On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to $N-1$ of OFFD; OFFD(N) need not be set, but is used by the routine. On exit, the contents of OFFD are destroyed.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $DIAG(i)$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

If $JOBZ = 'N'$, WORK is not referenced.

* **INFO** (*output*)

NAME

dstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

SYNOPSIS

```
SUBROUTINE DSTEVD( JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ  
INTEGER N, LDZ, LWORK, LIWORK, INFO  
INTEGER IWORK(*)  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)  
  
SUBROUTINE DSTEVD_64( JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ  
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEVD( JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
*      [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z  
  
SUBROUTINE STEVD_64( JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dstevd(char jobz, int n, double *d, double *e, double *z, int ldz, int *info);
```

```
void dstevd_64(char jobz, long n, double *d, double *e, double *z, long ldz, long *info);
```

PURPOSE

dstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A , stored in elements 1 to $N-1$ of E ; $E(N)$ need not be set, but is used by the routine. On exit, the contents of E are destroyed.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A , with the i -th column of Z holding the eigenvector associated with $D(i)$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension ($LWORK$) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array $WORK$. If $JOBZ = 'N'$ or $N \leq 1$ then $LWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then $LWORK$ must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* **LIWORK** (*input*)

The dimension of the array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$ then $LIWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then $LIWORK$ must be at least $3+5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued

by XERBLA.

```

PURPOSE

dstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSTEVR calls SSTEGR to compute the

eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T ,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSTEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSTEVR calls SSTEGBZ and SSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

* **VU** (*input*)

See the description of VL .

* **IL** (*input*)

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

* **IU** (*input*)

See the description of IL .

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If $ABSTOL$ is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set $ABSTOL$ to $SLAMCH('Safe\ minimum')$. Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If $RANGE = 'A'$, $M = N$, and if $RANGE = 'I'$, $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of M is not known in advance and an upper bound must be used.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK $\geq 20*N$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. LIWORK $\geq 10*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

dstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE DSTEVX( JOBZ, RANGE, N, DIAG, OFFD, VL, VU, IL, IU,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dstevx(char jobz, char range, int n, double *diag, double *offd, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, double *z, int ldz, int *ifail, int *info);
```

```
void dstevx_64(char jobz, char range, long n, double *diag, double *offd, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **DIAG** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, DIAG may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **OFFD** (*input/output*)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of OFFD; OFFD(N) need not be set. On exit, OFFD may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$ABTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

* **NFOUND (output)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

* **W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge ($\text{INFO} > 0$), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

* **WORK (workspace)**

dimension(5*N)

* **IWORK2 (workspace)**

* **IFAIL (output)**

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

* **INFO (output)**

```

```
void dstsv_64(long n, long nrhs, double *l, double *d, double *subl, double *b, long ldb, long *ipiv, long *info);
```

PURPOSE

dstsv computes the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides in B.

*** L (input/output)**

REAL array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** D (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** SUBL (output)**

REAL array, dimension (N)

On exit, part of the factorization of A.

*** B (input/output)**

The columns of B contain the right hand sides.

*** LDB (input)**

The leading dimension of B as specified in a type or DIMENSION statement.

*** IPIV (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** INFO (output)**

INTEGER

```

```
void dsttrs_64(long n, long nrhs, double *l, double *d, double *subl, double *b, long ldb, long *ipiv, long *info);
```

PURPOSE

dsttrs computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** L (input)**

REAL array, dimension (N-1)

On entry, the subdiagonal elements of LL and DD.

*** D (input)**

REAL array, dimension (N)

On entry, the diagonal elements of DD.

*** SUBL (input)**

REAL array, dimension (N-2)

On entry, the second subdiagonal elements of LL.

*** B (input/output)**

REAL array, dimension

(LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

INTEGER

The leading dimension of the array B. $LDB \geq \max(1, N)$

*** IPIV (output)**

INTEGER array, dimension (N)

Details of the interchanges and block pivot. If IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1 an interchange done; If IPIV(K) < 0, 2 by 2 pivot, no interchange required.

*** INFO (output)**

INTEGER

NAME

dsvdc - (obsolete) compute the singular value decomposition of a general matrix A.

SYNOPSIS

```
SUBROUTINE DSVDC( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
INTEGER LDA, N, P, LDL, LDR, JOB, INFO  
DOUBLE PRECISION A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
  
SUBROUTINE DSVDC_64( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
INTEGER*8 LDA, N, P, LDL, LDR, JOB, INFO  
DOUBLE PRECISION A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsvdc(double *a, int lda, int n, int p, double *svals, double *e, double *lsvec, int ldl, double *rsvec, int ldr, int job, int *info);
```

```
void dsvdc_64(double *a, long lda, long n, long p, double *svals, double *e, double *lsvec, long ldl, double *rsvec, long ldr, long job, long *info);
```

ARGUMENTS

*** A (input)**

Matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows of the matrix A. $N \geq 0$.

*** P (input)**

Number of columns of the matrix A. $P \geq 0$.

*** SVALS (input/output)**

On exit, the singular values of A arranged in descending order of magnitude.

*** E (input/output)**

On exit, normally contains zero, but see INFO below.

*** LSVEC (input/output)**

On exit, the matrix of left singular vectors; not referenced if the a digit of JOB = 0.

*** LDL (input)**

Leading dimension of LSVEC as specified in a dimension or type statement. $LDL \geq \max(1, N)$.

*** RSVEC (input/output)**

On exit, the matrix of right singular vectors; not referenced if the b digit of JOB = 0.

*** LDR (input)**

Leading dimension of RSVEC as specified in a dimension or type statement. $LDR \geq \max(1, P)$.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form ab; determines operation subroutine will perform:

a = 0	do not compute the left singular vectors
a = 1	return the n left singular vectors in LSVEC
a * 2	return the first min(N,P) singular vectors in LSVEC
b = 0	do not compute the right singular vectors
b = 1	return the right singular vectors in RSVEC

*** INFO (output)**

On exit, the singular values and their corresponding singular vectors $SVALS(INFO+1)$, $SVALS(INFO+2), \dots, SVALS(\min(N, P))$ are correct. If INFO = 0 then all singular values and singular vectors are correct. The matrix B defined as $LSVECT * A * RSVEC$ is the bidiagonal matrix with S on its diagonal and E on its superdiagonal. Therefore the singular values of A and B are the same.

NAME

dswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE DSWAP( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DSWAP_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SWAP( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE SWAP_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dswap(int n, double *x, int incx, double *y, int incy);
```

```
void dswap_64(long n, double *x, long incx, double *y, long incy);
```

PURPOSE

dswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input/output)*

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x. On exit, the y vector.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dsycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

SYNOPSIS

```
SUBROUTINE DSYCON( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,  
*                IWORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER N, LDA, INFO  
INTEGER IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)  
  
SUBROUTINE DSYCON_64( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,  
*                   IWORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER*8 N, LDA, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYCON( UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],  
*               [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,) :: A  
  
SUBROUTINE SYCON_64( UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],  
*                   [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsycon(char uplo, int n, double *a, int lda, int *ipivot, double anorm, double *rcond, int *info);
```

```
void dsycon_64(char uplo, long n, double *a, long lda, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dsycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* **INFO** (*output*)

NAME

dsyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE DSYEV( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

```
SUBROUTINE DSYEV_64( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEV( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYEV_64( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],
* [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyev(char jobz, char uplo, int n, double *a, int lda, double *w, int *info);
```

```
void dsyev_64(char jobz, char uplo, long n, double *a, long lda, double *w, long *info);
```

PURPOSE

dsyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. $LDWORK \geq \max(1, 3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dsyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE DSYEVD( JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,
*                LIWORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER N, LDA, LWORK, LIWORK, INFO
INTEGER IWORK(*)
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)

SUBROUTINE DSYEVD_64( JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,
*                  LIWORK, INFO)

INTEGER*8 N, LDA, LWORK, LIWORK, INFO
INTEGER*8 IWORK(*)
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEVD( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],
*              [IWORK], [LIWORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDA, LWORK, LIWORK, INFO
INTEGER, DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE SYEVD_64( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],
*                 [IWORK], [LIWORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyevd(char jobz, char uplo, int n, double *a, int lda, double *w, int *info);
```

```
void dsyevd_64(char jobz, char uplo, long n, double *a, long lda, double *w, long *info);
```

PURPOSE

dsyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, SSYEVD needs N^{**2} more workspace than SSYEVX.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + 2*N^{**2}$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK

array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dsyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyevr(char jobz, char range, char uplo, int n, double *a, int lda, double vl, double vu, int il, int iu, double abstol, int *m, double *w, double *z, int ldz, int *isuppz, int *info);
```

```
void dsyevr_64(char jobz, char range, char uplo, long n, double *a, long lda, double vl, double vu, long il, long iu, double abstol, long *m, double *w, double *z, long ldz, long *isuppz, long *info);
```

PURPOSE

dsyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSYEVR calls SSTEGR to compute the

eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSYEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSYEVR calls SSTEGBZ and SSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the

array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

* **ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq \max(1, 26 * N)$. For optimal efficiency, LWORK $\geq (NB+6) * N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

* **LIWORK (input)**

The dimension of the array IWORK. LIWORK $\geq \max(1, 10 * N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

INTEGER(8), DIMENSION(:) :: IWORK2, IFAIL
REAL(8) :: VL, VU, ABTOL
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyevx(char jobz, char range, char uplo, int n, double *a, int lda, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, double *z, int ldz, int *ifail, int *info);
```

```
void dsyevx_64(char jobz, char range, char uplo, long n, double *a, long lda, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dsyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$ABTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (output)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

*** W (output)**

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of the array WORK. $\text{LDWORK} \geq \max(1, 8 * N)$. For optimal efficiency, $\text{LDWORK} \geq (\text{NB} + 3) * N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** IWORK2 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

dsygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

SYNOPSIS

```
SUBROUTINE DSYGS2( ITYPE, UPLO, N, A, LDA, B, LDB, INFO)

```

```
void dsygs2(int itype, char uplo, int n, double *a, int lda, double *b, int ldb, int *info);
```

```
void dsygs2_64(long itype, char uplo, long n, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dsygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U'*U$ or $L*L'$ by SPOTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized.

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B* (input)

The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

void dsygst_64(long itype, char uplo, long n, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dsgyst reduces a real symmetric-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**T}$ or $L^{**T}*A*L$.

B must have been previously factorized as $U^{**T}*U$ or $L*L^{**T}$ by SPOTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B* (input)

The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO* (output)

void dsygv(int itype, char jobz, char uplo, int n, double *a, int lda, double *b, int ldb, double *w, int *info);
```

```
void dsygv_64(long itype, char jobz, char uplo, long n, double *a, long lda, double *b, long ldb, double *w, long *info);
```

PURPOSE

dsgyv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also

positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**T*B*Z = I$; if ITYPE = 3, $Z**T*inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO \leq N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of the array WORK. $LDWORK \geq \max(1,3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* *INFO (output)*

```

```
void dsygvd_64(long itype, char jobz, char uplo, long n, double *a, long lda, double *b, long ldb, double *w, long *info);
```

PURPOSE

dsygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^T B Z = I$; if ITYPE = 3, $Z^T \text{inv}(B) Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input/output)**

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T U$ or $B = L L^T$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** *W (output)***

If INFO = 0, the eigenvalues in ascending order.

*** *WORK (workspace)***

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** *LWORK (input)***

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *IWORK (workspace)***

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** *LIWORK (input)***

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** *INFO (output)***

```

PURPOSE

dsygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrix pencil (A,B). $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

See the description of VL.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

See the description of IL.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * DLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{*T} B Z = I$; if $ITYPE = 3$, $Z^{*T} \text{inv}(B) Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, 8 * N)$. For optimal efficiency, $LWORK \geq (NB + 3) * N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

dimension(5*N)

* **IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* *INFO (output)*

NAME

dsymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE DSYMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
*             LDC)
CHARACTER * 1 SIDE, UPLO
INTEGER M, N, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE DSYMM_64( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA,
*             C, LDC)
CHARACTER * 1 SIDE, UPLO
INTEGER*8 M, N, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYMM( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER :: M, N, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, B, C

SUBROUTINE SYMM_64( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER(8) :: M, N, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsymm(char side, char uplo, int m, int n, double alpha, double *a, int lda, double *b, int ldb, double beta, double *c, int ldc);
```

```
void dsymm_64(char side, char uplo, long m, long n, double alpha, double *a, long lda, double *b, long ldb, double beta,
```

double *c, long ldc);

PURPOSE

dsymm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE (input)*

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

* *M (input)*

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N (input)*

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

*** B (input)**

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

dsymv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE DSYMV( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER N, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)

SUBROUTINE DSYMV_64( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SYMV( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,) :: A

SUBROUTINE SYMV_64( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsymv(char uplo, int n, double alpha, double *a, int lda, double *x, int incx, double beta, double *y, int incy);
```

```
void dsymv_64(char uplo, long n, double alpha, double *a, long lda, double *x, long incx, double beta, double *y, long incy);
```

PURPOSE

dsymv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

* **UPLO** (*input*)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* **N** (*input*)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* **ALPHA** (*input*)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* **A** (*input*)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

* **LDA** (*input*)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* **X** (*input*)

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* **INCX** (*input*)

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* **Y** (*input/output*)

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* **INCY** (*input*)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dsyr - perform the symmetric rank 1 operation $A := \alpha * x * x' + A$

SYNOPSIS

```
SUBROUTINE DSYR( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
INTEGER N, INCX, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), A(LDA,*)
```

```
SUBROUTINE DSYR_64( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYR( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYR_64( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyr(char uplo, int n, double alpha, double *x, int incx, double *a, int lda);
```

```
void dsyr_64(char uplo, long n, double alpha, double *x, long incx, double *a, long lda);
```

PURPOSE

dsyr performs the symmetric rank 1 operation $A := \alpha * x * x' + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

dsyr2 - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

SYNOPSIS

```
SUBROUTINE DSYR2( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
CHARACTER * 1 UPLO
INTEGER N, INCX, INCY, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*), A(LDA,*)

SUBROUTINE DSYR2_64( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)

REAL(8), DIMENSION(:, :) :: A

SUBROUTINE SYR2_64( UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyr2(char uplo, int n, double alpha, double *x, int incx, double *y, int incy, double *a, int lda);
```

```
void dsyr2_64(char uplo, long n, double alpha, double *x, long incx, double *y, long incy, double *a, long lda);
```

PURPOSE

dsyr2 performs the symmetric rank 2 operation $A := \alpha * x * y' + \alpha * y * x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

dsyr2k - perform one of the symmetric rank 2k operations $C := \alpha*A*B' + \alpha*B*A' + \beta*C$ or $C := \alpha*A*B + \alpha*B'*A + \beta*C$

SYNOPSIS

```
SUBROUTINE DSYR2K( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,
*                C, LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER N, K, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE DSYR2K_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB,
*                   BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER*8 N, K, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYR2K( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],
*              BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,*) :: A, B, C

SUBROUTINE SYR2K_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
*                  [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,*) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyr2k(char uplo, char transa, int n, int k, double alpha, double *a, int lda, double *b, int ldb, double beta, double *c, int ldc);
```

```
void dsyr2k_64(char uplo, char transa, long n, long k, double alpha, double *a, long lda, double *b, long ldb, double beta, double *c, long ldc);
```

PURPOSE

dsyr2k K performs one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA (input)*

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * B' + \alpha * B * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A * B + \alpha * B * A + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * A * B + \alpha * B * A + \beta * C$.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K (input)*

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *B (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of

the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

* **LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

* **BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

* **C (input/output)**

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

dsyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DSYRFS( UPLO, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B, LDB,

```

PURPOSE

dsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ as computed by SSYTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If **XTRUE** is the true solution corresponding to $X(j)$, **FERR(j)** is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for **RCOND**, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(3*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

dsyrk - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

SYNOPSIS

```
SUBROUTINE DSYRK( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER N, K, LDA, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), C(LDC,*)
```

```
SUBROUTINE DSYRK_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C,
*                   LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER*8 N, K, LDA, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYRK( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
*              [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, C
```

```
SUBROUTINE SYRK_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
*                  C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyrk(char uplo, char transa, int n, int k, double alpha, double *a, int lda, double beta, double *c, int ldc);
```

```
void dsyrk_64(char uplo, char transa, long n, long k, double alpha, double *a, long lda, double beta, double *c, long ldc);
```

PURPOSE

dsyrk performs one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A' * A + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * A' * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

dsysv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

INTEGER*8 IPIV(*)
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYSV( UPLO, N, NRHS, A, [LDA], IPIV, B, [LDB], [WORK],
*              [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, LWORK, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A, B

SUBROUTINE SYSV_64( UPLO, N, NRHS, A, [LDA], IPIV, B, [LDB], [WORK],
*              [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsysv(char uplo, int n, int nrhs, double *a, int lda, int *ipiv, double *b, int ldb, int *info);
```

```
void dsysv_64(char uplo, long n, long nrhs, double *a, long lda, long *ipiv, double *b, long ldb, long *info);
```

PURPOSE

dsysv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by SSYTRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D, as determined by SSYTRF. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** *LWORK* (input)**

The length of WORK. LWORK ≥ 1 , and for best performance LWORK $\geq N \cdot NB$, where NB is the optimal blocksize for SSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *INFO* (output)**

NAME

dsysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsysvx(char fact, char uplo, int n, int nrhs, double *a, int lda, double *af, int ldaf, int *ipivot, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dsysvx_64(char fact, char uplo, long n, long nrhs, double *a, long lda, double *af, long ldaf, long *ipivot, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dsysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A. The form of the factorization is

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N

lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$.

* **LDAF (input)**

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

* **B (input)**

The N-by-NRHS right hand side matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK (input)**

The length of WORK. $LDWORK \geq 3*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for SSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* *WORK2 (workspace)*

* *INFO (output)*

NAME

dsytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE DSYTD2( UPLO, N, A, LDA, D, E, TAU, INFO)

REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE SYTD2_64( UPLO, N, A, [LDA], D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:) :: D, E, TAU
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytd2(char uplo, int n, double *a, int lda, double *d, double *e, double *tau, int *info);
```

```
void dsytd2_64(char uplo, long n, double *a, long lda, double *d, double *e, double *tau, long *info);
```

PURPOSE

dsytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T A$
* $Q = T$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

On entry, the symmetric matrix A . If $UPLO = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. On exit, if $UPLO = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array TAU , represent the orthogonal matrix Q as a product of elementary reflectors; if $UPLO$

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T : $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i, i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1, i)$ if $UPLO = 'L'$.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **INFO** (*output*)

NAME

dsytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

SUBROUTINE SYTF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytf2(char uplo, int n, double *a, int lda, int *ipiv, int *info);
```

```
void dsytf2_64(char uplo, long n, double *a, long lda, long *ipiv, long *info);
```

PURPOSE

dsytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U*D*U' \quad \text{or} \quad A = L*D*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

NAME

```

```
SUBROUTINE SYTRD_64( UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],
*                   [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E, TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytrd(char uplo, int n, double *a, int lda, double *d, double *e, double *tau, int *info);
```

```
void dsytrd_64(char uplo, long n, double *a, long lda, double *d, double *e, double *tau, long *info);
```

PURPOSE

dsytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation:
 $Q^* T^* A^* Q = T$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

On entry, the symmetric matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. On exit, if $UPLO = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array TAU , represent the orthogonal matrix Q as a product of elementary reflectors; if $UPLO$

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T : $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i, i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1, i)$ if $UPLO = 'L'$.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array $WORK$. $LWORK \geq 1$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **INFO** (*output*)

NAME

dsytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE DSYTRF( UPLO, N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)

SUBROUTINE DSYTRF_64( UPLO, N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRF( UPLO, N, A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE SYTRF_64( UPLO, N, A, [LDA], IPIVOT, [WORK], [LDWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytrf(char uplo, int n, double *a, int lda, int *ipivot, int *info);
```

```
void dsytrf_64(char uplo, long n, double *a, long lda, long *ipivot, long *info);
```

PURPOSE

dsytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U*D*U^{**T} \quad \text{or} \quad A = L*D*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK ≥ 1 . For best performance LDWORK $\geq N*NB$, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

dsytri - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

SYNOPSIS

```
SUBROUTINE DSYTRI( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```

DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRI( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE SYTRI_64( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytri(char uplo, int n, double *a, int lda, int *ipivot, int *info);
```

```
void dsytri_64(char uplo, long n, double *a, long lda, long *ipivot, long *info);
```

PURPOSE

dsytri computes the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

dsytrs - solve a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSYTRF

SYNOPSIS

```

```
void dsytrs_64(char uplo, long n, long nrhs, double *a, long lda, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dsytrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dtbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE DTBCON( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, NDIAG, LDA, INFO  
INTEGER WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)  
  
SUBROUTINE DTBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND,  
*      WORK, WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, NDIAG, LDA, INFO  
INTEGER*8 WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, NDIAG, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A  
  
SUBROUTINE TBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND,  
*      [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER(8) :: N, NDIAG, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtbcon(char norm, char uplo, char diag, int n, int ndiag, double *a, int lda, double *rcond, int *info);
```

```
void dtbcon_64(char norm, char uplo, char diag, long n, long ndiag, double *a, long lda, double *rcond, long *info);
```

PURPOSE

dtbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dtbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE DTBMV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NDIAG, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTBMV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NDIAG, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBMV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NDIAG, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TBMV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NDIAG, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtbmv(char uplo, char transa, char diag, int n, int ndiag, double *a, int lda, double *y, int incy);
```

```
void dtbmv_64(char uplo, char transa, char diag, long n, long ndiag, double *a, long lda, double *y, long incy);
```

PURPOSE

dtbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  = NDIAG + 1 - J
O 10, I = MAX( 1, J - NDIAG ), J
  A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

*** Y (input/output)**

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

NAME

dtbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

SYNOPSIS

```

INTEGER(8), DIMENSION(:) :: WORK2  
REAL(8), DIMENSION(:) :: FERR, BERR, WORK  
REAL(8), DIMENSION(:, :) :: A, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtbrfs(char uplo, char transa, char diag, int n, int ndiag, int nrhs, double *a, int lda, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dtbrfs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, double *a, long lda, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dtbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. STBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($3 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dtbsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTBSV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NDIAG, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)

SUBROUTINE DTBSV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NDIAG, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBSV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NDIAG, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TBSV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NDIAG, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtbsv(char uplo, char transa, char diag, int n, int ndiag, double *a, int lda, double *y, int incy);
```

```
void dtbsv_64(char uplo, char transa, char diag, long n, long ndiag, double *a, long lda, double *y, long incy);
```

PURPOSE

dtbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
```

```
A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

dtbtrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE DTBTRS( UPLO, TRANSA, DIAG, N, NDIAG, NRHS, A, LDA, B,
*   LDB, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG

INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TBTRS( UPLO, TRANSA, DIAG, N, NDIAG, NRHS, A, [LDA], B,
*   [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B

SUBROUTINE TBTRS_64( UPLO, TRANSA, DIAG, N, NDIAG, NRHS, A, [LDA],
*   B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtbtrs(char uplo, char transa, char diag, int n, int ndiag, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dtbtrs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dtbtrs solves a triangular system of the form

where A is a triangular band matrix of order N , and B is an N -by $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* *UPLO* (input)

* *TRANSA* (input)

Specifies the form the system of equations:

* *DIAG* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NDIAG* (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A . $NDIAG \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The upper or lower triangular band matrix A , stored in the first $kd+1$ rows of A . The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* *INFO* (output)

NAME

dtgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

SYNOPSIS

```

INTEGER(8) :: N, LDA, LDB, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A, B, VL, VR
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtgevc(char side, char howmny, logical *select, int n, double *a, int lda, double *b, int ldb, double *vl, int ldvl, double *vr, int ldvr, int mm, int *m, int *info);
```

void dtgevc_64(char side, char howmny, logical *select, long n, double *a, long lda, double *b, long ldb, double *vl, long ldvl, double *vr, long ldvr, long mm, long *m, long *info);

PURPOSE

dtgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{**H} * (A - wB) = 0$$

where y^{**H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices

$$(A0, B0) = (Q*A*Z^{**H}, Q*B*Z^{**H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A.

A must be block upper triangular, with 1-by-1 and 2-by-2 diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one

eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

* **SIDE** (input)

* **HOWMNY** (input)

* **SELECT** (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE..

* **N** (input)

The order of the matrices A and B. $N \geq 0$.

* **A** (input)

The upper quasi-triangular matrix A.

* **LDA** (input)

The leading dimension of array A. $LDA \geq \max(1, N)$.

* **B (input)**

The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive elements.

* **LDB (input)**

The leading dimension of array B. $LDB \geq \max(1, N)$.

* **VL (input/output)**

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix $Q*Y$; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

* **LDVL (input)**

The leading dimension of array VL. $LDVL \geq \max(1, N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix $Z*X$; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

* **LDVR (input)**

The leading dimension of the array VR. $LDVR \geq \max(1, N)$ if SIDE = 'R' or 'B'; $LDVR \geq 1$ otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. $MM \geq M$.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

* **WORK (workspace)**

dimension($6*N$)

* **INFO (output)**

NAME

dtgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q * (A, B) * Z'$,

SYNOPSIS

```
SUBROUTINE DTGEXC( WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,

REAL(8), DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtgexc(logical wantq, logical wantz, int n, double *a, int lda, double *b, int ldb, double *q, int ldq, double *z, int ldz, int *ifst, int *ilst, int *info);
```

```
void dtgexc_64(logical wantq, logical wantz, long n, double *a, long lda, double *b, long ldb, double *q, long ldq, double *z, long ldz, long *ifst, long *ilst, long *info);
```

PURPOSE

dtgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$\begin{aligned} Q(\text{in}) * A(\text{in}) * Z(\text{in})' &= Q(\text{out}) * A(\text{out}) * Z(\text{out})' \\ Q(\text{in}) * B(\text{in}) * Z(\text{in})' &= Q(\text{out}) * B(\text{out}) * Z(\text{out})' \end{aligned}$$

ARGUMENTS

* **WANTQ** (*input*)

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* **WANTZ** (*input*)

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **Q** (*input/output*)

On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq 1$. If WANTQ = .TRUE., $LDQ \geq N$.

* **Z** (*input/output*)

On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

* **IFST** (*input/output*)

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

* **ILST** (*input/output*)

See the description of IFST.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK >= 4*N + 16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dtgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q^* (A, B) Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

SYNOPSIS

```
#include <sunperf.h>
```

```
void dtgsen(int ijob, logical wantq, logical wantz, logical *select, int n, double *a, int lda, double *b, int ldb, double *alphar, double *alphai, double *beta, double *q, int ldq, double *z, int ldz, int *m, double *pl, double *pr, double *dif, int *info);
```

