. In addition, the group has
execute permission to search the directory contents
(list_directory/read_data/execute:allow).

4:everyone@ Everyone who is not the owner of the file or a member of the owning group of
the file is denied permission to add to or modify the contents of the directory
(add_file/write_data/add_subdirectory/append_data). In addition, the
permission to modify any attributes of the directory is denied
(write_xattr/write_attributes/write_acl/write_owner:deny).

5:everyone@ Everyone who is not the owner of the file or a member of the owning group of
the file is granted read and execute permissions on the directory contents and
the directory’s attributes
(list_directory/read_data/read_xattr/execute/read_attributes/write_acl/synchronize:allow). The synchronize access
permission is not currently implemented.

### Setting and Displaying ACLs on ZFS Files in Verbose Format

You can use the `chmod` command to modify ACLs on ZFS files. The following `chmod` syntax for modifying ACLs uses `acl-specification` to identify the format of the ACL. For a description of `acl-specification`, see “Syntax Descriptions for Setting ACLs” on page 220.

- **Adding ACL entries**
  - Adding an ACL entry for a user
    
    ```
    % chmod A+acl-specification filename
    ```
  - Adding an ACL entry by `index-ID`
    
    ```
    % chmod A[index-ID]+acl-specification filename
    ```

  This syntax inserts the new ACL entry at the specified `index-ID` location.

- **Replacing an ACL entry**
  
  ```
  % chmod A=acl-specification filename
  % chmod A[index-ID]=acl-specification filename
  ```

- **Removing ACL entries**
  - Removing an ACL entry by `index-ID`
    
    ```
    % chmod A[index-ID] filename
    ```
  - Removing an ACL entry by user
    
    ```
    % chmod A-acl-specification filename
    ```
  - Removing all non-trivial ACEs from a file
    
    ```
    % chmod A- filename
    ```

Verbose ACL information is displayed by using the `ls -v` command. For example:

```bash
# ls -v file.1
-rw-r----- 1 root root 206663 May 20 14:09 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes/write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize:allow
```

For information about using the compact ACL format, see “Setting and Displaying ACLs on ZFS Files in Compact Format” on page 239.
EXAMPLE 8-1  Modifying Trivial ACLs on ZFS Files

This section provides examples of setting and displaying trivial ACLs.

In the following example, a trivial ACL exists on file.1:

```
# ls -v file.1
-rw-r--r-- 1 root root 206663 May 20 15:03 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
   /write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
   /write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
   :allow
```

In the following example, write_data permissions are granted for group@:

```
# chmod A2=group@:append_data/execute:deny file.1
# chmod A3=group@:read_data/write_data:allow file.1
# ls -v file.1
-rw-rw-r-- 1 root root 206663 May 20 15:03 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
   /write_acl/write_owner:allow
2:group@:append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
   /write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
   :allow
```

In the following example, permissions on file.1 are set back to 644.

```
# chmod 644 file.1
# ls -v file.1
-rw-r--r-- 1 root root 206663 May 20 15:03 file.1
0:owner@:execute:deny
1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
   /write_acl/write_owner:allow
2:group@:write_data/append_data/execute:deny
3:group@:read_data:allow
4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
   /write_acl/write_owner:deny
5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
   :allow
```

EXAMPLE 8-2  Setting Non-Trivial ACLs on ZFS Files

This section provides examples of setting and displaying non-trivial ACLs.

In the following example, read_data/execute permissions are added for user gozer on the test.dir directory:
# EXAMPLE 8-2  Setting Non-Trivial ACLs on ZFS Files  (Continued)

```bash
# chmod A+user:gozer:read_data/execute:allow test.dir
# ls -dv test.dir
```

```
drwxr-xr-x  2 root  root  2 May 20 15:09 test.dir
  0:owner@::deny
  1:owner@:list_directory/read_data/execute:allow
  2:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
       /append_data/write_xattr/execute/write_attributes/write_acl
       /write_owner:allow
  3:group@:add_file/write_data/add_subdirectory/append_data:deny
  4:group@:list_directory/read_data/execute:allow
  5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
       /write_attributes/write_acl/write_owner:deny
  6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
       /read_acl/synchronize:allow
```

In the following example, `read_data/execute` permissions are removed for user gozer:

```bash
# chmod A0- test.dir
# ls -dv test.dir
```

```
drwxr-xr-x  2 root  root  2 May 20 15:09 test.dir
  0:owner@::deny
  1:owner@:list_directory/read_data/execute:allow
  2:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
       /append_data/write_xattr/execute/write_attributes/write_acl
       /write_owner:allow
  3:group@:add_file/write_data/add_subdirectory/append_data:deny
  4:group@:list_directory/read_data/execute:allow
  5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
       /write_attributes/write_acl/write_owner:deny
  6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
       /read_acl/synchronize:allow
```

# EXAMPLE 8-3  ACL Interaction With Permissions on ZFS Files

These examples illustrate the interaction between setting ACLs and then changing the file or directory's permissions.

In the following example, a trivial ACL exists on `file.2`:

```bash
# ls -v file.2
```

```
-rw-r--r--  1 root  root  3103 May 20 15:23 file.2
  0:owner@::deny
  1:owner@:read_data/write_data/append_data/write_xattr/write_attributes
       /write_acl/write_owner:allow
  2:group@:write_data/append_data/execute:deny
  3:group@:read_data:allow
  4:everyone@:write_data/append_data/write_xattr/execute/write_attributes
       /write_acl/write_owner:deny
  5:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
       :allow
```

In the following example, ACL allow permissions are removed from everyone@:
**EXAMPLE 8-3**  
**ACL Interaction With Permissions on ZFS Files (Continued)**

# chmod A5- file.2  
# ls -v file.2  
-rw-r-----+ 1 root root 3103 May 20 15:23 file.2  
0:owner@:execute:deny  
  1:owner@:read_data/write_data/append_data/write_xattr/write_attributes  
  /write_acl/write_owner:allow  
  2:group@:write_data/append_data/write_xattr/write_attributes  
  /write_acl/write_owner:allow  
  3:group@:read_data:allow  
  4:everyone@:write_data/append_data/write_xattr/write_attributes  
  /write_acl/write_owner:deny

In this output, the file's permissions are reset from 644 to 640. Read permissions for everyone@ are effectively removed from the file's permissions when the ACL allow permissions are removed for everyone@.

In the following example, the existing ACL is replaced with read_data/write_data permissions for everyone@:

# chmod A=everyone@:read_data/write_data:allow file.3  
# ls -v file.3  
-rw-rw-rw-+ 1 root root 6986 May 20 15:25 file.3  
0:everyone@:read_data/write_data:allow

In this output, the chmod syntax effectively replaces the existing ACL with read_data/write_data:allow permissions to read/write permissions for owner, group, and everyone@. In this model, everyone@ specifies access to any user or group. Because no owner@ or group@ ACL entry exists to override the permissions for owner and group, the permissions are set to 666.

In the following example, the existing ACL is replaced with read permissions for user gozer:

# chmod A=user:gozer:read_data:allow file.3  
# ls -v file.3  
----------+ 1 root root 6986 May 20 15:25 file.3  
0:user:gozer:read_data:allow

In this output, the file permissions are computed to be 000 because no ACL entries exist for owner@, group@, or everyone@, which represent the traditional permission components of a file. The owner of the file can resolve this problem by resetting the permissions (and the ACL) as follows:

# chmod 655 file.3  
# ls -v file.3  
-rw-r-xr-x+ 1 root root 6986 May 20 15:25 file.3  
0:user:gozer::deny  
  1:user:gozer:read_data:allow  
  2:owner@:execute:deny  
  3:owner@:read_data/write_data/append_data/write_xattr/write_attributes  
  /write_acl/write_owner:allow

---

Chapter 8 • Using ACLs to Protect Oracle Solaris ZFS Files 231
**EXAMPLE 8–3  ACL Interaction With Permissions on ZFS Files  (Continued)**

4:group@:write_data/append_data:deny
5:group@:read_data/execute:allow
6:everyone@:write_data/append_data/write_xattr/write_attributes/write_acl/write_owner:deny
7:everyone@:read_data/read_xattr/execute/read_attributes/read_acl/synchronize:allow

**EXAMPLE 8–4  Restoring Trivial ACLs on ZFS Files**

You can use the `chmod` command to remove all non-trivial ACLs on a file or directory, thus restoring the trivial ACLs on the file or directory.

In the following example, two non-trivial ACEs exist on `test5.dir`:

```
# ls -dv test5.dir
drwxr-xr-x  2 root  root  2 May 20 15:32 test5.dir
  0:user:lp:read_data:file_inherit:deny
  1:user:gozer:read_data:file_inherit:deny
  2:owner::deny
  3:owner@:list_directory/read_data/add_file/write_data/add_subdirectory/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:allow
  4:group@:add_file/write_data/add_subdirectory/append_data:deny
  5:group@:list_directory/read_data/execute:allow
  6:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr/write_attributes/write_acl/write_owner:deny
  7:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/read_acl/synchronize:allow
```

In the following example, the non-trivial ACLs for users gozer and lp are removed. The remaining ACL contains the six default values for owner@, group@, and everyone@.

```
# chmod A- test5.dir
# ls -dv test5.dir
drwxr-xr-x  2 root  root  2 May 20 15:32 test5.dir
  0:owner@:deny
  1:owner@:list_directory/read_data/add_file/write_data/add_subdirectory/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:allow
  2:group@:add_file/write_data/add_subdirectory/append_data:deny
  3:group@:list_directory/read_data/execute:allow
  4:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr/write_attributes/write_acl/write_owner:deny
  5:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/read_acl/synchronize:allow
```
Setting ACL Inheritance on ZFS Files in Verbose Format

You can specify whether and how ACLs are inherited on files and directories. By default, ACLs are not propagated. If you set a non-trivial ACL on a directory, the ACL is not inherited by any subsequent directory. You must specify the inheritance of an ACL on a file or directory.

In addition, two ACL properties can be set globally on file systems: aclinherit and aclmode. By default, aclinherit is set to restricted and aclmode is set to groupmask.

For more information, see “ACL Inheritance” on page 223.

EXAMPLE 8-5  Granting Default ACL Inheritance

By default, ACLs are not propagated through a directory structure.

In the following example, a non-trivial ACE of read_data/write_data/execute is applied for user gozer on the test.dir directory:

```
# chmod A+user:gozer:read_data/write_data/execute:allow test.dir
# ls -dv test.dir
drwxr-xr-x+ 2 root root 2 May 20 15:41 test.dir
0:owner@::deny
1:owner@:list_directory/read_data/add_file/write_data/read_xattr/execute/read_attributes/read_acl/write_attributes/write_acl/write_owner/write_xattr/write_attributes/write_acl/write_owner:allow
2:group@:add_file/write_data/add_subdirectory/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:allow
4:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/synchronize:allow
5:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/synchronize:allow
6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/synchronize:allow
```

If a test.dir subdirectory is created, the ACE for user gozer is not propagated. User gozer would only have access to the subdirectory if the permissions on the subdirectory granted him access as the file owner, group member, or everyone@. For example:

```
# mkdir test.dir/sub.dir
# ls -dv test.dir/sub.dir
drwxr-xr-x 2 root root 2 May 20 15:42 test.dir/sub.dir
0:owner@::deny
1:owner@:list_directory/read_data/add_file/write_data/add_subdirectory/append_data/write_xattr/execute/write_attributes/write_acl/write_owner:allow
2:group@:add_file/write_data/add_subdirectory/append_data:deny
4:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/synchronize:allow
5:everyone@:list_directory/read_data/read_xattr/execute/read_attributes/synchronize:allow
```
EXAMPLE 8–6  Granting ACL Inheritance on Files and Directories

The following examples identify the file and directory ACEs that are applied when the file_inherit flag is set.

In this example, read_data/write_data permissions are added for files in the test2.dir directory for user gozer so that he has read access on any newly created files:

```
# chmod A+user:gozer:read_data/write_data:file_inherit:allow test2.dir
# ls -dv test2.dir
drwxr-xr-x  2 root root 2 May 20 15:50 test2.dir
  0:user:gozer:read_data/write_data:file_inherit:allow
  1:owner::deny
  2:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
     /append_data/write_xattr/execute/write_attributes/write_acl
     /write_owner:allow
  3:group@:add_file/write_data/add_subdirectory/append_data:deny
  4:group@:list_directory/read_data/execute:allow
  5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
     /write_attributes/write_acl/write_owner:deny
  6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
     /read_acl/synchronize:allow
```

In this example, user gozer's permissions are applied on the newly created test2.dir/file.2 file. The ACL inheritance granted, read_data:file_inherit:allow, means that user gozer can read the contents of any newly created file.

```
# touch test2.dir/file.2
# ls -v test2.dir/file.2
-rw-r--r--  1 root  root  0 May 20 15:51 test2.dir/file.2
  0:user:gozer:write_data:deny
  1:user:gozer:read_data/write_data:allow
  2:owner:execute:deny
  3:owner@:read_data/write_data/append_data/write_xattr/write_attributes
     /write_acl/write_owner:allow
  4:group@:write_data/append_data/execute:deny
  5:group@:read_data:allow
  6:everyone@:write_data/append_data/write_xattr/execute/write_attributes
     /write_acl/write_owner:deny
  7:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize
     :allow
```

Because the aclmode property for this file is set to the default value, groupmask, user gozer does not have write_data permission on file.2 because the file's group permission does not allow it.

When using the inherit_only permission, which is applied when the file_inherit or dir_inherit flag is set, is used to propagate the ACL through the directory structure. As such, user gozer is only granted or denied permission from everyone@permissions unless he is the file owner or a member of the file's group owner. For example:
EXAMPLE 8-6  Granting ACL Inheritance on Files and Directories  (Continued)

```bash
# mkdir test2.dir/subdir.2
# ls -dv test2.dir/subdir.2
```

```text
drwxr-xr-x+ 2 root root 2 May 20 15:52 test2.dir/subdir.2  
0:user:gozer:list_directory/read_data/add_file/write_data:file_inherit
    /inherit only:allow
1:owner@::deny
2:owner@:list directory/add_file/write_data/add_subdirectory
    /append_data/write_xattr/execute/write_attributes/write_acl
    /write acl/write owner:allow
3:group@:add_file/write_data/add_subdirectory/append_data:deny
4:group@:list_directory/read_data/execute:allow
5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
    /write attributes/write acl/write owner:deny
6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
    /read acl/synchronize:allow
```

The following examples identify the file and directory ACLs that are applied when both the `file_inherit` and `dir_inherit` flags are set.

