A  Sun Cluster HA for Apache Extension Properties 41

Index 43
Preface

*Sun Cluster Data Service for Apache Guide for Solaris OS* explains how to install and configure Sun™ Cluster HA for Apache on both SPARC® and x86 based systems.

**Note** – In this document, the term “x86” refers to the Intel 32-bit family of microprocessor chips and compatible microprocessor chips made by AMD.

This document is intended for system administrators with extensive knowledge of Sun software and hardware. Do not use this document as a planning or presales guide. Before reading this document, you should have already determined your system requirements and purchased the appropriate equipment and software.

The instructions in this document assume knowledge of the Solaris™ Operating System and expertise with the volume manager software that is used with Sun Cluster.

**Note** – Sun Cluster software runs on two platforms, SPARC and x86. The information in this document pertains to both platforms unless otherwise specified in a special chapter, section, note, bulleted item, figure, table, or example.

### UNIX Commands

This document contains information about commands that are specific to installing and configuring Sun Cluster data services. The document does *not* contain comprehensive information about basic UNIX® commands and procedures, such as shutting down the system, booting the system, and configuring devices. Information about basic UNIX commands and procedures is available from the following sources:
Typographic Conventions

The following table describes the typographic changes that are used in this book.

**TABLE P-1** Typographic Conventions

Third-party URLs that are referenced in this document provide additional related information.

**Note** – Sun is not responsible for the availability of third-party web sites mentioned in this document. Sun does not endorse and is not responsible or liable for any content, advertising, products, or other materials that are available on or through such sites or resources. Sun will not be responsible or liable for any actual or alleged damage or loss caused or alleged to be caused by or in connection with use of or reliance on any such content, goods, or services that are available on or through such sites or resources.

Accessing Sun Documentation Online

The docs.sun.com℠ Web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. The URL is http://docs.sun.com

Ordering Sun Documentation

Sun Microsystems offers select product documentation in print. For a list of documents and how to order them, see “Buy printed documentation” at http://docs.sun.com.

Product Training

Sun Microsystems offers training in many Sun technologies through a variety of instructor-led courses and self-paced courses. For information about the training courses that Sun offers and to enroll in a class, visit Sun Microsystems Training at http://training.sun.com/
Getting Help

If you have problems installing or using Sun Cluster, contact your service provider and provide the following information:

- Your name and email address (if available)
- Your company name, address, and phone number
- The model and serial numbers of your systems
- The release number of the Solaris Operating System (for example, Solaris 8)
- The release number of Sun Cluster (for example, Sun Cluster 3.0)

Use the following commands to gather information about each node on your system for your service provider.

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>prtconf -v</td>
<td>Displays the size of the system memory and reports information about peripheral devices</td>
</tr>
<tr>
<td>psrinfo -v</td>
<td>Displays information about processors</td>
</tr>
<tr>
<td>showrev -p</td>
<td>Reports which patches are installed</td>
</tr>
<tr>
<td>SPARC: prtdiag -v</td>
<td>Displays system diagnostic information</td>
</tr>
<tr>
<td>scinstall -pv</td>
<td>Displays Sun Cluster release and package version information</td>
</tr>
</tbody>

Installing and Configuring Sun Cluster HA for Apache

This chapter describes the steps to install and configure Sun Cluster HA for Apache on your Sun Cluster servers.

This chapter contains the following sections.

- “Planning the Installation and Configuration” on page 11
- “Overview of the Installation and Configuration Process for Sun Cluster HA for Apache” on page 16
- “Installing and Configuring Apache” on page 16
- “Installing Sun Cluster HA for Apache Packages” on page 24
- “Registering and Configuring Sun Cluster HA for Apache” on page 26
- “Tuning the Sun Cluster HA for Apache Fault Monitor” on page 35
- “Upgrading the SUNW.apache Resource Type” on page 37

You can configure Sun Cluster HA for Apache as a failover or a scalable data service. See Chapter 1, “Planning for Sun Cluster Data Services,” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS and the Sun Cluster Concepts Guide for Solaris OS document for an overview of failover and scalable data services.

Note – You can use SunPlex™ Manager to install and configure this data service. See the SunPlex Manager online help for details.

Planning the Installation and Configuration

Before you install Sun Cluster HA for Apache, update the following information in the Apache configuration file httpd.conf.
The location of the httpd.conf file varies according to installation. System administrators typically install the httpd.conf file on the cluster file system. The default installation places the httpd.conf file in the /usr/local/apache/conf directory. When installing Apache packages bundled with Solaris, the file is located in the /etc/apache directory.

- **The ServerName directive that contains the hostname** – For Sun Cluster HA for Apache to be highly available, you must set this directive to the name of the network address (logical hostname or shared address) that is used to access the server. You should have set up the logical hostname or shared address when you installed the cluster. See the Sun Cluster Concepts Guide for Solaris OS document for details on network resources.

- **The BindAddress directive, which you must set to the logical host or shared address** – You can configure Apache to bind to INADDR_ANY. However, each resource must bind to a unique combination of network resource and port number. For example, if you run multiple resources, you can use INADDR_ANY provided that the port number for each resource is different.

- **The ServerType directive** – This directive must be set to standalone, the default.

- **Multiple instances of Apache** – If you have multiple instances of Apache, you must manage each instance with a separate resource. Furthermore, each separate resource must have a unique Bin_dir setting. Under the specified Bin_dir property that starts the particular instance of Apache, an apachectl script must exist.

Different Apache resources can share the same httpd binary, that is, the apachectl scripts for different resources can specify the path to the same httpd binary. However, you must modify each apachectl script to use a different configuration file for specific Apache resources. To do so, use the -f option of the httpd command to specify a specific httpd.conf file.

- **The DocumentRoot directive that specifies the location of the documentation root directory** – This directive is a pointer to a location on the cluster file system, where the HTML documents are installed.

- **The ScriptAlias directive that contains the location on a cluster file system of the cgi-bin directory** – This directive is a pointer to a location on the cluster file system, where the cgi-bin files are installed.
Note – You must follow certain conventions when you configure URL mappings for the Web server. For example, when setting the CGI directory, locate the CGI directory on the cluster file system to preserve availability. For example, you might map your CGI directory to `/global/diskgroup/ServerRoot/cgi-bin`, where `diskgroup` is the disk device group that contains the Apache software. In situations where the CGI programs access “back-end” servers, such as an RDBMS, ensure that the Sun Cluster software controls the “back-end” server. If the server is an RDBMS that the Sun Cluster software supports, use one of the highly available RDBMS packages. Alternatively, you can use the APIs that the *Sun Cluster Data Services Developer’s Guide for Solaris OS* documents to put the server under Sun Cluster control.