```
void dtgsen_64(long ijob, logical wantq, logical wantz, logical *select, long n, double *a, long lda, double *b, long ldb, double *alphar, double *alphai,
```

double *beta, double *q, long ldq, double *z, long ldz, long *m, double *pl, double *pr, double *dif, long *info);

PURPOSE

dtgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q^*(A, B)Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

DTGSEN also computes the generalized eigenvalues

$$w(j) = (\text{ALPHAR}(j) + i*\text{ALPHAI}(j))/\text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, DTGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

* IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

* WANTQ (input)

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* WANTZ (input)

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

* N (input)

The order of the matrices A and B. $N \geq 0$.

* A (input/output)

On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

* LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* B (input/output)

On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* ALPHAR (output)

On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $\text{ALPHAR}(j) + \text{ALPHAI}(j)*i$ and $\text{BETA}(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

* ALPHAI (output)

See the description of ALPHAR.

* BETA (output)

See the description of ALPHAR.

* Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. LDQ \geq 1; and if WANTQ = .TRUE., LDQ \geq N.

*** Z (input/output)**

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. LDZ \geq 1; If WANTZ = .TRUE., LDZ \geq N.

*** M (output)**

The dimension of the specified pair of left and right eigen- spaces (deflating subspaces). $0 \leq M \leq N$.

*** PL (output)**

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. $0 < PL, PR \leq 1$. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR are not referenced.

*** PR (output)**

See the description of PL.

*** DIF (output)**

If IJOB \geq 2, DIF(1:2) store the estimates of Difu and Difl.

If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on

Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

*** WORK (workspace)**

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK \geq $4*N+16$. If IJOB = 1, 2 or 4, LWORK \geq $\text{MAX}(4*N+16, 2*M*(N-M))$. If IJOB = 3 or 5, LWORK \geq $\text{MAX}(4*N+16, 4*M*(N-M))$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. LIWORK \geq 1. If IJOB = 1, 2 or 4, LIWORK \geq N+6. If IJOB = 3 or 5, LIWORK \geq $\text{MAX}(2*M*(N-M), N+6)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

dtgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSPV from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{aligned}
 A &= \begin{matrix} & & N-K-L & K & L \\ & K & (0 & A12 & A13) \\ & L & (0 & 0 & A23) \\ M-K-L & (0 & 0 & 0 &) \end{matrix} \text{ if } M-K-L \geq 0; \\
 A &= \begin{matrix} & & N-K-L & K & L \\ & K & (0 & A12 & A13) \\ & M-K & (0 & 0 & A23) \\ & & & & \\ B &= \begin{matrix} & & N-K-L & K & L \\ L & (0 & 0 & 0 & B13) \\ P-L & (0 & 0 & 0 &) \end{matrix} \text{ if } M-K-L < 0;
 \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L ≥ 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U' * A * Q = D1 * (0 \ R), \quad V' * B * Q = D2 * (0 \ R),$$

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are "diagonal" matrices, which are of the following structures:

If M-K-L ≥ 0,

$$\begin{aligned}
 D1 &= \begin{matrix} & & K & L \\ & K & (I & 0) \\ & L & (0 & C) \\ M-K-L & (0 & 0 &) \end{matrix} \\
 D2 &= \begin{matrix} & & K & L \\ L & (0 & S) \\ P-L & (0 & 0) \\ & & & \\ (0 \ R) &= \begin{matrix} & & N-K-L & K & L \\ K & (0 & R11 & R12) & K \\ L & (0 & 0 & R22) & L \end{matrix}
 \end{matrix}
 \end{aligned}$$

where

$$\begin{aligned}
 C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\
 S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\
 C^{**2} + S^{**2} &= I. \\
 R &\text{ is stored in } A(1:K+L, N-K-L+1:N) \text{ on exit.}
 \end{aligned}$$

If M-K-L < 0,

$$\begin{aligned}
 D1 &= \begin{matrix} & & K & M-K & K+L-M \\ & K & (I & 0 & 0) \\ M-K & (0 & C & 0 &) \end{matrix} \\
 D2 &= \begin{matrix} & & K & M-K & K+L-M \\ M-K & (0 & S & 0 &) \\ K+L-M & (0 & 0 & I &) \\ P-L & (0 & 0 & 0 &) \\ & & & & \\ M-K & (0 & 0 & R22 & R23) \end{matrix}
 \end{aligned}$$

$K+L-M$ (0 0 0 R33)

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$

$C^{**2} + S^{**2} = I.$

$R = (R11 R12 R13)$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored (0 R22 R23)

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the orthogonal transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1$, $V1$, or $Q1$.

STGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$$U1' * A13 * Q1 = C1 * R1; \quad V1' * B13 * Q1 = S1 * R1,$$

where $U1$, $V1$ and $Q1$ are orthogonal matrix, and Z' is the transpose of Z . $C1$ and $S1$ are diagonal matrices satisfying

$$C1^{**2} + S1^{**2} = I,$$

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **K** (*input*)

K and L specify the subblocks in the input matrices A and B:

$A23 = A(K+1:\min(K+L, M), N-L+1:N)$ and $B13 = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by STGSJA. See Further details.

* **L** (*input*)

See the description of K .

* **A** (*input/output*)

On entry, the M -by- N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L, M))$ contains the triangular matrix R or part of R. See Purpose for details.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the P -by- N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,P)$.

* **TOLA (input)**

TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$.

* **TOLB (input)**

See the description of TOLA.

* **ALPHA (output)**

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$,

$BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = \text{diag}(C)$,

$BETA(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $ALPHA(K+L+1:N) = 0$ and

$BETA(K+L+1:N) = 0$.

* **BETA (output)**

See the description of ALPHA.

* **U (input)**

On entry, if $JOBU = 'U'$, U must contain a matrix U1 (usually the orthogonal matrix returned by SGGSPV). On exit, if $JOBU = 'I'$, U contains the orthogonal matrix U; if $JOBU = 'U'$, U contains the product $U1 * U$. If $JOBU = 'N'$, U is not referenced.

* **LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1,M)$ if $JOBU = 'U'$; $LDU \geq 1$ otherwise.

* **V (input)**

On entry, if $JOBV = 'V'$, V must contain a matrix V1 (usually the orthogonal matrix returned by SGGSPV). On exit, if $JOBV = 'I'$, V contains the orthogonal matrix V; if $JOBV = 'V'$, V contains the product $V1 * V$. If $JOBV = 'N'$, V is not referenced.

* **LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1,P)$ if $JOBV = 'V'$; $LDV \geq 1$ otherwise.

* **Q (input)**

On entry, if $JOBQ = 'Q'$, Q must contain a matrix Q1 (usually the orthogonal matrix returned by SGGSPV). On exit, if $JOBQ = 'I'$, Q contains the orthogonal matrix Q; if $JOBQ = 'Q'$, Q contains the product $Q1 * Q$. If $JOBQ = 'N'$, Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1,N)$ if $JOBQ = 'Q'$; $LDQ \geq 1$ otherwise.

* **WORK (workspace)**

dimension(2*N)

* **NCYCLE (output)**

The number of cycles required for convergence.

* **INFO (output)**

NAME

dtgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z)

void dtgsna(char job, char howmnt, logical *select, int n, double *a, int lda, double *b, int ldb, double *vl, int ldvl, double *vr, int ldvr, double *s, double *dif, int mm, int *m, int *info);
```

```
void dtgsna_64(char job, char howmnt, logical *select, long n, double *a, long lda, double *b, long ldb, double *vl, long ldvl, double *vr, long ldvr, double *s, double *dif, long mm, long *m, long *info);
```

PURPOSE

dtgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z).

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):

*** HOWMNT (input)**

*** SELECT (input)**

If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

*** N (input)**

The order of the square matrix pair (A, B). $N \geq 0$.

*** A (input)**

The upper quasi-triangular matrix A in the pair (A,B).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input)**

The upper triangular matrix B in the pair (A,B).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by STGEVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. LDVL \geq 1. If JOB = 'E' or 'B', LDVL \geq N.

*** VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. LDVR \geq 1. If JOB = 'E' or 'B', LDVR \geq N.

*** S (output)**

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

*** DIF (output)**

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

*** MM (input)**

The number of elements in the arrays S and DIF. MM \geq M.

*** M (output)**

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

*** WORK (workspace)**

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK \geq N. If JOB = 'V' or 'B' LWORK \geq $2*N*(N+2)+16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

If JOB = 'E', IWORK is not referenced.

*** INFO (output)**

```

PURPOSE

dtgsyl solves the generalized Sylvester equation:

$$\begin{aligned} A * R - L * B &= \text{scale} * C \\ D * R - L * E &= \text{scale} * F \end{aligned} \quad (1)$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). $0 \leq \text{SCALE} \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix}. \quad (2)$$

Here I_k is the identity matrix of size k and X' is the transpose of X. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If $\text{TRANS} = 'T'$, STGSYL solves the transposed system $Z'^*y = \text{scale}*b$, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * (-F) \end{aligned} \quad (3)$$

This case ($\text{TRANS} = 'T'$) is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If $\text{IJOB} \geq 1$, STGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

* **TRANS** (*input*)

* **IJOB** (*input*)

Specifies what kind of functionality to be performed.

* **M** (*input*)

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

* **N** (*input*)

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

* **A** (*input*)

The upper quasi triangular matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper quasi triangular matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **D** (*input*)

The upper triangular matrix D.

* **LDD** (*input*)

The leading dimension of the array D. $LDD \geq \max(1, M)$.

* **E** (*input*)

The upper triangular matrix E.

* **LDE** (*input*)

The leading dimension of the array E. $LDE \geq \max(1, N)$.

* **F** (*input/output*)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

* **LDF** (*input*)

The leading dimension of the array F. $LDF \geq \max(1, M)$.

* **SCALE** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

* **DIF** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

* **WORK** (*workspace*)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq 1$. If IJOB = 1 or 2 and TRANS = 'N', $LWORK \geq 2 * M * N$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

dimension(M+N+2)

* **INFO** (*output*)

NAME

dtpccon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE DTPCON( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM, UPLO, DIAG
INTEGER N, INFO
INTEGER WORK2(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(*), WORK(*)
```

```
SUBROUTINE DTPCON_64( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM, UPLO, DIAG
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: A, WORK

SUBROUTINE TPCON_64( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtpcon(char norm, char uplo, char diag, int n, double *a, double *rcond, int *info);
```

```
void dtpcon_64(char norm, char uplo, char diag, long n, double *a, double *rcond, long *info);
```

PURPOSE

dtpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dtpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A^t*x$

SYNOPSIS

```
SUBROUTINE DTPMV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
DOUBLE PRECISION A(*), Y(*)
```

```
SUBROUTINE DTPMV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
DOUBLE PRECISION A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPMV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL(8), DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPMV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL(8), DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtpmv(char uplo, char transa, char diag, int n, double *a, double *y, int incy);
```

```
void dtpmv_64(char uplo, char transa, char diag, long n, double *a, double *y, long incy);
```

PURPOSE

dtpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1,1), A(2) and A(3) contain a(1,2) and a(2,2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1,1), A(2) and A(3) contain a(2,1) and a(3,1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*abs(INCY))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dtprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

SYNOPSIS

```
SUBROUTINE DTPRFS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, X, LDX,
*      FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDB, LDX, INFO
INTEGER WORK2(*)
DOUBLE PRECISION A(*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)

SUBROUTINE DTPRFS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, X,
*      LDX, FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDB, LDX, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION A(*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPRFS( UPLO, [TRANSA], DIAG, N, NRHS, A, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: A, FERR, BERR, WORK
REAL(8), DIMENSION(:, :) :: B, X

SUBROUTINE TPRFS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: A, FERR, BERR, WORK
REAL(8), DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtprfs(char uplo, char transa, char diag, int n, int nrhs, double *a, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dtprfs_64(char uplo, char transa, char diag, long n, long nrhs, double *a, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dtprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. STPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(3*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

dtpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTPSV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
DOUBLE PRECISION A(*), Y(*)
```

```
SUBROUTINE DTPSV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
DOUBLE PRECISION A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL(8), DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPSV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL(8), DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtpsv(char uplo, char transa, char diag, int n, double *a, double *y, int incy);
```

```
void dtpsv_64(char uplo, char transa, char diag, long n, double *a, double *y, long incy);
```

PURPOSE

dtpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*abs(INCY))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dtptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE DTPTRI( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, INFO
DOUBLE PRECISION A(*)
```

```
SUBROUTINE DTPTRI_64( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, INFO
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: A
```

```
SUBROUTINE TPTRI_64( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtptri(char uplo, char diag, int n, double *a, int *info);
```

```
void dtptri_64(char uplo, char diag, long n, double *a, long *info);
```

PURPOSE

dtptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

* *INFO* (*output*)

NAME

dtptrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE DTPTRS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDB, INFO
DOUBLE PRECISION A(*), B(LDB,*)
```

```
SUBROUTINE DTPTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDB, INFO
DOUBLE PRECISION A(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TPTRS( UPLO, TRANSA, DIAG, N, NRHS, A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: A
REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE TPTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: A
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtptrs(char uplo, char transa, char diag, int n, int nrhs, double *a, double *b, int ldb, int *info);
```

```
void dtptrs_64(char uplo, char transa, char diag, long n, long nrhs, double *a, double *b, long ldb, long *info);
```

PURPOSE

dtptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N -by- $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

dtrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE DTRANS( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
INTEGER M, N
DOUBLE PRECISION SCALE
DOUBLE PRECISION SOURCE(*), DEST(*)
```

```
SUBROUTINE DTRANS_64( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
INTEGER*8 M, N
DOUBLE PRECISION SCALE
DOUBLE PRECISION SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N
REAL(8) :: SCALE
REAL(8), DIMENSION(:) :: SOURCE, DEST
```

```
SUBROUTINE TRANS_64( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N
REAL(8) :: SCALE
REAL(8), DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrans(char place, double scale, double *source, int m, int n, double *dest);
```

```
void dtrans_64(char place, double scale, double *source, long m, long n, double *dest);
```

PURPOSE

dtrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'T' or 'i', and DEST when PLACE = 'O' or 'o'.

```
PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE '  
PLACE = 'O' or 'o': DEST = SCALE * SOURCE '
```

ARGUMENTS

* **PLACE** (*input*)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place.

* **SCALE** (*input*)

Scale factor on the SOURCE matrix.

* **SOURCE** (*input/output*)

(M, N) on input. Array of (N, M) on output if in-place transpose.

* **M** (*input*)

Number of rows in the SOURCE matrix on input.

* **N** (*input*)

Number of columns in the SOURCE matrix on input.

* **DEST** (*output*)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

dtcco - (obsolete) estimate the condition number of a triangular matrix A. It is typical to follow a call to STRCO with a call to STRSL to solve $Ax = b$ or to STRDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE DTRCO( A, LDA, N, RCOND, WORK, JOB)
INTEGER LDA, N, JOB
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DTRCO_64( A, LDA, N, RCOND, WORK, JOB)
INTEGER*8 LDA, N, JOB
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtcco(double *a, int lda, int n, double *rcond, int job);
```

```
void dtcco_64(double *a, long lda, long n, double *rcond, long job);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

If $JOB = 0$, then A is lower triangular; otherwise A is upper triangular.

NAME

dtrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE DTRCON( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
*      INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, LDA, INFO  
INTEGER WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)  
  
SUBROUTINE DTRCON_64( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, LDA, INFO  
INTEGER*8 WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,) :: A  
  
SUBROUTINE TRCON_64( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER(8) :: N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrcon(char norm, char uplo, char diag, int n, double *a, int lda, double *rcond, int *info);
```

```
void dtrcon_64(char norm, char uplo, char diag, long n, double *a, long lda, double *rcond, long *info);
```

PURPOSE

dtrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

dtrdi - (obsolete) compute the determinant and inverse of a triangular matrix A.

SYNOPSIS

```
SUBROUTINE DTRDI( A, LDA, N, DET, JOB, INFO)
INTEGER LDA, N, JOB, INFO
DOUBLE PRECISION A(LDA,*), DET(*)
```

```
SUBROUTINE DTRDI_64( A, LDA, N, DET, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
DOUBLE PRECISION A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrdi(double *a, int lda, int n, double *det, int job, int *info);
```

```
void dtrdi_64(double *a, long lda, long n, double *det, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, the inverse of the original matrix A if the inverse was requested, otherwise unchanged.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

* **N** (*input*)

Order of the original matrix A. N >= 0.

* **DET** (*output*)

On exit, the determinant of the matrix A. The determinant is stored as b * (10 ** expon) where b is stored in DET(1) and expon is stored in DET(2). 1.0 <= |DET(1)| <= 10.0 or DET(1) = 0.0.

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 010 no determinant, inverse of lower triangular A
- o 011 no determinant, inverse of upper triangular A
- o 100 determinant, no inverse

- 110 determinant, inverse of lower triangular A
- 111 determinant, inverse of upper triangular A

*** *INFO* (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Contains the index of a zero element of A if the inverse is requested and A is singular.

NAME

dtrevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

SYNOPSIS

```
SUBROUTINE DTREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrevc(char side, char howmny, logical *select, int n, double *t, int ldt, double *vl, int ldvl, double *vr, int ldvr, int mm, int *m, int *info);
```

void dtrevc_64(char side, char howmny, logical *select, long n, double *t, long ldt, double *vl, long ldvl, double *vr, long ldvr, long mm, long *m, long *info);

PURPOSE

dtrevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input orthogonal

matrix. If T was obtained from the real-Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

* **SIDE** (input)

* **HOWMNY** (input)

* **SELECT** (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex conjugate pair w(j) and w(j+1), either SELECT(j) or SELECT(j+1) must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

* **N** (input)

The order of the matrix T. N >= 0.

* **T** (input/output)

The upper quasi-triangular matrix T in Schur canonical form.

* **LDT** (input)

The leading dimension of the array T. LDT >= max(1,N).

* **VL** (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL has the same quasi-lower triangular form as T'. If T(i,i) is a real eigenvalue, then the i-th column VL(i) of VL is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VL(i)+sqrt(-1)*VL(i+1) is the complex eigenvector

corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q^*Y ; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

* **LDVL (input)**

The leading dimension of the array VL. LDVL $\geq \max(1, N)$ if SIDE = 'L' or 'B'; LDVL ≥ 1 otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then $VR(i) + \sqrt{-1} * VR(i+1)$ is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q^*X ; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR $\geq \max(1, N)$ if SIDE = 'R' or 'B'; LDVR ≥ 1 otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. MM $\geq M$.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

* **WORK (workspace)**

dimension(3*N)

* **INFO (output)**

NAME

dtrexc - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that the diagonal block of T with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE DTREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)
CHARACTER * 1 COMPQ
INTEGER N, LDT, LDQ, IFST, ILST, INFO
DOUBLE PRECISION T(LDT,*), Q(LDQ,*), WORK(*)
```

```
SUBROUTINE DTREXC_64( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK,
* INFO)
CHARACTER * 1 COMPQ
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
DOUBLE PRECISION T(LDT,*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREXC( COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
* [INFO])
CHARACTER(LEN=1) :: COMPQ
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: T, Q

SUBROUTINE TREXC_64( COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
* [INFO])
CHARACTER(LEN=1) :: COMPQ
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: T, Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrexc(char compq, int n, double *t, int ldt, double *q, int ldq, int *ifst, int *ilst, int *info);
```

```
void dtrexc_64(char compq, long n, double *t, long ldt, double *q, long ldq, long *ifst, long *ilst, long *info);
```

PURPOSE

dtrexc reorders the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation $Z^{**}T^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

* **COMPQ** (*input*)

* **N** (*input*)

The order of the matrix T . $N \geq 0$.

* **T** (*input/output*)

On entry, the upper quasi-triangular matrix T , in Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

* **LDT** (*input*)

The leading dimension of the array T . $LDT \geq \max(1, N)$.

* **Q** (*input*)

On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T . If $COMPQ = 'N'$, Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* **IFST** (*input/output*)

Specify the reordering of the diagonal blocks of T . The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). $1 \leq IFST \leq N$; $1 \leq ILST \leq N$.

* **ILST** (*input/output*)

See the description of IFST.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

dtrmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$

SYNOPSIS

```
SUBROUTINE DTRMM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*               LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)

SUBROUTINE DTRMM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*                  B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRMM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*               [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,*) :: A, B

SUBROUTINE TRMM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*                  [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrmm(char side, char uplo, char transa, char diag, int m, int n, double alpha, double *a, int lda, double *b, int ldb);
```

```
void dtrmm_64(char side, char uplo, char transa, char diag, long m, long n, double alpha, double *a, long lda, double *b, long ldb);
```

PURPOSE

dsymm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A'.$$

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, *TRANS* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' $\text{op}(A) = A$.

TRANS = 'T' or 't' $\text{op}(A) = A'$.

TRANS = 'C' or 'c' $\text{op}(A) = A'$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

* **ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

* **A (input)**

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

* **LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

* **B (input/output)**

Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

* **LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

NAME

dtrmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE DTRMV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTRMV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRMV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TRMV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrmv(char uplo, char transa, char diag, int n, double *a, int lda, double *y, int incy);
```

```
void dtrmv_64(char uplo, char transa, char diag, long n, double *a, long lda, double *y, long incy);
```

PURPOSE

dtmrv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$.

Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

dtrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

SYNOPSIS

```

```
void dtrrfs_64(char uplo, char transa, char diag, long n, long nrhs, double *a, long lda, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dtrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. STRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dtrsens - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

SYNOPSIS

#include <sunperf.h>
```

```
void dtrsens(char job, char compq, logical *select, int n, double *t, int ldt, double *q, int ldq, double *wr, double *wi, int *m, double *s, double *sep, int *info);
```

```
void dtrsens_64(char job, char compq, logical *select, long n, double *t, long ldt, double *q, long ldq, double *wr, double *wi, long *m, double *s, double *sep, long *info);
```

PURPOSE

dtrsens reorders the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

*** COMPQ (input)**

*** SELECT (input)**

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input/output)**

On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** Q (input)**

On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

*** WR (output)**

The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are stored in the same order as on the diagonal of T, with $WR(i) = T(i,i)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) > 0$ and $WI(i+1) = -WI(i)$. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

* **WI (output)**

See the description of WR.

* **M (output)**

The dimension of the specified invariant subspace. $0 < M \leq N$.

* **S (output)**

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If JOB = 'N' or 'V', S is not referenced.

* **SEP (output)**

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If $M = 0$ or N , $SEP = \text{norm}(T)$. If JOB = 'N' or 'E', SEP is not referenced.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If JOB = 'N', $LWORK \geq \max(1,N)$; if JOB = 'E', $LWORK \geq M*(N-M)$; if JOB = 'V' or 'B', $LWORK \geq 2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If JOB = 'N' or 'E', IWORK is not referenced.

* **LIWORK (input)**

The dimension of the array IWORK. If JOB = 'N' or 'E', $LIWORK \geq 1$; if JOB = 'V' or 'B', $LIWORK \geq M*(N-M)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

dtrsl - (obsolete) solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE DTRSL( A, LDA, N, B, JOB, INFO)
INTEGER LDA, N, JOB, INFO
DOUBLE PRECISION A(LDA,*), B(*)
```

```
SUBROUTINE DTRSL_64( A, LDA, N, B, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
DOUBLE PRECISION A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrsl(double *a, int lda, int n, double *b, int job, int *info);
```

```
void dtrsl_64(double *a, long lda, long n, double *b, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 00 Solve $Ax = b$, A lower triangular.
- o 01 Solve $Ax = b$, A upper triangular.
- o 10 Solve $AHx = b$, A lower triangular.
- o 11 Solve $AHx = b$, A upper triangular.

- Note that $ATx = AHx$ for real matrices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns the index of the first zero diagonal element of A.

NAME

dtrsm - solve one of the matrix equations $op(A) * X = alpha * B$, or $X * op(A) = alpha * B$

SYNOPSIS

```
SUBROUTINE DTRSM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*               LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)

SUBROUTINE DTRSM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*                  B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRSM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*              [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,*) :: A, B

SUBROUTINE TRSM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*                 [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrsm(char side, char uplo, char transa, char diag, int m, int n, double alpha, double *a, int lda, double *b, int ldb);
```

```
void dtrsm_64(char side, char uplo, char transa, char diag, long m, long n, double alpha, double *a, long lda, double *b, long
ldb);
```

PURPOSE

dtrsm solves one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A'.$$

The matrix X is overwritten on B .

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A) * X = \alpha * B$.

SIDE = 'R' or 'r' $X * \text{op}(A) = \alpha * B$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, *TRANSA* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $\text{op}(A) = A$.

TRANSA = 'T' or 't' $\text{op}(A) = A'$.

TRANSA = 'C' or 'c' $\text{op}(A) = A'$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** *A (input)***

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

*** *B (input/output)***

Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

*** *LDB (input)***

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

NAME

dtrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q^*T^*Q^{**}T$ with Q orthogonal)

SYNOPSIS

```
SUBROUTINE DTRSNA( JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrsna(char job, char howmny, logical *select, int n, double *t, int ldt, double *vl, int ldvl, double *vr, int ldvr, double *s, double *sep, int mm, int *m, int ldwork, int *info);
```

```
void dtrsna_64(char job, char howmny, logical *select, long n, double *t, long ldt, double *vl, long ldvl, double *vr, long ldvr, double *s, double *sep, long mm, long *m, long ldwork, long *info);
```

PURPOSE

dtrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q^*T^*Q^{**}T$ with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

*** HOWMNY (input)**

*** SELECT (input)**

If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input)**

The upper quasi-triangular matrix T, in Schur canonical form.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any $Q^*T^*Q^{**}T$ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

*** VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any $Q^*T^*Q^{**}T$ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

* **S** (*output*)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

* **SEP** (*output*)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

* **MM** (*input*)

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

* **M** (*output*)

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

* **WORK** (*workspace*)

If JOB = 'E', WORK is not referenced.

* **LDWORK** (*input*)

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

* **WORK1** (*workspace*)

If JOB = 'E', WORK1 is not referenced.

* **INFO** (*output*)

NAME

dtrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTRSV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTRSV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, LDA, INCY
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRSV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE TRSV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrsv(char uplo, char transa, char diag, int n, double *a, int lda, double *y, int incy);
```

```
void dtrsv_64(char uplo, char transa, char diag, long n, double *a, long lda, double *y, long incy);
```

PURPOSE

dtrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

SUBROUTINE TRSYL( TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,
*   [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE
REAL(8), DIMENSION(:, :) :: A, B, C

SUBROUTINE TRSYL_64( TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB],
*   C, [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE
REAL(8), DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrsyl(char trana, char tranb, int isgn, int m, int n, double *a, int lda, double *b, int ldb, double *c, int ldc, double *scale, int *info);
```

```
void dtrsyl_64(char trana, char tranb, long isgn, long m, long n, double *a, long lda, double *b, long ldb, double *c, long ldc,
```

double *scale, long *info);

PURPOSE

dtrsyl solves the real Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**T} , and A and B are both upper quasi-triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

A and B must be in Schur canonical form (as returned by `SHSEQR`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

* **TRANA** (*input*)

Specifies the option $\text{op}(A)$:

* **TRANB** (*input*)

Specifies the option $\text{op}(B)$:

* **ISGN** (*input*)

Specifies the sign in the equation:

* **M** (*input*)

The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

* **N** (*input*)

The order of the matrix B , and the number of columns in the matrices X and C . $N \geq 0$.

* **A** (*input*)

The upper quasi-triangular matrix A , in Schur canonical form.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper quasi-triangular matrix B , in Schur canonical form.

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, the M -by- N right hand side matrix C . On exit, C is overwritten by the solution matrix X .

* **LDC** (*input*)

The leading dimension of the array C . $LDC \geq \max(1, M)$

* **SCALE** (*output*)

The scale factor, scale , set ≤ 1 to avoid overflow in X .

** INFO (output)*

NAME

dtrti2 - compute the inverse of a real upper or lower triangular matrix

SYNOPSIS

```
SUBROUTINE DTRTI2( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DTRTI2_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE TRTI2( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TRTI2_64( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrti2(char uplo, char diag, int n, double *a, int lda, int *info);
```

```
void dtrti2_64(char uplo, char diag, long n, double *a, long lda, long *info);
```

PURPOSE

dtrti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the matrix A is upper or lower triangular.

* **DIAG** (*input*)

Specifies whether or not the matrix A is unit triangular.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dtrtri - compute the inverse of a real upper or lower triangular matrix A

SYNOPSIS

```
SUBROUTINE DTRTRI( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DTRTRI_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, LDA, INFO

void dtrtri(char uplo, char diag, int n, double *a, int lda, int *info);
```

```
void dtrtri_64(char uplo, char diag, long n, double *a, long lda, long *info);
```

PURPOSE

dtrtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular matrix A. If *UPLO* = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If *DIAG* = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

dtrtrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$.

SYNOPSIS

```
SUBROUTINE DTRTRS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)

SUBROUTINE DTRTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                   INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRTRS( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
*               [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,*) :: A, B

SUBROUTINE TRTRS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B,
*                  [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrtrs(char uplo, char transa, char diag, int n, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dtrtrs_64(char uplo, char transa, char diag, long n, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dtrtrs solves a triangular system of the form

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dtzrqf - routine is deprecated and has been replaced by routine STZRZF

SYNOPSIS

```
SUBROUTINE DTZRQF( M, N, A, LDA, TAU, INFO)
  INTEGER M, N, LDA, INFO
  DOUBLE PRECISION A(LDA,*), TAU(*)
```

```
SUBROUTINE DTZRQF_64( M, N, A, LDA, TAU, INFO)
  INTEGER*8 M, N, LDA, INFO
  DOUBLE PRECISION A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF( M, N, A, [LDA], TAU, [INFO])
  INTEGER :: M, N, LDA, INFO
  REAL(8), DIMENSION(:) :: TAU
  REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRQF_64( M, N, A, [LDA], TAU, [INFO])
  INTEGER(8) :: M, N, LDA, INFO
  REAL(8), DIMENSION(:) :: TAU
  REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtzrqf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dtzrqf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dtzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq M$.