In this example, user `gozer` is granted read, write, and execute permissions that are inherited for newly created files and directories:

```bash
# chmod A+user:gozer:read_data/write_data/execute:file_inherit/dir_inherit:allow
test3.dir
# ls -dv test3.dir
```

```text
drwxr-xr-x+ 2 root root 2 May 20 15:53 test3.dir  
0:user:gozer:list_directory/read_data/add_file/write_data:file_inherit
    /dir_inherit:allow
1:owner@::deny
2:owner@:list directory/add_file/write_data/add_subdirectory
    /append_data/write_xattr/execute/write_attributes/write_acl
    /write acl/write owner:allow
3:group@:add_file/write_data/add_subdirectory/append_data:deny
4:group@:list_directory/read_data/execute:allow
5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
    /write attributes/write acl/write owner:deny
6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
    /read acl/synchronize:allow
```

```bash
# touch test3.dir/file.3
# ls -v test3.dir/file.3
```

```text
-rw-r--r--+ 1 root root 0 May 20 15:58 test3.dir/file.3  
0:user:gozer:write_data/execute:deny
1:user:gozer:read_data/write_data/execute:allow
2:owner@:execute:deny
3:owner@:read_data/append_data/write_xattr/write_attributes
    /write acl/write owner:allow
4:group@:write data/append_data/execute:deny
5:group@:read_data:allow
6:everyone@:write_data/append_data/write_xattr/execute/write_attributes
    /write acl/write owner:deny
7:everyone@:read_data/read_xattr/execute/read_attributes/read_acl/synchronize
    :allow
```

Chapter 8 • Using ACLs to Protect Oracle Solaris ZFS Files 235
EXAMPLE 8–6  Granting ACL Inheritance on Files and Directories  (Continued)

```bash
# mkdir test3.dir/subdir.1
# ls -dv test3.dir/subdir.1
drwxr-xr-x+ 2 root root 2 May 20 15:59 test3.dir/subdir.1
  0:user:gozer:list_directory/read_data/add_file/write_data/execute
     :file_inherit/dir_inherit/inherit_only:allow
  1:user:gozer:add_file/write_data:deny
  2:user:gozer:read_data/add_file/write_data/execute:allow
  3:owner@::deny
  4:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
     /append_data/write_xattr/execute/write_attributes/write_acl
     /write_owner:allow
  5:group@:add_file/write_data/add_subdirectory/append_data:deny
  6:group@:read_data/execute:allow
  7:everyone@:add_file/write_data/add_subdirectory/write_xattr
     /append_data/write_acl/write_owner:deny
  8:everyone@:read_data/read_xattr/execute/read_attributes
     /read_acl/synchronize:allow
```

In these examples, because the permissions of the parent directory for group@ and everyone@ deny write and execute permissions, user gozer is denied write and execute permissions. The default aclinherit property is restricted, which means that write_data and execute permissions are not inherited.

In this example, user gozer is granted read, write, and execute permissions that are inherited for newly created files. However, they are not propagated to subsequent contents of the directory.

```bash
# chmod A+user:gozer:read_data/write_data/execute:file_inherit/no_propagate:allow
# ls -dv test4.dir
```

```
```

As the following example shows, when a new subdirectory is created, user gozer’s read_data/write_data/execute permissions for files are not propagated to the new sub4.dir directory:

```bash
mkdir test4.dir/sub4.dir
# ls -dv test4.dir/sub4.dir
```

```
```

Oracle Solaris ZFS Administration Guide • September 2010
EXAMPLE 8–6  Granting ACL Inheritance on Files and Directories  

(Continued)

/append_data/write_xattr/execute/write_attributes/write_acl
/write_owner:allow
2:group@:add_file/write_data/add_subdirectory/append_data:deny
3:group@:list_directory/read_data/execute:allow
4:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
/write_attributes/write_acl/write_owner:deny
5:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
/read_acl/synchronize:allow

As the following example shows, user gozer’s read_data/write_data/execute permissions for files are propagated to the newly created file:

# touch test4.dir/file.4
# ls -v test4.dir/file.4
-rw-r--r--+ 1 root root 0 May 20 16:04 test4.dir/file.4
 0:user:gozer:write_data/execute:deny
 1:user:gozer:read_data/write_data/execute:allow
 2:owner:execute:deny
 3:owner@:read_data/write_data/append_data/write_xattr/write_attributes
/write_acl/write_owner:allow
 4:group@:write_data/append_data/execute:deny
 5:group@:read_data:allow
 6:everyone@:write_data/append_data/write_xattr/execute/write_attributes
/write_acl/write_owner:deny
 7:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize:allow

EXAMPLE 8–7  ACL Inheritance With aclmode Property Set to passthrough

As the following example shows, when the aclmode property on the tank/cindys file system is set to passthrough, user gozer inherits the ACL applied on the test4.dir directory for the newly created file.4:

# zfs set aclmode=passthrough tank/cindys
# touch test4.dir/file.4
# ls -v test4.dir/file.4
-rw-r--r--+ 1 root root 0 May 20 16:08 test4.dir/file.4
 0:user:gozer:write_data/execute:deny
 1:user:gozer:read_data/write_data/execute:allow
 2:owner:execute:deny
 3:owner@:read_data/write_data/append_data/write_xattr/write_attributes
/write_acl/write_owner:allow
 4:group@:write_data/append_data/execute:deny
 5:group@:read_data:allow
 6:everyone@:write_data/append_data/write_xattr/execute/write_attributes
/write_acl/write_owner:deny
 7:everyone@:read_data/read_xattr/read_attributes/read_acl/synchronize:allow

This output shows that the read_data/write_data/execute:allow:file_inherit/dir_inherit ACL that was set on the parent directory, test4.dir, is passed through to user gozer.
EXAMPLE 8–8  ACL Inheritance With aclmode Property Set to discard

If the aclmode property on a file system is set to discard, then ACLs can potentially be discarded when the permissions on a directory change. For example:

```
# zfs set aclmode=discard tank/cindys
# chmod A+user:gozer:read_data/write_data/execute:dir_inherit:allow test5.dir
# ls -dv test5.dir
drwxr-xr-x+ 2 root  root 2 May 20 16:09 test5.dir
 0:user:gozer:list_directory/read_data/add_file/write_data/execute
   :dir_inherit:allow
 1:owner@::deny
 2:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
   /append_data/write_xattr/execute/write_attributes/write_acl
   /write owner:allow
 3:group@:add_file/write_data/add_subdirectory/append_data:deny
 4:group@:list_directory/read_data/execute:allow
 5:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
   /write attributes/write_acl/write owner:deny
 6:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
   /read_acl/synchronize:allow
```

If, at a later time, you decide to tighten the permissions on a directory, the non-trivial ACL is discarded. For example:

```
# chmod 744 test5.dir
# ls -dv test5.dir
drwxr--r-- 2 root  root 2 May 20 16:09 test5.dir
 0:owner@::deny
 1:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
   /append_data/write_xattr/execute/write_attributes/write_acl
   /write owner:allow
 2:group@:add_file/write_data/add_subdirectory/append_data/execute:deny
 3:group@:list_directory/read_data:allow
 4:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
   /execute/write_attributes/write_acl/write owner:deny
 5:everyone@:list_directory/read_data/read_xattr/read_attributes/read_acl
   /synchronize:allow
```

EXAMPLE 8–9  ACL Inheritance With the aclinherit Property Set to noallow

In the following example, two non-trivial ACLs with file inheritance are set. One ACL allows read_data permission, and one ACL denies read_data permission. This example also shows how you can specify two ACEs in the same chmod command.

```
# zfs set aclinherit=noallow tank/cindys
# chmod A+user:gozer:read_data:file_inherit:deny,user:lp:read_data:file_inherit:allow
test6.dir
# ls -dv test6.dir
drwxr-xr-x+ 2 root  root 2 May 20 16:11 test6.dir
 0:owner@:gozer:read_data:file_inherit:deny
 1:user:lp:read_data:file_inherit:allow
 2:owner@::deny
 3:owner@:list_directory/read_data/add_file/write_data/add_subdirectory
```
EXAMPLE 8–9  ACL Inheritance With the aclinherit Property Set to noallow  (Continued)

    /append_data/write_xattr/execute/write_attributes/write_acl
/write_owner:allow
4:group@:add_file/write_data/add_subdirectory/append_data:deny
5:group@:list_directory/read_data/execute:allow
6:everyone@:add_file/write_data/add_subdirectory/append_data/write_xattr
/write_attributes/write_acl/write_owner:deny
7:everyone@:list_directory/read_data/read_xattr/execute/read_attributes
/read_acl/synchronize:allow

As the following example shows, when a new file is created, the ACL that allows read_data permission is discarded.

```
# touch test6.dir/file.6
# ls -v test6.dir/file.6
-rw-r--r-- 1 root root 0 May 20 16:13 test6.dir/file.6
0:owner@:--x-----------:------:deny
1:owner@:rw-p---A-W-Co-:------:allow
2:group@:-wxp----------:------:deny
3:group@:r-------------:------:allow
4:everyone@:-wxp---A-W-Co-:------:deny
5:everyone@:r-----a-R-c--s:------:allow
```

This compact ACL output is described as follows:

owner@  The owner is denied execute permissions on the file (x=execute).

Setting and Displaying ACLs on ZFS Files in Compact Format

You can set and display permissions on ZFS files in a compact format that uses 14 unique letters to represent the permissions. The letters that represent the compact permissions are listed in Table 8–2 and Table 8–3.

You can display compact ACL listings for files and directories by using the `ls -V` command. For example:

```
# ls -V file.1
-rw-r--r-- 1 root root 206663 Jun 17 10:07 file.1
owner@:--x-----------:------:deny
owner@:rw-p---A-W-Co-:------:allow
group@:-wxp----------:------:deny
group@:r-------------:------:allow
everyone@:-wxp---A-W-Co-:------:deny
everyone@:r-----a-R-c--s:------:allow
```

This compact ACL output is described as follows:

owner@  The owner is denied execute permissions on the file (x=execute).

owner@  The owner can read and modify the contents of the file (rw=write_data/write_data, p=append_data). The owner can also modify the
file's attributes such as time stamps, extended attributes, and ACLs
(A=write_xattr, W=write_attributes, and C=write_acl). In addition, the
owner can modify the ownership of the file (o=write_owner).

**group@** The group is denied modify and execute permissions on the file (write_data,
p=append_data, and x=execute).

**group@** The group is granted read permissions on the file (r=read_data).

**everyone@** Everyone who is not the owner of the file or a member of the owning group of
the file is denied permission to execute or modify the contents of the file, and to
modify any attributes of the file (w=write_data, x=execute, p=append_data, 
A=write_xattr, W=write_attributes, C=write_acl, and o=write_owner).

**everyone@** Everyone who is not the owner of the file or a member of the owning group of
the file on the file and the file's attributes (r=read_data, a=append_data,
R=read_xattr, c=read_acl, and s=synchronize). The synchronize access
permission is not currently implemented.

The compact ACL format provides the following advantages over the verbose ACL format:

- Permissions can be specified as positional arguments to the chmod command.
- The hyphen (-) characters, which identify no permissions, can be removed. Only the
  required letters need to be specified.
- Both permissions and inheritance flags are set in the same fashion.

For information about using the verbose ACL format, see “Setting and Displaying ACLs on ZFS
Files in Verbose Format” on page 228.

**EXAMPLE 8–10** Setting and Displaying ACLs in Compact Format

In the following example, a trivial ACL exists on file.1:

```
# ls -V file.1
-rw-r--r-- 1 root root 206663 Jun 17 10:07 file.1
owner@:--x-----------:------:deny
owner@:rw-p---A-W-Co-:------:allow
group@:-wxp------------:deny
group@:r-------------:------:allow
everyone@:-wxp---A-W-Co-:------:deny
everyone@:r-----a-R-c--s:------:allow
```

In the following example, read_data/execute permissions are added for user gozer on
file.1:

```
# chmod A+user:gozer:rx:allow file.1
# ls -V file.1
-rw-r--r--+ 1 root root 206663 Jun 17 10:07 file.1
user:gozer:r-x-----------:------:allow
owner@:--x-----------:------:deny
```
Another way to add the same permissions for user gozer is to insert a new ACL entry at a specific position, 4, for example. As such, the existing ACLs at positions 4–6 are pushed down. For example:

```bash
# chmod A4+user:gozer:rx:allow file.1
# ls -V file.1
-rw-r--r--+ 1 root root 206663 Jun 17 10:16 file.1
  owner@:--x-----------:------:deny
  owner@:rw-p---A-W-Co-:------:allow
  group@:-wxp----------:------:deny
  group@:r-------------:------:allow
  everyone@:-wxp--A-W-Co-:------:deny
  everyone@:r-----a-R-c--s:------:allow
```

In the following example, user gozer is granted read, write, and execute permissions that are inherited for newly created files and directories.

```bash
# chmod A+user:gozer:rwx:fd:allow dir.2
# ls -dV dir.2
drwxr-xr-x+ 2 root root 2 Jun 17 10:19 dir.2
  user:gozer:rwx-----------:fd----:allow
  owner@:-------------------:deny
  owner@:rw-p---A-W-Co-:------:allow
  group@:w-p-------------:deny
  group@:r-x-----------:deny
  everyone@:w-p--A-W-Co-:------:deny
  everyone@:r-x-----a-R-c--s:------:allow
```

You can also cut and paste permissions and inheritance flags from the `ls -V` output into the compact `chmod` format. For example, to duplicate the permissions and inheritance flags on the `dir.2` directory for user gozer to user cindys on `dir.2`, copy and paste the permissions and inheritance flags (`rwx-----------:fd----:allow`) into your `chmod` command as follows:

```bash
# chmod A+user:cindys:rwx:fd:allow dir.2
# ls -dV dir.2
drwxr-xr-x+ 2 root root 2 Jun 17 10:19 dir.2
  user:cindys:rwx-----------:fd----:allow
  owner@:-------------------:deny
  owner@:rw-p---A-W-Co-:------:allow
  group@:w-p-------------:deny
  group@:r-x-----------:deny
  everyone@:w-p--A-W-Co-:------:deny
  everyone@:r-x-----a-R-c--s:------:allow
```
EXAMPLE 8–11 ACL Inheritance With the aclinherit Property Set to passthrough

A file system that has the aclinherit property set to passthrough inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. When this property is set to passthrough, files are created with permissions that are determined by the inheritable ACEs. If no inheritable ACEs exist that affect the permissions, then the permissions are set in accordance to the requested permissions from the application.

The following examples use compact ACL syntax to show how to inherit permissions by setting the aclinherit property to passthrough.