- **The lock file** – If you use a lock file, set the value of the `LockFile` directive in your `httpd.conf` file to a local file.

- **The PidFile directive** – Point this directive to a local file, as in the following example.

  ```
  PidFile /usr/local/apache/log/httpd.pid
  ```

- **The Port directive setting that the server port or ports access** – The defaults are set in each node’s `httpd.conf` file. The `Port_list` resource property must include all of the ports that the `httpd.conf` files specify.

  The `Port_list` property assumes that the Web server serves all combinations of ports and IP addresses from the network resources as defined in the `Network_resources_used` property.

  ```
  Port_list="80/tcp,443/tcp,8080/tcp"
  ```

  The preceding `Port_list` configuration, for example, probes the following IP-port combinations.

<table>
<thead>
<tr>
<th>Host</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>80</td>
<td>tcp</td>
</tr>
<tr>
<td>node1</td>
<td>443</td>
<td>tcp</td>
</tr>
<tr>
<td>node1</td>
<td>8080</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>80</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>443</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>8080</td>
<td>tcp</td>
</tr>
</tbody>
</table>

However, if `node1` serves ports 80 and 443 only and `node2` serves ports 80 and 8080 only, you can configure the `Port_list` property for Apache as follows.

```
Port_list=node1/80/tcp,node1/443/tcp,node2/80/tcp,node2/8080/tcp
```
Consider the following rules.

- You must specify hostnames or IP addresses (not network resource names) for node1 and node2.
- If Apache serves nodeN/port for every nodeN in the Network_resources_used property, you can use a short form to replace the combination of node1/port1, node2/port2, and so on. See the following examples.

Example One

Port_list="80/tcp,node1/443/tcp,node2/8080/tcp"
Network_resources_used=node1,node2

This example probes the following IP-port combinations.

<table>
<thead>
<tr>
<th>Host</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>80</td>
<td>tcp</td>
</tr>
<tr>
<td>node1</td>
<td>443</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>80</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>8080</td>
<td>tcp</td>
</tr>
</tbody>
</table>

Example Two

Port_list="node1/80/tcp,node2/80/tcp"
Network_resources_used=net-1,net-2
#net-1 contains node1.
#net-2 contains node2 and node3.

This example probes the following IP-port combinations.

<table>
<thead>
<tr>
<th>Host</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>80</td>
<td>tcp</td>
</tr>
<tr>
<td>node2</td>
<td>80</td>
<td>tcp</td>
</tr>
</tbody>
</table>

- All of the hostnames (IP addresses) that the Port_list property specifies must not belong to a network resource that is specified in any other scalable resource’s Network_resources_used property. Otherwise, as soon as a scalable service detects that another scalable resource already uses an IP address, creation of the Apache resource fails.
**Note** – If you run Sun Cluster HA for Apache and another HTTP server, configure the HTTP servers to listen on different ports. Otherwise, a port conflict can occur between the two servers.

To register and configure Sun Cluster HA for Apache, you must consider or provide information on the following points.

- Decide whether to run Sun Cluster HA for Apache as a failover or scalable data service.
- Decide whether to install a secure or non-secure version of the apache webserver.
- Decide which fault monitoring resource properties to set. In most cases, the default values suffice. See *Sun Cluster Data Services Planning and Administration Guide for Solaris OS* for information about the standard properties and Appendix A for information about the extension properties.
- Provide the name of the resource type for Sun Cluster HA for Apache. This name is `SUNW.apache`.
- Provide the names of the cluster nodes that will master the data service.
- Provide the logical hostname (failover services) or shared address (scalable services) that clients use to access the data service. You typically set up this IP address when you install the cluster. See the *Sun Cluster Concepts Guide for Solaris OS* document for details on network resources.
- Provide the path to the application binaries. You can install the binaries on the local disks or on the cluster file system. See “Configuration Guidelines for Sun Cluster Data Services” in *Sun Cluster Data Services Planning and Administration Guide for Solaris OS* for a discussion of the advantages and disadvantages of each location.
- Modify each copy of `apachectl` to use the appropriate `httpd.conf` configuration file.
- Exercise caution when you change the `Load_balancing_weights` property for an online scalable service that has the `Load_balancing_policy` property set to `LB_STICKY` or `LB_STICKY_WILD`. Changing these properties while the service is online can cause existing client affinities to be reset, hence a different node might service a subsequent client request even if another cluster member previously serviced the client.

Similarly, when a new instance of the service is started on a cluster, existing client affinities might be reset.

- Determine the entry for the `Port_list` property. The `Port_list` property can have multiple entries. See “How to Register and Configure Sun Cluster HA for Apache” on page 28 for details.
- Determine whether to utilize the `Monitor_Url_List` extension property. This extension property enables you to monitor an arbitrary list of URLs. Arbitrary monitoring of URLs is beneficial if you require the Sun Cluster HA for Apache agent probe to monitor any applications (URLs) deployed on the Sun Cluster HA for...
Apache server. Use of the Monitor Uri List extension property is not supported with secure instances of Sun Cluster HA for Apache. You must install release 3.1 10/03 of Sun Cluster HA for Apache to use this property. If you are upgrading Sun Cluster HA for Apache from a previous version, you must perform a resource type upgrade procedure to use the new property. For instructions, see “Upgrading a Resource Type” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS. See “Monitoring Arbitrary URIs” on page 27 for detailed information about using the Monitor(Uri) extension property.

Overview of the Installation and Configuration Process for Sun Cluster HA for Apache

The table below lists the sections that describe the installation and configuration tasks.

<table>

Installing and Configuring Apache

The Apache webserver can be installed and set up as either a non-secure or a secure webserver. This section provides procedures for both types of installations. To install a non-secure version of the webserver, see one of the following procedures.

- “How to Install and Configure the Apache Software from the Solaris CD-ROM” on page 17
To install a secure version of the webserver, see one of the following procedures.

- “How to Install and Configure the Apache Software Using mod_ssl” on page 20
- “How to Install and Configure the Apache Software Using apache-ssl” on page 22

Sun Cluster HA for Apache works with the Apache software configured as either a Web server or a proxy server.

See Apache documentation at http://www.apache.org for standard installation instructions. Contact your Sun sales representative for a complete list of Apache versions that are supported with the Sun Cluster software.