*** A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** INFO (output)**

NAME

dtzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

SYNOPSIS

```
SUBROUTINE DTZRZF( M, N, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER M, N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DTZRZF_64( M, N, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER*8 M, N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TZRZF( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
INTEGER :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRZF_64( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtzrzf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dtzrzf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dtzrzf reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

* **M (input)**

The number of rows of the matrix A. $M \geq 0$.

* **N (input)**

The number of columns of the matrix A. $N \geq 0$.

* **A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU (output)**

The scalar factors of the elementary reflectors.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

dwiener - perform Wiener deconvolution of two signals

SYNOPSIS

```
SUBROUTINE DWIENER( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER N_POINTS, ISW, IERR
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

```
SUBROUTINE DWIENER_64( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER*8 N_POINTS, ISW, IERR
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

F95 INTERFACE

```
SUBROUTINE WIENER( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER :: N_POINTS, ISW, IERR
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

```
SUBROUTINE WIENER_64( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER(8) :: N_POINTS, ISW, IERR
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dwiener(int n_points, double *acor, double *xcor, double *fltr, double *erop, int *isw, int *ierr);
```

```
void dwiener_64(long n_points, double *acor, double *xcor, double *fltr, double *erop, long *isw, long *ierr);
```

PURPOSE

dwienr performs Wiener deconvolution of two signals.

ARGUMENTS

* *N_POINTS (input)*

On entry, the number of points in the input correlations. Unchanged on exit.

* *ACOR (input)*

On entry, autocorrelation coefficients. Unchanged on exit.

* *XCOR (input)*

On entry, cross-correlation coefficients. Unchanged on exit.

* *FLTR (output)*

On exit, filter coefficients. Unchanged on exit.

* *EROP (input)*

On exit, the prediction error.

* *ISW (output)*

On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

* *IERR (output)*

On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

NAME

dzasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZASUM( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER N, INCX
```

```
DOUBLE PRECISION FUNCTION DZASUM_64( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
REAL(8) FUNCTION ASUM_64( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dzasum(int n, doublecomplex *x, int incx);
```

```
double dzasum_64(long n, doublecomplex *x, long incx);
```

PURPOSE

dzasum Return the sum of the absolute values of the elements of x where x is an n -vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

* N (*input*)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* X (*input/output*)

$(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array X must contain the vector x . On exit, X is overwritten by the updated vector x .

* INCX (*input*)

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

NAME

dznrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZNRM2( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER N, INCX
```

```
DOUBLE PRECISION FUNCTION DZNRM2_64( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
REAL(8) FUNCTION NRM2_64( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dznrm2(int n, doublecomplex *x, int incx);
```

```
double dznrm2_64(long n, doublecomplex *x, long incx);
```

PURPOSE

dznrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

*** *N* (input)**

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X* (input)**

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX* (input)**

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NAME

ellmm, sellmm, dellmm - Ellpack format matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE SELLMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                 VAL, INDX, LDA, MAXNZ,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, K, DESCRA(5), LDA, MAXNZ,
*         LDB, LDC, LWORK
INTEGER*4  INDX(LDA,MAXNZ)
REAL*4    ALPHA, BETA
REAL*4    VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DELLMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                 VAL, INDX, LDA, MAXNZ,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, K, DESCRA(5), LDA, MAXNZ,
*         LDB, LDC, LWORK
INTEGER*4  INDX(LDA,MAXNZ)
REAL*8    ALPHA, BETA
REAL*8    VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha A B + beta C
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure

0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.
 INDX() two-dimensional integer BLDA-by-MAXBNZ array such that INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ.
 LDA leading dimension of VAL and INDX.
 MAXNZ max number of nonzeros elements per row.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least MAX(M,N).
 LWORK length of WORK array

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

ellsm, sellsm, dellsm - Ellpack format triangular solve

SYNOPSIS

```
SUBROUTINE SELLSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                VAL, INDX, LDA, MAXNZ,
*                B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
*        LDB, LDC, LWORK
INTEGER*4 INDX(LDA,MAXNZ)
REAL*4    ALPHA, BETA
REAL*4    DV(NDV), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DELLSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                VAL, INDX, LDA, MAXNZ,
*                B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
*        LDB, LDC, LWORK
INTEGER*4 INDX(LDA,MAXNZ)
REAL*8    ALPHA, BETA
REAL*8    DV(NDV), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha D inv(A) B + beta C      C <- alpha D inv(A') B + beta C
C <- alpha inv(A) D B + beta C      C <- alpha inv(A') D B + beta C
                                     ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling)

DV() Array containing the diagonal entries of the (block) diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array

DESCRA(1) matrix structure

- 0 : general
- 1 : symmetric
- 2 : Hermitian
- 3 : Triangular
- 4 : Skew(Anti-Symmetric)
- 5 : Diagonal

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.

INDX() two-dimensional integer LDA-by-MAXNZ array such INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ.

LDA leading dimension of VAL and INDX.

MAXNZ max number of nonzeros elements per row.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. LWORK should be at least MAX(M,N).

LWORK length of WORK array

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

ezfftb - computes a periodic sequence from its Fourier coefficients. EZFFTB is a simplified but slower version of RFFTB.

SYNOPSIS

```
SUBROUTINE EZFFTB( N, R, AZERO, A, B, WSAVE)
INTEGER N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)
```

```
SUBROUTINE EZFFTB_64( N, R, AZERO, A, B, WSAVE)
INTEGER*8 N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTB( [N], R, AZERO, A, B, WSAVE)
INTEGER :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE EZFFTB_64( [N], R, AZERO, A, B, WSAVE)
INTEGER(8) :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ezfftb(int n, float *r, float azero, float *a, float *b, float *wsave);
```

```
void ezfftb_64(long n, float *r, float azero, float *a, float *b, float *wsave);
```

ARGUMENTS

* ***N (input)***

Length of the sequence to be synthesized. The method is most efficient when N is the product of small primes. $N \geq 0$.

* ***R (output)***

On exit, the Fourier synthesis of the inputs.

* ***AZERO (input)***

On entry, the constant Fourier coefficient A0. Unchanged on exit.

* ***A (input/output)***

On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***B (input/output)***

On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***WSAVE (input)***

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by EZFFTI.

NAME

ezfftf - computes the Fourier coefficients of a periodic sequence. EZFFTF is a simplified but slower version of RFFTF.

SYNOPSIS

```
SUBROUTINE EZFFTF( N, R, AZERO, A, B, WSAVE)
INTEGER N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)
```

```
SUBROUTINE EZFFTF_64( N, R, AZERO, A, B, WSAVE)
INTEGER*8 N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTF( [N], R, AZERO, A, B, WSAVE)
INTEGER :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE EZFFTF_64( [N], R, AZERO, A, B, WSAVE)
INTEGER(8) :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ezfftf(int n, float *r, float azero, float *a, float *b, float *wsave);
```

```
void ezfftf_64(long n, float *r, float azero, float *a, float *b, float *wsave);
```

ARGUMENTS

* ***N (input)***

Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. $N \geq 0$.

* ***R (output)***

A real array of length N containing the sequence to be transformed. On exit, R is unchanged.

* ***AZERO (output)***

On exit, the sum from $i=1$ to $i=n$ of $r(i)/n$.

* ***A (input/output)***

On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***B (input/output)***

On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***WSAVE (input)***

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by EZFFTI.

NAME

ezfft - initializes the array WSAVE, which is used in both EZFFTF and EZFFTB.

SYNOPSIS

```
SUBROUTINE EZFFTI( N, WSAVE)
INTEGER N
REAL WSAVE(*)

SUBROUTINE EZFFTI_64( N, WSAVE)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTI( N, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE EZFFTI_64( N, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void ezfft(int n, float *wsave);

void ezfft_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array with a dimension of at least $(3 * N + 15)$. The same work array can be used for both EZFFTF and EZFFTB as long as N remains unchanged. Different WSAVE arrays are required for different values of N . This initialization does not have to be repeated between calls to EZFFTF or EZFFTB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

icamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION ICAMAX( N, X, INCX)
COMPLEX X(*)
INTEGER N, INCX
```

```
INTEGER*8 FUNCTION ICAMAX_64( N, X, INCX)
COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
INTEGER(8) FUNCTION IAMAX_64( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
int icamax(int n, complex *x, int incx);
```

```
long icamax_64(long n, complex *x, long incx);
```

PURPOSE

icamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

*** N (input)**

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** X (input)**

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

.SH NOTES If the vector contains a NaN then the result of this function is the index of a NaN in the vector. If the vector contains multiple NaNs then there is no guarantee which NaN index this function will return, but it will return the index of some NaN in the vector.

NAME

idamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION IDAMAX( N, X, INCX)
INTEGER N, INCX
DOUBLE PRECISION X(*)

INTEGER*8 FUNCTION IDAMAX_64( N, X, INCX)
INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX( [N], X, [INCX])
INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X

INTEGER(8) FUNCTION IAMAX_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

int idamax(int n, double *x, int incx);

long idamax_64(long n, double *x, long incx);
```

PURPOSE

idamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

.SH NOTES If the vector contains a NaN then the result of this function is the index of a NaN in the vector. If the vector contains multiple NaNs then there is no guarantee which NaN index this function will return, but it will return the index of some NaN in the vector.

NAME

The name of the calling subroutine, in either upper case or lower case.

SYNOPSIS

```
INTEGER FUNCTION ILAENV( ISPEC, NAME, OPTS, N1, N2, N3, N4)
CHARACTER * 1 NAME, OPTS
INTEGER ISPEC, N1, N2, N3, N4
```

```
INTEGER*8 FUNCTION ILAENV_64( ISPEC, NAME, OPTS, N1, N2, N3, N4)
CHARACTER * 1 NAME, OPTS
INTEGER*8 ISPEC, N1, N2, N3, N4
```

F95 INTERFACE

```
INTEGER FUNCTION ILAENV( ISPEC, NAME, OPTS, N1, N2, N3, N4)
CHARACTER(LEN=1) :: NAME, OPTS
INTEGER :: ISPEC, N1, N2, N3, N4
```

```
INTEGER(8) FUNCTION ILAENV_64( ISPEC, NAME, OPTS, N1, N2, N3, N4)
CHARACTER(LEN=1) :: NAME, OPTS
INTEGER(8) :: ISPEC, N1, N2, N3, N4
```

C INTERFACE

```
#include <sunperf.h>
```

```
int ilaenv(int ispec, char name, char opts, int n1, int n2, int n3, int n4);
```

```
long ilaenv_64(long ispec, char name, char opts, long n1, long n2, long n3, long n4);
```

PURPOSE

ilaenv is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See ISPEC for a description of the parameters.

This version provides a set of parameters which should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

ARGUMENTS

* *ISPEC (input)*

Specifies the parameter to be returned as the value of ILAENV.

* *NAME (input)*

The name of the calling subroutine, in either upper case or lower case.

* *OPTS (input)*

The character options to the subroutine NAME, concatenated into a single character string. For example, UPLO = 'U', TRANS = 'T', and DIAG = 'N' for a triangular routine would be specified as OPTS = 'UTN'.

* *N1 (input)*

INTEGER

* *N2 (input)*

INTEGER

* *N3 (input)*

INTEGER

* *N4 (input)*

INTEGER

N1, N2, N3, N4 are problem dimensions for the subroutine NAME; these may not all be required.

≥ 0 : the value of the parameter specified by ISPEC

< 0 : if ILAENV = -k, the k-th argument had an illegal value.

< 0 : if ILAENV = -k, the k-th argument had an illegal value.

.SH FURTHER DETAILS The following conventions have been used when calling ILAENV from the LAPACK routines:

1) OPTS is a concatenation of all of the character options to subroutine NAME, in the same order that they appear in the argument list for NAME, even if they are not used in determining the value of the parameter specified by ISPEC.

2) The problem dimensions N1, N2, N3, N4 are specified in the order that they appear in the argument list for NAME. N1 is used first, N2 second, and so on, and unused problem dimensions are passed a value of -1.

3) The parameter value returned by ILAENV is checked for validity in the calling subroutine. For example, ILAENV is used to retrieve the optimal blocksize for STRTRI as follows:

```
NB = ILAENV( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )  
IF( NB.LE.1 ) NB = MAX( 1, N )
```

NAME

isamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION ISAMAX( N, X, INCX)
INTEGER N, INCX
REAL X(*)
```

```
INTEGER*8 FUNCTION ISAMAX_64( N, X, INCX)
INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX( [N], X, [INCX])
INTEGER :: N, INCX
REAL, DIMENSION(:) :: X
```

```
INTEGER(8) FUNCTION IAMAX_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
int isamax(int n, float *x, int incx);
```

```
long isamax_64(long n, float *x, long incx);
```

PURPOSE

isamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

.SH NOTES If the vector contains a NaN then the result of this function is the index of a NaN in the vector. If the vector contains multiple NaNs then there is no guarantee which NaN index this function will return, but it will return the index of some NaN in the vector.

NAME

izamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION IZAMAX( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER N, INCX
```

```
INTEGER*8 FUNCTION IZAMAX_64( N, X, INCX)
DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
INTEGER(8) FUNCTION IAMAX_64( [N], X, [INCX])
COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
int izamax(int n, doublecomplex *x, int incx);
```

```
long izamax_64(long n, doublecomplex *x, long incx);
```

PURPOSE

izamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

*** N (input)**

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** X (input)**

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

.SH NOTES If the vector contains a NaN then the result of this function is the index of a NaN in the vector. If the vector contains multiple NaNs then there is no guarantee which NaN index this function will return, but it will return the index of some NaN in the vector.

NAME

jadmm, sjadmm, djadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

SYNOPSIS

```
SUBROUTINE SJADMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                 VAL, INDX, PNTR, MAXNZ, IPERM,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, K, DESCRA(5), MAXNZ,
*         LDB, LDC, LWORK
INTEGER*4 INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)
REAL*4    ALPHA, BETA
REAL*4    VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DJADMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                 VAL, INDX, PNTR, MAXNZ, IPERM,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, K, DESCRA(5), MAXNZ,
*         LDB, LDC, LWORK
INTEGER*4 INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)
REAL*8    ALPHA, BETA
REAL*8    VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha A B + beta C
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure

0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator (only used for
 symmetric and skew-symmetric matrices)
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() array of length NNZ consisting of entries of A.
 VAL can be viewed as a column major ordering of a
 row permutation of the Ellpack representation of A,
 where the Ellpack representation is permuted so that
 the rows are non-increasing in the number of nonzero
 entries. Values added for padding in Ellpack are
 not included in the Jagged-Diagonal format.
 INDX() array of length NNZ consisting of the column indices
 of the corresponding entries in VAL.
 PNTR() array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
 points to the location in VAL of the first element
 in the row-permuted Ellpack representation of A.
 MAXNZ max number of nonzeros elements per row.
 IPERM() integer array of length M such that $I = \text{IPERM}(I')$,
 where row I in the original Ellpack representation
 corresponds to row I' in the permuted representation.
 If $\text{IPERM}(1) = 0$, it is assumed by convention that
 $\text{IPERM}(I) = I$.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least
 $\text{MAX}(M,N)$.
 LWORK length of WORK array

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

jadrp, sjadrp, djadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
SUBROUTINE SJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                IPERM, WORK, LWORK )
INTEGER*4  TRANSP, M, K, MAXNZ, LWORK
INTEGER*4  INDX(*), PNTR(MAXNZ+1), IPERM(K)
REAL*4     VAL(*), WORK(LWORK)
SUBROUTINE DJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                IPERM, WORK, LWORK )
INTEGER*4  TRANSP, M, K, MAXNZ, LWORK
INTEGER*4  INDX(*), PNTR(MAXNZ+1), IPERM(K)
REAL*8     VAL(*), WORK(LWORK)
```

DESCRIPTION

```
A <- A P
A <- A P'
```

(' indicates matrix transpose)

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symmetrically permuted jagged diagonal matrix P A P', one can explicitly permute the columns P A by calling

```
SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP Indicates how to operate with the permutation matrix
 0 : operate with matrix
 1 : operate with transpose matrix

M Number of rows in matrix A

K Number of columns in matrix A

VAL() array of length PNTR(MAXNZ+1)-PNTR(1) consisting of
 entries of A. VAL can be viewed as a column major
 ordering of a row permutation of the Ellpack
 representation of A, where the Ellpack representation
 is permuted so that the rows are non-increasing in
 the number of nonzero entries. Values added for
 padding in Ellpack are not included in the
 Jagged-Diagonal format.

INDX() array of length PNTR(MAXNZ+1)-PNTR(1) consisting of
 the column indices of the corresponding entries in
 VAL.

PNTR() array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
 points to the location in VAL of the first element
 in the row-permuted Ellpack representation of A.

MAXNZ max number of nonzeros elements per row.

IPERM() integer array of length K such that $I = \text{IPERM}(I')$.
 Array IPERM represents a permutation P, such that
 IPERM(I) is equal to the position of the only nonzero
 element in row I of permutation matrix P.
 For example, if

$$P = \begin{vmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{vmatrix}$$

 then IPERM = (3, 2, 1).

WORK() scratch array of length LWORK. LWORK should be at
 least K.

LWORK length of WORK array
 If LWORK = -1, then a workspace query is assumed;
 the routine only calculates the optimal size of the
 WORK array, returns this value as the first entry of
 the WORK array, and no error message related to LWORK
 is issued by XERBLA.

REAL*8    ALPHA, BETA
REAL*8    DV(NDV), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha D inv(A) B + beta C      C <- alpha D inv(A') B + beta C
C <- alpha inv(A) D B + beta C      C <- alpha inv(A') D B + beta C
                                     ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling)

DV() Array containing the diagonal entries of the (block) diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array

DESCRA(1) matrix structure

- 0 : general
- 1 : symmetric
- 2 : Hermitian
- 3 : Triangular
- 4 : Skew(Anti-Symmetric)
- 5 : Diagonal

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL() array of length NNZ consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() array of length NNZ consisting of the column indices of the corresponding entries in VAL.

PNTR() array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A.

MAXNZ max number of nonzeros elements per row.

IPERM() integer array of length M such that I = IPERM(I'), where row I in the original Ellpack representation corresponds to row I' in the permuted representation.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. LWORK should be at least MAX(M,N).

LWORK length of WORK array

NAME

lsame - returns .TRUE. if CA is the same letter as CB regardless of case

SYNOPSIS

```
LOGICAL FUNCTION LSAME( CA, CB)
CHARACTER * 1 CA, CB
```

```
LOGICAL*8 FUNCTION LSAME_64( CA, CB)
CHARACTER * 1 CA, CB
```

F95 INTERFACE

```
LOGICAL FUNCTION LSAME( CA, CB)
CHARACTER(LEN=1) :: CA, CB
```

```
LOGICAL(8) FUNCTION LSAME_64( CA, CB)
CHARACTER(LEN=1) :: CA, CB
```

C INTERFACE

```
#include <sunperf.h>
```

```
logical lsame(char ca, char cb);
```

```
logical lsame_64(char ca, char cb);
```

PURPOSE

lsame returns .TRUE. if CA is the same letter as CB regardless of case.

ARGUMENTS

* *CA (input)*

On entry, CA is a single character to compare with CB. Unchanged on exit.

* *CB (input)*

On entry, CB is a single character to compare with CA. Unchanged on exit.

NAME

rfft2b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE RFFT2B( PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)
```

```
SUBROUTINE RFFT2B_64( PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER*8 M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B( PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE FFT2B_64( PLACE, [M], [N], A, [LDA], B, [LDB], WORK,
* LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft2b(char place, int m, int n, float *a, int lda, float *b, int ldb, float *work, int lwork);
```

```
void rfft2b_64(char place, long m, long n, float *a, long lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

* **PLACE** (*input*)

Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

* **M** (*input*)

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* **N** (*input*)

Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* **A** (*input/output*)

Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

* **LDA** (*input*)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2 * (M/2 + 1)$.

* **B** (*input/output*)

Real array of dimension (2*LDB, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

* **LDB** (*input*)

Integer. If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and $2 * LDB \geq 2 * (M/2 + 1)$. Otherwise it is not referenced.

* **WORK** (*input/output*)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT2I.

* **LWORK** (*input*)

Integer. $LWORK \geq (M + 2 * N + \text{MAX}(M, 2 * N) + 30)$

NAME

rfft2f - compute the Fourier coefficients of a periodic sequence. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE RFFT2F( PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)
```

```
SUBROUTINE RFFT2F_64( PLACE, FULL, M, N, A, LDA, B, LDB, WORK,
* LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER*8 M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F( PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,
* LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A, B
```

```
SUBROUTINE FFT2F_64( PLACE, FULL, [M], [N], A, [LDA], B, [LDB],
* WORK, LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft2f(char place, char full, int m, int n, float *a, int lda, float *b, int ldb, float *work, int lwork);
```

```
void rfft2f_64(char place, char full, long m, long n, float *a, long lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

* *PLACE* (input)

Character. If *PLACE* = 'I' or 'i' (for in-place), the input and output data are stored in array A. If *PLACE* = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

* *FULL* (input)

Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause RFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

* *M* (input)

Integer specifying the number of rows to be transformed. It is most efficient when *M* is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* *N* (input)

Integer specifying the number of columns to be transformed. It is most most efficient when *N* is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* *A* (input/output)

On entry, a two-dimensional array $A(LDA,N)$ that contains the data to be transformed. Upon exit, *A* is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, $A(1:(M/2+1)*2,1:N)$ will contain the transformed results. If an in-place transform with full result is requested, $A(1:2*M,1:N)$ will contain complete transformed results.

* *LDA* (input)

Leading dimension of the array containing the data to be transformed. *LDA* must be even if the transformed sequences are to be stored in *A*.

If *PLACE* = ('O' or 'o') $LDA \geq M$

If *PLACE* = ('I' or 'i') *LDA* must be even. If

FULL = ('F' or 'f'), $LDA \geq 2*M$

FULL is not ('F' or 'f'), $LDA \geq (M/2+1)*2$

* *B* (input/output)

Upon exit, a two-dimensional array $B(2*LDB,N)$ that contains the transformed results if an out-of-place transform is done. Otherwise, *B* is not used.

If an out-of-place transform is done and *FULL* is not 'F' or 'f', $B(1:(M/2+1)*2,1:N)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $B(1:2*M,1:N)$ will contain the complete transformed results.

* *LDB* (input)

$2*LDB$ is the leading dimension of the array *B*. If an in-place transform is desired *LDB* is ignored.

If *PLACE* is ('O' or 'o') and

FULL is ('F' or 'f'), $LDB \geq M$

FULL is not ('F' or 'f') and *M* is even, $LDB \geq M/2+1$

Note that even though *LDB* is used in the argument list, $2*LDB$ is the actual leading dimension of *B*.

* *WORK* (input/output)

One-dimensional real array of length at least *LWORK*. On input, *WORK* must have been initialized by RFFT2I.

* *LWORK* (input)

Integer. $LWORK \geq (M + 2*N + \text{MAX}(M, 2*N) + 30)$

NAME

rfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE RFFT2I( M, N, WORK)
INTEGER M, N
REAL WORK(*)

SUBROUTINE RFFT2I_64( M, N, WORK)
INTEGER*8 M, N
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I( M, N, WORK)
INTEGER :: M, N
REAL, DIMENSION(:) :: WORK

SUBROUTINE FFT2I_64( M, N, WORK)
INTEGER(8) :: M, N
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void rfft2i(int m, int n, float *work);

void rfft2i_64(long m, long n, float *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(M + 2*N + \text{MAX}(M, 2*N) + 30)$ or greater. RFFT2I needs to be called only once to initialize array WORK before calling RFFT2F and/or RFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

rfft3b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE RFFT3B( PLACE, M, N, K, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER M, N, K, LDA, LDB, LWORK
REAL A(LDA,N,*), B(LDB,N,*), WORK(*)
```

```
SUBROUTINE RFFT3B_64( PLACE, M, N, K, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER*8 M, N, K, LDA, LDB, LWORK
REAL A(LDA,N,*), B(LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3B( PLACE, [M], [N], [K], A, [LDA], B, [LDB], WORK,
*              LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, K, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:,:) :: A, B
```

```
SUBROUTINE FFT3B_64( PLACE, [M], [N], [K], A, [LDA], B, [LDB], WORK,
*              LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft3b(char place, int m, int n, int k, float *a, int lda, float *b, int ldb, float *work, int lwork);
```

```
void rfft3b_64(char place, long m, long n, long k, float *a, long lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

* **PLACE** (*input*)

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

* **M** (*input*)

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* **N** (*input*)

Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* **K** (*input*)

Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

* **A** (*input/output*)

On entry, the three-dimensional array $A(LDA,N,K)$ contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in $A(1:M,1:N,1:K)$.

* **LDA** (*input*)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$.

* **B** (*input/output*)

Real array of dimension $B(2*LDB,N,K)$. On entry, if an out-of-place transform is requested $B(1:2*(M/2+1),1:N,1:K)$ contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

* **LDB** (*input*)

If an out-of-place transform is desired, $2*LDB$ is the leading dimension of the array B which contains the data to be transformed and $2*LDB \geq 2*(M/2+1)$. Otherwise it is not referenced.

* **WORK** (*input/output*)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT3I.

* **LWORK** (*input*)

Integer. $LWORK \geq (M + 2*(N + K) + 4*K + 45)$.

NAME

rfft3f - compute the Fourier coefficients of a real periodic sequence. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE RFFT3F( PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,  
*               LWORK)  
CHARACTER * 1 PLACE, FULL  
INTEGER M, N, K, LDA, LDB, LWORK  
REAL A(LDA,N,*), B(LDB,N,*), WORK(*)
```

```
SUBROUTINE RFFT3F_64( PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,  
*                   LWORK)  
CHARACTER * 1 PLACE, FULL  
INTEGER*8 M, N, K, LDA, LDB, LWORK  
REAL A(LDA,N,*), B(LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F( PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],  
*               WORK, LWORK)  
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER :: M, N, K, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:,:,:) :: A, B
```

```
SUBROUTINE FFT3F_64( PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],  
*                   WORK, LWORK)  
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER(8) :: M, N, K, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft3f(char place, char full, int m, int n, int k, float *a, int lda, float *b, int ldb, float *work, int lwork);
```

```
void rfft3f_64(char place, char full, long m, long n, long k, float *a, long lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

* *PLACE (input)*

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

* *FULL (input)*

Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an $M \times N \times K$ real array will transform to produce an $M \times N \times K$ complex array. If the caller does not select full representation then an $M \times N \times K$ real array will transform to a $(M/2+1) \times N \times K$ complex array that takes advantage of the symmetry properties of a transformed real sequence.

* *M (input)*

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* *N (input)*

Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* *K (input)*

Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

* *A (input/output)*

On entry, a three-dimensional array $A(LDA, N, K)$ that contains input data to be transformed. On exit, if an in-place transform is done and *FULL* is not 'F' or 'f', $A(1:2*(M/2+1), 1:N, 1:K)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $A(1:2*M, 1:N, 1:K)$ will contain the complete transformed results.

* *LDA (input)*

Leading dimension of the array containing the data to be transformed. *LDA* must be even if the transformed sequences are to be stored in *A*.

If *PLACE* = ('O' or 'o') $LDA \geq M$

If *PLACE* = ('I' or 'i') *LDA* must be even. If

FULL = ('F' or 'f'), $LDA \geq 2*M$

FULL is not ('F' or 'f'), $LDA \geq 2*(M/2+1)$

* *B (input/output)*

Upon exit, a three-dimensional array $B(2*LDB, N, K)$ that contains the transformed results if an out-of-place transform is done. Otherwise, *B* is not used.

If an out-of-place transform is done and *FULL* is not 'F' or 'f', $B(1:2*(M/2+1), 1:N, 1:K)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $B(1:2*M, 1:N, 1:K)$ will contain the complete transformed results.

* *LDB (input)*

$2*LDB$ is the leading dimension of the array *B*. If an in-place transform is desired *LDB* is ignored.

If *PLACE* is ('O' or 'o') and

FULL is ('F' or 'f'), then $LDB \geq M$

FULL is not ('F' or 'f'), then $LDB \geq M/2 + 1$

Note that even though *LDB* is used in the argument list, $2*LDB$ is the actual leading dimension of *B*.

* *WORK (input/output)*

One-dimensional real array of length at least LWORK. WORK must have been initialized by RFFT3I.

* **LWORK** (*input*)

Integer. LWORK $\geq (M + 2*(N + K) + 4*K + 45)$.

NAME

rfft3i - initialize the array WSAVE, which is used in both RFFT3F and RFFT3B.

SYNOPSIS

```
SUBROUTINE RFFT3I( M, N, K, WORK)
INTEGER M, N, K
REAL WORK(*)

SUBROUTINE RFFT3I_64( M, N, K, WORK)
INTEGER*8 M, N, K
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3I( M, N, K, WORK)
INTEGER :: M, N, K
REAL, DIMENSION(:) :: WORK

SUBROUTINE FFT3I_64( M, N, K, WORK)
INTEGER(8) :: M, N, K
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void rfft3i(int m, int n, int k, float *work);

void rfft3i_64(long m, long n, long k, float *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***K*** (*input*)

Number of planes to be transformed. $K \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(M + 2*(N + K) + 4*K + 45)$ or greater. RFFT3I needs to be called only once to initialize array WORK before calling RFFT3F and/or RFFT3B if M, N, K and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

rfftb - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE RFFTB( N, X, WSAVE)
INTEGER N
REAL X(*), WSAVE(*)
```

```
SUBROUTINE RFFTB_64( N, X, WSAVE)
INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [N], X, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE FFTB_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfftb(int n, float *x, float *wsave);
```

```
void rfftb_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input)*

On entry, an array of length N containing the sequence to be transformed.