In this example, an ACL is set on the test1.dir directory to force inheritance. The syntax creates an owner@, group@, and everyone@ ACL entry for newly created files. Newly created directories inherit an owner, group, and everyone ACL entry. Additionally, directories inherit six other ACEs that propagate the ACEs to the newly created directories and files.

```bash
# zfs set aclinherit=passthrough tank/cindys
# pwd /tank/cindys
# mkdir test1.dir
# chmod A=owner@:rwxpcosRrwaAdD:fd:allow,group@:rwxp:fd:allow,everyone@::fd:allow test1.dir
# ls -Vd test1.dir
drwxrwx---+ 2 root root 2 Jun 17 10:37 test1.dir
   owner@:rwxpdDaARWcCos:fd---:allow
   group@:rwxp------------:fd---:allow
   everyone@:-----------:fd---:allow
```

In this example, a newly created file inherits the ACL that was specified to be inherited by the newly created files.

```bash
# cd test1.dir
# touch file.1
# ls -V file.1
-rwxrwx---+ 1 root root 0 Jun 17 10:38 file.1
   owner@:rwxpdDaARWcCos:------:allow
   group@:rwxp------------:------:allow
   everyone@:------------:------:allow
```

In this example, a newly created directory inherits both ACEs that control access to this directory as well as ACEs for future propagation to children of the newly created directory.

```bash
# mkdir subdir.1
# ls -dV subdir.1
drwxrwx---+ 2 root root 2 Jun 17 10:39 subdir.1
   owner@:rwxpdDaARWcCos:fdi---:allow
   owner@:rwxpdDaARWcCos:------:allow
   group@:rwxp------------:fdi---:allow
   group@:rwxp------------:------:allow
   everyone@:---------:fdi---:allow
   everyone@:---------:------:allow
```
EXAMPLE 8–11  ACL Inheritance With the aclinherit Property Set to passthrough  (Continued)

The -di- - and f-i- - entries are for propagating inheritance and are not considered during access control. In this example, a file is created with a trivial ACL in another directory where inherited ACEs are not present.

```
# cd /tank/cindys
# mkdir test2.dir
# cd test2.dir
# touch file.2
# ls -V file.2
-rw-r--r-- 1 root root 0 Jun 17 10:40 file.2
```

EXCEPT 8–12  ACL Inheritance With the aclinherit Property Set to passthrough-x

When aclinherit property is set to passthrough-x, files are created with the execute (x) permission for owner@, group@, or everyone@, but only if execute permission is set in file creation mode and in an inheritable ACE that affects the mode.

The following example shows how to inherit the execute permission by setting the aclinherit property to passthrough-x.

```
# zfs set aclinherit=passthrough-x tank/cindys
```

The following ACL is set on /tank/cindys/test1.dir to provide executable ACL inheritance for files for owner@, group@, and everyone@.

```
# chmod A=owner@:rwxpcCosRwADd:fd:allow,group@:rwxp:fd:allow,everyone@::fd:allow test1.dir
# ls -Vd test1.dir
drwxrwx---+ 2 root root 2 Jun 17 10:41 test1.dir
 owner@:rwxpdBaARwCd:-----:allow
 group@:rwxp--------:fd:-----:allow
everyone@:--------a-A-r-c-:-----:allow
```

A file (file1) is created with requested permissions 0666. The resulting permissions are 0660. The execution permission was not inherited because the creation mode did not request it.

```
# touch test1.dir/file1
# ls -V test1.dir/file1
-rw---r--- 1 root root 0 Jun 17 10:42 test1.dir/file1
 owner@:rw-pdBaARwCd:-----:allow
 group@:rw--------:-----:allow
everyone@:----------:-----:allow
```

Next, an executable called t is generated by using the cc compiler in the testdir directory.
EXAMPLE 8–12  ACL Inheritance With the aclinherit Property Set to passthrough-x  (Continued)

```
# cc -o t t.c
# ls -V t
-rwxrwx----+ 1 root root  7396 Jun 17 10:50 t
  owner@:rwxpdDaARWcCos:-----:allow
  group@:rwxp------------:allow
  everyone@:--------------:allow
```

The resulting permissions are 0770 because cc requested permissions 0777, which caused the execute permission to be inherited from the owner@, group@, and everyone@ entries.
This chapter describes how to use delegated administration to allow nonprivileged users to perform ZFS administration tasks.

The following sections are provided in this chapter:

- “Overview of ZFS Delegated Administration” on page 245
- “Delegating ZFS Permissions” on page 246
- “Displaying ZFS Delegated Permissions (Examples)” on page 253
- "Delegating ZFS Permissions (Examples)" on page 250
- "Removing ZFS Delegated Permissions (Examples)" on page 255

**Overview of ZFS Delegated Administration**

ZFS delegated administration enables you to distribute refined permissions to specific users, groups, or everyone. Two types of delegated permissions are supported:

- Individual permissions can be explicitly delegated such as `create`, `destroy`, `mount`, `snapshot`, and so on.
- Groups of permissions called *permission sets* can be defined. A permission set can later be updated, and all of the consumers of the set automatically get the change. Permission sets begin with the `@` symbol and are limited to 64 characters in length. After the `@` symbol, the remaining characters in the set name have the same restrictions as normal ZFS file system names.

ZFS delegated administration provides features similar to the RBAC security model. ZFS delegation provides the following advantages for administering ZFS storage pools and file systems:

- Permissions follow the ZFS storage pool whenever a pool is migrated.
- Provides dynamic inheritance where you can control how the permissions propagate through the file systems.
Can be configured so that only the creator of a file system can destroy the file system.

You can delegate permissions to specific file systems. Newly created file systems can automatically pick up permissions.

Provides simple NFS administration. For example, a user with explicit permissions can create a snapshot over NFS in the appropriate .zfs/snapshot directory.

Disabling ZFS Delegated Permissions

You control the delegated administration features by using a pool’s delegation property. For example:

```bash
# zpool get delegation users
NAME PROPERTY VALUE SOURCE
users delegation on default
# zpool set delegation=off users
# zpool get delegation users
NAME PROPERTY VALUE SOURCE
users delegation off local
```

By default, the delegation property is enabled.

Delegating ZFS Permissions

You can use the zfs allow command to delegate permissions on ZFS datasets to non-root users in the following ways:

- Individual permissions can be delegated to a user, group, or everyone.
- Groups of individual permissions can be delegated as a permission set to a user, group, or everyone.
- Permissions can be delegated either locally to the current dataset only or to all descendents of the current dataset.

The following table describes the operations that can be delegated and any dependent permissions that are required to perform the delegated operations.

<table>
<thead>
<tr>
<th>Permission (Subcommand)</th>
<th>Description</th>
<th>Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow</td>
<td>The permission to grant permissions that you have to another user.</td>
<td>Must also have the permission that is being allowed.</td>
</tr>
<tr>
<td>Permission (Subcommand)</td>
<td>Description</td>
<td>Dependencies</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>clone</td>
<td>The permission to clone any of the dataset’s snapshots.</td>
<td>Must also have the create permission and the mount permission in the original file system.</td>
</tr>
<tr>
<td>create</td>
<td>The permission to create descendent datasets.</td>
<td>Must also have the mount permission.</td>
</tr>
<tr>
<td>destroy</td>
<td>The permission to destroy a dataset.</td>
<td>Must also have the mount permission.</td>
</tr>
<tr>
<td>promote</td>
<td>The permission to promote a clone to a dataset.</td>
<td>Must also have the mount permission and the promote permission in the original file system.</td>
</tr>
<tr>
<td>receive</td>
<td>The permission to create descendent file systems with the <code>zfs receive</code> command.</td>
<td>Must also have the mount permission and the create permission.</td>
</tr>
<tr>
<td>rename</td>
<td>The permission to rename a dataset.</td>
<td>Must also have the create permission and the mount permission in the new parent.</td>
</tr>
<tr>
<td>rollback</td>
<td>The permission to roll back a snapshot.</td>
<td></td>
</tr>
<tr>
<td>send</td>
<td>The permission to send a snapshot stream.</td>
<td></td>
</tr>
<tr>
<td>share</td>
<td>The permission to share and unshare a dataset.</td>
<td></td>
</tr>
<tr>
<td>snapshot</td>
<td>The permission to create a snapshot of a dataset.</td>
<td></td>
</tr>
</tbody>
</table>

You can delegate the following set of permissions but a permission might be limited to access, read, or change permission:

- groupquota
- groupused
- userprop
- userquota
- userused

In addition, you can delegate administration of the following ZFS properties to non-root users:

- aclinherit
- aclmode
- atime
- canmount
Some of these properties can be set only at dataset creation time. For a description of these properties, see “Introducing ZFS Properties” on page 171.

Delegating ZFS Permissions (zfs allow)

The zfs allow syntax follows:

```
zfs allow -[ldugecs] everyone|user|group[,...] perm[@setname,...] filesystem|volume
```

The following zfs allow syntax (in bold) identifies to whom the permissions are delegated:

```
zfs allow [-uge]user|group|everyone [,...] filesystem | volume
```

Multiple entities can be specified as a comma-separated list. If no -uge options are specified, then the argument is interpreted preferentially as the keyword everyone, then as a user name,
and lastly, as a group name. To specify a user or group named “everyone,” use the -u or -g option. To specify a group with the same name as a user, use the -g option. The -c option delegates create-time permissions.

The following `zfs allow` syntax (in bold) identifies how permissions and permission sets are specified:

```
zfs allow [-s] ... perm|@setname [,..] filesystem | volume
```

Multiple permissions can be specified as a comma-separated list. Permission names are the same as ZFS subcommands and properties. For more information, see the preceding section.

Permissions can be aggregated into permission sets and are identified by the -s option. Permission sets can be used by other `zfs allow` commands for the specified file system and its descendents. Permission sets are evaluated dynamically, so changes to a set are immediately updated. Permission sets follow the same naming requirements as ZFS file systems, but the name must begin with an at sign (@) and can be no more than 64 characters in length.

The following `zfs allow` syntax (in bold) identifies how the permissions are delegated:

```
zfs allow [-ld] ... filesystem | volume
```

The -l option indicates that the permissions are allowed for the specified dataset and not its descendents, unless the -d option is also specified. The -d option indicates that the permissions are allowed for the descendent datasets and not for this dataset, unless the -l option is also specified. If neither option is specified, then the permissions are allowed for the file system or volume and all of its descendents.

**Removing ZFS Delegated Permissions (zfs unallow)**

You can remove previously delegated permissions with the `zfs unallow` command.

For example, assume that you delegated create, destroy, mount, and snapshot permissions as follows:

```
# zfs allow cindys create,destroy,mount,snapshot tank/cindys
# zfs allow tank/cindys

Local+Descendent permissions on (tank/cindys)
user cindys create,destroy,mount,snapshot

```

To remove these permissions, you would use the following syntax:

```
# zfs unallow cindys tank/cindys
# zfs allow tank/cindys
```
Delegating ZFS Permissions (Examples)

**EXAMPLE 9-1  Delegating Permissions to an Individual User**

When you delegate create and mount permissions to an individual user, you must ensure that the user has permissions on the underlying mount point.

For example, to delegate user *marks* create and mount permissions on the *tank* file system, set the permissions first:

```
# chmod A+user:marks:add_subdirectory:fd:allow /tank
```

Then, use the `zfs allow` command to delegate create, destroy, and mount permissions. For example:

```
# zfs allow marks create,destroy,mount tank
```

Now, user *marks* can create his own file systems in the *tank* file system. For example:

```
# su marks
marks$ zfs create tank/marks
marks$ ^D
```

**EXAMPLE 9-2  Delegating create and destroy Permissions to a Group**

The following example shows how to set up a file system so that anyone in the *staff* group can create and mount file systems in the *tank* file system, as well as destroy their own file systems. However, *staff* group members cannot destroy anyone else's file systems.

```
# zfs allow staff create,mount tank
# zfs allow -c create,destroy tank
# zfs allow tank

Create time permissions on (tank)
create,destroy
Local+Descendent permissions on (tank)
group staff create,mount

# su cindys
Cindys% zfs create tank/cindys
Cindys% exit
# su marks
Marks% zfs create tank_marks/data
Marks% exit
Cindys% zfs destroy tank_marks/data
cannot destroy 'tank/mark': permission denied
```
EXAMPLE 9–3  Delegating Permissions at the Correct FileSystem Level

Ensure that you delegate users permission at the correct file system level. For example, user marks is delegated create, destroy, and mount permissions for the local and descendent file systems. User marks is delegated local permission to snapshot the tank file system, but he is not allowed to snapshot his own file system. So, he has not been delegated the snapshot permission at the correct file system level.

```
# zfs allow -l marks snapshot tank
# zfs allow tank
```

```
Local permissions on (tank)
user marks snapshot
Local+Descendent permissions on (tank)
user marks create, destroy, mount
```

```
# su marks
marks$ zfs snapshot tank/@snap1
marks$ zfs snapshot tank/marks@snap1
cannot create snapshot 'mark/marks@snap1': permission denied
```

To delegate user marks permission at the descendent file system level, use the zfs allow -d option. For example:

```
# zfs unallow -l marks snapshot tank
# zfs allow -d marks snapshot tank
# zfs allow tank
```

```
Descendent permissions on (tank)
user marks snapshot
Local+Descendent permissions on (tank)
user marks create, destroy, mount
```

```
# su marks
$ zfs snapshot tank@snap2
cannot create snapshot 'tank@snap2': permission denied
$ zfs snapshot tank/marks@snappy
```

Now, user marks can only create a snapshot below the tank file system level.

EXAMPLE 9–4  Defining and Using Complex Delegated Permissions

You can delegate specific permissions to users or groups. For example, the following zfs allow command delegates specific permissions to the staff group. In addition, destroy and snapshot permissions are delegated after tank file systems are created.

```
# zfs allow staff create,mount tank
# zfs allow -c destroy, snapshot tank
# zfs allow tank
```

```
Create time permissions on (tank)
destroy, snapshot
Local+Descendent permissions on (tank)
group staff create, mount
```

Chapter 9 • Oracle Solaris ZFS Delegated Administration 251
Because user marks is a member of the staff group, he can create file systems in tank. In addition, user marks can create a snapshot of tank/marks2 because he has specific permissions to do so. For example:

```
# su marks
$ zfs create tank/marks2
$ zfs allow tank/marks2
```

Local permissions on (tank/marks2)
user marks destroy, snapshot

Create time permissions on (tank)
destroy, snapshot

Local+Descendent permissions on (tank)
group staff create
everyone mount

```
But, user marks cannot create a snapshot in tank/marks because he doesn't have specific permissions to do so. For example:

```
$ zfs snapshot tank/marks2@snap1
$ zfs snapshot tank/marks@snapp
```
cannot create snapshot 'tank/marks@snapp': permission denied

In this example, user marks has create permission in his home directory, which means he can create snapshots. This scenario is helpful when your file system is NFS mounted.