## Installing a Non-Secure Apache Webserver

This section provides procedures for installing a non-secure Apache webserver. For procedures for installing a secure Apache webserver, see “Installing a Secure Apache Webserver” on page 20.

### How to Install and Configure the Apache Software from the Solaris CD-ROM

This procedure installs a non-secure version of the Apache webserver. For procedures for installing a secure Apache webserver, see “Installing a Secure Apache Webserver” on page 20.

The Apache binaries are included in three packages—SUNWapchr, SUNWapchu, and SUNWapchd—that form the SUNWCapache package metacluster. You must install the SUNWapchr package before you install the SUNWapchu package.

Place the Web server binaries on the local file system on each of your cluster nodes or on a cluster file system.

**Steps**

1. Run the `pkginfo(1)` command to determine if the Apache packages SUNWapchr, SUNWapchu, and SUNWapchd have been installed.
   
   If these packages have not been installed, install them as follows.

   - With Solaris 8 and Solaris 9, run the following command.
     
     ```
     # pkgadd -d Solaris-product-directory SUNWapchr SUNWapchu SUNWapchd
     ```

   - With Solaris 10, run the following command.
     
     ```
     # pkgadd -G -d Solaris-product-directory SUNWapchr SUNWapchu SUNWapchd
     ```

   The output from the command is as follows.

   ```
   Installing Apache Web Server (root) as SUNWapchr
   ```
2. Disable the **START** and **STOP** run control scripts that were just installed as part of the `SUNWapchr` package.

This step is necessary because Sun Cluster HA for Apache starts and stops the Apache application after you have configured the data service. Perform the following steps.

a. **List the Apache run control scripts.**

b. **Rename the Apache run control scripts.**

c. **Verify that all of the Apache-related scripts have been renamed.**

   The following example changes the first letter in the name of the run control script from uppercase to lowercase. However, you can rename the scripts to be consistent with your normal administration practices.

   ```
   # ls -1 /etc/rc?.d/*apache
   /etc/rc0.d/K16apache
   /etc/rc1.d/K16apache
   /etc/rc2.d/K16apache
   /etc/rc3.d/S50apache
   /etc/rcS.d/K16apache
   
   # mv /etc/rc0.d/K16apache /etc/rc0.d/k16apache
   # mv /etc/rc1.d/K16apache /etc/rc1.d/k16apache
   # mv /etc/rc2.d/K16apache /etc/rc2.d/k16apache
   # mv /etc/rc3.d/S50apache /etc/rc3.d/s50apache
   # mv /etc/rcS.d/K16apache /etc/rcS.d/k16apache
   
   # ls -1 /etc/rc?.d/*apache
   /etc/rc0.d/k16apache
   /etc/rc1.d/k16apache
   /etc/rc2.d/k16apache
   /etc/rc3.d/s50apache
   /etc/rcS.d/k16apache
   ```

▼ **How to Install and Configure the Apache Software from the Apache Web Site**

This procedure installs a non-secure version of the Apache webserver. For procedures for installing a secure Apache webserver, see “Installing a Secure Apache Webserver” on page 20.
Place the Web server binaries on the local file system on each of your cluster nodes or on a cluster file system.

**Steps**

1. **Become superuser on a cluster member.**

2. **Install the Apache software using the installation procedures found in the Apache installation documentation.**
   Install the Apache software using the Apache installation documentation you received with your Apache software or see the installation instructions at http://www.apache.org.

3. **Update the httpd.conf configuration file.**
   - Set the `ServerName` directive. (In Version 2.0 of Apache, the `ServerName` directive specifies the hostname and the port.)
   - Set the `BindAddress` directive (optional). (The `BindAddress` directive only exists in versions prior to Apache 2.0. For Apache 2.0, see the following bullet for the `Listen` directive.)
   - Set the `Listen` directive. The `Listen` directive must use the address of the logical host or shared address. (The `Listen` directive only exists in Apache 2.0 and beyond. For Apache versions prior to Apache 2.0, see the previous bullet for the `BindAddress` directive.)
   - Set the `ServerType`, `ServerRoot`, `DocumentRoot`, `ScriptAlias`, and `LockFile` directives.

   **Note** – The `ServerType` directive does not exist in Apache 2.0.

   - Set the `Port` directive to the same number as the `Port_list` standard resource property. See Step 4 for more information.
   - Make changes to run as a proxy server if you choose to run the Apache software as a proxy server. See the Apache documentation for more information. If you will run the Apache software as a proxy server, the `CacheRoot` setting must point to a location on the cluster file system.

4. **Verify that the port number or numbers in the httpd.conf file match those of the Port_list standard resource property.**
   You can edit the `httpd.conf` configuration file to change its port number or numbers to match the standard Sun Cluster resource property default (port 80). Alternatively, while you configure Sun Cluster HA for Apache, you can set the `Port_list` standard property to match the setting in the `httpd.conf` file.

5. **Update the paths in the Apache start/stop script file (Bin_dir/apachectl).**
   You must change the paths from the Apache defaults to match your Apache directory structure. For example, change the line in the `BIN_dir/apachectl`
script beginning with \texttt{HTTPD=/usr/local/apache/bin/httpd} to the following.
\texttt{HTTPD='\$\texttt{HTTPD} -f /global/foo/apache/conf/httpd.conf'}

6. Perform the following tasks to verify your configuration changes.
   
a. Run \texttt{apachectl configtest} to check the Apache \texttt{httpd.conf} file for correct syntax.

b. Ensure that any logical hostnames or shared addresses that Apache uses are configured and online.

c. Issue \texttt{apachectl start} to start up your Apache server by hand.  
   If Apache does not start up correctly, correct the problem.

d. After Apache has started, stop it before moving to the next procedure.

\section*{Installing a Secure Apache Webserver}

This section provides procedures for installing a secure Apache webserver. For procedures for installing a non-secure Apache webserver, see “Installing a Non-Secure Apache Webserver” on page 17.

\subsection*{How to Install and Configure the Apache Software Using mod_ssl}

This procedure installs a secure version of the Apache webserver. For procedures for installing a non-secure Apache webserver, see “Installing a Non-Secure Apache Webserver” on page 17.

\textbf{Steps}  

1. Become superuser on a cluster member.

2. Install the Apache software, including \texttt{mod_ssl}.
   
   To install \texttt{mod_ssl}, see the Apache installation documentation or the installation instructions at \url{http://www.modssl.org}.