* *WSAVE (input)*

On entry, WSAVE must be an array of dimension $(2 * N + 15)$ or greater and must have been initialized by RFFT1.

NAME

rfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE RFFTF( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)
```

```
SUBROUTINE RFFTF_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE FFTF_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfftf(int n, float *x, float *wsave);
```

```
void rfftf_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input)*

On entry, an array of length N containing the sequence to be transformed.

* *WSAVE (input)*

On entry, WSAVE must be an array of dimension $(2 * N + 15)$ or greater and must have been initialized by RFFT1.

NAME

rffti - initialize the array WSAVE, which is used in both RFFTF and RFFTB.

SYNOPSIS

```
SUBROUTINE RFFTI( N, WSAVE)
INTEGER N
REAL WSAVE(*)

SUBROUTINE RFFTI_64( N, WSAVE)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTI( N, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE FFTI_64( N, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void rffti(int n, float *wsave);

void rffti_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. RFFTI needs to be called only once to initialize array WORK before calling RFFTF and/or RFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

rfftopt - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION RFFTOPT( LEN)
INTEGER LEN
```

```
INTEGER*8 FUNCTION RFFTOPT_64( LEN)
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION RFFTOPT( LEN)
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION RFFTOPT_64( LEN)
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int rfftopt(int len);

long rfftopt_64(long len);
```

PURPOSE

rfftopt computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*2*2*2$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

RFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. RFFTOPT will return 16 for an input of N=16 and return $18=2*3*3$ for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value

returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then $N=51$ will return 51.

ARGUMENTS

NAME

sasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
REAL FUNCTION SASUM( N, X, INCX)
INTEGER N, INCX
REAL X(*)
```

```
REAL FUNCTION SASUM_64( N, X, INCX)
INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION ASUM( [N], X, [INCX])
INTEGER :: N, INCX
REAL, DIMENSION(:) :: X
```

```
REAL FUNCTION ASUM_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sasum(int n, float *x, int incx);
```

```
float sasum_64(long n, float *x, long incx);
```

PURPOSE

sasum Return the sum of the absolute values of x where x is an n -vector.

ARGUMENTS

* N (*input*)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* X (*input/output*)

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array X must contain the vector x . On exit, X is overwritten by the updated vector x .

* INCX (*input*)

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

NAME

saxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE SAXPY( N, ALPHA, X, INCX, Y, INCY)
  INTEGER N, INCX, INCY
  REAL ALPHA
  REAL X(*), Y(*)
```

```
SUBROUTINE SAXPY_64( N, ALPHA, X, INCX, Y, INCY)
  INTEGER*8 N, INCX, INCY
  REAL ALPHA
  REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE AXPY( [N], ALPHA, X, [INCX], Y, [INCY])
  INTEGER :: N, INCX, INCY
  REAL :: ALPHA
  REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE AXPY_64( [N], ALPHA, X, [INCX], Y, [INCY])
  INTEGER(8) :: N, INCX, INCY
  REAL :: ALPHA
  REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void saxpy(int n, float alpha, float *x, int incx, float *y, int incy);
```

```
void saxpy_64(long n, float alpha, float *x, long incx, float *y, long incy);
```

PURPOSE

saxpy compute $y := \alpha * x + y$ where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

* ***N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* ***ALPHA (input)***

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* ***X (input)***

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* ***INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* ***Y (input/output)***

$(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* ***INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

sbdsdc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

SYNOPSIS

```
SUBROUTINE SBSDSDC( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ,
*   WORK, IWORK, INFO)
CHARACTER * 1 UPLO, COMPQ
INTEGER N, LDU, LDVT, INFO
INTEGER IQ(*), IWORK(*)
REAL D(*), E(*), U(LDU,*), VT(LDVT,*), Q(*), WORK(*)

SUBROUTINE SBSDSDC_64( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ,
*   WORK, IWORK, INFO)
CHARACTER * 1 UPLO, COMPQ
INTEGER*8 N, LDU, LDVT, INFO
INTEGER*8 IQ(*), IWORK(*)
REAL D(*), E(*), U(LDU,*), VT(LDVT,*), Q(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE BDSDC( UPLO, COMPQ, [N], D, E, U, [LDU], VT, [LDVT], Q,
*   IQ, [WORK], [IWORK], [INFO])
CHARACTER(LEN=1) :: UPLO, COMPQ
INTEGER :: N, LDU, LDVT, INFO
INTEGER, DIMENSION(:) :: IQ, IWORK
REAL, DIMENSION(:) :: D, E, Q, WORK
REAL, DIMENSION(:, :) :: U, VT

SUBROUTINE BDSDC_64( UPLO, COMPQ, [N], D, E, U, [LDU], VT, [LDVT],
*   Q, IQ, [WORK], [IWORK], [INFO])
CHARACTER(LEN=1) :: UPLO, COMPQ
INTEGER(8) :: N, LDU, LDVT, INFO
INTEGER(8), DIMENSION(:) :: IQ, IWORK
REAL, DIMENSION(:) :: D, E, Q, WORK
REAL, DIMENSION(:, :) :: U, VT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sbdsdc(char uplo, char compq, int n, float *d, float *e, float *u, int ldu, float *vt, int ldvt, float *q, int *iq, int *info);
```

```
void sbdsdc_64(char uplo, char compq, long n, float *d, float *e, float *u, long ldu, float *vt, long ldvt, float *q, long *iq, long *info);
```

PURPOSE

sbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = U * S * VT$, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

* **UPLO** (*input*)

* **COMPQ** (*input*)

Specifies whether singular vectors are to be computed as follows:

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

* **U** (*output*)

If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq 1$. If singular vectors are desired, then $LDU \geq \max(1, N)$.

* **VT** (*output*)

If COMPQ = 'I', then: On exit, if INFO = 0, VT contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq 1$. If singular vectors are desired, then $LDVT \geq \max(1, N)$.

* **Q** (*input*)

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2 * N^2$. In particular, Q contains all the REAL data in $LDQ \geq N * (11 + 2 * SMLSIZ + 8 * \text{INT}(\text{LOG}_2(N / (SMLSIZ + 1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other

values of COMPO, Q is not referenced.

*** IQ (output)**

If COMPO = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2 * N^2$. In particular, IQ contains all INTEGER data in LDIO $\geq N * (3 + 3 * \text{INT}(\text{LOG}_2(N/(\text{SMLSIZ}+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPO, IQ is not referenced.

*** WORK (workspace)**

If COMPO = 'N' then LWORK $\geq (2 * N)$. If COMPO = 'P' then LWORK $\geq (6 * N)$. If COMPO = 'I' then LWORK $\geq (3 * N^2 + 4 * N)$.

*** IWORK (workspace)**

dimension(8*N)

*** INFO (output)**

NAME

sbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

SYNOPSIS

```
SUBROUTINE SBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,
*      C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL D(*), E(*), VT(LDVT,*), U(LDU,*), C(LDC,*), WORK(*)

SUBROUTINE SBDSQR_64( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
*      LDU, C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL D(*), E(*), VT(LDVT,*), U(LDU,*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE BDSQR( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT, [LDVT],
*      U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: VT, U, C

SUBROUTINE BDSQR_64( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT,
*      [LDVT], U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: VT, U, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sbdsqr(char uplo, int n, int ncv, int nru, int ncc, float *d, float *e, float *vt, int ldvt, float *u, int ldu, float *c, int ldc, int *info);
```

```
void sbdsqr_64(char uplo, long n, long ncv, long nru, long ncc, float *d, float *e, float *vt, long ldvt, float *u, long ldu, float *c, long ldc, long *info);
```

PURPOSE

sbdssqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and

"Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **NCVT** (*input*)

The number of columns of the matrix VT. $NCVT \geq 0$.

* **NRU** (*input*)

The number of rows of the matrix U. $NRU \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

* **VT** (*input/output*)

On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

* **U** (*input/output*)

On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq \max(1, NRU)$.

* **C** (*input/output*)

On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

scasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
REAL FUNCTION SCASUM( N, X, INCX)
COMPLEX X(*)
INTEGER N, INCX
```

```
REAL FUNCTION SCASUM_64( N, X, INCX)
COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION ASUM( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
REAL FUNCTION ASUM_64( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
float scasum(int n, complex *x, int incx);
```

```
float scasum_64(long n, complex *x, long incx);
```

PURPOSE

scasum Return the sum of the absolute values of the elements of x where x is an n -vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

* N (*input*)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* X (*input/output*)

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array X must contain the vector x . On exit, X is overwritten by the updated vector x .

* INCX (*input*)

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

NAME

schdc - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE SCHDC( A, LDA, N, WORK, IPIVOT, JOB, INFO)
INTEGER LDA, N, JOB, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SCHDC_64( A, LDA, N, WORK, IPIVOT, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void schdc(float *a, int lda, int n, int *ipivot, int job, int *info);
```

```
void schdc_64(float *a, long lda, long n, long *ipivot, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of A. On exit, the upper triangle of the Cholesky factor, as permuted by pivoting if pivoting was selected. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **IPIVOT** (*input*)

If JOB selected no pivoting then IPIVOT is not referenced. On entry, if JOB selected pivoting, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

$IPIVOT(k) > 0$ $A(k,k)$ is an initial element.

$IPIVOT(k) = 0$ $A(k,k)$ is a free element.

$IPIVOT(k) < 0$ $A(k,k)$ is a final element.

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A . During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, $IPIVOT(k)$ contains the index of the diagonal element of A that was moved into the k th position.

*** *JOB* (input)**

Determines how decomposition is done:

- 0 without pivoting

not 0 with pivoting

*** *INFO* (output)**

On exit: Returns the index of the last positive diagonal element of the Cholesky factor. The subroutine was successful if $INFO = N$.

NAME

schdd - (obsolete) downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE SCHDD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN, INFO)
INTEGER LDA, N, LDZ, NZ, INFO
REAL A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

```
SUBROUTINE SCHDD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN,
* INFO)
INTEGER*8 LDA, N, LDZ, NZ, INFO
REAL A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void schdd(float *a, int lda, int n, float *x, float *z, int ldz, int nz, float *y, float *rho, float *cos, float *sin, int *info);
```

```
void schdd_64(float *a, long lda, long n, float *x, float *z, long ldz, long nz, float *y, float *rho, float *cos, float *sin, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been downdated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be downdated with A.

*** LDZ (input)**

Leading dimension on the array Z as specified in a dimension or type statement. $LDZ \geq \max(1, N)$.

* ***NZ (input)***

Number of vectors to be downdated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for downdating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be downdated. On exit, RHO has been downdated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input/output)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO = -1 A could not be downdated; all values are left unchanged.

INFO = 1 Some RHOs could not be downdated; all RHOs that could not be downdated are changed to -1.

NAME

schex - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE SCHEX( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
INTEGER LDA, N, K, L, LDZ, NZ, JOB
REAL A(LDA,*), Z(LDZ,*), COS(*), SIN(*)
```

```
SUBROUTINE SCHEX_64( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
INTEGER*8 LDA, N, K, L, LDZ, NZ, JOB
REAL A(LDA,*), Z(LDZ,*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void schex(float *a, int lda, int n, int k, int l, float *z, int ldz, int nz, float *cos, float *sin, int job);
```

```
void schex_64(float *a, long lda, long n, long k, long l, float *z, long ldz, long nz, float *cos, float *sin, long job);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, the upper triangle of A contains the upper triangle of the updated factor. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

* **N** (*input*)

Order of the matrix A. N \geq 0.

* **K** (*input*)

First column to be permuted. $1 \leq K \leq L$.

* **L** (*input*)

Last column to be permuted; must be strictly greater than K. $K \leq L \leq N$.

* **Z** (*input/output*)

Array of vectors into which the transformation U is multiplied. Not used if NZ = 0.

* **LDZ** (*input*)

Leading dimension of the array Z as specified in a dimension or type statement. $LDZ \geq \max(1,N)$.

* ***NZ (input)***

Number of columns in the matrix Z. $NZ \geq 0$.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***JOB (input)***

Determines the type of permutation:

- 1 right circular shift
- 2 left circular shift

NAME

schud - (obsolete) update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE SCHUD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
INTEGER LDA, N, LDZ, NZ
REAL A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

```
SUBROUTINE SCHUD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
INTEGER*8 LDA, N, LDZ, NZ
REAL A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void schud(float *a, int lda, int n, float *x, float *z, int ldz, int nz, float *y, float *rho, float *cos, float *sin);
```

```
void schud_64(float *a, long lda, long n, float *x, float *z, long ldz, long nz, float *y, float *rho, float *cos, float *sin);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangular matrix A. On exit, A has been updated. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

* **N** (*input*)

Order of the matrix A. N \geq 0.

* **X** (*input*)

Row to be added to A.

* **Z** (*input/output*)

Vectors to be updated with A.

* **LDZ** (*input*)

Leading dimension on the array Z as specified in a dimension or type statement. LDZ \geq max(1,N).

* **NZ** (*input*)

Number of vectors to be updated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for updating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be updated. On exit, RHO has been updated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (input)***

Sines of the transforming rotations.

NAME

scnrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
REAL FUNCTION SCNRM2( N, X, INCX)
COMPLEX X(*)
INTEGER N, INCX
```

```
REAL FUNCTION SCNRM2_64( N, X, INCX)
COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION NRM2( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX
```

```
REAL FUNCTION NRM2_64( [N], X, [INCX])
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
float scnrm2(int n, complex *x, int incx);
```

```
float scnrm2_64(long n, complex *x, long incx);
```

PURPOSE

scnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NAME

scnvcor - compute the convolution or correlation of real vectors

SYNOPSIS

```
SUBROUTINE SCNVCOR( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRES, M, Y,

*      M, Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK,  
*      [LWORK])  
CHARACTER(LEN=1) :: CNVCOR, FOUR  
INTEGER(8) :: NX, IFX, INCX, NY, NPRES, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK  
REAL, DIMENSION(:) :: X, Y, Z, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void scnvcor(char cnvcor, char four, int nx, float *x, int ifx, int incx, int ny, int npre, int m, float *y, int ify, int inc1y, int inc2y, int nz, int k, float *z, int ifz, int inc1z, int inc2z, float *work, int lwork);
```

```
void scnvcor_64(char cnvcor, char four, long nx, float *x, long ifx, long incx, long ny, long npre, long m, float *y, long ify, long inc1y, long inc2y, long nz, long k, float *z, long ifz, long inc1z, long inc2z, float *work, long lwork);
```

PURPOSE

scnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

* **FOUR** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

* **NX** (*input*)

Length of the filter vector. $NX \geq 0$. SCNVCOR will return immediately if $NX = 0$.

* **X** (*input*)

Filter vector.

* **IFX** (*input*)

Index of the first element of X. $NX \geq IFX \geq 1$.

* **INCX** (*input*)

Stride between elements of the filter vector in X. $INCX > 0$.

* **NY** (*input*)

Length of the input vectors. $NY \geq 0$. SCNVCOR will return immediately if $NY = 0$.

* **NPRE** (*input*)

The number of implicit zeros prepended to the Y vectors. $NPRE \geq 0$.

* **M** (*input*)

Number of input vectors. $M \geq 0$. SCNVCOR will return immediately if $M = 0$.

* **Y** (*input*)

Input vectors.

* **IFY** (*input*)

Index of the first element of Y. $NY \geq IFY \geq 1$.

* **INCIY** (*input*)

Stride between elements of the input vectors in Y. $INCIY > 0$.

* **INC2Y** (*input*)

Stride between the input vectors in Y. $INC2Y > 0$.

* **NZ** (*input*)

Length of the output vectors. $NZ \geq 0$. SCNVCOR will return immediately if $NZ = 0$. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

* **K** (*input*)

Number of Z vectors. $K \geq 0$. If $K = 0$ then SCNVCOR will return immediately. If $K < M$ then only the first K input vectors will be processed. If $K > M$ then M input vectors will be processed.

* **Z** (*output*)

Result vectors.

* **IFZ** (*input*)

Index of the first element of Z. $NZ \geq IFZ \geq 1$.

* **INCIZ** (*input*)

Stride between elements of the output vectors in Z. $INCIZ > 0$.

* **INC2Z** (*input*)

Stride between the output vectors in Z. INC2Z > 0.

* **WORK** (*input/output*)

Scratch space. Before the first call to SCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to SCNVCOR or if SCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make SCNVCOR run faster.

* **LWORK** (*input*)

Length of WORK. LWORK >= 4*MAX(NX,NY,NZ)+15. .SH NOTES If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y >= NY, INC1Z = 1, INC2Z >= NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y >= NY, INC2Y = 1, INC1Z >= NZ, and INC2Z = 1.

A common use of convolution is to compute the products of polynomials. The following code uses SCNVCOR to compute the product of $1 + 2x + 3x^2$ and $4 + 5x + 6x^2$:

NAME

scnvcor2 - compute the convolution or correlation of real matrices

SYNOPSIS

```
SUBROUTINE SCNVCOR2( CNVCOR, METHOD, TRANSX, SCRATCHX, TRANSY,  
*   SCRATCHY, MX, NX, X, LDX, MY, NY, MPRE, NPRES, Y, LDY, MZ, NZ, Z,

C INTERFACE

```
#include <sunperf.h>
```

```
void scnvcor2(char cnvcor, char method, char transx, char scratchx, char transy, char scratchy, int mx, int nx, float *x, int ldx, int my, int ny, int mpre, int npre, float *y, int ldy, int mz, int nz, float *z, int ldz, complex *workin, int lwork);
```

```
void scnvcor2_64(char cnvcor, char method, char transx, char scratchx, char transy, char scratchy, long mx, long nx, float *x, long ldx, long my, long ny, long mpre, long npre, float *y, long ldy, long mz, long nz, float *z, long ldz, complex *workin, long lwork);
```

PURPOSE

scnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

* **METHOD** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

* **TRANSX** (*input*)

'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

* **SCRATCHX** (*input*)

'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

* **TRANSY** (*input*)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

* **SCRATCHY** (*input*)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

* **MX** (*input*)

Number of rows in the filter matrix. $MX \geq 0$.

* **NX** (*input*)

Number of columns in the filter matrix. $NX \geq 0$.

* **X** (*input*)

```
dimension(LDX, NX)
```

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

* **LDX** (*input*)

Leading dimension of the array that contains the filter matrix.

* **MY (input)**

Number of rows in the input matrix. $MY \geq 0$.

* **NY (input)**

Number of columns in the input matrix. $NY \geq 0$.

* **MPRE (input)**

Number of implicit zeros to prepend to each row of the input matrix. $MPRE \geq 0$.

* **NPRE (input)**

Number of implicit zeros to prepend to each column of the input matrix. $NPRE \geq 0$.

* **Y (input)**

`dimension(LDY, *)`

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

* **LDY (input)**

Leading dimension of the array that contains the input matrix.

* **MZ (input)**

Number of rows in the output matrix. $MZ \geq 0$. SCNVCOR2 will return immediately if $MZ = 0$.

* **NZ (input)**

Number of columns in the output matrix. $NZ \geq 0$. SCNVCOR2 will return immediately if $NZ = 0$.

* **Z (output)**

`dimension(LDZ, *)`

Result matrix.

* **LDZ (input)**

Leading dimension of the array that contains the result matrix. $LDZ \geq \text{MAX}(1, MZ)$.

* **WORKIN (input/output)**

(input/scratch) `dimension(LWORK)`

On entry for the first call to SCNVCOR2, WORKIN(1) must contain 0.0. After the first call, WORKIN(1) must be set to 0.0 iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

* **LWORK (input)**

Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

NAME

scopy - Copy x to y

SYNOPSIS

```
SUBROUTINE SCOPY( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
REAL X(*), Y(*)
```

```
SUBROUTINE SCOPY_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE COPY_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void scopy(int n, float *x, int incx, float *y, int incy);
```

```
void scopy_64(long n, float *x, long incx, float *y, long incy);
```

PURPOSE

scopy Copy x to y where x and y are n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

($1 + (n - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input/output)***

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

sdisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

SYNOPSIS

```
SUBROUTINE SDISNA( JOB, M, N, D, SEP, INFO)
CHARACTER * 1 JOB
INTEGER M, N, INFO
REAL D(*), SEP(*)
```

```
SUBROUTINE SDISNA_64( JOB, M, N, D, SEP, INFO)
CHARACTER * 1 JOB
INTEGER*8 M, N, INFO
REAL D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA( JOB, M, N, D, SEP, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: M, N, INFO
REAL, DIMENSION(:) :: D, SEP
```

```
SUBROUTINE DISNA_64( JOB, M, N, D, SEP, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: M, N, INFO
REAL, DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sdisna(char job, int m, int n, float *d, float *sep, int *info);
```

```
void sdisna_64(char job, long m, long n, float *d, float *sep, long *info);
```

PURPOSE

sdisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

$$\text{SLAMCH}('E') * (\text{ANORM} / \text{SEP}(I))$$

where $\text{ANORM} = 2\text{-norm}(A) = \max(\text{abs}(D(j)))$. $\text{SEP}(I)$ is not allowed to be smaller than $\text{SLAMCH}('E') * \text{ANORM}$ in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

*** JOB (input)**

Specifies for which problem the reciprocal condition numbers should be computed:

*** M (input)**

The number of rows of the matrix. $M \geq 0$.

*** N (input)**

If JOB = 'L' or 'R', the number of columns of the matrix, in which case $N \geq 0$. Ignored if JOB = 'E'.

*** D (input)**

dimension ($\min(M,N)$) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

*** SEP (output)**

dimension ($\min(M,N)$) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

*** INFO (output)**

NAME

sdot - compute the dot product of two vectors x and y.

SYNOPSIS

```
REAL FUNCTION SDOT( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
REAL X(*), Y(*)
```

```
REAL FUNCTION SDOT_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
REAL FUNCTION DOT( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

```
REAL FUNCTION DOT_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sdot(int n, float *x, int incx, float *y, int incy);
```

```
float sdot_64(long n, float *x, long incx, float *y, long incy);
```

PURPOSE

sdot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

* *X (input)*

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input)*

(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

sdsdot - compute a constant plus the double precision dot product of two single precision vectors x and y

SYNOPSIS

```
REAL FUNCTION SDSDOT( N, SB, SX, INCX, SY, INCY)
INTEGER N, INCX, INCY
REAL SB
REAL SX(*), SY(*)
```

```
REAL FUNCTION SDSDOT_64( N, SB, SX, INCX, SY, INCY)
INTEGER*8 N, INCX, INCY
REAL SB
REAL SX(*), SY(*)
```

F95 INTERFACE

```
REAL FUNCTION SDSDOT( [N], SB, SX, [INCX], SY, [INCY])
INTEGER :: N, INCX, INCY
REAL :: SB
REAL, DIMENSION(:) :: SX, SY
```

```
REAL FUNCTION SDSDOT_64( [N], SB, SX, [INCX], SY, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL :: SB
REAL, DIMENSION(:) :: SX, SY
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sdsdot(int n, float sb, float *sx, int incx, float *sy, int incy);
```

```
float sdsdot_64(long n, float sb, float *sx, long incx, float *sy, long incy);
```

PURPOSE

sdsdot Computes a constant plus the double precision dot product of x and y where x and y are single precision n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

* *SB (input)*

On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

* *SX (input)*

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array SX must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of SX. INCX must not be zero. Unchanged on exit.

* *SY (input)*

$(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array SY must contain the vector y. Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of SY. INCY must not be zero. Unchanged on exit.

NAME

second - return the user time for a process in seconds

SYNOPSIS

```
REAL FUNCTION SECOND( )
```

```
REAL FUNCTION SECOND_64( )
```

F95 INTERFACE

```
REAL FUNCTION SECOND( )
```

```
REAL FUNCTION SECOND_64( )
```

C INTERFACE

```
#include <sunperf.h>
```

```
float second();
```

```
float second_64();
```

PURPOSE

second returns the user time for a process in seconds. This version gets the time from the system function ETIME.

ARGUMENTS

NAME

sgbbrd - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

SYNOPSIS

```
SUBROUTINE SGBBRD( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ,
* PT, LDPT, C, LDC, WORK, INFO)
CHARACTER * 1 VECT
INTEGER M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL AB(LDAB,*), D(*), E(*), Q(LDQ,*), PT(LDPT,*), C(LDC,*), WORK(*)

SUBROUTINE SGBBRD_64( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q,
* LDQ, PT, LDPT, C, LDC, WORK, INFO)
CHARACTER * 1 VECT
INTEGER*8 M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL AB(LDAB,*), D(*), E(*), Q(LDQ,*), PT(LDPT,*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBBRD( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D, E,
* Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: VECT
INTEGER :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: AB, Q, PT, C

SUBROUTINE GBBRD_64( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D,
* E, Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: VECT
INTEGER(8) :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: AB, Q, PT, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbbrd(char vect, int m, int n, int ncc, int kl, int ku, float *ab, int ldab, float *d, float *e, float *q, int ldq, float *pt, int ldpt, float *c, int ldc, int *info);
```

```
void sgbbrd_64(char vect, long m, long n, long ncc, long kl, long ku, float *ab, long ldab, float *d, float *e, float *q, long ldq, float *pt, long ldpt, float *c, long ldc, long *info);
```

PURPOSE

sgbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

* **VECT** (*input*)

Specifies whether or not the matrices Q and P' are to be formed.

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **KL** (*input*)

The number of subdiagonals of the matrix A. $KL \geq 0$.

* **KU** (*input*)

The number of superdiagonals of the matrix A. $KU \geq 0$.

* **AB** (*input/output*)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

* **D** (*output*)

The diagonal elements of the bidiagonal matrix B.

* **E** (*output*)

The superdiagonal elements of the bidiagonal matrix B.

* **Q** (*output*)

If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq \max(1,M)$ if VECT = 'Q' or 'B'; $LDQ \geq 1$ otherwise.

* **PT** (*output*)

If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

* **LDPT** (*input*)

The leading dimension of the array PT. $LDPT \geq \max(1,N)$ if VECT = 'P' or 'B'; $LDPT \geq 1$ otherwise.

* **C** (*input/output*)

On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^*C . C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

dimension($\text{MAX}(M, N)$)

* **INFO** (*output*)

NAME

sgbco - (obsolete) compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then SGBFA is slightly faster. It is typical to follow a call to SGBCO with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SGBCO( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SGBCO_64( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbco(float *a, int lda, int n, int nsub, int nsuper, int *ipivot, float *rcond);
```

```
void sgbco_64(float *a, long lda, long n, long nsub, long nsuper, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of the matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

* **NSUPER** (*input*)

Number of superdiagonals of A. $N-1 \geq \text{NSUPER} \geq 0$ but if $N = 0$ then $\text{NSUPER} = 0$.