```
$ cd /tank/marks2
$ ls
$ cd .zfs
$ ls -l
snapshot
$ cd snapshot
$ ls -l
total 3
drwxr-xr-x 2 marks staff 2 Dec 15 13:53 snap1
$ pwd
/tank/marks2/.zfs/snapshot
$ mkdir snap2
$ zfs list
NAME USED AVAIL REFER MOUNTPOINT
tank 264K 33.2G 33.5K /tank
tank/marks 24.5K 33.2G 24.5K /tank/marks
tank/marks2 46K 33.2G 24.5K /tank/marks2
tank/marks2@snap1 21.5K - 24.5K -
tank/marks2@snap2 0 - 24.5K -
$ ls
snap1 snap2
$ rmdir snap2
$ ls
snap1
EXAMPLE 9–5  Defining and Using a ZFS Delegated Permission Set

The following example shows how to create the permission set @myset and delegates the permission set and the rename permission to the group staff for the tank filesystem. User cindys, a staff group member, has the permission to create a file system in tank. However, user lp does not have permission to create a file system in tank.

```bash
# zfs allow -s @myset create, destroy, mount, snapshot, promote, clone, readonly tank
# zfs allow tank
-------------------------------------------------------------
Permission sets on (tank)
  @myset clone, create, destroy, mount, promote, readonly, snapshot
  -------------------------------------------------------------
# zfs allow staff @myset, rename tank
# zfs allow tank
-------------------------------------------------------------
Permission sets on (tank)
  @myset clone, create, destroy, mount, promote, readonly, snapshot
Local+Descendent permissions on (tank)
  group staff @myset, rename
# chmod A+group:staff:add_subdirectory:fd:allow tank
# su cindys
cindys% zfs create tank/data
Cindys% zfs allow tank
-------------------------------------------------------------
Permission sets on (tank)
  @myset clone, create, destroy, mount, promote, readonly, snapshot
Local+Descendent permissions on (tank)
  group staff @myset, rename
-------------------------------------------------------------
cindys% ls -l /tank
total 15
drwxr-xr-x 2 cindys staff 2 Aug 8 14:10 data
cindys% exit
# su lp
$ zfs create tank/lp
cannot create 'tank/lp': permission denied
```

Displaying ZFS Delegated Permissions (Examples)

You can use the following command to display permissions:

```bash
# zfs allow dataset
```

This command displays permissions that are set or allowed on the specified dataset. The output contains the following components:

- Permission sets
- Individual permissions or create-time permissions
- Local dataset
- Local and descendent datasets
- Descendent datasets only
EXAMPLE 9–6  Displaying Basic Delegated Administration Permissions

The following output indicates that user cindys has create, destroy, mount, snapshot permissions on the tank/cindys file system.

```
# zfs allow tank/cindys
```

```
Local+Descendent permissions on (tank/cindys)
user cindys create,destroy,mount,snapshot
```

EXAMPLE 9–7  Displaying Complex Delegated Administration Permissions

The output in this example indicates the following permissions on the pool/fred and pool\ file systems.

For the pool/fred file system:
- Two permission sets are defined:
  - @eng (create, destroy, snapshot, mount, clone, promote, rename)
  - @simple (create, mount)
  - Create-time permissions are set for the @eng permission set and the mountpoint property. Create-time means that after a dataset set is created, the @eng permission set and the permission to set the mountpoint property are delegated.
  - User tom is delegated the @eng permission set, and user joe is granted create, destroy, and mount permissions for local file systems.
  - User fred is delegated the @basic permission set, and share and rename permissions for the local and descendent file systems.
  - User barney and the staff group are delegated the @basic permission set for descendent file systems only.

For the pool file system:
- The permission set @simple (create, destroy, mount) is defined.
- The group staff is granted the @simple permission set on the local file system.

Here is the output for this example:

```
$ zfs allow pool/fred
```

```
Permission sets on (pool/fred)
  @eng create,destroy,snapshot,mount,clone,promote,rename
  @simple create,mount
Create time permissions on (pool/fred)
  @eng,mountpoint
Local permissions on (pool/fred)
  user tom @eng
  user joe create,destroy,mount
Local+Descendent permissions on (pool/fred)
  user fred @basic,share,rename
```
EXAMPLE 9–7 Displaying Complex Delegated Administration Permissions (Continued)

Descendent permissions on (pool/fred)
  user barney @basic
  group staff @basic

Permission sets on (pool)
  @simple create,destroy,mount
Local permissions on (pool)
  group staff @simple

Removing ZFS Delegated Permissions (Examples)

You can use the `zfs unallow` command to remove delegated permissions. For example, user cindys has create, destroy, mount, and snapshot permissions on the tank/cindys file system.

```
# zfs allow cindys create,destroy,mount,snapshot tank/cindys
# zfs allow tank/cindys
```

The following `zfs unallow` syntax removes user cindys’s snapshot permission from the tank/cindys file system:

```
# zfs unallow cindys snapshot tank/cindys
# zfs allow tank/cindys
```

cindys% `zfs create tank/cindys/data`
cindys% `zfs snapshot tank/cindys@today`
cannot create snapshot ‘tank/cindys@today’: permission denied

As another example, user marks has the following permissions on the tank/marks file system:

```
# zfs allow tank/marks
```

The following `zfs unallow` syntax removes all permissions for user marks from the tank/marks file system:

```
# zfs unallow marks tank/marks
```

The following `zfs unallow` syntax removes a permission set on the tank file system.
Removing ZFS Delegated Permissions (Examples)

```
# zfs allow tank
-------------------------------------------------------------
Permission sets on (tank)
  @myset clone, create, destroy, mount, promote, readonly, snapshot
Create time permissions on (tank)
  create, destroy, mount
Local+Descendent permissions on (tank)
  group staff create, mount
-------------------------------------------------------------
# zfs unallow -s @myset tank
$ zfs allow tank
-------------------------------------------------------------
Create time permissions on (tank)
  create, destroy, mount
Local+Descendent permissions on (tank)
  group staff create, mount
-------------------------------------------------------------
```
This chapter describes ZFS volumes, using ZFS on a Solaris system with zones installed, ZFS alternate root pools, and ZFS rights profiles.

The following sections are provided in this chapter:

- “ZFS Volumes” on page 257
- “Using ZFS on a Solaris System With Zones Installed” on page 259
- “Using ZFS Alternate Root Pools” on page 265
- “ZFS Rights Profiles” on page 266

**ZFS Volumes**

A ZFS volume is a dataset that represents a block device. ZFS volumes are identified as devices in the `/dev/zvol/{dsk, rdsk}/pool` directory.

In the following example, a 5-GB ZFS volume, `tank/vol`, is created:

```
# zfs create -V 5gb tank/vol
```

When you create a volume, a reservation is automatically set to the initial size of the volume so that unexpected behavior doesn’t occur. For example, if the size of the volume shrinks, data corruption might occur. You must be careful when changing the size of the volume.

In addition, if you create a snapshot of a volume that changes in size, you might introduce inconsistencies if you attempt to roll back the snapshot or create a clone from the snapshot.

For information about file system properties that can be applied to volumes, see Table 6–1.

If you are using a Solaris system with zones installed, you cannot create or clone a ZFS volume in a non-global zone. Any attempt to do so will fail. For information about using ZFS volumes in a global zone, see “Adding ZFS Volumes to a Non-Global Zone” on page 262.
Using a ZFS Volume as a Swap or Dump Device

During installation of a ZFS root file system or a migration from a UFS root file system, a swap device is created on a ZFS volume in the ZFS root pool. For example:

```
# swap -l
swapfile dev swaplo blocks free
/dev/zvol/dsk/rpool/swap 253,3 16 8257520 8257520
```

During installation of a ZFS root file system or a migration from a UFS root file system, a dump device is created on a ZFS volume in the ZFS root pool. The dump device requires no administration after it is set up. For example:

```
# dumpadm
Dump content: kernel pages
Dump device: /dev/zvol/dsk/rpool/dump (dedicated)
Savecore directory: /var/crash/t2000
Savecore enabled: yes
```

If you need to change your swap area or dump device after the system is installed or upgraded, use the `swap` and `dumpadm` commands as in previous Solaris releases. If you need to create an additional swap volume, create a ZFS volume of a specific size and then enable swap on that device. For example:

```
# zfs create -V 2G rpool/swap2
# swap -a /dev/zvol/dsk/rpool/swap2
# swap -l
swapfile dev swaplo blocks free
/dev/zvol/dsk/rpool/swap 256,1 16 2097136 2097136
/dev/zvol/dsk/rpool/swap2 256,5 16 4194288 4194288
```

Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

For information about adjusting the size of the swap and dump volumes, see “Adjusting the Sizes of Your ZFS Swap Device and Dump Device” on page 149.

Using a ZFS Volume as a Solaris iSCSI Target

You can easily create a ZFS volume as an iSCSI target by setting the `shareiscsi` property on the volume. For example:

```
# zfs create -V 2G tank/volumes/v2
# zfs set shareiscsi=on tank/volumes/v2
# iscsitadm list target
Target: tank/volumes/v2
  iSCSI Name: iqn.1986-03.com.sun:02:984fe301-c412-ccc1-cc80-cf9a72aa062a
  Connections: 0
```

After the iSCSI target is created, set up the iSCSI initiator. For more information about Solaris iSCSI targets and initiators, see Chapter 14, “Configuring Oracle Solaris iSCSI Targets and Initiators (Tasks),” in System Administration Guide: Devices and File Systems.
**Note** – Solaris iSCSI targets can also be created and managed with the `iscsitadm` command. If you set the `shareiscsi` property on a ZFS volume, do not use the `iscsitadm` command to also create the same target device. Otherwise, you create duplicate target information for the same device.

A ZFS volume as an iSCSI target is managed just like any other ZFS dataset. However, the `rename`, `export`, and `import` operations work a little differently for iSCSI targets.

- **When you rename a ZFS volume, the iSCSI target name remains the same.** For example:

  ```
  # zfs rename tank/volumes/v2 tank/volumes/v1
  # iscsitadm list target
  Target: tank/volumes/v1
  iSCSI Name: iqn.1986-03.com.sun:02:984fe301-c412-ccc1-cc80-cf9a72aa062a
  Connections: 0
  ```

- **Exporting a pool that contains a shared ZFS volume causes the target to be removed.** Importing a pool that contains a shared ZFS volume causes the target to be shared. For example:

  ```
  # zpool export tank
  # iscsitadm list target
  # zpool import tank
  # iscsitadm list target
  Target: tank/volumes/v1
  iSCSI Name: iqn.1986-03.com.sun:02:984fe301-c412-ccc1-cc80-cf9a72aa062a
  Connections: 0
  ```

All iSCSI target configuration information is stored within the dataset. Like an NFS shared file system, an iSCSI target that is imported on a different system is shared appropriately.

---

**Using ZFS on a Solaris System With Zones Installed**

The following sections describe how to use ZFS on a system with Oracle Solaris zones:

- “Adding ZFS File Systems to a Non-Global Zone” on page 260
- “Delegating Datasets to a Non-Global Zone” on page 261
- “Adding ZFS Volumes to a Non-Global Zone” on page 262
- “Using ZFS Storage Pools Within a Zone” on page 262
- “Managing ZFS Properties Within a Zone” on page 263
- “Understanding the zoned Property” on page 264

For information about configuring zones on a system with a ZFS root file system that will be migrated or patched with Oracle Solaris Live Upgrade, see "Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (Solaris 10 10/08)" on page 134 or "Using Oracle Solaris Live Upgrade to Migrate or Upgrade a System With Zones (at Least Solaris 10 5/09)" on page 139.
Keep the following points in mind when associating ZFS datasets with zones:

- You can add a ZFS file system or a clone to a non-global zone with or without delegating administrative control.
- You can add a ZFS volume as a device to non-global zones.
- You cannot associate ZFS snapshots with zones at this time.

In the following sections, a ZFS dataset refers to a file system or a clone.

Adding a dataset allows the non-global zone to share disk space with the global zone, though the zone administrator cannot control properties or create new file systems in the underlying file system hierarchy. This operation is identical to adding any other type of file system to a zone and should be used when the primary purpose is solely to share common disk space.

ZFS also allows datasets to be delegated to a non-global zone, giving complete control over the dataset and all its children to the zone administrator. The zone administrator can create and destroy file systems or clones within that dataset, as well as modify properties of the datasets. The zone administrator cannot affect datasets that have not been added to the zone, including exceeding any top-level quotas set on the delegated dataset.

Consider the following when working with ZFS on a system with Oracle Solaris zones installed:

- A ZFS file system that is added to a non-global zone must have its mountpoint property set to legacy.
- Due to CR 6449301, do not add a ZFS dataset to a non-global zone when the non-global zone is configured. Instead, add a ZFS dataset after the zone is installed.
- When both a source zonepath and a target zonepath reside on a ZFS file system and are in the same pool, zoneadm clone will now automatically use the ZFS clone to clone a zone. The zoneadm clone command will create a ZFS snapshot of the source zonepath and set up the target zonopath. You cannot use the zfs clone command to clone a zone. For more information, see Part II, “Zones,” in System Administration Guide: Oracle Solaris Containers-Resource Management and Oracle Solaris Zones.
- If you delegate a ZFS file system to a non-global zone, you must remove that file system from the non-global zone before using Oracle Solaris Live Upgrade. Otherwise, Oracle Live Upgrade will fail due to a read-only file system error.

**Adding ZFS File Systems to a Non-Global Zone**

You can add a ZFS file system as a generic file system when the goal is solely to share space with the global zone. A ZFS file system that is added to a non-global zone must have its mountpoint property set to legacy.

You can add a ZFS file system to a non-global zone by using the zonecfg command’s add fs subcommand.
In the following example, a ZFS file system is added to a non-global zone by a global zone administrator from the global zone:

```bash
# zonecfg -z zion
zonecfg:zion> add fs
zonecfg:zion:fs> set type=zfs
zonecfg:zion:fs> set special=tank/zone/zion
zonecfg:zion:fs> set dir=/export/shared
zonecfg:zion:fs> end
```

This syntax adds the ZFS file system, `tank/zone/zion`, to the already configured `zion` zone, which is mounted at `/export/shared`. The mountpoint property of the file system must be set to `legacy`, and the file system cannot already be mounted in another location. The zone administrator can create and destroy files within the file system. The file system cannot be remounted in a different location, nor can the zone administrator change properties on the file system such as `atime`, `readonly`, `compression`, and so on. The global zone administrator is responsible for setting and controlling properties of the file system.

For more information about the `zonecfg` command and about configuring resource types with `zonecfg`, see Part II, "Zones," in *System Administration Guide: Oracle Solaris Containers-Resource Management and Oracle Solaris Zones*.

### Delegating Datasets to a Non-Global Zone

To meet the primary goal of delegating the administration of storage to a zone, ZFS supports adding datasets to a non-global zone through the use of the `zonecfg` command's `add dataset` subcommand.

In the following example, a ZFS file system is delegated to a non-global zone by a global zone administrator from the global zone:

```bash
# zonecfg -z zion
zonecfg:zion> add dataset
zonecfg:zion:dataset> set name=tank/zone/zion
zonecfg:zion:dataset> end
```

Unlike adding a file system, this syntax causes the ZFS file system `tank/zone/zion` to be visible within the already configured `zion` zone. The zone administrator can set file system properties, as well as create descendent file systems. In addition, the zone administrator can create snapshots and clones, and otherwise control the entire file system hierarchy.

If you are using Oracle Solaris Live Upgrade to upgrade your ZFS BE with non-global zones, first remove any delegated datasets. Otherwise, Oracle Solaris Live Upgrade will fail with a read-only file system error. For example:

```bash
zonecfg:zion>
zonecfg:zion> remove dataset name=tank/zone/zion
zonecfg:zion1> exit
```
For more information about what actions are allowed within zones, see “Managing ZFS Properties Within a Zone” on page 263.