3. Update the \texttt{httpd.conf} configuration file.
   
   - Set the \texttt{ServerName} directive.
   - Set the \texttt{BindAddress} directive (optional).
   - Set the \texttt{ServerType}, \texttt{ServerRoot}, \texttt{DocumentRoot}, \texttt{ScriptAlias}, and \texttt{LockFile} directives.
   - Set the \texttt{Port} directive to the same number as the \texttt{Port_list} standard resource property. See Step 4 for more information.
   - Make changes to run as a proxy server if you choose to run the Apache software as a proxy server. See the Apache documentation for more information. If you will run the Apache software as a proxy server, the \texttt{CacheRoot} setting must
point to a location on the cluster file system.

4. Verify that the port number or numbers in the httpd.conf file match those of the Port_list standard resource property.
   You can edit the httpd.conf configuration file to change its port number or numbers to match the standard Sun Cluster resource property default (port 80). Alternatively, while you configure Sun Cluster HA for Apache, you can set the Port_list standard property to match the setting in the httpd.conf file.

5. Install all certificates and keys.

6. In Bin_dir directory, create a file called keypass. Make sure that no one other than the owner has any permissions for this file.
   
   ```
   # cd Bin_dir
   # touch keypass
   # chmod 700 keypass
   ```

7. If you are using encrypted private key(s), perform the following Step a and Step b.
   
   a. In the httpd.conf file, look for SSLPassPhraseDialog directive and modify it as follows.

   ```
   # SSLPassPhraseDialog exec:/Bin_dir/keypass
   ```
   See the mod_ssl documentation for details about the SSLPassPhraseDialog directive.

   b. Edit the keypass file so that it prints the pass phrase for the encrypted key corresponding to a host and a port.
   This file will be called with server:port algorithm as arguments. Make sure that the file can print the pass phrase for each of your encrypted keys when called with the correct parameters.
   Later, when you attempt to start the webserver manually, it must not prompt you for a pass phrase. For example, for a secure webserver listening on ports 8080 and 8888, with private keys for both encrypted using RSA, the keypass file could be the following.

   ```
   # !/bin/ksh
   host='echo $1 | cut -d: -f1'
   port='echo $1 | cut -d: -f2'
   algorithm=$2

   if [ "$host" = "button-1-eng.sun.com" -a "$algorithm" = "RSA" ]; then
     case "Port" in
     8080) echo passphrase-for-8080;;
     8888) echo passphrase-for-8888;;
     esac
   fi
   ```
8. In the httpd.conf file, set the SSLLogLevel to warn to avoid logging a message every time the webserver is probed by Sun Cluster HA for Apache.

SSLLogLevel warn

9. Update the paths in the Apache start/stop script file (Bin_dir/apachectl).
   You must change the paths from the Apache defaults to match your Apache directory structure.

10. Perform the following tasks to verify your configuration changes.
    a. Run apachectl configtest to check the Apache httpd.conf file for correct syntax.
    b. Ensure that any logical hostnames or shared addresses that Apache uses are configured and online.
    c. Issue apachectl start to start up your Apache server by hand.
       Make sure that the webserver does not ask you for a passphrase.
       If Apache does not start up correctly, correct the problem.
    d. After Apache has started, stop it before moving to the next procedure.

▼ How to Install and Configure the Apache Software Using apache-ssl

This procedure installs a secure version of the Apache webserver. For procedures for installing a non-secure Apache webserver, see "Installing a Non-Secure Apache Webserver" on page 17.

Steps

1. Become superuser on a cluster member.

2. Install the Apache software, including apache-ssl, using the installation procedures found in the Apache installation documentation.
   To install apache-ssl, see the Apache installation documentation or the installation instructions at http://www.apache-ssl.org.

3. Update the httpd.conf configuration file.
   - Set the ServerName directive.
   - Set the BindAddress directive (optional).
- Set the `ServerType`, `ServerRoot`, `DocumentRoot`, `ScriptAlias`, and `LockFile` directives.
- Set the `Port` directive to the same number as the `Port_list` standard resource property. See Step 4 for more information.
- Make changes to run as a proxy server if you choose to run the Apache software as a proxy server. See the Apache documentation for more information. If you will run the Apache software as a proxy server, the `CacheRoot` setting must point to a location on the cluster file system.

4. Verify that the port number or numbers in the `httpd.conf` file match those of the `Port_list` standard resource property.
   
   You can edit the `httpd.conf` configuration file to change its port number or numbers to match the standard Sun Cluster resource property default (port 80). Alternatively, while you configure Sun Cluster HA for Apache, you can set the `Port_list` standard property to match the setting in the `httpd.conf` file.

5. Install all certificates and keys.

6. Make sure that all your private keys are stored unencrypted.
   
   Later, when you attempt to start the webserver manually, it must not prompt you for a pass phrase.

7. Update the paths in the Apache start/stop script file (`Bin_dir/httpsdctl`).
   
   You must change the paths from the Apache defaults to match your Apache directory structure.

8. Perform the following tasks to verify your configuration changes.
   
   a. Run `httpsdctl configtest` to check the Apache `httpd.conf` file for correct syntax.
   
   b. Ensure that any logical hostnames or shared addresses that Apache uses are configured and online.
   
   c. Issue `httpsdctl start` to start up your Apache server by hand.
      
      If Apache does not start up correctly, correct the problem.
   
   d. After Apache has started, stop it before moving to the next procedure.

**Next Steps**

If you did not install the Sun Cluster HA for Apache during your initial Sun Cluster installation, go to “Installing Sun Cluster HA for Apache Packages” on page 24. Otherwise, go to “Registering and Configuring Sun Cluster HA for Apache” on page 26.
Installing Sun Cluster HA for Apache Packages

If you did not install the Sun Cluster HA for Apache packages during your initial Sun Cluster installation, perform this procedure to install the packages. Perform this procedure on each cluster node where you are installing the Sun Cluster HA for Apache packages. To complete this procedure, you need the Sun Cluster Agents CD.

If you are installing more than one data service simultaneously, perform the procedure in “Installing the Software” in Sun Cluster Software Installation Guide for Solaris OS.

Install the Sun Cluster HA for Apache packages by using one of the following installation tools:

- The Web Start program
- The scinstall utility

Note – If you are using Solaris 10, install these packages only in the global zone. To ensure that these packages are not propagated to any local zones that are created after you install the packages, use the scinstall utility to install these packages. Do not use the Web Start program.

▼ How to Install Sun Cluster HA for Apache Packages by Using the Web Start Program

You can run the Web Start program with a command-line interface (CLI) or with a graphical user interface (GUI). The content and sequence of instructions in the CLI and the GUI are similar. For more information about the Web Start program, see the installer(1M) man page.