* ***IPIVOT*** (*output*)

On exit, a vector of pivot indices.

* ***RCOND*** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* ***WORK*** (*workspace*)

Scratch array with a dimension of N.

NAME

sgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

SYNOPSIS

```
SUBROUTINE SGBCON( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER N, NSUB, NSUPER, LDA, INFO  
INTEGER IPIVOT(*), WORK2(*)  
REAL ANORM, RCOND  
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SGBCON_64( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER*8 N, NSUB, NSUPER, LDA, INFO  
INTEGER*8 IPIVOT(*), WORK2(*)  
REAL ANORM, RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,  
*      RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER :: N, NSUB, NSUPER, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, WORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GBCON_64( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT,  
*      ANORM, RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbcon(char norm, int n, int nsub, int nsuper, float *a, int lda, int *ipivot, float anorm, float *rcond, int *info);
```

```
void sgbcon_64(char norm, long n, long nsub, long nsuper, float *a, long lda, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

sgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **ANORM** (*input*)

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgbdi - (obsolete) compute the determinant of a general matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA.

SYNOPSIS

```
SUBROUTINE SGBDI( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
REAL A(LDA,*), DET(*)
```

```
SUBROUTINE SGBDI_64( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbdi(float *a, int lda, int n, int nsub, int nsuper, int *ipivot, float *det);
```

```
void sgbdi_64(float *a, long lda, long n, long nsub, long nsuper, long *ipivot, float *det);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A, as computed by SGBCO or SGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGBCO or SGBFA.

*** *DET (output)***

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

NAME

sgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE SGBEQU( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC, ROWCN,
*                COLCN, AMAX, INFO)
INTEGER M, N, NSUB, NSUPER, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), ROWSC(*), COLSC(*)
```

```
SUBROUTINE SGBEQU_64( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC,
*                   ROWCN, COLCN, AMAX, INFO)
INTEGER*8 M, N, NSUB, NSUPER, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*               ROWCN, COLCN, AMAX, [INFO])
INTEGER :: M, N, NSUB, NSUPER, LDA, INFO
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: ROWSC, COLSC
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GBEQU_64( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*                  ROWCN, COLCN, AMAX, [INFO])
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INFO
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: ROWSC, COLSC
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbequ(int m, int n, int nsub, int nsuper, float *a, int lda, float *rowsc, float *colsc, float *rowcn, float *colcn, float *amax, int *info);
```

```
void sgbequ_64(long m, long n, long nsub, long nsuper, float *a, long lda, float *rowsc, float *colsc, float *rowcn, float *colcn, float *amax, long *info);
```

PURPOSE

sgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

* **M (input)**

The number of rows of the matrix A. $M \geq 0$.

* **N (input)**

The number of columns of the matrix A. $N \geq 0$.

* **NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **A (input)**

The band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **ROWSC (output)**

If $INFO = 0$, or $INFO > M$, ROWSC contains the row scale factors for A.

* **COLSC (output)**

If $INFO = 0$, COLSC contains the column scale factors for A.

* **ROWCN (output)**

If $INFO = 0$ or $INFO > M$, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If $ROWCN \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

* **COLCN (output)**

If $INFO = 0$, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If $COLCN \geq 0.1$, it is not worth scaling by COLSC.

* **AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO (output)**

NAME

sgbfa - (obsolete) compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to SGBFA with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SGBFA( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
INTEGER LDA, N, NSUB, NSUPER, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*)
```

```
SUBROUTINE SGBFA_64( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
INTEGER*8 LDA, N, NSUB, NSUPER, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbfa(float *a, int lda, int n, int nsub, int nsuper, int *ipivot, int *info);
```

```
void sgbfa_64(float *a, long lda, long n, long nsub, long nsuper, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SGBSL will divide by zero if called.

NAME

sgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

SYNOPSIS

```
SUBROUTINE SGBMV( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
*      INCX, BETA, Y, INCY)
CHARACTER * 1 TRANSA
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)

SUBROUTINE SGBMV_64( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
*      INCX, BETA, Y, INCY)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GBMV( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
*      X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

SUBROUTINE GBMV_64( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
*      X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbmv(char transa, int m, int n, int nsub, int nsuper, float alpha, float *a, int lda, float *x, int incx, float beta, float *y, int incy);
```

void sgbmv_64(char transa, long m, long n, long nsub, long nsuper, float alpha, float *a, long lda, float *x, long incx, float beta, float *y, long incy);

PURPOSE

sgbmv performs one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$, where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha * A * x + \beta * y$.

TRANSA = 'T' or 't' $y := \alpha * A' * x + \beta * y$.

TRANSA = 'C' or 'c' $y := \alpha * A' * x + \beta * y$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

* *NSUB* (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. $NSUB \geq 0$. Unchanged on exit.

* *NSUPER* (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. $NSUPER \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NSUPER + 1 - J
      O 10, I = MAX( 1, J - NSUPER ), MIN( M, J + NSUB )
         A( K + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

* **LDA** (*input*)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (kl + ku + 1)$. Unchanged on exit.

* **X** (*input*)

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANS = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* **INCX** (*input*)

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* **Y** (*input/output*)

$(1 + (m - 1) * \text{abs}(INCY))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(INCY))$ otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* **INCY** (*input*)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

sgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SGBRFS( TRANSA, N, NSUB, NSUPER, NRHS, A, LDA, AF, LDAF,

REAL, DIMENSION(:, :) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbtrfs(char transa, int n, int nsub, int nsuper, int nrhs, float *a, int lda, float *af, int ldaf, int *ipivot, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void sgbtrfs_64(char transa, long n, long nsub, long nsuper, long nrhs, float *a, long lda, float *af, long ldaf, long *ipivot, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sgbtrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(n,j+kl)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **AF** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq 2*NSUB*NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices from SGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgbsl - (obsolete) solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SGBSL( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
INTEGER LDA, N, NSUB, NSUPER, JOB
INTEGER IPIVOT(*)
REAL A(LDA,*), B(*)
```

```
SUBROUTINE SGBSL_64( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
INTEGER*8 LDA, N, NSUB, NSUPER, JOB
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbsl(float *a, int lda, int n, int nsub, int nsuper, int *ipivot, float *b, int job);
```

```
void sgbsl_64(float *a, long lda, long n, long nsub, long nsuper, long *ipivot, float *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by SGBCO or SGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A . $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A . $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGBCO or SGBFA.

*** *B* (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** *JOB* (input)**

Determines which operation this subroutine will perform:

o 0 solve the system $Ax = b$

not 0 solve the linear system $AHx = b$
Note that $ATx = AHx$ for real matrices.

NAME

sgbsv - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

SYNOPSIS

```
SUBROUTINE SGBSV( N, NSUB, NSUPER, NRHS, A, LDA, IPIVOT, B, LDB,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbsv(int n, int nsub, int nsuper, int nrhs, float *a, int lda, int *ipivot, float *b, int ldb, int *info);
```

```
void sgbsv_64(long n, long nsub, long nsuper, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sgbsv computes the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to NSUB of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(NSUB+NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

*** IPIVOT (output)**

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

sgbsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbsvx(char fact, char transa, int n, int nsub, int nsuper, int nrhs, float *a, int lda, float *af, int ldaf, int *ipivot, char equed, float *rowsc, float *colsc, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sgbsvx_64(char fact, char transa, long n, long nsub, long nsuper, long nrhs, float *a, long lda, float *af, long ldaf, long *ipivot, char equed, float *rowsc, float *colsc, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sgbsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.
-

ARGUMENTS

* *FACT (input)*

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *TRANSA (input)*

Specifies the form of the system of equations.

* *N (input)*

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NSUB (input)*

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* *NSUPER (input)*

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* *NRHS (input)*

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A (input/output)*

On entry, the matrix A in band storage, in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUPER)$

If $FACT = 'F'$ and $EQUED$ is not 'N', then A must have been equilibrated by the scaling factors in $ROWSC$ and/or $COLSC$. A is not modified if $FACT = 'F'$ or 'N', or if $FACT = 'E'$ and $EQUED = 'N'$ on exit.

On exit, if $EQUED$.ne. 'N', A is scaled as follows: $EQUED = 'ROWSC': A := \text{diag}(ROWSC) * A$

$EQUED = 'COLSC': A := A * \text{diag}(COLSC)$

$EQUED = 'B': A := \text{diag}(ROWSC) * A * \text{diag}(COLSC)$.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* *AF (input/output)*

If $FACT = 'F'$, then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. If $EQUED$.ne. 'N', then AF is the factored form of the equilibrated matrix A.

If $FACT = 'N'$, then AF is an output argument and on exit returns details of the LU factorization of A.

If $FACT = 'E'$, then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF (input)*

The leading dimension of the array AF. $LDAF \geq 2*NSUB+NSUPER+1$.

* *IPIVOT (input)*

If $FACT = 'F'$, then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = L*U$ as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If $FACT = 'N'$, then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A.

If $FACT = 'E'$, then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A.

* *EQUED (input)*

Specifies the form of equilibration that was done.

* *ROWSC (input/output)*

The row scale factors for A. If $EQUED = 'ROWSC'$ or 'B', A is multiplied on the left by $\text{diag}(ROWSC)$; if $EQUED = 'N'$ or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if $FACT = 'F'$; otherwise, ROWSC is an output argument. If $FACT = 'F'$ and $EQUED = 'ROWSC'$ or 'B', each element of ROWSC must be positive.

* **COLSC** (*input/output*)

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by diag(COLSC); if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by diag(ROWSC)*B; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by diag(COLSC)*B.

* **LDB** (*input*)

The leading dimension of the array B. LDB >= max(1,N).

* **X** (*output*)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(COLSC))*X if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or inv(diag(ROWSC))*X if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

* **LDX** (*input*)

The leading dimension of the array X. LDX >= max(1,N).

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0 < INFO <= N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE SGBTF2( M, N, KL, KU, AB, LDAB, IPIV, INFO)
INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)
REAL AB(LDAB,*)
```

```
SUBROUTINE SGBTF2_64( M, N, KL, KU, AB, LDAB, IPIV, INFO)
INTEGER*8 M, N, KL, KU, LDAB, INFO
INTEGER*8 IPIV(*)
REAL AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTF2( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
INTEGER :: M, N, KL, KU, LDAB, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: AB
```

```
SUBROUTINE GBTF2_64( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgbtf2(int m, int n, int kl, int ku, float *ab, int ldab, int *ipiv, int *info);
```

```
void sgbtf2_64(long m, long n, long kl, long ku, float *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

sgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***KL (input)***

The number of subdiagonals within the band of A. $KL \geq 0$.

* ***KU (input)***

The number of superdiagonals within the band of A. $KU \geq 0$.

* ***AB (input/output)***

On entry, the matrix A in band storage, in rows $KL+1$ to $2*KL+KU+1$; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $KL+KU$ superdiagonals in rows 1 to $KL+KU+1$, and the multipliers used during the factorization are stored in rows $KL+KU+2$ to $2*KL+KU+1$. See below for further details.

* ***LDAB (input)***

The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

* ***IPIV (output)***

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIV(i)$.

* ***INFO (output)***

NAME

```

```
void sgbtrf_64(long m, long n, long nsub, long nsuper, float *a, long lda, long *ipivot, long *info);
```

PURPOSE

sgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIVOT(i)$.

*** INFO (output)**

NAME

```

```
void sgbtrs_64(char transa, long n, long nsub, long nsuper, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long
```

*info);

PURPOSE

sgbtrs solves a system of linear equations $A * X = B$ or $A' * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

sgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

SYNOPSIS

```
SUBROUTINE SGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
CHARACTER * 1 JOB, SIDE
INTEGER N, ILO, IHI, M, LDV, INFO
REAL SCALE(*), V(LDV,*)
```

```
SUBROUTINE SGEBAK_64( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV,
* INFO)
CHARACTER * 1 JOB, SIDE
INTEGER*8 N, ILO, IHI, M, LDV, INFO
REAL SCALE(*), V(LDV,*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: V

SUBROUTINE GEBAK_64( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: V
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgebak(char job, char side, int n, int ilo, int ihi, float *scale, int m, float *v, int ldv, int *info);
```

```
void sgebak_64(char job, char side, long n, long ilo, long ihi, float *scale, long m, float *v, long ldv, long *info);
```

PURPOSE

sgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

* ***JOB*** (*input*)

Specifies the type of backward transformation required:

* ***SIDE*** (*input*)

* ***N*** (*input*)

The number of rows of the matrix V . $N \geq 0$.

* ***ILO*** (*input*)

The integers ILO and IHI determined by SGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description for ILO .

* ***SCALE*** (*input*)

Details of the permutation and scaling factors, as returned by SGEBAL.

* ***M*** (*input*)

The number of columns of the matrix V . $M \geq 0$.

* ***V*** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

* ***LDV*** (*input*)

The leading dimension of the array V . $LDV \geq \max(1, N)$.

* ***INFO*** (*output*)

NAME

sgebal - balance a general real matrix A

SYNOPSIS

```
SUBROUTINE SGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
INTEGER N, LDA, ILO, IHI, INFO
REAL A(LDA,*), SCALE(*)
```

```
SUBROUTINE SGEBAL_64( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
INTEGER*8 N, LDA, ILO, IHI, INFO
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBAL_64( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgebal(char job, int n, float *a, int lda, int *ilo, int *ihi, float *scale, int *info);
```

```
void sgebal_64(char job, long n, float *a, long lda, long *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

sgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first I to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

* **JOB** (*input*)

Specifies the operations to be performed on A:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **ILO** (*output*)

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

* **IHI** (*output*)

See the description for ILO.

* **SCALE** (*output*)

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1$

* **INFO** (*output*)

NAME

sgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

SYNOPSIS

```
SUBROUTINE SGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,  
* INFO)  
INTEGER M, N, LDA, LWORK, INFO  
REAL A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)
```

```
SUBROUTINE SGEBRD_64( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,  
* INFO)  
INTEGER*8 M, N, LDA, LWORK, INFO  
REAL A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
* [LWORK], [INFO])  
INTEGER :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBRD_64( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
* [LWORK], [INFO])  
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgebrd(int m, int n, float *a, int lda, float *d, float *e, float *tauq, float *taup, int *info);
```

```
void sgebrd_64(long m, long n, float *a, long lda, float *d, float *e, float *tauq, float *taup, long *info);
```

PURPOSE

sgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: $Q^*A = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

*** M (input)**

The number of rows in the matrix A. $M \geq 0$.

*** N (input)**

The number of columns in the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** D (output)**

The diagonal elements of the bidiagonal matrix B: $D(i) = A(i, i)$.

*** E (output)**

The off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

*** TAUQ (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

*** TAUP (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, M, N)$. For optimum performance $LWORK \geq (M+N)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

sgeco - (obsolete) compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then SGEFA is slightly faster. It is typical to follow a call to SGECO with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE SGECO( A, LDA, N, IPIVOT, RCOND, WORK)
INTEGER LDA, N
INTEGER IPIVOT(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SGECO_64( A, LDA, N, IPIVOT, RCOND, WORK)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeco(float *a, int lda, int n, int *ipivot, float *rcond);
```

```
void sgeco_64(float *a, long lda, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets

smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

sgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

SYNOPSIS

```
SUBROUTINE SGECON( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
INTEGER N, LDA, INFO
INTEGER WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SGECON_64( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GECON( NORM, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A
```

```
SUBROUTINE GECON_64( NORM, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgecon(char norm, int n, float *a, int lda, float anorm, float *rcond, int *info);
```

```
void sgecon_64(char norm, long n, float *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

sgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ANORM (input)**

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

sgedi - (obsolete) compute the determinant and inverse of a general matrix A, which has been LU-factored by SGECO or SGEFA.

SYNOPSIS

```
SUBROUTINE SGEDI( A, LDA, N, IPIVOT, DET, WORK, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
REAL A(LDA,*), DET(*), WORK(*)
```

```
SUBROUTINE SGEDI_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgedi(float *a, int lda, int n, int *ipivot, float *det, int job);
```

```
void sgedi_64(float *a, long lda, long n, long *ipivot, float *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the LU factorization of the matrix A, as computed by SGECO or SGEFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise it is unchanged.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGECO or SGEFA.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \geq |DET(1)| \geq 10.0$ or $DET(1) = 0.0$.

*** WORK (workspace)**

Scratch array with a dimension of N.

* ***JOB (input)***

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

sgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE SGEEQU( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN, AMAX,
*                INFO)
  INTEGER M, N, LDA, INFO
  REAL ROWCN, COLCN, AMAX
  REAL A(LDA,*), ROWSC(*), COLSC(*)

SUBROUTINE SGEEQU_64( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN,
*                AMAX, INFO)
  INTEGER*8 M, N, LDA, INFO
  REAL ROWCN, COLCN, AMAX
  REAL A(LDA,*), ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*                AMAX, [INFO])
  INTEGER :: M, N, LDA, INFO
  REAL :: ROWCN, COLCN, AMAX
  REAL, DIMENSION(:) :: ROWSC, COLSC
  REAL, DIMENSION(:, :) :: A

SUBROUTINE GEEQU_64( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*                AMAX, [INFO])
  INTEGER(8) :: M, N, LDA, INFO
  REAL :: ROWCN, COLCN, AMAX
  REAL, DIMENSION(:) :: ROWSC, COLSC
  REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeequ(int m, int n, float *a, int lda, float *rowsc, float *colsc, float *rowcn, float *colcn, float *amax, int *info);
```

```
void sgeequ_64(long m, long n, float *a, long lda, float *rowsc, float *colsc, float *rowcn, float *colcn, float *amax, long *info);
```

PURPOSE

sgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input)**

The M-by-N matrix whose equilibration factors are to be computed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** ROWSC (output)**

If INFO = 0 or INFO > M, ROWSC contains the row scale factors for A.

*** COLSC (output)**

If INFO = 0, COLSC contains the column scale factors for A.

*** ROWCN (output)**

If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If ROWCN ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

*** COLCN (output)**

If INFO = 0, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCN ≥ 0.1 , it is not worth scaling by COLSC.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

sgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

SYNOPSIS

```
SUBROUTINE SGEES( JOBZ, SORTEV, SELECT, N, A, LDA, NOUT, WR, WI, Z,  
*      LDZ, WORK, LDWORK, WORK3, INFO)

LOGICAL(8), DIMENSION(:) :: WORK3  
REAL, DIMENSION(:) :: WR, WI, WORK  
REAL, DIMENSION(:, :) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgees(char jobz, char sortev, logical(*select)(float,float), int n, float *a, int lda, int *nout, float *wr, float *wi, float *z, int ldz, int *info);
```

```
void sgees_64(char jobz, char sortev, logical(*select)(float,float), long n, float *a, long lda, long *nout, float *wr, float *wi, float *z, long ldz, long *info);
```

PURPOSE

sgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j) + \sqrt{-1} * WI(j)$ is selected if $SELECT(WR(j), WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j), WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOU**T (*output*)

If `SORTEV = 'N'`, `NOUT = 0`. If `SORTEV = 'S'`, `NOUT =` number of eigenvalues (after sorting) for which `SELECT` is true. (Complex conjugate pairs for which `SELECT` is true for either eigenvalue count as 2.)

* ***WR (output)***

`WR` and `WI` contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form `T`. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

* ***WI (output)***

See the description for `WR`.

* ***Z (output)***

If `JOBZ = 'V'`, `Z` contains the orthogonal matrix `Z` of Schur vectors. If `JOBZ = 'N'`, `Z` is not referenced.

* ***LDZ (input)***

The leading dimension of the array `Z`. `LDZ >= 1`; if `JOBZ = 'V'`, `LDZ >= N`.

* ***WORK (workspace)***

On exit, if `INFO = 0`, `WORK(1)` contains the optimal `LDWORK`.

* ***LDWORK (input)***

The dimension of the array `WORK`. `LDWORK >= max(1,3*N)`. For good performance, `LDWORK` must generally be larger.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

* ***WORK3 (workspace)***

Not referenced if `SORTEV = 'N'`.

* ***INFO (output)***

```

PURPOSE

sgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j)+\sqrt{-1}*WI(j)$ is selected if $SELECT(WR(j),WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j),WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* **NOUT** (*output*)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

* **WR** (*output*)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI** (*output*)

See the description for WR.

* **Z** (*output*)

If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **SRCONE** (*output*)

If SENSE = 'E' or 'B', SRCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* **RCONV** (*output*)

If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1,3*N)$. Also, if SENSE = 'E' or 'V' or 'B', $LDWORK \geq N+2*NOUT*(N-NOUT)$, where NOUT is the number of selected eigenvalues computed by this routine. Note that $N+2*NOUT*(N-NOUT) \leq N+N*N/2$. For good performance, LDWORK must generally be larger.

* **IWORK2** (*workspace*)

Not referenced if SENSE = 'N' or 'E'. On exit, if INFO = 0, IWORK2(1) returns the optimal LDWRK2.

* **LDWRK2** (*input*)

The dimension of the array IWORK2. LDWRK2 \geq 1; if SENSE = 'V' or 'B', LDWRK2 \geq NOUT*(N-NOUT).

* **BWORK3** (*workspace*)

Not referenced if SORTEV = 'N'.

* **INFO** (*output*)

CHARACTER(LEN=1) :: JOBVL, JOBVR  
INTEGER(8) :: N, LDA, LDVL, LDVR, LDWORK, INFO  
REAL, DIMENSION(:) :: WR, WI, WORK  
REAL, DIMENSION(:,) :: A, VL, VR
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeev(char jobvl, char jobvr, int n, float *a, int lda, float *wr, float *wi, float *vl, int ldvl, float *vr, int ldvr, int *info);
```

```
void sgeev_64(char jobvl, char jobvr, long n, float *a, long lda, float *wr, float *wi, float *vl, long ldvl, float *vr, long ldvr, long *info);
```

PURPOSE

sgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **WR** (*output*)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI** (*output*)

See the description for WR.

* **VL** (*output*)

If **JOBVL** = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If **JOBVL** = 'N', VL is not referenced. If the j-th eigenvalue is real, then $u(j) = VL(:,j)$, the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i*VL(:,j+1)$ and

$$u(j+1) = VL(:,j) - i*VL(:,j+1).$$

* **LDVL** (*input*)

The leading dimension of the array VL. $LDVL \geq 1$; if **JOBVL** = 'V', $LDVL \geq N$.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and

$$v(j+1) = VR(:,j) - i*VR(:,j+1).$$

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR ≥ 1 ; if JOBVR = 'V', LDVR $\geq N$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, 3*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 4*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

```

PURPOSE

sgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{*-1}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

* **BALANC** (*input*)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur

form of the balanced version of the input matrix *A*.

* **LDA (input)**

The leading dimension of the array *A*. LDA $\geq \max(1, N)$.

* **WR (output)**

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI (output)**

See the description for WR.

* **VL (output)**

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the *j*-th eigenvalue is real, then $u(j) = VL(:, j)$, the *j*-th column of VL. If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:, j) + i*VL(:, j+1)$ and

$$u(j+1) = VL(:, j) - i*VL(:, j+1).$$

* **LDVL (input)**

The leading dimension of the array VL. LDVL ≥ 1 ; if JOBVL = 'V', LDVL $\geq N$.

* **VR (output)**

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the *j*-th eigenvalue is real, then $v(j) = VR(:, j)$, the *j*-th column of VR. If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then $v(j) = VR(:, j) + i*VR(:, j+1)$ and

$$v(j+1) = VR(:, j) - i*VR(:, j+1).$$

* **LDVR (input)**

The leading dimension of the array VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

* **ILO (output)**

ILO and IHI are integer values determined when *A* was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

* **IHI (output)**

See the description of ILO.

* **SCALE (output)**

Details of the permutations and scaling factors applied when balancing *A*. If $P(j)$ is the index of the row and column interchanged with row and column *j*, and $D(j)$ is the scaling factor applied to row and column *j*, then $SCALE(J) = P(J)$, for $J = 1, \dots, ILO-1$

* **ABNRM (output)**

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

* **RCONE (output)**

RCONE(*j*) is the reciprocal condition number of the *j*-th eigenvalue.

* **RCONV (output)**

RCONV(*j*) is the reciprocal condition number of the *j*-th right eigenvector.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK (input)**

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK $\geq \max(1, 2*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 3*N$. If SENSE = 'V' or 'B', LDWORK $\geq N*(N+6)$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **IWORK2 (workspace)**

If SENSE = 'N' or 'E', not referenced.

* **INFO (output)**

NAME

sgefa - (obsolete) compute the LU factorization of a general matrix A. It is typical to follow a call to SGEFA with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SGEFA( A, LDA, N, IPIVOT, INFO)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*)
```

```
SUBROUTINE SGEFA_64( A, LDA, N, IPIVOT, INFO)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgefa(float *a, int lda, int n, int *ipivot, int *info);
```

```
void sgefa_64(float *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SGESL will divide by zero if called.

```

PURPOSE

sgegs routine is deprecated and has been replaced by routine SGGES.

SGEGS computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues (alpha +/- alpha*i, beta), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of A will be "standardized" by making the corresponding elements of B have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in A and B will have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the orthogonal matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**T A (VSR), (VSL)**T B (VSR))

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A. Note: to avoid overflow, the Frobenius norm of the matrix A should be less than the overflow threshold.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B. Note: to avoid overflow, the Frobenius norm of the matrix B should be less than the overflow threshold.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHA1(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHA1(j)*i, j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHA1(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHA1(j+1) negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

* ***ALPHAI (output)***

See the description for ALPHAR .

* ***BETA (output)***

See the description for ALPHAR .

* ***VSL (input)***

If $\text{JOBVSL} = 'V'$, VSL will contain the left Schur vectors. (See ``Purpose'', above.) Not referenced if $\text{JOBVSL} = 'N'$.

* ***LDVSL (input)***

The leading dimension of the matrix VSL . $\text{LDVSL} \geq 1$, and if $\text{JOBVSL} = 'V'$, $\text{LDVSL} \geq N$.

* ***VSR (input)***

If $\text{JOBVSR} = 'V'$, VSR will contain the right Schur vectors. (See ``Purpose'', above.) Not referenced if $\text{JOBVSR} = 'N'$.

* ***LDVSR (input)***

The leading dimension of the matrix VSR . $\text{LDVSR} \geq 1$, and if $\text{JOBVSR} = 'V'$, $\text{LDVSR} \geq N$.

* ***WORK (workspace)***

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LDWORK .

* ***LDWORK (input)***

The dimension of the array WORK . $\text{LDWORK} \geq \max(1, 4*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK , call ILAENV to get block sizes (for SGEQRF , SORMQR , and SORGQR .) Then compute: $\text{NB} \leftarrow \text{MAX}$ of the block sizes for SGEQRF , SORMQR , and SORGQR . The optimal LDWORK is $2*N + N*(\text{NB}+1)$.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA .

* ***INFO (output)***

NAME

sgegv - routine is deprecated and has been replaced by routine SGGEV

SYNOPSIS

```
SUBROUTINE SGEGV( JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI,

long ldvl, float *vr, long ldvr, long *info);
```

PURPOSE

sgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n -by- n real nonsymmetric matrices A and B , the generalized eigenvalues ($\alpha \pm i\beta$), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α,β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - wB)r = 0$. A left generalized eigenvector is a vector l such that $l^*H^*(A - wB) = 0$, where l^*H is the

conjugate-transpose of l .

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A , B , VL , and VR . $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

* **LDA** (*input*)

The leading dimension of A . $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

* **LDB** (*input*)

The leading dimension of B . $LDB \geq \max(1,N)$.

* **ALPHAR** (*output*)

On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. If $ALPHAI(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $ALPHAI(j+1)$ negative.

Note: the quotients $ALPHAR(j)/BETA(j)$ and $ALPHAI(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, $ALPHAR$ and $ALPHAI$ will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $BETA$ always less than and usually comparable with $\text{norm}(B)$.

* **ALPHAI** (*output*)

See the description of $ALPHAR$.

* **BETA** (*output*)

See the description of $ALPHAR$.

* **VL** (*output*)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex

take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $\text{JOBVL} = 'N'$.