## Adding ZFS Volumes to a Non-Global Zone

ZFS volumes cannot be added to a non-global zone by using the `zonecfg` command's `add dataset` subcommand. However, volumes can be added to a zone by using the `zonecfg` command's `add device` subcommand.

In the following example, a ZFS volume is added to a non-global zone by a global zone administrator from the global zone:

```
# zonecfg -z zion
zion: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:zion> create
zonecfg:zion> add device
zonecfg:zion:device> set match=/dev/zvol/dsk/tank/vol
zonecfg:zion:device> end
```

This syntax adds the `tank/vol` volume to the `zion` zone. Note that adding a raw volume to a zone has implicit security risks, even if the volume doesn’t correspond to a physical device. In particular, the zone administrator could create malformed file systems that would panic the system when a mount is attempted. For more information about adding devices to zones and the related security risks, see “Understanding the zoned Property” on page 264.

## Using ZFS Storage Pools Within a Zone

ZFS storage pools cannot be created or modified within a zone. The delegated administration model centralizes control of physical storage devices within the global zone and control of virtual storage to non-global zones. Although a pool-level dataset can be added to a zone, any command that modifies the physical characteristics of the pool, such as creating, adding, or removing devices, is not allowed from within a zone. Even if physical devices are added to a zone by using the `zonecfg` command's `add device` subcommand, or if files are used, the `zpool` command does not allow the creation of any new pools within the zone.
Managing ZFS Properties Within a Zone

After a dataset is delegated to a zone, the zone administrator can control specific dataset properties. After a dataset is delegated to a zone, all its ancestors are visible as read-only datasets, while the dataset itself is writable, as are all of its descendents. For example, consider the following configuration:

global# zfs list -Ho name
tank
tank/home
tank/data
tank/data/matrix
tank/data/zion
tank/data/zion/home

If tank/data/zion were added to a zone, each dataset would have the following properties:

<table>
<thead>
<tr>
<th>Dataset</th>
<th>Visible</th>
<th>Writable</th>
<th>Immutable Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>Yes</td>
<td>No</td>
<td>-</td>
</tr>
<tr>
<td>tank/home</td>
<td>No</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>tank/data</td>
<td>Yes</td>
<td>No</td>
<td>-</td>
</tr>
<tr>
<td>tank/data/matrix</td>
<td>No</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>tank/data/zion</td>
<td>Yes</td>
<td>Yes</td>
<td>shareufs, zoned, quota, reservation</td>
</tr>
<tr>
<td>tank/data/zion/home</td>
<td>Yes</td>
<td>Yes</td>
<td>shareufs, zoned</td>
</tr>
</tbody>
</table>

Note that every parent of tank/zone/zion is visible as read-only, all descendents are writable, and datasets that are not part of the parent hierarchy are not visible at all. The zone administrator cannot change the shareufs property because non-global zones cannot act as NFS servers. The zone administrator cannot change the zoned property because doing so would expose a security risk as described in the next section.

Privileged users in the zone can change any other settable property, except for quota and reservation properties. This behavior allows the global zone administrator to control the disk space consumption of all datasets used by the non-global zone.

In addition, the shareufs and mountpoint properties cannot be changed by the global zone administrator after a dataset has been delegated to a non-global zone.
Understanding the zoned Property

When a dataset is delegated to a non-global zone, the dataset must be specially marked so that certain properties are not interpreted within the context of the global zone. After a dataset has been delegated to a non-global zone and is under the control of a zone administrator, its contents can no longer be trusted. As with any file system, there might be setuid binaries, symbolic links, or otherwise questionable contents that might adversely affect the security of the global zone. In addition, the mountpoint property cannot be interpreted in the context of the global zone. Otherwise, the zone administrator could affect the global zone’s namespace. To address the latter, ZFS uses the zoned property to indicate that a dataset has been delegated to a non-global zone at one point in time.

The zoned property is a boolean value that is automatically turned on when a zone containing a ZFS dataset is first booted. A zone administrator does not need to manually turn on this property. If the zoned property is set, the dataset cannot be mounted or shared in the global zone. In the following example, tank/zone/zion has been delegated to a zone, while tank/zone/global has not:

```
# zfs list -o name,zoned,mountpoint -r tank/zone
NAME ZONED MOUNTPOINT
 tank/zone/global off /tank/zone/global
 tank/zone/zion on /tank/zone/zion
```

Note the difference between the mountpoint property and the directory where the tank/zone/zion dataset is currently mounted. The mountpoint property reflects the property as it is stored on disk, not where the dataset is currently mounted on the system.

When a dataset is removed from a zone or a zone is destroyed, the zoned property is not automatically cleared. This behavior is due to the inherent security risks associated with these tasks. Because an untrusted user has had complete access to the dataset and its descendents, the mountpoint property might be set to bad values, or setuid binaries might exist on the file systems.

To prevent accidental security risks, the zoned property must be manually cleared by the global zone administrator if you want to reuse the dataset in any way. Before setting the zoned property to off, ensure that the mountpoint property for the dataset and all its descendents are set to reasonable values and that no setuid binaries exist, or turn off the setuid property.

After you have verified that no security vulnerabilities are left, the zoned property can be turned off by using the zfs set or zfs inherit command. If the zoned property is turned off while a dataset is in use within a zone, the system might behave in unpredictable ways. Only change the property if you are sure the dataset is no longer in use by a non-global zone.
Using ZFS Alternate Root Pools

When a pool is created, it is intrinsically tied to the host system. The host system maintains information about the pool so that it can detect when the pool is unavailable. Although useful for normal operations, this information can prove a hindrance when you are booting from alternate media or creating a pool on removable media. To solve this problem, ZFS provides an alternate root pool feature. An alternate root pool does not persist across system reboots, and all mount points are modified to be relative to the root of the pool.

Creating ZFS Alternate Root Pools

The most common reason for creating an alternate root pool is for use with removable media. In these circumstances, users typically want a single file system, and they want it to be mounted wherever they choose on the target system. When an alternate root pool is created by using the `zpool create -R` option, the mount point of the root file system is automatically set to `/`, which is the equivalent of the alternate root value.

In the following example, a pool called `morpheus` is created with `/mnt` as the alternate root path:

```
# zpool create -R /mnt morpheus c0t0d0
# zfs list morpheus
NAME      USED  AVAIL REFER MOUNTPOINT
morpheus  32.5K 33.5G  8K /mnt
```

Note the single file system, `morpheus`, whose mount point is the alternate root of the pool, `/mnt`. The mount point that is stored on disk is `/` and the full path to `/mnt` is interpreted only in this initial context of the pool creation. This file system can then be exported and imported under an arbitrary alternate root pool on a different system by using `-R` alternate root value syntax.

```
# zpool export morpheus
# zpool import morpheus
# zpool export morpheus
# zpool import -R /mnt morpheus
# zfs list morpheus
NAME      USED  AVAIL REFER MOUNTPOINT
morpheus  32.5K 33.5G  8K /mnt
```

Importing Alternate Root Pools

Pools can also be imported using an alternate root. This feature allows for recovery situations, where the mount points should not be interpreted in context of the current root, but under some temporary directory where repairs can be performed. This feature also can be used when you are mounting removable media as described in the preceding section.

In the following example, a pool called `morpheus` is imported with `/mnt` as the alternate root path. This example assumes that `morpheus` was previously exported.
ZFS Rights Profiles

If you want to perform ZFS management tasks without using the superuser (root) account, you can assume a role with either of the following profiles to perform ZFS administration tasks:

- **ZFS Storage Management** – Provides the privilege to create, destroy, and manipulate devices within a ZFS storage pool
- **ZFS File system Management** – Provides the privilege to create, destroy, and modify ZFS file systems

For more information about creating or assigning roles, see *System Administration Guide: Security Services*.

In addition to using RBAC roles for administering ZFS file systems, you might also consider using ZFS delegated administration for distributed ZFS administration tasks. For more information, see Chapter 9, "Oracle Solaris ZFS Delegated Administration."
Oracle Solaris ZFS Troubleshooting and Pool Recovery

This chapter describes how to identify and recover from ZFS failures. Information for preventing failures is provided as well.

The following sections are provided in this chapter:

- “Identifying ZFS Failures” on page 267
- “Checking ZFS File System Integrity” on page 269
- “Resolving Problems With ZFS” on page 271
- “Repairing a Damaged ZFS Configuration” on page 276
- “Resolving a Missing Device” on page 276
- “Replacing or Repairing a Damaged Device” on page 278
- “Repairing Damaged Data” on page 287
- “Repairing an Unbootable System” on page 291

Identifying ZFS Failures

As a combined file system and volume manager, ZFS can exhibit many different failures. This chapter begins by outlining the various failures, then discusses how to identify them on a running system. This chapter concludes by discussing how to repair the problems. ZFS can encounter three basic types of errors:

- “Missing Devices in a ZFS Storage Pool” on page 268
- “Damaged Devices in a ZFS Storage Pool” on page 268
- “Corrupted ZFS Data” on page 268

Note that a single pool can experience all three errors, so a complete repair procedure involves finding and correcting one error, proceeding to the next error, and so on.
Missing Devices in a ZFS Storage Pool

If a device is completely removed from the system, ZFS detects that the device cannot be opened and places it in the REMOVED state. Depending on the data replication level of the pool, this removal might or might not result in the entire pool becoming unavailable. If one disk in a mirrored or RAID-Z device is removed, the pool continues to be accessible. A pool might become FAULTED, which means no data is accessible until the device is reattached, under the following conditions:

- If all components of a mirror are removed
- If more than one device in a RAID-Z (raidz1) device is removed
- If top-level device is removed in a single-disk configuration

Damaged Devices in a ZFS Storage Pool

The term “damaged” covers a wide variety of possible errors. Examples include the following:

- Transient I/O errors due to a bad disk or controller
- On-disk data corruption due to cosmic rays
- Driver bugs resulting in data being transferred to or from the wrong location
- A user overwriting portions of the physical device by accident

In some cases, these errors are transient, such as a random I/O error while the controller is having problems. In other cases, the damage is permanent, such as on-disk corruption. Even still, whether the damage is permanent does not necessarily indicate that the error is likely to occur again. For example, if an administrator accidentally overwrites part of a disk, no type of hardware failure has occurred, and the device does not need to be replaced. Identifying the exact problem with a device is not an easy task and is covered in more detail in a later section.

Corrupted ZFS Data

Data corruption occurs when one or more device errors (indicating one or more missing or damaged devices) affects a top-level virtual device. For example, one half of a mirror can experience thousands of device errors without ever causing data corruption. If an error is encountered on the other side of the mirror in the exact same location, corrupted data is the result.

Data corruption is always permanent and requires special consideration during repair. Even if the underlying devices are repaired or replaced, the original data is lost forever. Most often, this scenario requires restoring data from backups. Data errors are recorded as they are encountered, and they can be controlled through routine pool scrubbing as explained in the following section. When a corrupted block is removed, the next scrubbing pass recognizes that the corruption is no longer present and removes any trace of the error from the system.
Checking ZFS File System Integrity

No fsck utility equivalent exists for ZFS. This utility has traditionally served two purposes, those of file system repair and file system validation.

File System Repair

With traditional file systems, the way in which data is written is inherently vulnerable to unexpected failure causing file system inconsistencies. Because a traditional file system is not transactional, unreferenced blocks, bad link counts, or other inconsistent file system structures are possible. The addition of journaling does solve some of these problems, but can introduce additional problems when the log cannot be rolled back. The only way for inconsistent data to exist on disk in a ZFS configuration is through hardware failure (in which case the pool should have been redundant) or when a bug exists in the ZFS software.

The fsck utility repairs known problems specific to UFS file systems. Most ZFS storage pool problems are generally related to failing hardware or power failures. Many problems can be avoided by using redundant pools. If your pool is damaged due to failing hardware or a power outage, see "Repairing ZFS Storage Pool-Wide Damage" on page 289.

If your pool is not redundant, the risk that file system corruption can render some or all of your data inaccessible is always present.

File System Validation

In addition to performing file system repair, the fsck utility validates that the data on disk has no problems. Traditionally, this task requires unmounting the file system and running the fsck utility, possibly taking the system to single-user mode in the process. This scenario results in downtime that is proportional to the size of the file system being checked. Instead of requiring an explicit utility to perform the necessary checking, ZFS provides a mechanism to perform routine checking of all inconsistencies. This feature, known as scrubbing, is commonly used in memory and other systems as a method of detecting and preventing errors before they result in a hardware or software failure.

Controlling ZFS Data Scrubbing

Whenever ZFS encounters an error, either through scrubbing or when accessing a file on demand, the error is logged internally so that you can obtain quick overview of all known errors within the pool.
Explicit ZFS Data Scrubbing

The simplest way to check data integrity is to initiate an explicit scrubbing of all data within the pool. This operation traverses all the data in the pool once and verifies that all blocks can be read. Scrubbing proceeds as fast as the devices allow, though the priority of any I/O remains below that of normal operations. This operation might negatively impact performance, though the pool’s data should remain usable and nearly as responsive while the scrubbing occurs. To initiate an explicit scrub, use the `zpool scrub` command. For example:

```
# zpool scrub tank
```

The status of the current scrubbing operation can be displayed by using the `zpool status` command. For example:

```
# zpool status -v tank
pool: tank
state: ONLINE
scrub: scrub completed after 0h7m with 0 errors on Tue Tue Feb 2 12:54:00 2010
config:
NAME    STATE  READ WRITE CKSUM
tank     ONLINE 0 0 0
mirror-0 ONLINE 0 0 0
c1t0d0   ONLINE 0 0 0
c1t1d0   ONLINE 0 0 0
```

errors: No known data errors

Only one active scrubbing operation per pool can occur at one time.

You can stop a scrubbing operation that is in progress by using the `-s` option. For example:

```
# zpool scrub -s tank
```

In most cases, a scrubbing operation to ensure data integrity should continue to completion. Stop a scrubbing operation at your own discretion if system performance is impacted by the operation.

Performing routine scrubbing guarantees continuous I/O to all disks on the system. Routine scrubbing has the side effect of preventing power management from placing idle disks in low-power mode. If the system is generally performing I/O all the time, or if power consumption is not a concern, then this issue can safely be ignored.

For more information about interpreting `zpool status` output, see “Querying ZFS Storage Pool Status” on page 95.

ZFS Data Scrubbing and Resilvering

When a device is replaced, a resilvering operation is initiated to move data from the good copies to the new device. This action is a form of disk scrubbing. Therefore, only one such action can occur at a given time in the pool. If a scrubbing operation is in progress, a resilvering operation suspends the current scrubbing and restarts it after the resilvering is completed.
For more information about resilvering, see "Viewing Resilivering Status" on page 285.