**Steps**

1. On the cluster node where you are installing the Sun Cluster HA for Apache packages, become superuser.
2. (Optional) If you intend to run the Web Start program with a GUI, ensure that your DISPLAY environment variable is set.
3. Insert the Sun Cluster Agents CD into the CD-ROM drive.
   
   If the Volume Management daemon vold(1M) is running and configured to manage CD-ROM devices, it automatically mounts the CD-ROM on the /cdrom/cdrom0 directory.
4. Change to the Sun Cluster HA for Apache component directory of the CD-ROM.
The Web Start program for the Sun Cluster HA for Apache data service resides in this directory.

```
# cd /cdrom/cdrom0/components/SunCluster_HA_Apache_3.1
```

5. Start the Web Start program.

```
# ./installer
```

6. When you are prompted, select the type of installation.
   - To install only the C locale, select Typical.
   - To install other locales, select Custom.

7. Follow the instructions on the screen to install the Sun Cluster HA for Apache packages on the node.

   After the installation is finished, the Web Start program provides an installation summary. This summary enables you to view logs that the Web Start program created during the installation. These logs are located in the `/var/sadm/install/logs` directory.

8. Exit the Web Start program.

9. Remove the Sun Cluster Agents CD from the CD-ROM drive.
   a. To ensure that the CD-ROM is not being used, change to a directory that does not reside on the CD-ROM.

   ```
   # eject cdrom
   ```

Next Steps  Go to “Registering and Configuring Sun Cluster HA for Apache” on page 26.

▼ How to Install Sun Cluster HA for Apache Packages by Using the `scinstall` Utility

Perform this procedure on all of the cluster members that can master Sun Cluster HA for Apache.

Before You Begin  Ensure that you have the Sun Cluster Agents CD.

Steps  1. Load the Sun Cluster Agents CD into the CD-ROM drive.

   2. Run the `scinstall` utility with no options.

   This step starts the `scinstall` utility in interactive mode.
3. Select the menu option, Add Support for New Data Service to This Cluster Node.
   The scinstall utility prompts you for additional information.

4. Provide the path to the Sun Cluster Agents CD.
   The utility refers to the CD as the “data services cd.”

5. Specify the data service to install.
   The scinstall utility lists the data service that you selected and asks you to confirm your choice.

6. Exit the scinstall utility.

7. Unload the CD from the drive.

**Next Steps**
Go to “Registering and Configuring Sun Cluster HA for Apache” on page 26.

---

**Registering and Configuring Sun Cluster HA for Apache**

This procedure describes how to use the scrgadm(1M) command to register and configure Sun Cluster HA for Apache.

You can configure Apache as a failover service or as a scalable service, as follows.

- When you configure Apache as a failover service, you place the Apache application resources and the network resources in a single resource group.
- When you configure Apache as a scalable service, you create a scalable resource group for the Apache application resources and a failover resource group for the network resources.

The scalable resource group depends on the failover resource group. Additional steps are required to configure Apache as a scalable service. The leading text “For scalable services only” in the following procedure identifies these steps. If you are not configuring Apache as a scalable service, skip the steps marked “For scalable services only.”
Setting Sun Cluster HA for Apache Extension Properties

The sections that follow contain instructions for registering and configuring Sun Cluster HA for Apache resources. For information about the extension properties, see Appendix A. The Tunable entry indicates when you can update a property.

To set an extension property of a resource, include the following option in the scrgadm(1M) command that creates or modifies the resource:

```
-x property=value
```

- `x property` Identifies the extension property that you are setting
- `value` Specifies the value to which you are setting the extension property

You can also use the procedures in Chapter 2, “Administering Data Service Resources,” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS to configure resources after the resources are created.

Monitoring Arbitrary URIs

Set the `Monitor_Uri_List` extension property if you want the web server fault monitor to probe an arbitrary list of applications (URIs) served by the web server. This extension property provides extended probing functionality and is useful if you are layering services in addition to your web server. The `Monitor_Uri_List` extension property is not supported with a secure Sun Cluster HA for Apache instance. If you do not set the `Monitor_Uri_List` extension property, the fault monitor will perform the basic probing. See “Tuning the Sun Cluster HA for Apache Fault Monitor” on page 35 for details. The following examples show how to set the `Monitor_Uri_List` extension property when you add the Sun Cluster HA for Apache instance to your configuration.

Example— Setting `Monitor_Uri_List` for Scalable Sun Cluster HA for Apache Instance

*(Add an insecure Apache instance with default load balancing.)*

```
# scrgadm -a -j apache-insecure-1 -g resource-group-1 \
-t SUNW.apache -y Network_resources_used=schost-1, ... \n- y Scalable=True -y Port_list=8000/tcp -x Bin_dir=/opt/apache/bin \
```

Installing and Configuring Sun Cluster HA for Apache
Example— Setting Monitor_Uri_List for Failover Sun Cluster HA for ApacheInstance

(Add an insecure Apache application resource instance.)

```bash
# scrgadm -a -j apache-insecure-1 -g resource-group-1 \
-t SUNW.apache -y Network_resources_used=schost-1 \
-y Scalable=False -y Port_list=80/tcp \
-x Bin_dir=/opt/apache/bin \
-x Monitor_Uri_list=http://schost-1:80/servlet/monitor
```

▼ How to Register and Configure Sun Cluster HA for Apache

**Note** – Run this procedure on any cluster member.

**Steps**

1. **Become superuser on a cluster member.**

2. **Register the resource type for the data service.**

   ```bash
   # scrgadm -a -t SUNW.apache \
   -a
   Adds the data service resource type.
   -t SUNW.apache
   Specifies the predefined resource type name for your data service.
   ```

3. **Create a failover resource group to hold the network and application resources.**
   This resource group is required for both failover and scalable services. For failover services, the resource group contains both network and failover application resources. For scalable services, the resource group contains network resources only. A dependency is created between this group and the resource group that contains the application resources.

   Optionally, you can select the set of nodes on which the data service can run with the `-h` option.

   ```bash
   # scrgadm -a -g resource-group [-h nodelist]
   -a
   Adds a new configuration.
   -g resource-group
   Specifies the name of the failover resource group to add. This name can be your choice but must be unique for the resource groups within the cluster.
   ```
[-h nodelist]
An optional comma-separated list of physical node names or IDs that identify potential masters. The order specified here determines the order in which the nodes are considered as primary during failover.