* **LDVL (input)**

The leading dimension of the matrix VL. $\text{LDVL} \geq 1$, and if $\text{JOBVL} = 'V'$, $\text{LDVL} \geq N$.

* **VR (output)**

If $\text{JOBVR} = 'V'$, the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $\text{JOBVR} = 'N'$.

* **LDVR (input)**

The leading dimension of the matrix VR. $\text{LDVR} \geq 1$, and if $\text{JOBVR} = 'V'$, $\text{LDVR} \geq N$.

* **WORK (workspace)**

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LDWORK .

* **LDWORK (input)**

The dimension of the array WORK. $\text{LDWORK} \geq \max(1, 8*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK , call ILAENV to get block sizes (for SGEQR , SORMQR , and SORGQR .) Then compute: $\text{NB} = \text{MAX}$ of the block sizes for SGEQR , SORMQR , and SORGQR ; The optimal LDWORK is: $2*N + \text{MAX}(6*N, N*(\text{NB}+1))$.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO (output)**

NAME

sgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE SGEHRD( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)
INTEGER N, ILO, IHI, LDA, LWORKIN, INFO
REAL A(LDA,*), TAU(*), WORKIN(*)
```

```
SUBROUTINE SGEHRD_64( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN,
* INFO)
INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
REAL A(LDA,*), TAU(*), WORKIN(*)
```

F95 INTERFACE

```
SUBROUTINE GEHRD( [N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
* [INFO])
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL, DIMENSION(:) :: TAU, WORKIN
REAL, DIMENSION(:,:) :: A
```

```
SUBROUTINE GEHRD_64( [N], ILO, IHI, A, [LDA], TAU, [WORKIN],
* [LWORKIN], [INFO])
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL, DIMENSION(:) :: TAU, WORKIN
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgehrd(int n, int ilo, int ihi, float *a, int lda, float *tau, int *info);
```

```
void sgehrd_64(long n, long ilo, long ihi, float *a, long lda, float *tau, long *info);
```

PURPOSE

sgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** ILO (input)**

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

*** IHI (input)**

See the description of ILO.

*** A (input/output)**

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** TAU (output)**

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

*** WORKIN (workspace)**

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

*** LWORKIN (input)**

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

*** INFO (output)**

NAME

sgelqf - compute an LQ factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE SGELQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGELQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GELQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgelqf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void sgelqf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

sge1qf computes an LQ factorization of a real M-by-N matrix A: $A = L * Q$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

sgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

SYNOPSIS

```
SUBROUTINE SGELS( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK, LDWORK,
*              INFO)
CHARACTER * 1 TRANSA
INTEGER M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE SGELS_64( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK,
*              LDWORK, INFO)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELS( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B

SUBROUTINE GELS_64( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgels(char transa, int m, int n, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void sgels_64(char transa, long m, long n, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

sgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A * X \|$.
2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.
3. If TRANS = 'T' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{**T} * X = B$.
4. If TRANS = 'T' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A^{**T} * X \|$.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

* **TRANSA** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $M \geq N$, A is overwritten by details of its QR factorization as returned by SGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by SGELQF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'T'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgelsd(int m, int n, int nrhs, float *a, int lda, float *b, int ldb, float *s, float rcond, int *rank, int *info);
```

```
void sgelsd_64(long m, long n, long nrhs, float *a, long lda, float *b, long ldb, float *s, float rcond, long *rank, long *info);
```

PURPOSE

sgelsd computes the minimum-norm solution to a real linear least squares problem: minimize $\|b - A*x\|_2$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

(1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)

(2) Solve the BLS using a divide and conquer approach.

(3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** M (input)**

The number of rows of A. $M \geq 0$.

*** N (input)**

The number of columns of A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $RANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, \max(M, N))$.

*** S (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m,n))$.

* **RCOND** (*input*)

RCOND is used to determine the effective rank of A. Singular values $S(i) \leq \text{RCOND} * S(1)$ are treated as zero. If $\text{RCOND} < 0$, machine precision is used instead.

* **RANK** (*output*)

The effective rank of A, i.e., the number of singular values which are greater than $\text{RCOND} * S(1)$.

* **WORK** (*workspace*)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $\text{LWORK} \geq 1$. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least $12 * N + 2 * N * \text{SMLSIZ} + 8 * N * \text{NLVL} + N * \text{NRHS} * (\text{SMLSIZ} + 1) ** 2$, if M is greater than or equal to N or $12 * M + 2 * M * \text{SMLSIZ} + 8 * M * \text{NLVL} + M * \text{NRHS} + (\text{SMLSIZ} + 1) ** 2$, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $\text{NLVL} = \text{INT}(\text{LOG}_2(\text{MIN}(M, N) / (\text{SMLSIZ} + 1))) + 1$. For good performance, LWORK should generally be larger.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

$\text{LIWORK} \geq 3 * \text{MINMN} * \text{NLVL} + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M, N)$.

* **INFO** (*output*)

NAME

sgelss - compute the minimum norm solution to a real linear least squares problem

SYNOPSIS

```
SUBROUTINE SGELSS( M, N, NRHS, A, LDA, B, LDB, SING, RCOND, IRANK,

```

```
void sgelss_64(long m, long n, long nrhs, float *a, long lda, float *b, long ldb, float *sing, float rcond, long *irank, long *info);
```

PURPOSE

sgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm($| b - A*x |$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,\max(M,N))$.

*** SING (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $SING(1)/SING(\min(m,n))$.

*** RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $SING(i) \leq RCOND * SING(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

*** IRANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * SING(1)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq 1$, and also: $LDWORK \geq 3 * \min(M,N) + \max(2 * \min(M,N),$

$\max(M,N)$, NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* *INFO* (output)

NAME

sgelsx - routine is deprecated and has been replaced by routine SGELSY

SYNOPSIS

```
SUBROUTINE SGELSX( M, N, NRHS, A, LDA, B, LDB, JPIVOT, RCOND, IRANK,

```

```
void sgelsx_64(long m, long n, long nrhs, float *a, long lda, float *b, long ldb, long *jpivot, float rcond, long *irank, long *info);
```

PURPOSE

sgelsx routine is deprecated and has been replaced by routine SGELSY.

SGELSX computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$[\ 0 \ R22 \]$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. M >= 0.

*** N (input)**

The number of columns of the matrix A. N >= 0.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **JPIVOT** (*input*)

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* **RCOND** (*input*)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* **IRANK** (*output*)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* **WORK** (*workspace*)

$(\max(\min(M, N) + 3 * N, 2 * \min(M, N) + NRHS))$,

* **INFO** (*output*)

NAME

sgelsy - compute the minimum-norm solution to a real linear least squares problem

SYNOPSIS

```
SUBROUTINE SGELSY( M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK,

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgelsy(int m, int n, int nrhs, float *a, int lda, float *b, int ldb, int *jpvt, float rcond, int *rank, int *info);
```

```
void sgelsy_64(long m, long n, long nrhs, float *a, long lda, float *b, long ldb, long *jpvt, float rcond, long *rank, long *info);
```

PURPOSE

sgelsy computes the minimum-norm solution to a real linear least squares problem: minimize $\|A * X - B\|$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$[\ 0 \ R22 \]$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The call to the subroutine xGEQPF has been substituted by the the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
 - o Matrix B (the right hand side) is updated with Blas-3.
 - o The permutation of matrix B (the right hand side) is faster and more simple.
-

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPVT (input/output)***

On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of AP was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***RANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq \max(MN + 3 \cdot N + 1, 2 \cdot MN + NRHS)$, where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq \max(MN + 2 \cdot N + NB \cdot (N + 1), 2 \cdot MN + NB \cdot NRHS)$, where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO (output)***

NAME

sgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

SYNOPSIS

```
SUBROUTINE SGEMM( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*   BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB
INTEGER M, N, K, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE SGEMM_64( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*   BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB
INTEGER*8 M, N, K, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE GEMM( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
*   B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER :: M, N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

SUBROUTINE GEMM_64( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A,
*   [LDA], B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER(8) :: M, N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgemm(char transa, char transb, int m, int n, int k, float alpha, float *a, int lda, float *b, int ldb, float beta, float *c, int ldc);
```

```
void sgemm_64(char transa, char transb, long m, long n, long k, float alpha, float *a, long lda, float *b, long ldb, float beta,
```

float *c, long ldc);

PURPOSE

sgemmm performs one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$ where $\text{op}(X)$ is one of

$$\text{op}(X) = X \quad \text{or} \quad \text{op}(X) = X',$$

alpha and beta are scalars, and A, B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

* *TRANSA (input)*

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = A'$.

Unchanged on exit.

* *TRANSB (input)*

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = B'$.

Unchanged on exit.

* *M (input)*

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. M must be at least zero. Unchanged on exit.

* *N (input)*

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

* *K (input)*

On entry, K specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. K must be at least zero. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of

the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, k)$. Unchanged on exit.

*** B (input)**

n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, otherwise $LDB \geq \max(1, n)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix $(\alpha * \text{op}(A) * \text{op}(B) + \text{beta} * C)$.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

sgemv - perform one of the matrix-vector operations $y := \alpha A x + \beta y$ or $y := \alpha A^T x + \beta y$

SYNOPSIS

```
SUBROUTINE SGEMV( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
*              INCY)

REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)

SUBROUTINE SGEMV_64( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
*              INCY)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GEMV( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEMV_64( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgemv(char transa, int m, int n, float alpha, float *a, int lda, float *x, int incx, float beta, float *y, int incy);
```

```
void sgemv_64(char transa, long m, long n, float alpha, float *a, long lda, float *x, long incx, float beta, float *y, long incy);
```

PURPOSE

sgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^T x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A^H x + \beta y$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *A* (input)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar β . When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y* (input/output)

$(1 + (m - 1) * \text{abs}(INCY))$ when TRANSA = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(INCY))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

sgeqlf - compute a QL factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE SGEQLF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGEQLF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQLF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqlf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void sgeqlf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

sgeqlf computes a QL factorization of a real M-by-N matrix A: $A = Q * L$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m < n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

sgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE SGEQP3( M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
INTEGER M, N, LDA, LWORK, INFO
INTEGER JPVT(*)
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGEQP3_64( M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
INTEGER*8 M, N, LDA, LWORK, INFO
INTEGER*8 JPVT(*)
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*               [INFO])

INTEGER, DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQP3_64( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*               [INFO])
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqp3(int m, int n, float *a, int lda, int *jpvt, float *tau, int *info);
```

```
void sgeqp3_64(long m, long n, float *a, long lda, long *jpvt, float *tau, long *info);
```

PURPOSE

sgeqp3 computes a QR factorization with column pivoting of a matrix A: $A * P = Q * R$ using Level 3 BLAS.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(M,N)$ elementary reflectors.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***JPVT (input/output)***

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of $A * P$ (a leading column); if $JPVT(J) = 0$, the J-th column of A is a free column. On exit, if $JPVT(J) = K$, then the J-th column of $A * P$ was the K-th column of A.

* ***TAU (output)***

The scalar factors of the elementary reflectors.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq 3 * N + 1$. For optimal performance $LWORK \geq 2 * N + (N + 1) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO (output)***

NAME

sgeqpf - routine is deprecated and has been replaced by routine SGEQP3

SYNOPSIS

```
SUBROUTINE SGEQPF( M, N, A, LDA, JPIVOT, TAU, WORK, INFO)
INTEGER M, N, LDA, INFO
INTEGER JPIVOT(*)
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGEQPF_64( M, N, A, LDA, JPIVOT, TAU, WORK, INFO)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 JPIVOT(*)
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQPF( [M], [N], A, [LDA], JPIVOT, TAU, [WORK], [INFO])
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: JPIVOT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQPF_64( [M], [N], A, [LDA], JPIVOT, TAU, [WORK], [INFO])
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: JPIVOT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqpf(int m, int n, float *a, int lda, int *jpivot, float *tau, int *info);
```

```
void sgeqpf_64(long m, long n, float *a, long lda, long *jpivot, float *tau, long *info);
```

PURPOSE

sgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: $A * P = Q * R$.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** JPIVOT (input)**

On entry, if JPIVOT(i) $\neq 0$, the i-th column of A is permuted to the front of A * P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then the i-th column of A * P was the k-th column of A.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

NAME

sgeqrf - compute a QR factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE SGEQRF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGEQRF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQRF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQRF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqrf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void sgeqrf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

sgeqrf computes a QR factorization of a real M-by-N matrix A: $A = Q * R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(M,N)$ -by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

sger - perform the rank 1 operation $A := \alpha * x * y' + A$

SYNOPSIS

```
SUBROUTINE SGER( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
INTEGER M, N, INCX, INCY, LDA
REAL ALPHA
REAL X(*), Y(*), A(LDA,*)
```

```
SUBROUTINE SGER_64( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
INTEGER*8 M, N, INCX, INCY, LDA
REAL ALPHA
REAL X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
INTEGER :: M, N, INCX, INCY, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GER_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
INTEGER(8) :: M, N, INCX, INCY, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sger(int m, int n, float alpha, float *x, int incx, float *y, int incy, float *a, int lda);
```

```
void sger_64(long m, long n, float alpha, float *x, long incx, float *y, long incy, float *a, long lda);
```

PURPOSE

sger performs the rank 1 operation $A := \alpha * x * y' + A$, where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** *M (input)***

On entry, M specifies the number of rows of the matrix A . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of the matrix A . $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

*** *X (input)***

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

*** *INCX (input)***

On entry, $INCX$ specifies the increment for the elements of X . $INCX \neq 0$. Unchanged on exit.

*** *Y (input)***

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

*** *INCY (input)***

On entry, $INCY$ specifies the increment for the elements of Y . $INCY \neq 0$. Unchanged on exit.

*** *A (input/output)***

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

sgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SGERFS( TRANSA, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B,

REAL, DIMENSION(:, :) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgerfs(char transa, int n, int nrhs, float *a, int lda, float *af, int ldaf, int *ipivot, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void sgerfs_64(char transa, long n, long nrhs, float *a, long lda, float *af, long ldaf, long *ipivot, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

*** TRANSA (input)**

Specifies the form of the system of equations:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input)**

The original N-by-N matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** AF (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

*** LDAF (input)**

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

*** IPIVOT (input)**

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

*** B (input)**

The right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (input/output)**

On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgerqf - compute an RQ factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE SGERQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGERQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GERQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GERQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgerqf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void sgerqf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

sgerqf computes an RQ factorization of a real M-by-N matrix A: $A = R * Q$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray $A(1:m, n-m+1:n)$ contains the M-by-M upper triangular matrix R; if $m > n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

sgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

SYNOPSIS

```
SUBROUTINE SGESDD( JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,  
*               LWORK, IWORK, INFO)

*               [LDVT], [WORK], [LWORK], [IWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER(8) :: M, N, LDA, LDU, LDVT, LWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: S, WORK  
REAL, DIMENSION(:, :) :: A, U, VT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesdd(char jobz, int m, int n, float *a, int lda, float *s, float *u, int ldu, float *vt, int ldvt, int *info);
```

```
void sgesdd_64(char jobz, long m, long n, float *a, long lda, float *s, float *u, long ldu, float *vt, long ldvt, long *info);
```

PURPOSE

sgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written

$$= U * SIGMA * transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns $VT = V^{**T}$, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** JOBZ (input)**

Specifies options for computing all or part of the matrix U:

*** M (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of V^{**T} (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** S (output)**

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

*** U (output)**

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = $\min(M,N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first $\min(M,N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq 1$; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

*** VT (output)**

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N orthogonal matrix $V^{*}T$; if JOBZ = 'S', VT contains the first $\min(M,N)$ rows of $V^{*}T$ (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

*** LDVT (input)**

The leading dimension of the array VT. $LDVT \geq 1$; if JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, $LDVT \geq N$; if JOBZ = 'S', $LDVT \geq \min(M,N)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq 1$. If JOBZ = 'N', $LWORK \geq 3 * \min(M,N) + \max(\max(M,N), 6 * \min(M,N))$. If JOBZ = 'O', $LWORK \geq 3 * \min(M,N) * \min(M,N) + \max(\max(M,N), 5 * \min(M,N)) * \min(M,N) + 4 * \min(M,N)$. If JOBZ = 'S' or 'A' $LWORK \geq 3 * \min(M,N) * \min(M,N) + \max(\max(M,N), 4 * \min(M,N)) * \min(M,N) + 4 * \min(M,N)$. For good performance, LWORK should generally be larger. If $LWORK < 0$ but other input arguments are legal, WORK(1) returns optimal LWORK.

*** IWORK (workspace)**

dimension(8*MIN(M,N))

*** INFO (output)**

NAME

sgesl - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been LU- factored by SGECO or SGEFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SGESL( A, LDA, N, IPIVOT, B, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
REAL A(LDA,*), B(*)
```

```
SUBROUTINE SGESL_64( A, LDA, N, IPIVOT, B, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesl(float *a, int lda, int n, int *ipivot, float *b, int job);
```

```
void sgesl_64(float *a, long lda, long n, long *ipivot, float *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by SGECO or SGEFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGECO or SGEFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** JOB (input)**

Determines which operation the subroutine will perform:

o 0 Solve the system $Ax = b$.

not 0 Solve the linear system $A^T x = b$.
for real matrices.

NAME

sgesv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SGESV( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SGESV_64( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
INTEGER*8 N, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GESV( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GESV_64( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesv(int n, int nrhs, float *a, int lda, int *ipivot, float *b, int ldb, int *info);
```

```
void sgesv_64(long n, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sgesv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

*** B (input/output)**

On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

sgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

SYNOPSIS

```
SUBROUTINE SGESVD( JOBU, JOBVT, M, N, A, LDA, SING, U, LDU, VT,

* LDVT, WORK, LDWORK, INFO)  
CHARACTER * 1 JOBU, JOBVT  
INTEGER*8 M, N, LDA, LDU, LDVT, LDWORK, INFO  
REAL A(LDA,*), SING(*), U(LDU,*), VT(LDVT,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GESVD( JOBU, JOBVT, [M], [N], A, [LDA], SING, U, [LDU],  
* VT, [LDVT], [WORK], [LDWORK], [INFO])  
CHARACTER(LEN=1) :: JOBU, JOBVT  
INTEGER :: M, N, LDA, LDU, LDVT, LDWORK, INFO  
REAL, DIMENSION(:) :: SING, WORK  
REAL, DIMENSION(:, :) :: A, U, VT
```

```
SUBROUTINE GESVD_64( JOBU, JOBVT, [M], [N], A, [LDA], SING, U, [LDU],  
* VT, [LDVT], [WORK], [LDWORK], [INFO])  
CHARACTER(LEN=1) :: JOBU, JOBVT  
INTEGER(8) :: M, N, LDA, LDU, LDVT, LDWORK, INFO  
REAL, DIMENSION(:) :: SING, WORK  
REAL, DIMENSION(:, :) :: A, U, VT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesvd(char jobu, char jobvt, int m, int n, float *a, int lda, float *sing, float *u, int ldu, float *vt, int ldvt, int *info);
```

```
void sgesvd_64(char jobu, char jobvt, long m, long n, float *a, long lda, float *sing, float *u, long ldu, float *vt, long ldvt, long *info);
```

PURPOSE

sgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written $A = U * SIGMA * transpose(V)$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^{**T} , not V.

ARGUMENTS

*** *JOBU* (input)**

Specifies options for computing all or part of the matrix U:

*** *JOBVT* (input)**

Specifies options for computing all or part of the matrix V^{**T} :

*** *M* (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** *N* (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** *A* (input/output)**

On entry, the M-by-N matrix A. On exit, if *JOBU* = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if *JOBVT* = 'O', A is overwritten with the first min(m,n) rows of V^{**T} (the right singular vectors, stored rowwise); if *JOBU* .ne. 'O' and *JOBVT* .ne. 'O', the contents of A are destroyed.

*** *LDA* (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** *SING* (output)**

The singular values of A, sorted so that $SING(i) \geq SING(i+1)$.

*** *U* (input)**

(LDU, M) if *JOBU* = 'A' or (LDU, min(M, N)) if *JOBU* = 'SING'. If *JOBU* = 'A', U contains the M-by-M orthogonal matrix U; if *JOBU* = 'SING', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if *JOBU* = 'N' or 'O', U is not referenced.

*** *LDU* (input)**

The leading dimension of the array U. $LDU \geq 1$; if *JOBU* = 'SING' or 'A', $LDU \geq M$.

*** *VT* (input)**

If *JOBVT* = 'A', VT contains the N-by-N orthogonal matrix V^{**T} ; if *JOBVT* = 'SING', VT contains the first min(m,n) rows of V^{**T} (the right singular vectors, stored rowwise); if *JOBVT* = 'N' or 'O', VT is not referenced.

*** *LDVT* (input)**

The leading dimension of the array VT. $LDVT \geq 1$; if *JOBVT* = 'A', $LDVT \geq N$; if *JOBVT* = 'SING', $LDVT \geq \min(M, N)$.

*** *WORK* (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$; if $INFO > 0$, $WORK(2:MIN(M,N))$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in $SING$ (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A , and singular vectors related by U and VT .

* ***LDWORK (input)***

The dimension of the array $WORK$. $LDWORK \geq 1$. $LDWORK \geq \text{MAX}(3 * \text{MIN}(M,N) + \text{MAX}(M,N), 5 * \text{MIN}(M,N))$. For good performance, $LDWORK$ should generally be larger.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

* ***INFO (output)***

NAME

sgesvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

SUBROUTINE SGESVX( FACT, TRANSA, N, NRHS, A, LDA, AF, LDAF, IPIVOT,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesvx(char fact, char transa, int n, int nrhs, float *a, int lda, float *af, int ldaf, int *ipivot, char equed, float *rowsc, float *colsc, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sgesvx_64(char fact, char transa, long n, long nrhs, float *a, long lda, float *af, long ldaf, long *ipivot, char equed, float *rowsc, float *colsc, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sgesvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.
-

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *TRANS* (input)

Specifies the form of the system of equations:

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the N-by-N matrix A. If *FACT* = 'F' and *EQUED* is not 'N', then A must have been equilibrated by the scaling factors in *ROWSC* and/or *COLSC*. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *EQUED* .ne. 'N', A is scaled as follows: *EQUED* = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$

EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *AF* (input/output)

If *FACT* = 'F', then *AF* is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by SGETRF. If *EQUED* .ne. 'N', then *AF* is the factored form of the equilibrated matrix A.

If *FACT* = 'N', then *AF* is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If *FACT* = 'E', then *AF* is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* *IPIVOT* (input)

If *FACT* = 'F', then *IPIVOT* is an input argument and on entry contains the pivot indices from the factorization $A = P * L * U$ as computed by SGETRF; row i of the matrix was interchanged with row *IPIVOT*(i).

If *FACT* = 'N', then *IPIVOT* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A.

If *FACT* = 'E', then *IPIVOT* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the equilibrated matrix A.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *ROWSC* (input/output)

The row scale factors for A. If *EQUED* = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if *EQUED* = 'N' or 'COLSC', *ROWSC* is not accessed. *ROWSC* is an input argument if *FACT* = 'F'; otherwise, *ROWSC* is an output argument. If *FACT* = 'F' and *EQUED* = 'ROWSC' or 'B', each element of *ROWSC* must be positive.

* *COLSC* (input/output)

The column scale factors for A. If *EQUED* = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if *EQUED* = 'N' or 'ROWSC', *COLSC* is not accessed. *COLSC* is an input argument if *FACT* = 'F'; otherwise, *COLSC* is an output argument. If *FACT* = 'F' and *EQUED* = 'COLSC' or 'B', each element of *COLSC* must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if *EQUED* = 'N', B is not modified; if *TRANS* = 'N' and *EQUED* = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if *TRANS* = 'T' or 'COLSC' and *EQUED* = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (output)**

If $INFO = 0$ or $INFO = N+1$, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if $EQUED = 'N'$, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if $TRANSA = 'N'$ and $EQUED = 'COLSC'$ or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if $TRANSA = 'T'$ or 'COLSC' and $EQUED = 'ROWSC'$ or 'B'.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < INFO \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

* **WORK2 (workspace)**

* **INFO (output)**

NAME

sgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE SGETF2( M, N, A, LDA, IPIV, INFO)
INTEGER M, N, LDA, INFO
INTEGER IPIV(*)
REAL A(LDA,*)
```

```
SUBROUTINE SGETF2_64( M, N, A, LDA, IPIV, INFO)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 IPIV(*)
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GETF2( [M], [N], A, [LDA], IPIV, [INFO])
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GETF2_64( [M], [N], A, [LDA], IPIV, [INFO])
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgetf2(int m, int n, float *a, int lda, int *ipiv, int *info);
```

```
void sgetf2_64(long m, long n, float *a, long lda, long *ipiv, long *info);
```

PURPOSE

sgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

*** INFO (output)**

NAME

sgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE SGETRF( M, N, A, LDA, IPIVOT, INFO)
INTEGER M, N, LDA, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*)
```

```
SUBROUTINE SGETRF_64( M, N, A, LDA, IPIVOT, INFO)

```

```
void sgetrf_64(long m, long n, float *a, long lda, long *ipivot, long *info);
```

PURPOSE

sgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

*** INFO (output)**

NAME

sgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

SYNOPSIS

```
SUBROUTINE SGETRI( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SGETRI_64( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GETRI_64( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgetri(int n, float *a, int lda, int *ipivot, int *info);
```

```
void sgetri_64(long n, float *a, long lda, long *ipivot, long *info);
```

PURPOSE

sgetri computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by SGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** IPIVOT (input)**

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

*** WORK (workspace)**

On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimal performance $LDWORK \geq N*NB$, where NB is the optimal blocksize returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

C INTERFACE

```
#include <sunperf.h>
```

```
void sgetrs(char transa, int n, int nrhs, float *a, int lda, int *ipivot, float *b, int ldb, int *info);
```

```
void sgetrs_64(char transa, long n, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sgetrs solves a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

srgbak - form the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGBAL

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void srgbak(char job, char side, int n, int ilo, int ihi, float *lscale, float *rscale, int m, float *v, int ldv, int *info);
```

```
void srgbak_64(char job, char side, long n, long ilo, long ihi, float *lscale, float *rscale, long m, float *v, long ldv, long *info);
```

PURPOSE

sggbak forms the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

* ***JOB*** (*input*)

Specifies the type of backward transformation required:

* ***SIDE*** (*input*)

* ***N*** (*input*)

The number of rows of the matrix V. $N \geq 0$.

* ***ILO*** (*input*)

The integers ILO and IHI determined by SGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description for ILO.

* ***LSCALE*** (*input*)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGGBAL.

* ***RSCALE*** (*input*)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGGBAL.

* ***M*** (*input*)

The number of columns of the matrix V. $M \geq 0$.

* ***V*** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

* ***LDV*** (*input*)

The leading dimension of the matrix V. $LDV \geq \max(1,N)$.

* ***INFO*** (*output*)

NAME

sggbal - balance a pair of general real matrices (A,B)

SYNOPSIS

```
SUBROUTINE SGGBAL( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
*   WORK, INFO)
CHARACTER * 1 JOB
INTEGER N, LDA, LDB, ILO, IHI, INFO
REAL A(LDA,*), B(LDB,*), LSCALE(*), RSCALE(*), WORK(*)

SUBROUTINE SGGBAL_64( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE,
*   RSCALE, WORK, INFO)
CHARACTER * 1 JOB
INTEGER*8 N, LDA, LDB, ILO, IHI, INFO
REAL A(LDA,*), B(LDB,*), LSCALE(*), RSCALE(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GGBAL( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: N, LDA, LDB, ILO, IHI, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL, DIMENSION(:,) :: A, B

SUBROUTINE GGBAL_64( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL, DIMENSION(:,) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sggbal(char job, int n, float *a, int lda, float *b, int ldb, int *ilo, int *ihi, float *lscale, float *rscale, int *info);
```

```
void sggbal_64(char job, long n, float *a, long lda, float *b, long ldb, long *ilo, long *ihi, float *lscale, float *rscale, long *info);
```

PURPOSE

sggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

* **JOB** (*input*)

Specifies the operations to be performed on A and B:

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* **B** (*input*)

On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **ILO** (*output*)

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.
If JOB = 'N' or 'S', ILO = 1 and IHI = N.

* **IHI** (*output*)

See the description for ILO.