Resolving Problems With ZFS

The following sections describe how to identify and resolve problems with your ZFS file systems or storage pools:

- "Determining If Problems Exist in a ZFS Storage Pool" on page 272
- "Reviewing zpool status Output" on page 272
- "System Reporting of ZFS Error Messages" on page 275

You can use the following features to identify problems with your ZFS configuration:

- Detailed ZFS storage pool information can be displayed by using the zpool status command.
- Pool and device failures are reported through ZFS/FMA diagnostic messages.
- Previous ZFS commands that modified pool state information can be displayed by using the zpool history command.

Most ZFS troubleshooting involves the zpool status command. This command analyzes the various failures in a system and identifies the most severe problem, presenting you with a suggested action and a link to a knowledge article for more information. Note that the command only identifies a single problem with a pool, though multiple problems can exist. For example, data corruption errors generally imply that one of the devices has failed, but replacing the failed device might not resolve all of the data corruption problems.

In addition, a ZFS diagnostic engine diagnoses and reports pool failures and device failures. Checksum, I/O, device, and pool errors associated with these failures are also reported. ZFS failures as reported by fmd are displayed on the console as well as the system messages file. In most cases, the fmd message directs you to the zpool status command for further recovery instructions.

The basic recovery process is as follows:

- If appropriate, use the zpool history command to identify the ZFS commands that preceded the error scenario. For example:

  ```
  # zpool history tank
  History for 'tank':
  2010-07-15 12:06:50 zpool create tank mirror c0t1d0 c0t2d0 c0t3d0
  2010-07-15 12:06:58 zfs create tank/erick
  2010-07-15 12:07:01 zfs set checksum=off tank/erick
  ```

  In this output, note that checksums are disabled for the tank/erick file system. This configuration is not recommended.

- Identify the errors through the fmd messages that are displayed on the system console or in the /var/adm/messages file.
Resolving Problems With ZFS

- Find further repair instructions by using the `zpool status -x` command.
- Repair the failures, which involves the following steps:
  - Replacing the faulted or missing device and bring it online.
  - Restoring the faulted configuration or corrupted data from a backup.
  - Verifying the recovery by using the `zpool status -x` command.
  - Backing up your restored configuration, if applicable.

This section describes how to interpret `zpool status` output in order to diagnose the type of failures that can occur. Although most of the work is performed automatically by the command, it is important to understand exactly what problems are being identified in order to diagnose the failure. Subsequent sections describe how to repair the various problems that you might encounter.

## Determining If Problems Exist in a ZFS Storage Pool

The easiest way to determine if any known problems exist on a system is to use the `zpool status -x` command. This command describes only pools that are exhibiting problems. If no unhealthy pools exist on the system, then the command displays the following:

```
# zpool status -x
all pools are healthy
```

Without the `-x` flag, the command displays the complete status for all pools (or the requested pool, if specified on the command line), even if the pools are otherwise healthy.

For more information about command-line options to the `zpool status` command, see “Querying ZFS Storage Pool Status” on page 95.

## Reviewing `zpool status` Output

The complete `zpool status` output looks similar to the following:

```
# zpool status tank
# zpool status tank
pool: tank
  state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas exist for
the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using ‘zpool online’.
  see: http://www.sun.com/msg/ZFS-8000-2Q
scrub: none requested
config:
  NAME     STATE  READ WRITE CKSUM
  tank     DEGRADED 0  0  0
  mirror-0 DEGRADED 0  0  0
```
errors: No known data errors

This output is described next:

**Overall Pool Status Information**

This section in the `zpool status` output contains the following fields, some of which are only displayed for pools exhibiting problems:

- **pool**: Identifies the name of the pool.
- **state**: Indicates the current health of the pool. This information refers only to the ability of the pool to provide the necessary replication level.
- **status**: Describes what is wrong with the pool. This field is omitted if no errors are found.
- **action**: A recommended action for repairing the errors. This field is omitted if no errors are found.
- **see**: Refers to a knowledge article containing detailed repair information. Online articles are updated more often than this guide can be updated. So, always reference them for the most up-to-date repair procedures. This field is omitted if no errors are found.
- **scrub**: Identifies the current status of a scrub operation, which might include the date and time that the last scrub was completed, a scrub is in progress, or if no scrub was requested.
- **errors**: Identifies known data errors or the absence of known data errors.

**Pool Configuration Information**

The `config` field in the `zpool status` output describes the configuration of the devices in the pool, as well as their state and any errors generated from the devices. The state can be one of the following: ONLINE, FAULTED, DEGRADED, UNAVAIL, or OFFLINE. If the state is anything but ONLINE, the fault tolerance of the pool has been compromised.

The second section of the configuration output displays error statistics. These errors are divided into three categories:

- **READ** – I/O errors that occurred while issuing a read request
- **WRITE** – I/O errors that occurred while issuing a write request
- **CKSUM** – Checksum errors, meaning that the device returned corrupted data as the result of a read request
These errors can be used to determine if the damage is permanent. A small number of I/O errors might indicate a temporary outage, while a large number might indicate a permanent problem with the device. These errors do not necessarily correspond to data corruption as interpreted by applications. If the device is in a redundant configuration, the devices might show uncorrectable errors, while no errors appear at the mirror or RAID-Z device level. In such cases, ZFS successfully retrieved the good data and attempted to heal the damaged data from existing replicas.

For more information about interpreting these errors, see “Determining the Type of Device Failure” on page 278.

Finally, additional auxiliary information is displayed in the last column of the `zpool status` output. This information expands on the state field, aiding in the diagnosis of failures. If a device is FAULTED, this field indicates whether the device is inaccessible or whether the data on the device is corrupted. If the device is undergoing resilvering, this field displays the current progress.

For information about monitoring resilvering progress, see “Viewing Resilvering Status” on page 285.

**Scrubbing Status**

The scrub section of the `zpool status` output describes the current status of any explicit scrubbing operations. This information is distinct from whether any errors are detected on the system, though this information can be used to determine the accuracy of the data corruption error reporting. If the last scrub ended recently, most likely, any known data corruption has been discovered.

Scrub completion messages persist across system reboots.

For more information about the data scrubbing and how to interpret this information, see “Checking ZFS File System Integrity” on page 269.

**Data Corruption Errors**

The `zpool status` command also shows whether any known errors are associated with the pool. These errors might have been found during data scrubbing or during normal operation. ZFS maintains a persistent log of all data errors associated with a pool. This log is rotated whenever a complete scrub of the system finishes.

Data corruption errors are always fatal. Their presence indicates that at least one application experienced an I/O error due to corrupt data within the pool. Device errors within a redundant pool do not result in data corruption and are not recorded as part of this log. By default, only the number of errors found is displayed. A complete list of errors and their specifics can be found by using the `zpool status -v` option. For example:
# zpool status -v
pool: tank
state: UNAVAIL
status: One or more devices are faulted in response to IO failures.
action: Make sure the affected devices are connected, then run 'zpool clear'.
see: http://www.sun.com/msg/ZFS-8000-HC
scrub: scrub completed after 0h0m with 0 errors on Tue Feb 2 13:08:42 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>insufficient replicas</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>UNAVAIL</td>
<td>4</td>
<td>1</td>
<td>cannot open</td>
</tr>
</tbody>
</table>

errors: Permanent errors have been detected in the following files:

/tank/data/aaa
/tank/data/bbb
/tank/data/ccc

A similar message is also displayed by fmd on the system console and the /var/adm/messages file. These messages can also be tracked by using the fmdump command.

For more information about interpreting data corruption errors, see “Identifying the Type of Data Corruption” on page 287.

System Reporting of ZFS Error Messages

In addition to persistently tracking errors within the pool, ZFS also displays syslog messages when events of interest occur. The following scenarios generate events to notify the administrator:

- **Device state transition** – If a device becomes FAULTED, ZFS logs a message indicating that the fault tolerance of the pool might be compromised. A similar message is sent if the device is later brought online, restoring the pool to health.

- **Data corruption** – If any data corruption is detected, ZFS logs a message describing when and where the corruption was detected. This message is only logged the first time it is detected. Subsequent accesses do not generate a message.

- **Pool failures and device failures** – If a pool failure or a device failure occurs, the fault manager daemon reports these errors through syslog messages as well as the fmdump command.

If ZFS detects a device error and automatically recovers from it, no notification occurs. Such errors do not constitute a failure in the pool redundancy or in data integrity. Moreover, such errors are typically the result of a driver problem accompanied by its own set of error messages.
Repairing a Damaged ZFS Configuration

ZFS maintains a cache of active pools and their configuration in the root file system. If this cache file is corrupted or somehow becomes out of sync with configuration information that is stored on disk, the pool can no longer be opened. ZFS tries to avoid this situation, though arbitrary corruption is always possible given the qualities of the underlying storage. This situation typically results in a pool disappearing from the system when it should otherwise be available. This situation can also manifest as a partial configuration that is missing an unknown number of top-level virtual devices. In either case, the configuration can be recovered by exporting the pool (if it is visible at all) and re-importing it.

For information about importing and exporting pools, see "Migrating ZFS Storage Pools" on page 103.

Resolving a Missing Device

If a device cannot be opened, it displays the UNAVAIL state in the zpool status output. This state means that ZFS was unable to open the device when the pool was first accessed, or the device has since become unavailable. If the device causes a top-level virtual device to be unavailable, then nothing in the pool can be accessed. Otherwise, the fault tolerance of the pool might be compromised. In either case, the device just needs to be reattached to the system to restore normal operations.

For example, you might see a message similar to the following from fmd after a device failure:

SUNW-MSG-ID: ZFS-8000-FD, TYPE: Fault, VER: 1, SEVERITY: Major
EVENT-TIME: Thu Jun 24 10:42:36 PDT 2010
PLATFORM: SUNW,Sun-Fire-T200, CSN: -, HOSTNAME: neo2
SOURCE: zfs-diagnosis, REV: 1.0
EVENT-ID: a1fb66d0-cc51-cd14-a835-961c1569fcb
DESC: The number of I/O errors associated with a ZFS device exceeded acceptable levels. Refer to http://sun.com/msg/ZFS-8000-FD for more information.
AUTO-RESPONSE: The device has been offline and marked as faulted. An attempt will be made to activate a hot spare if available.
IMPACT: Fault tolerance of the pool may be compromised.
REC-ACTION: Run 'zpool status -x' and replace the bad device.

To view more detailed information about the device problem and the resolution, use the zpool status -x command. For example:

```
# zpool status -x
pool: tank
state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
see: http://www.sun.com/msg/ZFS-8000-2Q
```
Resolving a Missing Device

scrub: scrub completed after 0h0m with 0 errors on Tue Feb 2 13:15:20 2010
config:

<table>
<thead>
<tr>

<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors

You can see from this output that the missing c1t1d0 device is not functioning. If you determine that the device is faulty, replace it.

Then, use the `zpool online` command to bring online the replaced device. For example:

```
# zpool online tank c1t1d0
```

As a last step, confirm that the pool with the replaced device is healthy. For example:

```
# zpool status -x tank
pool 'tank' is healthy
```

Physically Reattaching a Device

Exactly how a missing device is reattached depends on the device in question. If the device is a network-attached drive, connectivity to the network should be restored. If the device is a USB device or other removable media, it should be reattached to the system. If the device is a local disk, a controller might have failed such that the device is no longer visible to the system. In this case, the controller should be replaced, at which point the disks will again be available. Other problems can exist and depend on the type of hardware and its configuration. If a drive fails and it is no longer visible to the system, the device should be treated as a damaged device. Follow the procedures in "Replacing or Repairing a Damaged Device" on page 278.

Notifying ZFS of Device Availability

After a device is reattached to the system, ZFS might or might not automatically detect its availability. If the pool was previously faulted, or the system was rebooted as part of the attach procedure, then ZFS automatically rescans all devices when it tries to open the pool. If the pool was degraded and the device was replaced while the system was running, you must notify ZFS that the device is now available and ready to be reopened by using the `zpool online` command. For example:

```
# zpool online tank c0t1d0
```
For more information about bringing devices online, see “Bringing a Device Online” on page 83.

Replacing or Repairing a Damaged Device

This section describes how to determine device failure types, clear transient errors, and replacing a device.

Determining the Type of Device Failure

The term damaged device is rather vague and can describe a number of possible situations:

- **Bit rot** – Over time, random events such as magnetic influences and cosmic rays can cause bits stored on disk to flip. These events are relatively rare but common enough to cause potential data corruption in large or long-running systems.

- **Misdirected reads or writes** – Firmware bugs or hardware faults can cause reads or writes of entire blocks to reference the incorrect location on disk. These errors are typically transient, though a large number of them might indicate a faulty drive.

- **Administrator error** – Administrators can unknowingly overwrite portions of a disk with bad data (such as copying /dev/zero over portions of the disk) that cause permanent corruption on disk. These errors are always transient.

- **Temporary outage** – A disk might become unavailable for a period of time, causing I/Os to fail. This situation is typically associated with network-attached devices, though local disks can experience temporary outages as well. These errors might or might not be transient.

- **Bad or flaky hardware** – This situation is a catch-all for the various problems that faulty hardware exhibits, including consistent I/O errors, faulty transports causing random corruption, or any number of failures. These errors are typically permanent.

- **Offline device** – If a device is offline, it is assumed that the administrator placed the device in this state because it is faulty. The administrator who placed the device in this state can determine if this assumption is accurate.

Determining exactly what is wrong with a device can be a difficult process. The first step is to examine the error counts in the zpool status output. For example:

```
# zpool status -v tpool
pool: tpool
  state: ONLINE
status: One or more devices has experienced an error resulting in data corruption. Applications may be affected.
action: Restore the file in question if possible. Otherwise restore the entire pool from backup.
see: http://www.sun.com/msg/ZFS-8000-8A
```
scrub: scrub completed after 0h0m with 2 errors on Tue Jul 13 11:08:37 2010

config:

</tr>
<tr>
<td>c1t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: Permanent errors have been detected in the following files:

/tpool/words

The errors are divided into I/O errors and checksum errors, both of which might indicate the possible failure type. Typical operation predicts a very small number of errors (just a few over long periods of time). If you are seeing a large number of errors, then this situation probably indicates impending or complete device failure. However, an administrator error can also result in large error counts. The other source of information is the syslog system log. If the log shows a large number of SCSI or Fibre Channel driver messages, then this situation probably indicates serious hardware problems. If no syslog messages are generated, then the damage is likely transient.

The goal is to answer the following question:

*Is another error likely to occur on this device?*

Errors that happen only once are considered transient and do not indicate potential failure. Errors that are persistent or severe enough to indicate potential hardware failure are considered fatal. The act of determining the type of error is beyond the scope of any automated software currently available with ZFS, and so much must be done manually by you, the administrator. After determination is made, the appropriate action can be taken. Either clear the transient errors or replace the device due to fatal errors. These repair procedures are described in the next sections.

Even if the device errors are considered transient, they still might have caused uncorrectable data errors within the pool. These errors require special repair procedures, even if the underlying device is deemed healthy or otherwise repaired. For more information about repairing data errors, see "Repairing Damaged Data" on page 287.