**Note** – Use -h to specify the order of the node list. If all of the nodes that are in the cluster are potential masters, you do not need to use the -h option.

4. **Verify that all of the network addresses that you use have been added to your name service database.**

You should have performed this verification during your initial Sun Cluster installation. See the planning chapter in the *Sun Cluster Software Installation Guide for Solaris OS* for details.

**Note** – To avoid failures because of name service lookup, verify that all of the network addresses are present in the `/etc/inet/hosts` file on all of the cluster nodes. Configure name service mapping in the `/etc/nsswitch.conf` file on the servers to first check the local files prior to accessing NIS, NIS+, or DNS.

5. **Add a network resource (logical hostname or shared address) to the failover resource group that you created in Step 3.**

```
# scrgadm -a {-S | -L} -g resource-group \ 
    -l hostname, ... [-j resource] \ 
    [-X auxnodelist] [-n netiflist]
```

- `-S | -L`
  The -S option specifies shared address resources. The -L option specifies logical hostname resources.

- `-l hostname, ...`
  Specifies a comma-separated list of network resources to add. You can use the -j option to specify a name for the resources. If you do not do so, the network resources have the name of the first entry on the list.

- `-g resource-group`
  Specifies the name of the failover resource group that you created in Step 3.

- `-j resource`
  Specifies a resource name. If you do not supply your choice for a resource name, the name of the network resource defaults to the first name that is specified after the -l option.

- `-X auxnodelist`
  Specifies a comma-separated list of physical node names or node IDs that identify cluster nodes that can host the shared address but never serve as

---

*Installing and Configuring Sun Cluster HA for Apache* 29
primary in the case of failover. These nodes are mutually exclusive with the nodes identified in `nodelist` for the resource group, if specified.

```
-n netiflist
```

Specifies an optional, comma-separated list that identifies the IP Networking Multipathing groups that are on each node. Each element in `netiflist` must be in the form of `netif@node`. `netif` can be given as an IP Networking Multipathing group name, such as `sc_ipmp0`. The node can be identified by the node name or node ID, such as `sc_ipmp0@1` or `sc_ipmp@phys-schost-1`.

---

**Note** – Sun Cluster does not currently support using the adapter name for `netif`.

---

6. **For scalable services only** – Create a scalable resource group to run on all of the desired cluster nodes.

If you run Sun Cluster HA for Apache as a failover data service, proceed to **Step 8**.

Create a resource group to hold a data service application resource. You must specify the maximum and desired number of primary nodes.

```
# scrgadm -a -g resource-group \
-y Maximum_primaries=m -y Desired_primaries=n \
-y RG_dependencies=resource-group \
[-h nodelist]
```

**-g resource-group**

Specifies the name of the scalable service resource group to add.

**-y Maximum_primaries=m**

Specifies the maximum number of active primary nodes allowed for this resource group. If you do not assign a value to this property, the default is 1.

**-y Desired_primaries=n**

Specifies the desired number of active primary nodes allowed for this resource group. If you do not assign a value to this property, the default is 1.
-y RG_dependencies= resource-group
Identifies the resource group that contains the shared address resource on which
the resource group being created depends, that is, the name of the failover
resource group that you created in Step 3.

-h nodelist
An optional list of nodes that can be primaries for this resource group. You only
need to specify this list if some nodes cannot act as primaries for this resource
group.

7. For scalable services only – Create an application resource in the scalable
resource group.
If you run Sun Cluster HA for Apache as a failover data service, proceed to Step 8.

# scrgadm -a -j resource -g resource-group \
-t resource-type -y Network_resources_used=network-resource, ... \
-y Port_list=port-number/protocol[, ...] -y Scalable=True \
-x Bin_dir=bin-directory, ... \n
-j resource
Specifies your choice for the name of the resource to add.

-g resource-group
Specifies the name of the scalable resource group into which the resources are to
be placed.

-t resource-type
Specifies the type of the resource to add.

-y Network_resources_used= network-resource, ...
Specifies a comma-separated list of network resource names that identify the
shared addresses that the data service uses.

-y Port_list=port-number/protocol, ...
Specifies a comma-separated list of port numbers and protocol to be used, for
example, 80/tcp, 81/tcp.

-y Scalable=
Specifies a required parameter for scalable services. This parameter must be set
to True.

-x Bin_dir=bin-directory
Specifies the location where the Apache binaries—in particular,
apachet1—are installed. Sun Cluster HA for Apache requires this extension
property.

---

Note – Optionally, you can set additional extension properties that belong to the
Apache data service to override their default values. See Appendix A for a list of
extension properties.
8. For failover services only – Create an application resource in the failover resource group.

Perform this step only if you run Sun Cluster HA for Apache as a failover data service. If you run Sun Cluster HA for Apache as a scalable data service, you should have performed Step 6 and Step 7 and should now proceed to Step 10.

```bash
# scrgadm -a -j resource -g resource-group \
-t resource-type -y Network_resources_used=network-resource, ... \
-y Port_list=port-number/protocol, ... -y Scalable=False \ 
-x Bin_dir=bin-directory
```

- `-j resource`
  Specifies your choice for the name of the resource to add.

- `-g resource-group`
  Specifies the name of the resource group into which the resources are to be placed, created in Step 3.

- `-t resource-type`
  Specifies the type of the resource to add.

- `-y Network_resources_used= network-resource, ...`
  Specifies a comma-separated list of network resources that identify the shared addresses that the data service uses.

- `-y Port_list=port-number/protocol, ...`
  Specifies a comma-separated list of port numbers and protocol to be used, for example, 80/tcp, 81/tcp.

- `-y Scalable=`
  This property is required for scalable services only. Here the value is set to False or can be omitted.

- `-x Bin_dir=bin-directory`
  Specifies the location where the Apache binaries—in particular, apachectl—are installed. Sun Cluster HA for Apache requires this extension property.

9. Bring the failover resource group online.

```bash
# scswitch -Z -g resource-group
```

- `-Z`
  Enables the shared address resource and fault monitoring, switches the resource group into a MANAGED state, and brings the resource group online.

- `-g resource-group`
  Specifies the name of the failover resource group.

10. For scalable services only – Bring the scalable resource group online.

```bash
# scswitch -Z -g resource-group
```
Enables the resource and monitor, moves the resource group to the MANAGED state, and brings the resource group online.

-g resource-group
Specifies the name of the scalable resource group.

Example 1
Registering Scalable Sun Cluster HA for Apache

For scalable services, you create the following resource groups.