* **LSCALE** (*input*)

Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

* **RSCALE** (*input*)

Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

* **WORK** (*workspace*)

dimension(6*N)

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void sgges(char jobvsl, char jobvsr, char sort, logical(*selctg)(float,float,float), int n, float *a, int lda, float *b, int ldb, int *sdim, float *alphar, float *alphai, float *beta, float *vsl, int ldvsl, float *vsr, int ldvsr, int *info);
```

```
void sgges_64(char jobvsl, char jobvsr, char sort, logical(*selctg)(float,float,float), long n, float *a, long lda, float *b, long ldb, long *sdim, float *alphar, float *alphai, float *beta, float *vsl, long ldvsl, float *vsr, long ldvsr, long *info);
```

PURPOSE

sgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A, B) = ((VSL) * S * (VSR) ** T, (VSL) * T * (VSR) ** T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **SELCTG** (*input*)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA (input)**

The leading dimension of A. $LDA \geq \max(1, N)$.

* **B (input/output)**

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB (input)**

The leading dimension of B. $LDB \geq \max(1, N)$.

* **SDIM (output)**

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

* **ALPHAR (output)**

On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $ALPHAR(j) + ALPHAI(j)*i$, and $BETA(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A, B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients $ALPHAR(j)/BETA(j)$ and $ALPHAI(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

* **ALPHAI (output)**

See the description for ALPHAR.

* **BETA (output)**

See the description for ALPHAR.

* **VSL (input)**

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL (input)**

The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if JOBVSL = 'V', $LDVSL \geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if JOBVSR = 'V', $LDVSR \geq N$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 8*N+16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

NAME

```

PURPOSE

sggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$A,B) = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **SELCTG** (*input*)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **SDIM** (*output*)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (*output*)

See the description for ALPHAR.

* **BETA** (*output*)

See the description for ALPHAR.

* **VSL** (*input*)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL (input)**

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

* **RCONDE (output)**

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* **RCONDV (output)**

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq 8*(N+1)+16$. If SENSE = 'E', 'V', or 'B', LWORK $\geq \text{MAX}(8*(N+1)+16, 2*SDIM*(N-SDIM))$.

* **IWORK (workspace)**

Not referenced if SENSE = 'N'.

* **LIWORK (input)**

The dimension of the array WORK. LIWORK $\geq N+6$.

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

C INTERFACE

```
#include <sunperf.h>
```

```
void sggev(char jobvl, char jobvr, int n, float *a, int lda, float *b, int ldb, float *alphar, float *alphai, float *beta, float *vl, int ldvl,  
float *vr, int ldvr, int *info);
```

```
void sggev_64(char jobvl, char jobvr, long n, float *a, long lda, float *b, long ldb, float *alphar, float *alphai, float *beta, float *vl,  
long ldvl, float *vr, long ldvr, long *info);
```

PURPOSE

sggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j).$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B.$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (*output*)

See the description for ALPHAR.

* **BETA** (*output*)

See the description for ALPHAR.

* **VL** (*input*)

If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their

eigenvalues. If the j -th eigenvalue is real, then $u(j) = VL(:,j)$, the j -th column of VL . If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i * VL(:,j+1)$ and $u(j+1) = VL(:,j) - i * VL(:,j+1)$. Each eigenvector will be scaled so the largest component have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVL = 'N'$.

* **LDVL (input)**

The leading dimension of the matrix VL . $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

* **VR (input)**

If $JOBVR = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of VR , in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR . If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i * VR(:,j+1)$ and $v(j+1) = VR(:,j) - i * VR(:,j+1)$. Each eigenvector will be scaled so the largest component have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

* **LDVR (input)**

The leading dimension of the matrix VR . $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK (input)**

The dimension of the array $WORK$. $LWORK \geq \max(1, 8 * N)$. For good performance, $LWORK$ must generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **INFO (output)**

```

PURPOSE

sggev_x computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B .$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **BALANC** (*input*)

Specifies the balance option to be performed.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (*output*)

See the description of ALPHAR.

* **BETA** (*output*)

See the description of ALPHAR.

* **VL** (*output*)

If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

* **VR** (*output*)

If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real,

then $v(j) = VR(:,j)$, the j -th column of VR . If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and $v(j+1) = VR(:,j) - i*VR(:,j+1)$. Each eigenvector will be scaled so the largest component have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

* **LDVR (input)**

The leading dimension of the matrix VR . $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

* **ILO (output)**

ILO and IHI are integer values such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If $BALANC = 'N'$ or $'S'$, $ILO = 1$ and $IHI = N$.

* **IHI (output)**

See the description of ILO .

* **LSCALE (output)**

Details of the permutations and scaling factors applied to the left side of A and B . If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then $LSCALE(j) = PL(j)$ for $j = 1, \dots, ILO-1$

* **RSCALE (output)**

Details of the permutations and scaling factors applied to the right side of A and B . If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then $RSCALE(j) = PR(j)$ for $j = 1, \dots, ILO-1$

* **ABNRM (output)**

The one-norm of the balanced matrix A .

* **BBNRM (output)**

The one-norm of the balanced matrix B .

* **RCONDE (output)**

If $SENSE = 'E'$ or $'B'$, the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of $RCONDE$ are set to the same value. Thus $RCONDE(j)$, $RCONDV(j)$, and the j -th columns of VL and VR all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected). If $SENSE = 'V'$, $RCONDE$ is not referenced.

* **RCONDV (output)**

If $SENSE = 'V'$ or $'B'$, the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of $RCONDV$ are set to the same value. If the eigenvalues cannot be reordered to compute $RCONDV(j)$, $RCONDV(j)$ is set to 0; this can only occur when the true value would be very small anyway. If $SENSE = 'E'$, $RCONDV$ is not referenced.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK (input)**

The dimension of the array $WORK$. $LWORK \geq \max(1, 6*N)$. If $SENSE = 'E'$, $LWORK \geq 12*N$. If $SENSE = 'V'$ or $'B'$, $LWORK \geq 2*N*N + 12*N + 16$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **IWORK (workspace)**

If $SENSE = 'E'$, $IWORK$ is not referenced.

* **BWORK (workspace)**

If $SENSE = 'N'$, $BWORK$ is not referenced.

* **INFO (output)**

```

```
void sggglm(int n, int m, int p, float *a, int lda, float *b, int ldb, float *d, float *x, float *y, int *info);
```

```
void sggglm_64(long n, long m, long p, float *a, long lda, float *b, long ldb, float *d, float *x, float *y, long *info);
```

PURPOSE

sgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $0 \leq M \leq N$.

*** P (input)**

The number of columns of the matrix B. $P \geq N-M$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** D (input/output)**

On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

*** X (output)**

On exit, X and Y are the solutions of the GLM problem.

*** Y (output)**

See the description of X.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal block sizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

sgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```
SUBROUTINE SGGHRD( COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q,

SUBROUTINE GGHRD_64( COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],  
* Q, [LDQ], Z, [LDZ], [INFO])  
CHARACTER(LEN=1) :: COMPQ, COMPZ  
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO  
REAL, DIMENSION(:, :) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgghrd(char compq, char compz, int n, int ilo, int ihi, float *a, int lda, float *b, int ldb, float *q, int ldq, float *z, int ldz,  
int *info);
```

```
void sgghrd_64(char compq, char compz, long n, long ilo, long ihi, float *a, long lda, float *b, long ldb, float *q, long ldq,  
float *z, long ldz, long *info);
```

PURPOSE

sgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)' \quad 1 * B * Z1' = (Q1*Q) * T * (Z1*Z)'$$

ARGUMENTS

* **COMPQ** (*input*)

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **ILO** (*input*)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input/output*)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **Q** (*input/output*)

If COMPQ='N': Q is not referenced.

If COMPQ='I': on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by $Q1 * Q$.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

* **Z** (*input/output*)

If COMPZ='N': Z is not referenced.

If COMPZ='I': on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of

the Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by Z1*Z.

* **LDZ (input)**

The leading dimension of the array Z. LDZ \geq N if COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

* **INFO (output)**

NAME

sgglse - solve the linear equality-constrained least squares (LSE) problem

SYNOPSIS

```

  REAL, DIMENSION(:) :: C, D, X, WORK
  REAL, DIMENSION(:, :) :: A, B

SUBROUTINE GGLSE_64( [M], [N], [P], A, [LDA], B, [LDB], C, D, X,
*                  [WORK], [LDWORK], [INFO])
  INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
  REAL, DIMENSION(:) :: C, D, X, WORK
  REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgglse(int m, int n, int p, float *a, int lda, float *b, int ldb, float *c, float *d, float *x, int *info);
```

```
void sgglse_64(long m, long n, long p, float *a, long lda, float *b, long ldb, float *c, float *d, float *x, long *info);
```

PURPOSE

sgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } || c - A*x ||_2 \quad \text{subject to } B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that $P \leq N \leq M+P$, and

$$\text{rank}(B) = P \quad \text{and} \quad \text{rank} \left(\begin{pmatrix} A \\ B \end{pmatrix} \right) = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** P (input)**

The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** C (input/output)**

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

*** D (input/output)**

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

*** X (output)**

On exit, X is the solution of the LSE problem.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. LDWORK $\geq \max(1, M+N+P)$. For optimum performance LDWORK $\geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (output)

NAME

sggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

SYNOPSIS

SUBROUTINE GGQRF_64( [N], [M], [P], A, [LDA], TAU, B, [LDB], TAUB,
*                  [WORK], [LWORK], [INFO])
  INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
  REAL, DIMENSION(:) :: TAU, TAUB, WORK
  REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sggqrf(int n, int m, int p, float *a, int lda, float *tau, float *b, int ldb, float *taub, int *info);
```

```
void sggqrf_64(long n, long m, long p, float *a, long lda, float *tau, float *b, long ldb, float *taub, long *info);
```

PURPOSE

sggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if $N \geq M$, $R = \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}$, or if $N < M$, $R = \begin{pmatrix} R_{11} & R_{12} \\ 0 & 0 \end{pmatrix}$

where R_{11} is upper triangular, and

if $N \leq P$, $T = \begin{pmatrix} 0 & T_{12} \\ 0 & 0 \end{pmatrix}$, or if $N > P$, $T = \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix}$

where T_{12} or T_{21} is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'^*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $M \geq 0$.

*** P (input)**

The number of columns of the matrix B. $P \geq 0$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **TAUB (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1,N,M,P)$. For optimum performance $LWORK \geq \max(N,M,P) * \max(NB1,NB2,NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of SORMQR.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

SUBROUTINE GGRQF_64( [M], [P], [N], A, [LDA], TAU, B, [LDB], TAUB,
*                   [WORK], [LWORK], [INFO])
  INTEGER(8) :: M, P, N, LDA, LDB, LWORK, INFO
  REAL, DIMENSION(:) :: TAU, TAUB, WORK
  REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sggrqf(int m, int p, int n, float *a, int lda, float *tau, float *b, int ldb, float *taub, int *info);
```

```
void sggrqf_64(long m, long p, long n, float *a, long lda, float *tau, float *b, long ldb, float *taub, long *info);
```

PURPOSE

sggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if $M \leq N$, $R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} M$, or if $M > N$, $R = \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix} M-N, N-M M \begin{pmatrix} R_{21} \\ R_{11} \end{pmatrix} N-N$

where R_{12} or R_{21} is upper triangular, and

if $P \geq N$, $T = \begin{pmatrix} T_{11} \end{pmatrix} N$, or if $P < N$, $T = \begin{pmatrix} T_{11} & T_{12} \\ 0 & T_{21} \end{pmatrix} P, (0) P-N P N-P N$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*inv(B)$:

$$A*inv(B) = (R*inv(T))*Z'$$

where $inv(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** P (input)**

The number of rows of the matrix B. $P \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray $A(1:M, N-M+1:N)$ contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P, N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** TAUB (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK $\geq \max(1, N, M, P)$. For optimum performance LWORK $\geq \max(N, M, P) * \max(\text{NB1}, \text{NB2}, \text{NB3})$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

C INTERFACE

```
#include <sunperf.h>
```

```
void sggsvd(char jobu, char jobv, char jobq, int m, int n, int p, int *k, int *l, float *a, int lda, float *b, int ldb, float *alpha, float *beta, float *u, int ldu, float *v, int ldv, float *q, int ldq, int *iwork3, int *info);
```

```
void sggsvd_64(char jobu, char jobv, char jobq, long m, long n, long p, long *k, long *l, float *a, long lda, float *b, long ldb, float *alpha, float *beta, float *u, long ldu, float *v, long ldv, float *q, long ldq, long *iwork3, long *info);
```

PURPOSE

sggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix}$$

where U, V and Q are orthogonal matrices, and Z' is the transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B'), then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$\begin{aligned} D1 &= \begin{matrix} & & K & L \\ & K & (I & 0) \\ & & L & (0 & C) \\ M-K-L & (0 & 0) \end{matrix} \\ D2 &= \begin{matrix} & & K & L \\ & L & (0 & S) \\ P-L & (0 & 0) \\ & N-K-L & K & L \end{matrix} \\ \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{matrix} K & (0 & R11 & R12) \\ L & (0 & 0 & R22) \end{matrix} \end{aligned}$$

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),  
S = diag( BETA(K+1), ... , BETA(K+L) ),  
C**2 + S**2 = I.  
R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

$$\begin{aligned} D1 &= \begin{matrix} & & K & M-K & K+L-M \\ & K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{matrix} \\ D2 &= \begin{matrix} & & K & M-K & K+L-M \\ & M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \\ & N-K-L & K & M-K & K+L-M \end{matrix} \\ \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{matrix} K & (0 & R11 & R12 & R13) \end{matrix} \end{aligned}$$

$$\begin{array}{cccc} M-K & (& 0 & 0 & R22 & R23 &) \\ K+L-M & (& 0 & 0 & 0 & R33 &) \end{array}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1), ... , BETA(M) ),
C**2 + S**2 = I.
(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0 R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.

```

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V'$$

If (A',B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem: $A' \cdot A \cdot x = \text{lambda} \cdot B' \cdot B \cdot x$.

In some literature, the GSVD of A and B is presented in the form $U' \cdot A \cdot X = (0 \ D1)$, $V' \cdot B \cdot X = (0 \ D2)$

where U and V are orthogonal and X is nonsingular, D1 and D2 are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q \cdot \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}$$

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **K** (*output*)

On exit, K and L specify the dimension of the subblocks described in the Purpose section. $K + L =$ effective numerical rank of (A',B').

* **L** (*output*)

See the description of K.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if $M-K-L < 0$. See Purpose for details.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **ALPHA (output)**

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$,

$BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = C$,

$BETA(K+1:K+L) = S$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and $ALPHA(K+L+1:N) = 0$

$BETA(K+L+1:N) = 0$

* **BETA (output)**

See the description of ALPHA.

* **U (output)**

If $JOBU = 'U'$, U contains the M-by-M orthogonal matrix U. If $JOBU = 'N'$, U is not referenced.

* **LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1, M)$ if $JOBU = 'U'$; $LDU \geq 1$ otherwise.

* **V (output)**

If $JOBV = 'V'$, V contains the P-by-P orthogonal matrix V. If $JOBV = 'N'$, V is not referenced.

* **LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1, P)$ if $JOBV = 'V'$; $LDV \geq 1$ otherwise.

* **Q (output)**

If $JOBQ = 'Q'$, Q contains the N-by-N orthogonal matrix Q. If $JOBQ = 'N'$, Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if $JOBQ = 'Q'$; $LDQ \geq 1$ otherwise.

* **WORK (workspace)**

dimension $(\max(3*N, M, P) + N)$

* **IWORK3 (output)**

On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for $I = K+1$, $\min(M, K+L)$ swap $ALPHA(I)$ and $ALPHA(IWORK3(I))$ endfor such that $ALPHA(1) \geq ALPHA(2) \geq \dots \geq ALPHA(N)$.

* **INFO (output)**

NAME

sggsvp - compute orthogonal matrices U, V and Q such that $N-K-L \text{ K L U}^* \text{A}^* \text{Q} = \text{K} (\text{0 A12 A13})$ if $M-K-L \geq 0$

void sggsvp(char jobu, char jobv, char jobq, int m, int p, int n, float *a, int lda, float *b, int ldb, float tola, float tolb, int *k, int *l, float *u, int ldu, float *v, int ldv, float *q, int ldq, int *info);
```

```
void sggsvp_64(char jobu, char jobv, char jobq, long m, long p, long n, float *a, long lda, float *b, long ldb, float tola, float tolb, long *k, long *l, float *u, long ldu, float *v, long ldv, float *q, long ldq, long *info);
```

PURPOSE

sggsvp computes orthogonal matrices U, V and Q such that $L \begin{pmatrix} 0 & 0 & A23 \end{pmatrix}$

$$\begin{aligned} & \begin{matrix} M-K-L & (& 0 & & 0 &) \\ & N-K-L & K & & L & \\ & K & (& 0 & A12 & A13 &) \end{matrix} \quad \text{if } M-K-L < 0; \\ & \begin{matrix} M-K & (& 0 & & 0 & A23 &) \\ & N-K-L & K & & L & \\ & L & (& 0 & 0 & B13 &) \\ & P-L & (& 0 & 0 & 0 &) \end{matrix} \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal. $K+L$ = the effective numerical rank of the (M+P)-by-N matrix (A',B)'. Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSD.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,P)$.

*** TOLA (input)**

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

*** TOLB (input)**

See the description of TOLA.

*** K (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose. $K + L =$ effective numerical rank of $(A',B)'$.

*** L (output)**

See the description of K.

*** U (input)**

If JOBU = 'U', U contains the orthogonal matrix U. If JOBU = 'N', U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1,M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

*** V (input)**

If JOBV = 'V', V contains the orthogonal matrix V. If JOBV = 'N', V is not referenced.

*** LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1,P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

*** Q (input)**

If JOBQ = 'Q', Q contains the orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1,N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

*** IWORK (workspace)**

dimension(N)

*** TAU (workspace)**

dimension(N)

*** WORK (workspace)**

dimension($\max(3*N,M,P)$)

*** INFO (output)**

NAME

sgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

SYNOPSIS

```
SUBROUTINE SGTCON( NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, WORK, IWORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER N, INFO  
INTEGER IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)  
  
SUBROUTINE SGTCON_64( NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, WORK, IWORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GTCON( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [IWORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK  
  
SUBROUTINE GTCON_64( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [IWORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgtcon(char norm, int n, float *low, float *diag, float *up1, float *up2, int *ipivot, float anorm, float *rcond, int *info);
```

```
void sgtcon_64(char norm, long n, float *low, float *diag, float *up1, float *up2, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

sgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPI** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **ANORM** (*input*)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

#include <sunperf.h>
```

```
void sgtrfs(char transa, int n, int nrhs, float *low, float *diag, float *up, float *lowf, float *diagf, float *upf1, float *upf2, int *ipivot, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void sgtrfs_64(char transa, long n, long nrhs, float *low, float *diag, float *up, float *lowf, float *diagf, float *upf1, float *upf2, long *ipivot, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **LOW** (*input*)

The (n-1) subdiagonal elements of A.

* **DIAG** (*input*)

The diagonal elements of A.

* **UP** (*input*)

The (n-1) superdiagonal elements of A.

* **LOWF** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

* **DIAGF** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPF1** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UPF2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices: for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgtstl - (obsolete) solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE SGTSL( N, SUB, DIAG, SUPER, B, INFO)
INTEGER N, INFO
REAL SUB(*), DIAG(*), SUPER(*), B(*)
```

```
SUBROUTINE SGTSL_64( N, SUB, DIAG, SUPER, B, INFO)
INTEGER*8 N, INFO
REAL SUB(*), DIAG(*), SUPER(*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgtstl(int n, float *sub, float *diag, float *super, float *b, int *info);
```

```
void sgtstl_64(long n, float *sub, float *diag, float *super, float *b, long *info);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *SUB* (*input*)

Subdiagonal of A . $SUB(2)$ through $SUB(N)$ contain the subdiagonal and $SUB(1)$ is not referenced.

* *DIAG* (*input*)

Diagonal of A .

* *SUPER* (*input*)

Superdiagonal of A . $SUPER(1)$ through $SUPER(N-1)$ contain the superdiagonal and $SUPER(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* *INFO* (*output*)

On exit:

$INFO = 0$ Subroutine completed normally.

INFO < 0 Returns a value k when the kth element of the diagonal becomes exactly zero.

NAME

sgtsv - solve the equation $A \cdot X = B$,

SYNOPSIS

```
SUBROUTINE SGTSV( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
INTEGER N, NRHS, LDB, INFO
REAL LOW(*), DIAG(*), UP(*), B(LDB,*)
```

```
SUBROUTINE SGTSV_64( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
INTEGER*8 N, NRHS, LDB, INFO
REAL LOW(*), DIAG(*), UP(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GTSV( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: LOW, DIAG, UP
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE GTSV_64( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: LOW, DIAG, UP
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgtsv(int n, int nrhs, float *low, float *diag, float *up, float *b, int ldb, int *info);
```

```
void sgtsv_64(long n, long nrhs, float *low, float *diag, float *up, float *b, long ldb, long *info);
```

PURPOSE

sgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^*X = B$ may be solved by interchanging the order of the arguments DU and DL .

ARGUMENTS

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** LOW (input/output)**

On entry, LOW must contain the $(n-1)$ sub-diagonal elements of A .

On exit, LOW is overwritten by the $(n-2)$ elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A , in $LOW(1)$, ..., $LOW(n-2)$.

*** $DIAG$ (input/output)**

On entry, $DIAG$ must contain the diagonal elements of A .

On exit, $DIAG$ is overwritten by the n diagonal elements of U .

*** UP (input/output)**

On entry, UP must contain the $(n-1)$ super-diagonal elements of A .

On exit, UP is overwritten by the $(n-1)$ elements of the first super-diagonal of U .

*** B (input/output)**

On entry, the N by $NRHS$ matrix of right hand side matrix B . On exit, if $INFO = 0$, the N by $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** $INFO$ (output)**

NAME

sgtsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE SGTSVX( FACT, TRANSA, N, NRHS, LOW, DIAG, UP, LOWF,

C INTERFACE

```
#include <sunperf.h>
```

```
void sgtsvx(char fact, char transa, int n, int nrhs, float *low, float *diag, float *up, float *lowf, float *diagf, float *upf1, float *upf2, int *ipivot, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sgtsvx_64(char fact, char transa, long n, long nrhs, float *low, float *diag, float *up, float *lowf, float *diagf, float *upf1, float *upf2, long *ipivot, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sgtsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.
 2. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* FACT (input)

Specifies whether or not the factored form of A has been supplied on entry.

* TRANSA (input)

Specifies the form of the system of equations:

* N (input)

The order of the matrix A. $N \geq 0$.

* NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* LOW (input)

The (n-1) subdiagonal elements of A.

* DIAG (input)

The n diagonal elements of A.

* UP (input/output)

The (n-1) superdiagonal elements of A.

* LOWF (input/output)

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

* DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* UPF1 (input/output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

* UPF2 (input/output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

* IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* B (input)

The N-by-NRHS right hand side matrix B.

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. LDX \geq max(1,N).

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sgttrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

```

```
void sgttrf_64(long n, float *low, float *diag, float *up1, float *up2, long *ipivot, long *info);
```

PURPOSE

sgttrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

*** N (input)**

The order of the matrix A.

*** LOW (input/output)**

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

*** DIAG (input/output)**

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

*** UP1 (input/output)**

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

*** UP2 (output)**

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

*** INFO (output)**

NAME

sgttrs - solve one of the systems of equations $A*X = B$ or $A'*X = B$,

SYNOPSIS

```
SUBROUTINE SGTTRS( TRANSA, N, NRHS, LOW, DIAG, UP1, UP2, IPIVOT, B,

```
void sgtrfs_64(char transa, long n, long nrhs, float *low, float *diag, float *up1, float *up2, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sgtrfs solves one of the systems of equations $A \cdot X = B$ or $A' \cdot X = B$, with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS ≥ 0 .

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPI** (*input*)

The (n-1) elements of the first super-diagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second super-diagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B** (*input/output*)

On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

* **LDB** (*input*)

The leading dimension of the array B. LDB $\geq \max(1, N)$.

* **INFO** (*output*)

NAME

shgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j)=(\text{ALPHAR}(j) + i*\text{ALPHAI}(j))/\text{BETAR}(j)$ of the equation $\det(A-w(i)B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

SYNOPSIS

```

void shgeqz_64(char job, char compq, char compz, long n, long ilo, long ihi, float *a, long lda, float *b, long ldb, float *alphar, float *alphai, float *beta, float *q, long ldq, float *z, long ldz, long *info);
```

PURPOSE

shgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal transformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the orthogonal transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

(in) A(in) Z(in)* = Q(out) A(out) Z(out)* (in) B(in) Z(in)* = Q(out) B(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

* **JOB** (*input*)

* **COMPQ** (*input*)

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrices A, B, Q, and Z. N >= 0.

* **ILO** (*input*)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input*)

On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

* **LDA** (*input*)

The leading dimension of the array A. LDA >= max(1, N).

* **B** (*input*)

On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.) If JOB='S', then on exit A and B will have been

simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements corresponding to diagonal blocks of A will be correct, but the off-diagonal portion will be meaningless.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **ALPHAR (output)**

ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., $A(j+1,j)=A(j,j+1)=0$), then $ALPHAR(j)=A(j,j)$. Note that the (real or complex) values $(ALPHAR(j) + i*ALPHAI(j))/BETA(j)$, $j=1,\dots,N$, are the generalized eigenvalues of the matrix pencil $A - wB$.

* **ALPHAI (output)**

ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., $A(j+1,j)=A(j,j+1)=0$), then $ALPHAI(j)=0$. Note that the (real or complex) values $(ALPHAR(j) + i*ALPHAI(j))/BETA(j)$, $j=1,\dots,N$, are the generalized eigenvalues of the matrix pencil $A - wB$.

* **BETA (output)**

BETA(1:N) will be set to the (real) diagonal elements of B that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., $A(j+1,j)=A(j,j+1)=0$), then $BETA(j)=B(j,j)$. Note that the (real or complex) values $(ALPHAR(j) + i*ALPHAI(j))/BETA(j)$, $j=1,\dots,N$, are the generalized eigenvalues of the matrix pencil $A - wB$. (Note that BETA(1:N) will always be non-negative, and no BETAI is necessary.)

* **Q (input/output)**

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the transpose of the orthogonal transformations which are applied to A and B on the left will be applied to the array Q on the right.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$. If COMPQ='V' or 'I', then $LDQ \geq N$.

* **Z (input/output)**

If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the orthogonal transformations which are applied to A and B on the right will be applied to the array Z on the right.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$. If COMPZ='V' or 'I', then $LDZ \geq N$.

* **WORK (workspace)**

On exit, if INFO ≥ 0 , WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1,N)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

shsein - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

SYNOPSIS

```
SUBROUTINE SHSEIN( SIDE, EIGSRC, INITV, SELECT, N, H, LDH, WR, WI,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void shsein(char side, char eigsrc, char initv, logical *select, int n, float *h, int ldh, float *wr, float *wi, float *vl, int ldvl, float *vr, int ldvr, int mm, int *m, int *ifaill, int *ifailr, int *info);
```

```
void shsein_64(char side, char eigsrc, char initv, logical *select, long n, float *h, long ldh, float *wr, float *wi, float *vl, long ldvl, float *vr, long ldvr, long mm, long *m, long *ifaill, long *ifailr, long *info);
```

PURPOSE

shsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y.

ARGUMENTS

* *SIDE* (input)

* *EIGSRC* (input)

Specifies the source of eigenvalues supplied in (WR,WI):

* *INITV* (input)

* *SELECT* (input/output)

Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

* *N* (input)

The order of the matrix H. N >= 0.

* *H* (input)

The upper Hessenberg matrix H.

* *LDH* (input)

The leading dimension of the array H. LDH >= max(1,N).

* *WR* (input/output)

On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

* *WI* (input)

See the description of WR.

* **VL (input/output)**

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

* **LDVL (input)**

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

* **VR (input/output)**

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. MM \geq M.