### Clearing Transient Errors

If the device errors are deemed transient, in that they are unlikely to affect the future health of the device, they can be safely cleared to indicate that no fatal error occurred. To clear error counters for RAID-Z or mirrored devices, use the `zpool clear` command. For example:

```
# zpool clear tank c1t1d0
```

This syntax clears any device errors and clears any data error counts associated with the device.
To clear all errors associated with the virtual devices in a pool, and to clear any data error counts associated with the pool, use the following syntax:

```bash
# zpool clear tank
```

For more information about clearing pool errors, see “Clearing Storage Pool Device Errors” on page 84.

**Replacing a Device in a ZFS Storage Pool**

If device damage is permanent or future permanent damage is likely, the device must be replaced. Whether the device can be replaced depends on the configuration.

- “Determining If a Device Can Be Replaced” on page 280
- “Devices That Cannot be Replaced” on page 281
- “Replacing a Device in a ZFS Storage Pool” on page 281
- “Viewing Resilvering Status” on page 285

**Determining If a Device Can Be Replaced**

For a device to be replaced, the pool must be in the `ONLINE` state. The device must be part of a redundant configuration, or it must be healthy (in the `ONLINE` state). If the device is part of a redundant configuration, sufficient replicas from which to retrieve good data must exist. If two disks in a four-way mirror are faulted, then either disk can be replaced because healthy replicas are available. However, if two disks in a four-way RAID-Z (`raidz1`) virtual device are faulted, then neither disk can be replaced because insufficient replicas from which to retrieve data exist. If the device is damaged but otherwise online, it can be replaced as long as the pool is not in the `FAULTED` state. However, any corrupted data on the device is copied to the new device, unless sufficient replicas with good data exist.

In the following configuration, the `c1t1d0` disk can be replaced, and any data in the pool is copied from the healthy replica, `c1t0d0`:

<table>
<thead>
<tr>
<th>mirror</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>FAULTED</td>
</tr>
</tbody>
</table>

The `c1t0d0` disk can also be replaced, though no self-healing of data can take place because no good replica is available.

In the following configuration, neither faulted disk can be replaced. The `ONLINE` disks cannot be replaced either because the pool itself is faulted:

<table>
<thead>
<tr>
<th>raidz</th>
<th>FAULTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1t0d0</td>
<td>ONLINE</td>
</tr>
<tr>
<td>c2t0d0</td>
<td>FAULTED</td>
</tr>
</tbody>
</table>
Replacing or Repairing a Damaged Device

In the following configuration, either top-level disk can be replaced, though any bad data present on the disk is copied to the new disk.

<table>
<thead>
<tr>
<th>Device</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>c3t0d0</td>
<td>FAULTED</td>
</tr>
<tr>
<td>c4t0d0</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

If either disk is faulted, then no replacement can be performed because the pool itself is faulted.

**Devices That Cannot be Replaced**

If the loss of a device causes the pool to become faulted or the device contains too many data errors in a non-redundant configuration, then the device cannot be safely replaced. Without sufficient redundancy, no good data with which to heal the damaged device exists. In this case, the only option is to destroy the pool and re-create the configuration, and then to restore your data from a backup copy.

For more information about restoring an entire pool, see “Repairing ZFS Storage Pool-Wide Damage” on page 289.

**Replacing a Device in a ZFS Storage Pool**

After you have determined that a device can be replaced, use the `zpool replace` command to replace the device. If you are replacing the damaged device with different device, use syntax similar to the following:

```
# zpool replace tank c1t1d0 c2t0d0
```

This command migrates data to the new device from the damaged device or from other devices in the pool if it is in a redundant configuration. When the command is finished, it detaches the damaged device from the configuration, at which point the device can be removed from the system. If you have already removed the device and replaced it with a new device in the same location, use the single device form of the command. For example:

```
# zpool replace tank c1t1d0
```

This command takes an unformatted disk, formats it appropriately, and then resilvers data from the rest of the configuration.

For more information about the `zpool replace` command, see "Replacing Devices in a Storage Pool" on page 85.
Replacing or Repairing a Damaged Device

EXAMPLE 11-1 Replacing a Device in a ZFS Storage Pool

The following example shows how to replace a device (c1t3d0) in a mirrored storage pool tank on Oracle's Sun Fire x4500 system. To replace the disk c1t3d0 with a new disk at the same location (c1t3d0), then you must unconfigure the disk before you attempt to replace it. The basic steps follow:

■ Take offline the disk (c1t3d0) to be replaced. You cannot unconfigure a disk that is currently being used.
■ Use the `cfgadm` command to identify the disk (c1t3d0) to be unconfigured and unconfigure it. The pool will be degraded with the offline disk in this mirrored configuration, but the pool will continue to be available.
■ Physically replace the disk (c1t3d0). Ensure that the blue Ready to Remove LED is illuminated before you physically remove the faulted drive.
■ Reconfigure the disk (c1t3d0).
■ Bring the new disk (c1t3d0) online.
■ Run the `zpool replace` command to replace the disk (c1t3d0).

Note – If you had previously set the pool property autoreplace to on, then any new device, found in the same physical location as a device that previously belonged to the pool is automatically formatted and replaced without using the `zpool replace` command. This feature might not be supported on all hardware.

■ If a failed disk is automatically replaced with a hot spare, you might need to detach the hot spare after the failed disk is replaced. For example, if c2t4d0 is still an active hot spare after the failed disk is replaced, then detach it.

```
# zpool detach tank c2t4d0
```

The following example walks through the steps to replace a disk in a ZFS storage pool.

```
# zpool offline tank c1t3d0
# cfgadm | grep c1t3d0
sata1/3::dsk/c1t3d0 disk connected configured ok
# cfgadm -c unconfigure sata1/3
Unconfigure the device at: /devices/pci@0,0/pci1022,7458@2/pci11ab,11ab@1:3
This operation will suspend activity on the SATA device
Continue (yes/no)? yes
# cfgadm | grep sata1/3
sata1/3 disk connected unconfigured ok

<Physically replace the failed disk c1t3d0>
# cfgadm -c configure sata1/3
# cfgadm | grep sata1/3
sata1/3::dsk/c1t3d0 disk connected configured ok
# zpool online tank c1t3d0
# zpool replace tank c1t3d0
```
Replacing or Repairing a Damaged Device

Example 11-1  Replacing a Device in a ZFS Storage Pool  (Continued)

```
# zpool status tank
pool: tank
state: ONLINE
scrub: resilver completed after 0h0m with 0 errors on Tue Feb  2 13:17:32 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-1</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t2d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t2d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-2</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c0t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

errors: No known data errors

Note that the preceding zpool output might show both the new and old disks under a replacing heading. For example:

```
replacing  DEGRADED  0  0  0
c1t3d0s0/o FAULTED  0  0  0
c1t3d0   ONLINE  0  0  0
```

This means that the replacement process is in progress and the new disk is being resilvered.

If you are going to replace a disk (c1t3d0) with another disk (c4t3d0), then you only need to run the zpool replace command. For example:

```
# zpool replace tank c1t3d0 c4t3d0
# zpool status
pool: tank
state: DEGRADED
scrub: resilver completed after 0h0m with 0 errors on Tue Feb  2 13:35:41 2010
config:

  c4t3d0   ONLINE    0      0       0
```

EXAMPLE 11–2  Replacing a Failed Log Device

The following example shows how to recover from a failed log device (c0t5d0) in the storage pool (pool). The basic steps follow:

- Review the `zpool status -x` output and FMA diagnostic message, described here:
  

- Physically replace the failed log device.
- Bring the new log device online.
- Clear the pool's error condition.

```
# zpool status -x
pool: pool
  state: FAULTED
status: One or more of the intent logs could not be read.
        Waiting for administrator intervention to fix the faulted pool.
action: Either restore the affected device(s) and run 'zpool online',
        or ignore the intent log records by running 'zpool clear'.
scrub: none requested
config:

  NAME     STATE     READ  WRITE   CKSUM
  pool     FAULTED    0      0       0 bad intent log

<Physically replace the failed log device>
# zpool online pool c0t5d0
# zpool clear pool
```

**Viewing Resilvering Status**

The process of replacing a device can take an extended period of time, depending on the size of the device and the amount of data in the pool. The process of moving data from one device to another device is known as resilvering and can be monitored by using the `zpool status` command.

Traditional file systems resilver data at the block level. Because ZFS eliminates the artificial layering of the volume manager, it can perform resilvering in a much more powerful and controlled manner. The two main advantages of this feature are as follows:

- ZFS only resilver the minimum amount of necessary data. In the case of a short outage (as opposed to a complete device replacement), the entire disk can be resivered in a matter of minutes or seconds. When an entire disk is replaced, the resilvering process takes time proportional to the amount of data used on disk. Replacing a 500-GB disk can take seconds if a pool has only a few gigabytes of used disk space.

- Resilvering is interruptible and safe. If the system loses power or is rebooted, the resilvering process resumes exactly where it left off, without any need for manual intervention.

To view the resilvering process, use the `zpool status` command. For example:
Replacing or Repairing a Damaged Device

```bash
# zpool status tank
pool: tank
state: DEGRADED
status: One or more devices is currently being resilvered. The pool will continue to function, possibly in a degraded state.
action: Wait for the resilver to complete.
scrub: resilver in progress for 0h0m, 22.60% done, 0h1m to go
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>DEGRADED</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>DEGRADED</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>replacing-0</td>
<td>DEGRADED</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c1t0d0</td>
<td>UNAVAIL</td>
<td>0</td>
<td>0</td>
<td>0 cannot open</td>
</tr>
<tr>
<td>c2t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0 85.0M resilvered</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

class: No known data errors

In this example, the disk c1t0d0 is being replaced by c2t0d0. This event is observed in the status output by the presence of the replacing virtual device in the configuration. This device is not real, nor is it possible for you to create a pool by using it. The purpose of this device is solely to display the resilvering progress and to identify which device is being replaced.

Note that any pool currently undergoing resilvering is placed in the ONLINE or DEGRADED state because the pool cannot provide the desired level of redundancy until the resilvering process is completed. Resilvering proceeds as fast as possible, though the I/O is always scheduled with a lower priority than user-requested I/O, to minimize impact on the system. After the resilvering is completed, the configuration reverts to the new, complete, configuration. For example:

```bash
# zpool status tank
pool: tank
state: ONLINE
scrub: resilver completed after 0h1m with 0 errors on Tue Feb 2 13:54:30 2010
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c2t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>377M resilvered</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

class: No known data errors

The pool is once again ONLINE, and the original failed disk (c1t0d0) has been removed from the configuration.
Repairing Damaged Data

The following sections describe how to identify the type of data corruption and how to repair the data, if possible.

- “Identifying the Type of Data Corruption” on page 287
- “Repairing a Corrupted File or Directory” on page 288
- “Repairing ZFS Storage Pool-Wide Damage” on page 289

ZFS uses checksums, redundancy, and self-healing data to minimize the risk of data corruption. Nonetheless, data corruption can occur if a pool isn’t redundant, if corruption occurred while a pool was degraded, or an unlikely series of events conspired to corrupt multiple copies of a piece of data. Regardless of the source, the result is the same: The data is corrupted and therefore no longer accessible. The action taken depends on the type of data being corrupted and its relative value. Two basic types of data can be corrupted:

- Pool metadata – ZFS requires a certain amount of data to be parsed to open a pool and access datasets. If this data is corrupted, the entire pool or portions of the dataset hierarchy will become unavailable.
- Object data – In this case, the corruption is within a specific file or directory. This problem might result in a portion of the file or directory being inaccessible, or this problem might cause the object to be broken altogether.

Data is verified during normal operations as well as through a scrubbing. For information about how to verify the integrity of pool data, see “Checking ZFS File System Integrity” on page 269.

Identifying the Type of Data Corruption

By default, the zpool status command shows only that corruption has occurred, but not where this corruption occurred. For example:

```
# zpool status monkey
pool: monkey
  state: ONLINE
status: One or more devices has experienced an error resulting in data
corruption. Applications may be affected.
action: Restore the file in question if possible. Otherwise restore the
  entire pool from backup.
  see: http://www.sun.com/msg/ZFS-8000-8A
scrub: scrub completed after @h@m with 8 errors on Tue Jul 13 13:17:32 2010
config:

  NAME   STATE  READ  WRITE  CKSUM
  monkey ONLINE  8    0      0
  c1t1d0 ONLINE  2    0      0
  c2t5d0 ONLINE  6    0      0
```
errors: 8 data errors, use `-v' for a list

Each error indicates only that an error occurred at a given point in time. Each error is not necessarily still present on the system. Under normal circumstances, this is the case. Certain temporary outages might result in data corruption that is automatically repaired after the outage ends. A complete scrub of the pool is guaranteed to examine every active block in the pool, so the error log is reset whenever a scrub finishes. If you determine that the errors are no longer present, and you don’t want to wait for a scrub to complete, reset all errors in the pool by using the `zpool online' command.

If the data corruption is in pool-wide metadata, the output is slightly different. For example:

```
# zpool status -v morpheus
  pool: morpheus
    id: 1422736090544688191
  state: FAULTED
  status: The pool metadata is corrupted.
  action: The pool cannot be imported due to damaged devices or data.
  see: http://www.sun.com/msg/ZFS-8000-72
  config:
    morpheus FAULTED corrupted data
c1t1d0 ONLINE
```

In the case of pool-wide corruption, the pool is placed into the FAULTED state because the pool cannot provide the required redundancy level.

**Repairing a Corrupted File or Directory**

If a file or directory is corrupted, the system might still function, depending on the type of corruption. Any damage is effectively unrecoverable if no good copies of the data exist on the system. If the data is valuable, you must restore the affected data from backup. Even so, you might be able to recover from this corruption without restoring the entire pool.

If the damage is within a file data block, then the file can be safely removed, thereby clearing the error from the system. Use the `zpool status -v' command to display a list of file names with persistent errors. For example:

```
# zpool status -v
  pool: monkey
  state: ONLINE
  status: One or more devices has experienced an error resulting in data corruption. Applications may be affected.
  action: Restore the file in question if possible. Otherwise restore the entire pool from backup.
  see: http://www.sun.com/msg/ZFS-8000-8A
  scrub: scrub completed after 0h0m with 8 errors on Tue Jul 13 13:17:32 2010
  config:
```
errors: Permanent errors have been detected in the following files:

/monkey/a.txt
/monkey/bananas/b.txt
/monkey/sub/dir/d.txt
/monkey/ghost/e.txt
/monkey/ghost/boo/f.txt

The list of file names with persistent errors might be described as follows:

- If the full path to the file is found and the dataset is mounted, the full path to the file is displayed. For example:

  /monkey/a.txt

- If the full path to the file is found, but the dataset is not mounted, then the dataset name with no preceding slash (/), followed by the path within the dataset to the file, is displayed. For example:

  monkey/ghost/e.txt

- If the object number to a file path cannot be successfully translated, either due to an error or because the object doesn't have a real file path associated with it, as is the case for a node_t, then the dataset name followed by the object's number is displayed. For example:

  monkey/dnode:<0x0>

- If an object in the metaobject set (MOS) is corrupted, then a special tag of <metadata>, followed by the object number, is displayed.

If the corruption is within a directory or a file's metadata, the only choice is to move the file elsewhere. You can safely move any file or directory to a less convenient location, allowing the original object to be restored in its place.

### Repairing ZFS Storage Pool-Wide Damage

If the damage is in pool metadata and that damage prevents the pool from being opened or imported, then the following options are available:

- Attempt to recover the pool by using the `zpool clear -F` command or the `zpool import -F` command. These commands attempt to roll back the last few pool transactions to an operational state. You can use the `zpool status` command to review a damaged pool and the recommended recovery steps. For example:

  ```
  # zpool status
  pool: tpool
  ```
state: FAULTED
status: The pool metadata is corrupted and the pool cannot be opened.
action: Recovery is possible, but will result in some data loss. Returning the pool to its state as of Wed Jul 14 11:44:10 2010 should correct the problem. Approximately 5 seconds of data must be discarded, irreversibly. Recovery can be attempted by executing 'zpool clear -F tpool'. A scrub of the pool is strongly recommended after recovery.
see: http://www.sun.com/msg/ZFS-8000-72
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tpool</td>
<td>FAULTED</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>c1t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>c1t3d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

The recovery process as described above is to use the following command:

```
# zpool clear -F tpool
```

If you attempt to import a damaged storage pool, you will see messages similar to the following:

```
# zpool import tpool
cannot import 'tpool': I/O error
  Recovery is possible, but will result in some data loss.
  Returning the pool to its state as of Wed Jul 14 11:44:10 2010 should correct the problem. Approximately 5 seconds of data must be discarded, irreversibly. Recovery can be attempted by executing 'zpool import -F tpool'. A scrub of the pool is strongly recommended after recovery.
```

The recovery process as described above is to use the following command:

```
# zpool import -F tpool
```

Pool tpool returned to its state as of Wed Jul 14 11:44:10 2010.
Discarded approximately 5 seconds of transactions

If the damaged pool is in the zpool.cache file, the problem is discovered when the system is booted, and the damaged pool is reported in the zpool status command. If the pool isn’t in the zpool.cache file, it won’t successfully import or open and you’ll see the damaged pool messages when you attempt to import the pool.

- If the pool cannot be recovered by the pool recovery method described above, you must restore the pool and all its data from a backup copy. The mechanism you use varies widely depending on the pool configuration and backup strategy. First, save the configuration as displayed by the zpool status command so that you can recreate it after the pool is destroyed. Then, use the zpool destroy -f command to destroy the pool. Also, keep a file describing the layout of the datasets and the various locally set properties somewhere safe, as this information will become inaccessible if the pool is ever rendered inaccessible. With the pool configuration and dataset layout, you can reconstruct your complete configuration after destroying the pool. The data can then be populated by using whatever backup or restoration strategy you use.
Repairing an Unbootable System

ZFS is designed to be robust and stable despite errors. Even so, software bugs or certain unexpected problems might cause the system to panic when a pool is accessed. As part of the boot process, each pool must be opened, which means that such failures will cause a system to enter into a panic-reboot loop. To recover from this situation, ZFS must be informed not to look for any pools on startup.

ZFS maintains an internal cache of available pools and their configurations in /etc/zfs/zpool.cache. The location and contents of this file are private and are subject to change. If the system becomes unbootable, boot to the milestone none by using the -m milestone=none boot option. After the system is up, remount your root file system as writable and then rename or move the /etc/zfs/zpool.cache file to another location. These actions cause ZFS to forget that any pools exist on the system, preventing it from trying to access the unhealthy pool causing the problem. You can then proceed to a normal system state by issuing the svcadm milestone all command. You can use a similar process when booting from an alternate root to perform repairs.

After the system is up, you can attempt to import the pool by using the zpool import command. However, doing so will likely cause the same error that occurred during boot, because the command uses the same mechanism to access pools. If multiple pools exist on the system, do the following:

- Rename or move the zpool.cache file to another location as discussed in the preceding text.
- Determine which pool might have problems by using the fmdump -eV command to display the pools with reported fatal errors.
- Import the pools one by one, skipping the pools that are having problems, as described in the fmdump output.
This appendix describes available ZFS versions, features of each version, and the Solaris OS that provides the ZFS version and feature.

The following sections are provided in this appendix:

- “Overview of ZFS Versions” on page 293
- “ZFS Pool Versions” on page 293
- “ZFS File System Versions” on page 294

## Overview of ZFS Versions

New ZFS pool and file system features are introduced and accessible by using a specific ZFS version that is available in Solaris releases. You can use the `zpool upgrade` or `zfs upgrade` to identify whether a pool or file system is at lower version than the currently running Solaris release provides. You can also use these commands to upgrade your pool and file system versions.

For information about using the `zpool upgrade` and `zfs upgrade` commands, see “Upgrading ZFS File Systems (`zfs upgrade`)” on page 30 and “Upgrading ZFS Storage Pools” on page 109.

## ZFS Pool Versions

The following table provides a list of ZFS pool versions that are available in the Solaris releases.

<table>
<thead>
<tr>
<th>Version</th>
<th>Solaris 10</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Solaris 10 6/06</td>
<td>Initial ZFS version</td>
</tr>
<tr>
<td>2</td>
<td>Solaris 10 11/06</td>
<td>Ditto blocks (replicated metadata)</td>
</tr>
</tbody>
</table>
### ZFS File System Versions

The following table lists the ZFS file system versions that are available in the Solaris releases.

<table>
<thead>
<tr>
<th>Version</th>
<th>Solaris 10</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Solaris 10 6/06</td>
<td>Initial ZFS file system version</td>

    clone, 44
    dataset, 44
    file system, 44
    mirror, 44
    pool, 44
    RAID-Z, 45
    resilvering, 45
    snapshot, 45
    virtual device, 45
    volume, 45
traditional volume management, differences between
  ZFS and traditional file systems, 55
transactional semantics, description, 42
troubleshooting
  clear device errors (zpool clear)
    (example of), 279
  damaged devices, 268
  data corruption identified (zpool status -v)
    (example of), 274
troubleshooting (Continued)
determining if a device can be replaced
description, 280
determining if problems exist (zpool status
-x), 272
determining type of data corruption (zpool status
-v)
(example of), 287
determining type of device failure
description, 278
identifying problems, 271
missing (faulted) devices, 268
notifying ZFS of reattached device (zpool online)
(example of), 277
overall pool status information
description, 273
repairing a corrupted file or directory
description, 288
repairing a damaged ZFS configuration, 276
repairing an unbootable system
description, 291
repairing pool-wide damage
description, 290
replacing a device (zpool replace)
(example of), 281, 285
replacing a missing device
(example of), 276
syslog reporting of ZFS error messages, 275
ZFS failures, 267
type property, description, 176

used property (Continued)
detailed description, 179
usedbychildren property, description, 176
usedbydataset property, description, 177
usedbyrefreservation property, description, 177
usedbysnapshots property, description, 177
user properties of ZFS
(example of), 182
detailed description, 182

V
version property, description, 177
version property, description, 94
virtual device, definition, 45
virtual devices, as components of ZFS storage pools, 68
volblocksize property, description, 177
gols size property
description, 177
detailed description, 181
volume, definition, 45

W
whole disks, as components of ZFS storage pools, 58

X
xattr property, description, 178

Z
zfs allow
description, 248
displaying delegated permissions, 253
zfs create
(example of), 51, 168
description, 168
ZFS delegated administration, overview, 245
zfs destroy, (example of), 169
zfs destroy -r, (example of), 169
Index

ZFS file system
  description, 167
  versions
    description, 293
ZFS file systems
  ACL on ZFS directory
    detailed description, 227
  ACL on ZFS file
    detailed description, 226
  adding ZFS file system to a non-global zone
    (example of), 260
  adding ZFS volume to a non-global zone
    (example of), 262
  booting a root file system
    description, 152
  booting a ZFS BE with boot -L and boot -Z
    (SPARC example of), 154
  checksum
    definition, 44
  checksummed data
    description, 42
  clone
    replacing a file system with (example of), 210
  clones
    definition, 44
    description, 209
  component naming requirements, 45
  creating
    (example of), 168
  creating a clone, 210
  creating a ZFS volume
    (example of), 257
  dataset
    definition, 44
  dataset types
    description, 184
  default mountpoint
    (example of), 168
  delegating dataset to a non-global zone
    (example of), 261
  description, 41
  destroying
    (example of), 169
    destroying a clone, 210
ZFS file systems (Continued)
  destroying with dependents
    (example of), 169
  file system
    definition, 44
  inheriting property of (zfs inherit)
    (example of), 186
  initial installation of ZFS root file system, 115
  installation and Oracle Solaris Live Upgrade
    requirements, 113
  installing a root file system, 112
  JumpStart installation of root file system, 124
  listing
    (example of), 183
  listing descendents
    (example of), 184
  listing properties by source value
    (example of), 189
  listing properties for scripting
    (example of), 189
  listing properties of (zfs list)
    (example of), 187
  listing types of
    (example of), 185
  listing without header information
    (example of), 185
  managing automatic mount points, 190
  managing legacy mount points
    description, 190
  managing mount points
    description, 190
  modifying trivial ACL on ZFS file (verbose format)
    (example of), 229
  mounting
    (example of), 192
  pooled storage
    description, 41
  property management within a zone
    description, 263
  receiving data streams (zfs receive)
    (example of), 213
  renaming
    (example of), 170
ZFS file systems (Continued)
restoring trivial ACL on ZFS file (verbose format)
(example of), 232
rights profiles, 266
root file system migration issues, 129
root file system migration with Oracle Solaris Live Upgrade, 128
(example of), 130
saving data streams (zfs send)
(example of), 212
sending and receiving
description, 211
setting a reservation
(example of), 200
setting ACL inheritance on ZFS file (verbose format)
(example of), 233
setting ACLs on ZFS file (compact format)
(example of), 240
description, 239
setting ACLs on ZFS file (verbose format)
description, 228
setting ACLs on ZFS files
description, 225
setting atime property
(example of), 185
setting legacy mount point
(example of), 192
setting mount point (zfs set mountpoint)
(example of), 191
setting quota property
(example of), 186
sharing
description, 194
eexample of, 194
simplified administration
description, 43
snapshot
accessing, 207
creating, 204
definition, 45
description, 203
destroying, 205
renaming, 206
rolling back, 209
ZFS file systems (Continued)
networking
snapshot space accounting, 208
swap and dump devices
adjusting sizes of, 149
description, 148
issues, 149
transactional semantics
description, 42
unmounting
(example of), 194
unsharing
example of, 195
using on a Solaris system with zones installed
description, 260
volume
definition, 45
ZFS file systems (zfs set quota)
setting a quota
description, 196
zfs get, (example of), 187
zfs get -H -o, (example of), 189
zfs get -s, (example of), 189
zfs inherit, (example of), 186
ZFS intent log (ZIL), description, 31
zfs list
(example of), 52, 183
zfs list -H, (example of), 185
zfs list -r, (example of), 184
zfs list -t, (example of), 185
zfs mount, (example of), 192
ZFS pool properties

ZFS storage pools (Continued)
components, 57
corrupted data
description, 268
creating (zpool create)
(example of), 63
creating a RAID-Z configuration (zpool create)
(example of), 65
creating mirrored configuration (zpool create)
(example of), 64
damaged devices
description, 268
data corruption identified (zpool status -v)
(example of), 274
data repair
description, 269
data scrubbing
(example of), 270
description, 269
data scrubbing and resilvering
description, 270
data validation
description, 269
default mount point, 71
destroying (zpool destroy)
(example of), 71
detaching devices from (zpool detach)
(example of), 79
determining if a device can be replaced
description, 280
determining if problems exist (zpool status -x)
description, 272
determining type of device failure
description, 278
displaying detailed health status
(example of), 102
displaying health status, 100
(example of), 101
doing a dry run (zpool create -n)
(example of), 71
dynamic striping, 62
exporting
(example of), 104
failures, 267

ZFS storage pools (Continued)
identifying for import (zpool import -a)
(example of), 104
identifying problems
description, 271
identifying type of data corruption (zpool status
-v)
(example of), 287
importing
(example of), 107
importing from alternate directories (zpool import
-d)
(example of), 106
listing
(example of), 96
migrating
description, 103
mirror
definition, 44
mirrored configuration, description, 61
missing (faulted) devices
description, 268
notifying ZFS of reattached device (zpool online)
(example of), 277
offlining a device (zpool offline)
(example of), 83
onlining and offlining devices
description, 82
overall pool status information for troubleshooting
description, 273
pool
definition, 44
pool-wide I/O statistics
(example of), 98
RAID-Z
definition, 45
RAID-Z configuration, description, 61
recovering a destroyed pool
(example of), 108
repairing a corrupted file or directory
description, 288
repairing a damaged ZFS configuration, 276
repairing an unbootable system
description, 291
ZFS storage pools (Continued)
repairing pool-wide damage
   description, 290
replacing a device (zpool replace)
   (example of), 85, 281
replacing a missing device
   (example of), 276
resilvering
   definition, 45
   rights profiles, 266
scripting storage pool output
   (example of), 96
splitting a mirrored storage pool (zpool split)
   (example of), 79
system error messages
   description, 275
upgrading
   description, 109
   using files, 60
   using whole disks, 58
vdev I/O statistics
   (example of), 99
viewing resilvering process
   (example of), 285
virtual device
   definition, 45
   virtual devices, 68
ZFS storage pools (zpool online)
onlining a device
   (example of), 84
zfs unallow, description, 249
zfs unmount, (example of), 194
ZFS version
   ZFS feature and Solaris OS
      description, 293
ZFS volume, description, 257
zoned property
   description, 178
   detailed description, 264
zones
   adding ZFS file system to a non-global zone
      (example of), 260
   adding ZFS volume to a non-global zone
      (example of), 262
zones (Continued)
   delegating dataset to a non-global zone
      (example of), 261
   using with ZFS file systems
      description, 260
   ZFS property management within a zone
      description, 263
   zoned property
      detailed description, 264
zpool add, (example of), 73
zpool attach, (example of), 77
zpool clear
   (example of), 85
   description, 84
zpool create
   (example of), 48, 50
   basic pool
      (example of), 63
   mirrored storage pool
      (example of), 64
   RAID-Z storage pool
      (example of), 65
zpool create -n, dry run (example of), 71
zpool destroy, (example of), 71
zpool detach, (example of), 79
zpool export, (example of), 104
zpool history, (example of), 35
zpool import -a, (example of), 104
zpool import -d, (example of), 108
zpool import -d, (example of), 106
zpool import name, (example of), 107
zpool iostat, pool-wide (example of), 98
zpool iostat -v, vdev (example of), 99