- A failover resource group that contains the network resources
- A scalable resource group that contains the application resources

The following example shows how to register a scalable Apache service on a two-node cluster.

Cluster Information
Node names: phys-schost-1, phys-schost-2
Shared address: schost-1
Resource groups: resource-group-1 (for shared addresses), resource-group-2 (for scalable Apache application resources)
Resources: schost-1 (shared address), apache-1 (Apache application resource)

(Add a failover resource group to contain shared addresses.)
# scrgadm -a -g resource-group-1

(Add the shared address resource to the failover resource group.)
# scrgadm -a -S -g resource-group-1 -l schost-1

(Register the Apache resource type.)
# scrgadm -a -t SUNW.apache

(Add a scalable resource group.)
# scrgadm -a -g resource-group-2 -y Maximum_primaries=2 \
- y Desired_primaries=2 -y RG_dependencies=resource-group-1

(Add Apache application resources to the scalable resource group.)
# scrgadm -a -j apache-1 -g resource-group-2 \
- t SUNW.apache -y Network_resources_used=schost-1 \
- y Scalable=True -y Port_list=80/tcp \
- x Bin_dir=/opt/apache/bin

(Bring the failover resource group online.)
# scswitch -Z -g resource-group-1

(Bring the scalable resource group online on both nodes.)
# scswitch -Z -g resource-group-2

Example 2
Registering Failover Sun Cluster HA for Apache

The following example shows how to register a failover Apache service on a two-node cluster.
Cluster Information
Node names: phys-schost-1, phys-schost-2
Logical hostname: schost-1
Resource group: resource-group-1 (for all of the resources)
Resources: schost-1 (logical hostname),
apache-1 (Apache application resource)

(Add a failover resource group to contain all of the resources.)
# scrgadm -a -g resource-group-1

(Add the logical hostname resource to the failover resource group.)
# scrgadm -a -L -g resource-group-1 -l schost-1

(Register the Apache resource type.)
# scrgadm -a -t SUNW.apache

(Add Apache application resources to the failover resource group.)
# scrgadm -a -j apache-1 -g resource-group-1 \
 -t SUNW.apache -y Network_resources_used=schost-1 \
 -y Scalable=False -y Port_list=80/tcp \
 -x Bin_dir=/opt/apache/bin

(Bring the failover resource group online.)
# scswitch -Z -g resource-group-1

How to Configure SUNW.HAStoragePlus Resource Type

The SUNW.HAStoragePlus resource type was introduced in Sun Cluster 3.0 5/02. This new resource type performs the same functions as SUNW.HAStorage, and synchronizes actions between HA storage and the data service.

SUNW.HAStoragePlus also has an additional feature to make a local file system highly available.

See the SUNW.HAStoragePlus(5) man page and “Relationship Between Resource Groups and Disk Device Groups” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS for background information. See “Synchronizing the Startups Between Resource Groups and Disk Device Groups” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS for the procedure. (If you are using a Sun Cluster 3.0 version prior to 5/02, you must set up SUNW.HAStorage instead of SUNW.HAStoragePlus. See “Synchronizing the Startups Between Resource Groups and Disk Device Groups” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS for the procedure.)
How to Verify Data Service Installation and Configuration

After you configure Sun Cluster HA for Apache, verify that you can open a web page with the network resources (logical hostnames or shared addresses) and port number from a web browser. Perform a switchover with the `scswitch(1M)` command to verify that the service continues to run on a secondary node and can be switched back to the original primary.

Tuning the Sun Cluster HA for Apache Fault Monitor

The Sun Cluster HA for Apache fault monitor is contained in a resource whose resource type is `SUNW.apache`.

System properties and extension properties of the resource control the behavior of the fault monitor. The default values of these properties determine the preset behavior of the fault monitor. The preset behavior should be suitable for most Sun Cluster installations. Therefore, you should tune the Sun Cluster HA for Apache fault monitor only if you need to modify this preset behavior.

Tuning the Sun Cluster HA for Apache fault monitor involves the following tasks:

- Setting the interval between fault monitor probes
- Setting the timeout for fault monitor probes
- Defining the criteria for persistent faults
- Specifying the failover behavior of a resource

Information about the Sun Cluster HA for Apache fault monitor that you need to perform these tasks is provided in the subsections that follow.

Tune the Sun Cluster HA for Apache fault monitor when you register and configure Sun Cluster HA for Apache. For more information, see “Registering and Configuring Sun Cluster HA for Apache” on page 26.

For detailed information, see “Tuning Fault Monitors for Sun Cluster Data Services” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS.

Operations by the Sun Cluster HA for Apache Fault Monitor

The Sun Cluster HA for Apache probe sends a request to the server to query the health of the Apache server.
Operations by the Fault Monitor Before a Probe

Before querying the Apache server, the probe checks to confirm that network resources are configured for this Apache resource. If no network resources are configured, an error message (No network resources found for resource) is logged, and the probe exits with failure.

Operations for a Nonsecure Web Server

For a nonsecure web server, the probe connects to the Apache server and performs an HTTP 1.0 HEAD check by sending the HTTP request and receiving a response. In turn, the probe connects to the Apache server on each IP address/port combination.

The result of this query can be either a failure or a success. If the probe successfully receives a reply from the Apache server, the probe returns to its infinite loop and continues the next cycle of probing and sleeping.

The query can fail for various reasons, such as heavy network traffic, heavy system load, and misconfiguration. Misconfiguration can occur if you did not configure the Apache server to listen on all of the IP address/port combinations that are being probed. The Apache server should service every port for every IP address that is specified for this resource.

The following probe failures are considered as complete failures.

- Failure to connect to the server, as the following error message flags, with %s indicating the hostname and %d the port number.
  
  Failed to connect to %s port %d %s

- Running out of time (exceeding the resource property timeout Probe_timeout) after trying to connect to the server.

- Failure to successfully send the probe string to the server, as the following error message flags, with the first %s indicating the hostname, %d the port number, and the second %s indicating further details about the error.

  Failed to communicate with server %s port %d: %s

When the monitor accumulates two partial failures within the resource property interval Retry_interval, it counts them as one complete failure.

The following probe failures are considered as partial failures:

- Running out of time (exceeding the resource property timeout Probe_timeout) while trying to read the reply from the server to the probe’s query.

- Failing to read data from the server for other reasons, as the following error message flags, with the first %s indicating the hostname and %d the port number. The second %s indicates further details about the error.

  Failed to communicate with server %s port %d: %s
Operations for a Monitored URI List

If you have configured URIs in the `Monitor_Uri_List` extension property, then the probe connects to the Sun Cluster HA for Apache server and performs an HTTP 1.1 GET check by sending a HTTP request and receiving a response to each of the URIs in `Monitor_Uri_List`. If the HTTP server return code is 500 (Internal Server Error) or if the connect fails, the probe will take action.

The result of the HTTP requests is either failure or success. If all of the requests successfully receive a reply from the Sun Cluster HA for Apache server, the probe returns and continues the next cycle of probing and sleeping.

Heavy network traffic, heavy system load, and misconfiguration can cause the HTTP GET probe to fail. Misconfiguration of the `Monitor_Uri_List` property can cause a failure if a URI in the `Monitor_Uri_List` includes an incorrect port or hostname. For example, if the web server instance is listening on logical host `schost-1` and the URI was specified as `http://schost-2/servlet/monitor`, the probe will try to contact `schost-2` to request `/servlet/monitor`.

Operations for a Secure Web Server

For a secure web server, the probe connects to each IP address and port combination. If this connection attempt succeeds, the probe disconnects and returns with a success status. No further checks are performed.

Actions in Response to Faults

Based on the history of failures, a failure can cause either a local restart or a failover of the data service. For detailed information, see “Tuning Fault Monitors for Sun Cluster Data Services” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS.

Upgrading the SUNW.apache Resource Type

Upgrade the SUNW.apache resource type if the following conditions apply:

- You are upgrading from an earlier version of the Sun Cluster HA for Apache data service.
- You need to use the new features of this data service.
For general instructions that explain how to upgrade a resource type, see “Upgrading a Resource Type” in Sun Cluster Data Services Planning and Administration Guide for Solaris OS. The information that you require to complete the upgrade of the SUNW.apache resource type is provided in the subsections that follow.

Information for Registering the New Resource Type Version

The relationship between a resource type version and the release of Sun Cluster data services is shown in the following table. The release of Sun Cluster data services indicates the release in which the version of the resource type was introduced.

<table>
<thead>
<tr>
<th>Resource Type Version</th>
<th>Sun Cluster Data Services Release</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.0</td>
</tr>
<tr>
<td>3.1</td>
<td>3.1 5/03</td>
</tr>
<tr>
<td>4</td>
<td>3.1 10/03</td>
</tr>
</tbody>
</table>

To determine the version of the resource type that is registered, use one command from the following list:

- `scrgadm -p`
- `scrgadm -pv`

The resource type registration (RTR) file for this resource type is `/opt/SUNWscapc/etc/SUNW.apache`.

Information for Migrating Existing Instances of the Resource Type

The information that you require to edit each instance of the SUNW.apache resource type is as follows:

- You can perform the migration at any time.
- If you need to use the new features of the Sun Cluster HA for Apache data service, the required value of the Type_version property is 4.
- If you need to monitor deployed applications, set the Monitor_Uri_List extension property to a single URI or a list of URIs to specify the locations of the applications that are to be probed.

The following example shows a command for modifying an instance of the SUNW.apache resource type.
EXAMPLE 3 Migrating Instances of the SUNW.apache Resource Type

# scrgadm -c -j apache-rs -y Type_version=4 \
   -x Monitor_URI_List=http://schost-1/test.html

This command modifies the SUNW.apache resource named apache-rs as follows:

- The Type_version property of this resource is set to 4.
- The Fault Monitor probe will monitor the URI http://schost-1/test.html.
Sun Cluster HA for Apache Extension Properties

This section describes the extension properties for the resource type SUNW.apache. This resource type represents the Apache application in a Sun Cluster configuration.

For details about system-defined properties, see the r_properties(5) man page and the rg_properties(5) man page.

The extension properties of the SUNW.apache resource type are as follows:

**Bin_dir**
The path to the Apache binaries, in particular, apachect1. Sun Cluster HA for Apache requires this extension property.

<table>
<thead>
<tr>
<th>Data type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>No default defined</td>
</tr>
<tr>
<td>Range</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Tunable</td>
<td>At creation</td>
</tr>
</tbody>
</table>

**Monitor_retry_count**
The number of times that the process monitor facility (PMF) restarts the fault monitor during the time window that the Monitor_retry_interval property specifies. This property refers to restarts of the fault monitor itself rather than to the resource. The system-defined properties Retry_interval and Retry_count control restarting of the resource.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2,147,483,641</td>
</tr>
</tbody>
</table>

–1 indicates an infinite number of retry attempts.

| Tunable    | At any time           |

APPENDIX A

Sun Cluster HA for Apache Extension Properties

This section describes the extension properties for the resource type SUNW.apache. This resource type represents the Apache application in a Sun Cluster configuration.

For details about system-defined properties, see the r_properties(5) man page and the rg_properties(5) man page.

The extension properties of the SUNW.apache resource type are as follows:

**Bin_dir**
The path to the Apache binaries, in particular, apachect1. Sun Cluster HA for Apache requires this extension property.

<table>
<thead>
<tr>
<th>Data type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>No default defined</td>
</tr>
<tr>
<td>Range</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Tunable</td>
<td>At creation</td>
</tr>
</tbody>
</table>

**Monitor_retry_count**
The number of times that the process monitor facility (PMF) restarts the fault monitor during the time window that the Monitor_retry_interval property specifies. This property refers to restarts of the fault monitor itself rather than to the resource. The system-defined properties Retry_interval and Retry_count control restarting of the resource.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2,147,483,641</td>
</tr>
</tbody>
</table>

–1 indicates an infinite number of retry attempts.

| Tunable    | At any time           |
Monitor_retry_interval
The time (in minutes) over which failures of the fault monitor are counted. If the
number of times that the fault monitor fails exceeds the value that is specified in the
extension property Monitor_retry_count within this period, the PMF does not
restart the fault monitor.
Data type Integer
Default 2
Range 0 – 2,147,483,641
-1 indicates an infinite retry interval.
Tunable At any time

Monitor_Uri_List
A single URI or a list of URIs that can be used by the fault monitor to probe any
deployed applications on the Sun Cluster HA for Apache Web Server. Probe
deployed applications by setting the property to one or more URIs that are serviced
by applications deployed on the Sun Cluster HA for Apache Web Server.
Introduced in release 3.1 10/03.
Data type String
Default Null
Range Not applicable
Tunable At any time

Probe_timeout
The timeout value (in seconds) that the fault monitor uses to probe an Apache
instance.
Data type Integer
Default 90
Range 0 – 2,147,483,641
Tunable At any time