* **M (output)**

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

* **WORK (workspace)**

dimension((N+2)*N)

* **IFAILL (output)**

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

* **IFAILR (output)**

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

* **INFO (output)**

NAME

shseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{*} T$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

SYNOPSIS

```
SUBROUTINE SHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH, WR, WI, Z, LDZ,
*      WORK, LWORK, INFO)

REAL H(LDH,*), WR(*), WI(*), Z(LDZ,*), WORK(*)

SUBROUTINE SHSEQR_64( JOB, COMPZ, N, ILO, IHI, H, LDH, WR, WI, Z,
*      LDZ, WORK, LWORK, INFO)
CHARACTER * 1 JOB, COMPZ
INTEGER*8 N, ILO, IHI, LDH, LDZ, LWORK, INFO
REAL H(LDH,*), WR(*), WI(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE HSEQR( JOB, COMPZ, N, ILO, IHI, H, [LDH], WR, WI, Z, [LDZ],
*      [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
INTEGER :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
REAL, DIMENSION(:) :: WR, WI, WORK
REAL, DIMENSION(:, :) :: H, Z

SUBROUTINE HSEQR_64( JOB, COMPZ, N, ILO, IHI, H, [LDH], WR, WI, Z,
*      [LDZ], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
REAL, DIMENSION(:) :: WR, WI, WORK
REAL, DIMENSION(:, :) :: H, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void shseqr(char job, char compz, int n, int ilo, int ihi, float *h, int ldh, float *wr, float *wi, float *z, int ldz, int *info);
```

```
void shseqr_64(char job, char compz, long n, long ilo, long ihi, float *h, long ldh, float *wr, float *wi, float *z, long ldz, long *info);
```

PURPOSE

shseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q , so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q^*H^*Q^{**T} = (QZ)^*T^*(QZ)^{**T}$.

ARGUMENTS

* **JOB** (*input*)

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix H . $N \geq 0$.

* **ILO** (*input*)

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* **IHI** (*input*)

See the description of ILO.

* **H** (*input/output*)

On entry, the upper Hessenberg matrix H . On exit, if JOB = 'S', H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i) \cdot H(i,i+1) < 0$. If JOB = 'E', the contents of H are unspecified on exit.

* **LDH** (*input*)

The leading dimension of the array H . $LDH \geq \max(1,N)$.

* **WR** (*output*)

The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI , say the i -th and $(i+1)$ -th, with $WI(i) > 0$ and $WI(i+1) < 0$. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H , with $WR(i) = H(i,i)$ and, if $H(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) = \sqrt{H(i+1,i) \cdot H(i,i+1)}$ and $WI(i+1) = -WI(i)$.

* **WI** (*output*)

See the description of WR .

* **Z** (*input*)

If COMPZ = 'N': Z is not referenced.

If COMPZ = 'I': on entry, Z need not be set, and on exit, Z contains the orthogonal matrix Z of the Schur vectors of H . If COMPZ = 'V': on entry Z must contain an N -by- N matrix Q , which is assumed to be equal to the unit matrix except for the submatrix $Z(ILO:IHI,ILO:IHI)$; on exit Z contains Q^*Z . Normally Q is the orthogonal matrix generated by SORGHR after the call to SGEHRD which formed the Hessenberg matrix H .

* ***LDZ (input)***

The leading dimension of the array Z. $LDZ \geq \max(1, N)$ if $COMPZ = 'I'$ or $'V'$; $LDZ \geq 1$ otherwise.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq \max(1, N)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LWORK$ is issued by XERBLA.

* ***INFO (output)***

NAME

sinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SING operations are unnormalized inverses of themselves, so a call to SINGF followed by a call to SINQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE SINQB( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)

SUBROUTINE SINQB_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQB_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinqb(int n, float *x, float *wsave);

void sinqb_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine synthesis of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

sinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SING operations are unnormalized inverses of themselves, so a call to SINGF followed by a call to SINGB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE SINGF( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)

SUBROUTINE SINGF_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINGF( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE SINGF_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinqf(int n, float *x, float *wsave);

void sinqf_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine transform of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

sinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

SYNOPSIS

```
SUBROUTINE SINQI( N, WSAVE)
  INTEGER N
  REAL WSAVE( *)
```

```
SUBROUTINE SINQI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE( *)
```

F95 INTERFACE

```
SUBROUTINE SINQI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sinqi(int n, float *wsave);
```

```
void sinqi_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. SINQI needs to be called only once to initialize WSAVE before calling SINQF and/or SINQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

sint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

SYNOPSIS

```
SUBROUTINE SINT( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)

SUBROUTINE SINT_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE SINT_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sint(int n, float *x, float *wsave);

void sint_64(long n, float *x, float *wsave);
```

ARGUMENTS

*** *N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

*** *X (input/output)***

On entry, an array of length N containing the sequence to be transformed. On exit, the sine transform of the input.

*** *WSAVE (input/output)***

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by SINT1.

NAME

sinti - initialize the array WSAVE, which is used in subroutine SINT.

SYNOPSIS

```
SUBROUTINE SINTI( N, WSAVE)
  INTEGER N
  REAL WSAVE( *)
```

```
SUBROUTINE SINTI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE( *)
```

F95 INTERFACE

```
SUBROUTINE SINTI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sinti(int n, float *wsave);
```

```
void sinti_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input/output)*

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

skymm, sskymm, dskymm - Skyline format matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE SSKYMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                VAL, PNTR,
*                B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, K, DESCRA(5),
*        LDB, LDC, LWORK
INTEGER*4 PNTR(*),
REAL*4    ALPHA, BETA
REAL*4    VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DSKYMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                VAL, PNTR,
*                B, LDB, BETA, C, LDC, WORK, LWORK)
INTEGER*4 TRANSA, M, N, K, DESCRA(5),
*        LDB, LDC, LWORK
INTEGER*4 PNTR(*),
REAL*8    ALPHA, BETA
REAL*8    VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
where NNZ = PNTR(M+1)-1 (upper triangular)
        NNZ = PNTR(K+1)-1 (lower triangular)
        PNTR() size = (M+1) (upper triangular)
        PNTR() size = (K+1) (lower triangular)
```

DESCRIPTION

```
C <- alpha A B + beta C
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix

M Number of rows in matrix A

N Number of columns in matrix C

K Number of columns in matrix A

ALPHA Scalar parameter

DESCRA()
DESCRA(1) matrix structure
 0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal

DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper

DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL()
array contain the nonzeros of A in skyline profile form.
Row-oriented if DESCRA(2) = 1 (lower triangular),
column oriented if DESCRA(2) = 2 (upper triangular).

PNTR()
integer array of length M+1 (lower triangular) or
K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
points to the location in VAL of the first element of
the skyline profile in row (column) I.

B()
rectangular array with first dimension LDB.

LDB
leading dimension of B

BETA
Scalar parameter

C()
rectangular array with first dimension LDC.

LDC
leading dimension of C

WORK()
scratch array of length LWORK. LWORK should be at least
MAX(M,N).

LWORK
length of WORK array

SEE ALSO

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array containing the diagonal entries of the (block)
 diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti-Symmetric
 5 : Diagonal
DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() array contain the nonzeros of A in skyline profile form.
 Row-oriented if DESCRA(2) = 1 (lower triangular),
 column oriented if DESCRA(2) = 2 (upper triangular).

PNTR() integer array of length M+1 (lower triangular) or
 K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
 points to the location in VAL of the first element of
 the skyline profile in row (column) I.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. LWORK should be at least
 MAX(M,N).

LWORK length of WORK array

NAME

slagtf - factorize the matrix $(T-\lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T-\lambda I = \text{PLU}$

SYNOPSIS

```
SUBROUTINE SLAGTF( N, A, LAMBDA, B, C, TOL, D, IN, INFO)
INTEGER N, INFO
INTEGER IN(*)
REAL LAMBDA, TOL
REAL A(*), B(*), C(*), D(*)
```

```
SUBROUTINE SLAGTF_64( N, A, LAMBDA, B, C, TOL, D, IN, INFO)
INTEGER*8 N, INFO
INTEGER*8 IN(*)
REAL LAMBDA, TOL
REAL A(*), B(*), C(*), D(*)
```

F95 INTERFACE

```
SUBROUTINE LAGTF( [N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D
```

```
SUBROUTINE LAGTF_64( [N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slagtf(int n, float *a, float lambda, float *b, float *c, float tol, float *d, int *in, int *info);
```

```
void slagtf_64(long n, float *a, float lambda, float *b, float *c, float tol, float *d, long *in, long *info);
```

PURPOSE

slagtf factorizes the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that SLAGTF may be used, in conjunction with SLAGTS, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

*** N (input)**

The order of the matrix T .

*** A (input/output)**

On entry, A must contain the diagonal elements of T .

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .

*** $LAMBDA$ (input)**

On entry, the scalar λ .

*** B (input/output)**

On entry, B must contain the $(n-1)$ super-diagonal elements of T .

On exit, B is overwritten by the $(n-1)$ super-diagonal elements of the matrix U of the factorization of T .

*** C (input/output)**

On entry, C must contain the $(n-1)$ sub-diagonal elements of T .

On exit, C is overwritten by the $(n-1)$ sub-diagonal elements of the matrix L of the factorization of T .

*** TOL (input/output)**

On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. TOL should normally be chosen as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5×10^{-4} . If TOL is supplied as less than ϵ , where ϵ is the relative machine precision, then the value ϵ is used in place of TOL .

*** D (output)**

On exit, D is overwritten by the $(n-2)$ second super-diagonal elements of the matrix U of the factorization of T .

*** IN (output)**

On exit, IN contains details of the permutation matrix P . If an interchange occurred at the k th step of the elimination, then $IN(k) = 1$, otherwise $IN(k) = 0$. The element $IN(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}((T - \lambda I)(j)) * TOL,$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the j th row of the matrix A . If no such j exists then $IN(n)$ is returned as zero. If $IN(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \lambda I)$ is singular or nearly singular,

*** $INFO$ (output)**

NAME

slamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

SYNOPSIS

```
SUBROUTINE SLAMRG( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER N1, N2, TRD1, TRD2
INTEGER INDEX(*)
REAL A(*)
```

```
SUBROUTINE SLAMRG_64( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER*8 N1, N2, TRD1, TRD2
INTEGER*8 INDEX(*)
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE LAMRG( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER :: N1, N2, TRD1, TRD2
INTEGER, DIMENSION(:) :: INDEX
REAL, DIMENSION(:) :: A
```

```
SUBROUTINE LAMRG_64( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER(8) :: N1, N2, TRD1, TRD2
INTEGER(8), DIMENSION(:) :: INDEX
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slamrg(int n1, int n2, float *a, int trd1, int trd2, int *index);
```

```
void slamrg_64(long n1, long n2, float *a, long trd1, long trd2, long *index);
```

PURPOSE

slamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

* *N1 (input)*

Length of the first sequence to be merged.

* *N2 (input)*

Length of the second sequence to be merged.

* *A (input)*

On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

* *TRD1 (input)*

Describes the stride to be taken through the array A for the first N1 elements.

* *TRD2 (input)*

Describes the stride to be taken through the array A for the first N1 elements.

* *INDEX (output)*

On exit this array will contain a permutation such that if $B(I) = A(\text{INDEX}(I))$ for $I=1, N1+N2$, then B will be sorted in ascending order.

NAME

slarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

SYNOPSIS

```
SUBROUTINE SLARZ( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER M, N, L, INCV, LDC
REAL TAU
REAL V(*), C(LDC,*), WORK(*)

SUBROUTINE SLARZ_64( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER*8 M, N, L, INCV, LDC
REAL TAU
REAL V(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LARZ( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, L, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:,) :: C

SUBROUTINE LARZ_64( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER(8) :: M, N, L, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:,) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slarz(char side, int m, int n, int l, float *v, int incv, float tau, float *c, int ldc);
```

```
void slarz_64(char side, long m, long n, long l, float *v, long incv, float tau, float *c, long ldc);
```

PURPOSE

slarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C.

* **N** (*input*)

The number of columns of the matrix C.

* **L** (*input*)

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

* **V** (*input*)

The vector v in the representation of H as returned by STZRZF. V is not used if TAU = 0.

* **INCV** (*input*)

The increment between elements of v. INCV <> 0.

* **TAU** (*input*)

The value tau in the representation of H.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

* **LDC** (*input*)

The leading dimension of the array C. LDC >= max(1,M).

* **WORK** (*workspace*)

(N) if SIDE = 'L' or (M) if SIDE = 'R'. SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

NAME

slarzb - applies a real block reflector H or its transpose H**T to a real distributed M-by-N C from the left or the right

SYNOPSIS

```
SUBROUTINE SLARZB( SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV,  
*      T, LDT, C, LDC, WORK, LDWORK)  
CHARACTER * 1 SIDE, TRANS, DIRECT, STOREV  
INTEGER M, N, K, L, LDV, LDT, LDC, LDWORK  
REAL V(LDV,*), T(LDT,*), C(LDC,*), WORK(LDWORK,*)
```

```
SUBROUTINE SLARZB_64( SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V,  
*      LDV, T, LDT, C, LDC, WORK, LDWORK)  
CHARACTER * 1 SIDE, TRANS, DIRECT, STOREV  
INTEGER*8 M, N, K, L, LDV, LDT, LDC, LDWORK  
REAL V(LDV,*), T(LDT,*), C(LDC,*), WORK(LDWORK,*)
```

F95 INTERFACE

```
SUBROUTINE LARZB( SIDE, TRANS, DIRECT, STOREV, [M], [N], K, L, V,  
*      [LDV], T, [LDT], C, [LDC], [WORK], [LDWORK])  
CHARACTER(LEN=1) :: SIDE, TRANS, DIRECT, STOREV  
INTEGER :: M, N, K, L, LDV, LDT, LDC, LDWORK  
REAL, DIMENSION(:,:) :: V, T, C, WORK
```

```
SUBROUTINE LARZB_64( SIDE, TRANS, DIRECT, STOREV, [M], [N], K, L, V,  
*      [LDV], T, [LDT], C, [LDC], [WORK], [LDWORK])  
CHARACTER(LEN=1) :: SIDE, TRANS, DIRECT, STOREV  
INTEGER(8) :: M, N, K, L, LDV, LDT, LDC, LDWORK  
REAL, DIMENSION(:,:) :: V, T, C, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slarzb(char side, char trans, char direct, char storev, int m, int n, int k, int l, float *v, int ldv, float *t, int ldt, float *c, int ldc, int ldwork);
```

```
void slarzb_64(char side, char trans, char direct, char storev, long m, long n, long k, long l, float *v, long ldv, float *t, long ldt, float *c, long ldc, long ldwork);
```

PURPOSE

slarzb applies a real block reflector H or its transpose H^*T to a real distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

* *SIDE (input)*

* *TRANS (input)*

* *DIRECT (input)*

Indicates how H is formed from a product of elementary reflectors

* *STOREV (input)*

Indicates how the vectors which define the elementary reflectors are stored:

* *M (input)*

The number of rows of the matrix C .

* *N (input)*

The number of columns of the matrix C .

* *K (input)*

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

* *L (input)*

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If $SIDE = 'L'$, $M \geq L \geq 0$, if $SIDE = 'R'$, $N \geq L \geq 0$.

* *V (input)*

If $STOREV = 'C'$, $NV = K$; if $STOREV = 'R'$, $NV = L$.

* *LDV (input)*

The leading dimension of the array V . If $STOREV = 'C'$, $LDV \geq L$; if $STOREV = 'R'$, $LDV \geq K$.

* *T (input)*

The triangular K -by- K matrix T in the representation of the block reflector.

* *LDT (input)*

The leading dimension of the array T . $LDT \geq K$.

* *C (input/output)*

On entry, the M -by- N matrix C . On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

* *LDC (input)*

The leading dimension of the array C . $LDC \geq \max(1, M)$.

* *WORK (workspace)*

$\text{dimension}(\text{MAX}(M, N), K)$

* *LDWORK (input)*

The leading dimension of the array $WORK$. If $SIDE = 'L'$, $LDWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LDWORK \geq \max(1, M)$. .SH FURTHER DETAILS Based on contributions by

NAME

slarzt - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE SLARZT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
INTEGER N, K, LDV, LDT
REAL V(LDV,*), TAU(*), T(LDT,*)
```

```
SUBROUTINE SLARZT_64( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
INTEGER*8 N, K, LDV, LDT
REAL V(LDV,*), TAU(*), T(LDT,*)
```

F95 INTERFACE

```
SUBROUTINE LARZT( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER :: N, K, LDV, LDT
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:, :) :: V, T
```

```
SUBROUTINE LARZT_64( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER(8) :: N, K, LDV, LDT
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:, :) :: V, T
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slarzt(char direct, char storev, int n, int k, float *v, int ldv, float *tau, float *t, int ldt);
```

```
void slarzt_64(char direct, char storev, long n, long k, float *v, long ldv, float *tau, float *t, long ldt);
```

PURPOSE

slarzt forms the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If DIRECT = 'B', $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

$$H = I - V * T * V'$$

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

$$H = I - V' * T * V$$

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

*** DIRECT (input)**

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

*** STOREV (input)**

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):

*** N (input)**

The order of the block reflector H. $N \geq 0$.

*** K (input)**

The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

*** V (input)**

(LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R' The matrix V. See further details.

*** LDV (input)**

The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i).

*** T (input)**

The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq K$. .SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following

example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

$ \begin{array}{l} (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \\ \text{V} = (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \\ \cdot \quad \cdot \quad \cdot \\ \cdot \quad \cdot \quad \cdot \\ 1 \quad \cdot \quad \cdot \\ \quad \quad 1 \quad \cdot \\ \quad \quad \quad 1 \end{array} $	$ \begin{array}{c} \text{-----V-----} \\ / \qquad \qquad \qquad \backslash \\ (\text{v1} \text{ v1} \text{ v1} \text{ v1} \text{ v1} \cdot \cdot \cdot \cdot 1) \\ (\text{v2} \text{ v2} \text{ v2} \text{ v2} \text{ v2} \cdot \cdot \cdot 1) \\ (\text{v3} \text{ v3} \text{ v3} \text{ v3} \text{ v3} \cdot \cdot 1) \end{array} $
---	---

DIRECT = 'B' and STOREV = 'C': DIRECT = 'B' and STOREV = 'R':

$ \begin{array}{l} 1 \\ \cdot \quad 1 \\ \cdot \quad \cdot \quad 1 \\ \cdot \quad \cdot \quad \cdot \\ \cdot \quad \cdot \quad \cdot \\ (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \\ \text{V} = (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \\ (\text{v1} \text{ v2} \text{ v3}) \end{array} $	$ \begin{array}{c} \text{-----V-----} \\ / \qquad \qquad \qquad \backslash \\ (1 \cdot \cdot \cdot \cdot \text{v1} \text{ v1} \text{ v1} \text{ v1} \text{ v1}) \\ (\cdot 1 \cdot \cdot \cdot \cdot \text{v2} \text{ v2} \text{ v2} \text{ v2} \text{ v2}) \\ (\cdot \cdot 1 \cdot \cdot \cdot \cdot \text{v3} \text{ v3} \text{ v3} \text{ v3} \text{ v3}) \end{array} $

NAME

slasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

SYNOPSIS

```
SUBROUTINE SLASRT( ID, N, D, INFO)
CHARACTER * 1 ID
INTEGER N, INFO
REAL D(*)
```

```
SUBROUTINE SLASRT_64( ID, N, D, INFO)
CHARACTER * 1 ID
INTEGER*8 N, INFO
REAL D(*)
```

F95 INTERFACE

```
SUBROUTINE LASRT( ID, [N], D, [INFO])
CHARACTER(LEN=1) :: ID
INTEGER :: N, INFO
REAL, DIMENSION(:) :: D
```

```
SUBROUTINE LASRT_64( ID, [N], D, [INFO])
CHARACTER(LEN=1) :: ID
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slasrt(char id, int n, float *d, int *info);
```

```
void slasrt_64(char id, long n, float *d, long *info);
```

PURPOSE

sort the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of

size ≤ 20 . Dimension of STACK limits N to about 2^{32} .

ARGUMENTS

* **ID** (*input*)

* **N** (*input*)

The length of the array D.

* **D** (*input/output*)

On entry, the array to be sorted. On exit, D has been sorted into increasing order ($D(1) \leq \dots \leq D(N)$) or into decreasing order ($D(1) \geq \dots \geq D(N)$), depending on ID.

* **INFO** (*output*)

NAME

slatzm - routine is deprecated and has been replaced by routine SORMRZ

SYNOPSIS

```
SUBROUTINE SLATZM( SIDE, M, N, V, INCV, TAU, C1, C2, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER M, N, INCV, LDC
REAL TAU
REAL V(*), C1(LDC,*), C2(LDC,*), WORK(*)

SUBROUTINE SLATZM_64( SIDE, M, N, V, INCV, TAU, C1, C2, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER*8 M, N, INCV, LDC
REAL TAU
REAL V(*), C1(LDC,*), C2(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LATZM( SIDE, [M], [N], V, [INCV], TAU, C1, C2, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:, :) :: C1, C2

SUBROUTINE LATZM_64( SIDE, [M], [N], V, [INCV], TAU, C1, C2, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER(8) :: M, N, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:, :) :: C1, C2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slatzm(char side, int m, int n, float *v, int incv, float tau, float *c1, float *c2, int ldc);
```

```
void slatzm_64(char side, long m, long n, float *v, long incv, float tau, float *c1, float *c2, long ldc);
```

PURPOSE

slatzm routine is deprecated and has been replaced by routine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a matrix.

Let $P = I - \tau * u * u'$, $u = \begin{pmatrix} 1 \\ \vdots \\ 0 \end{pmatrix}$,

$$\begin{pmatrix} \vdots \\ v \end{pmatrix}$$

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals 'L', let

$$C = \begin{bmatrix} C1 &] & 1 \\ C2 &] & m-1 \\ & & n \end{bmatrix}$$

Then C is overwritten by $P * C$.

If $SIDE$ equals 'R', let

$$C = \begin{bmatrix} C1, & C2 &] & m \\ & 1 & & n-1 \end{bmatrix}$$

Then C is overwritten by $C * P$.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C .

* **N** (*input*)

The number of columns of the matrix C .

* **V** (*input*)

$(1 + (M-1) * \text{abs}(\text{INCV}))$ if $SIDE = 'L'$ $(1 + (N-1) * \text{abs}(\text{INCV}))$ if $SIDE = 'R'$ The vector v in the representation of P .
 V is not used if $\text{TAU} = 0$.

* **INCV** (*input*)

The increment between elements of v . $\text{INCV} <> 0$

* **TAU** (*input*)

The value τ in the representation of P .

* **C1** (*input/output*)

(LDC, N) if $SIDE = 'L'$ $(M, 1)$ if $SIDE = 'R'$ On entry, the n -vector $C1$ if $SIDE = 'L'$, or the m -vector $C1$ if $SIDE = 'R'$.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

* **C2 (input/output)**

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

* **LDC (input)**

The leading dimension of the arrays C1 and C2. LDC >= (1,M).

* **WORK (workspace)**

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

snrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
REAL FUNCTION SNRM2( N, X, INCX)
INTEGER N, INCX
REAL X(*)
```

```
REAL FUNCTION SNRM2_64( N, X, INCX)
INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION NRM2( [N], X, [INCX])
INTEGER :: N, INCX
REAL, DIMENSION(:) :: X
```

```
REAL FUNCTION NRM2_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
float snrm2(int n, float *x, int incx);
```

```
float snrm2_64(long n, float *x, long incx);
```

PURPOSE

snrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NAME

sopgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage

SYNOPSIS

```
SUBROUTINE SOPGTR( UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDQ, INFO
REAL AP(*), TAU(*), Q(LDQ,*), WORK(*)
```

```
SUBROUTINE SOPGTR_64( UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDQ, INFO
REAL AP(*), TAU(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE OPGTR( UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDQ, INFO
REAL, DIMENSION(:) :: AP, TAU, WORK
REAL, DIMENSION(:, :) :: Q
```

```
SUBROUTINE OPGTR_64( UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDQ, INFO
REAL, DIMENSION(:) :: AP, TAU, WORK
REAL, DIMENSION(:, :) :: Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sopgtr(char uplo, int n, float *ap, float *tau, float *q, int ldq, int *info);
```

```
void sopgtr_64(char uplo, long n, float *ap, float *tau, float *q, long ldq, long *info);
```

PURPOSE

sopgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **AP** (*input*)

The vectors which define the elementary reflectors, as returned by SSPTRD.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSPTRD.

* **Q** (*output*)

The N -by- N orthogonal matrix Q .

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension($N-1$)

* **INFO** (*output*)

NAME

sopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE SOPMTR( SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK,  
* INFO)  
CHARACTER * 1 SIDE, UPLO, TRANS  
INTEGER M, N, LDC, INFO  
REAL AP(*), TAU(*), C(LDC,*), WORK(*)  
  
SUBROUTINE SOPMTR_64( SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC,  
* WORK, INFO)  
CHARACTER * 1 SIDE, UPLO, TRANS  
INTEGER*8 M, N, LDC, INFO  
REAL AP(*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE OPMTR( SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS  
INTEGER :: M, N, LDC, INFO  
REAL, DIMENSION(:) :: AP, TAU, WORK  
REAL, DIMENSION(:, :) :: C  
  
SUBROUTINE OPMTR_64( SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS  
INTEGER(8) :: M, N, LDC, INFO  
REAL, DIMENSION(:) :: AP, TAU, WORK  
REAL, DIMENSION(:, :) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sopmtr(char side, char uplo, char trans, int m, int n, float *ap, float *tau, float *c, int ldc, int *info);
```

```
void sopmtr_64(char side, char uplo, char trans, long m, long n, float *ap, float *tau, float *c, long ldc, long *info);
```

PURPOSE

sopmtr overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSPTRD using packed storage:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *AP (input)*

$(M*(M+1)/2)$ if SIDE = 'L' $(N*(N+1)/2)$ if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

* *TAU (input)*

or $(N-1)$ if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* *WORK (workspace)*

(N) if SIDE = 'L' (M) if SIDE = 'R'

* *INFO (output)*

NAME

sorg2l - generate an m by n real matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE SORG2L( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORG2L_64( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER*8 M, N, K, LDA, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORG2L( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER :: M, N, K, LDA, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A
```

```
SUBROUTINE ORG2L_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER(8) :: M, N, K, LDA, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorg2l(int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorg2l_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorg21 L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix Q . $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix Q . $M \geq N \geq 0$.

* ***K*** (*input*)

The number of elementary reflectors whose product defines the matrix Q . $N \geq K \geq 0$.

* ***A*** (*input/output*)

On entry, the $(n-k+i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A . On exit, the m by n matrix Q .

* ***LDA*** (*input*)

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU*** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQLF.

* ***WORK*** (*workspace*)

dimension(N)

* ***INFO*** (*output*)

NAME

sorg2r - generate an m by n real matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE SORG2R( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```

```
void sorg2r(int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorg2r_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorg2r R generates an m by n real matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGEQRF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $M \geq N \geq 0$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $N \geq K \geq 0$.

* ***A (input/output)***

On entry, the i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQRF in the first k columns of its array argument A . On exit, the m -by- n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQRF.

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

sorgbr - generate one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form

SYNOPSIS

```
SUBROUTINE SORGBR( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
INTEGER M, N, K, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGBR_64( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
INTEGER*8 M, N, K, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGBR( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
CHARACTER(LEN=1) :: VECT
INTEGER :: M, N, K, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGBR_64( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
CHARACTER(LEN=1) :: VECT
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgbr(char vect, int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorgbr_64(char vect, long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorgbr generates one of the real orthogonal matrices Q or P^{**T} determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and SORGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and SORGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{**T} is of order N :

if $k < n$, $P^{**T} = G(k) \dots G(2) G(1)$ and SORGBR returns the first m rows of P^{**T} , where $n \geq m \geq k$;

if $k \geq n$, $P^{**T} = G(n-1) \dots G(2) G(1)$ and SORGBR returns P^{**T} as an N -by- N matrix.

ARGUMENTS

* *VECT* (input)

Specifies whether the matrix Q or the matrix P^{**T} is required, as defined in the transformation applied by SGEBRD:

* *M* (input)

The number of rows of the matrix Q or P^{**T} to be returned. $M \geq 0$.

* *N* (input)

The number of columns of the matrix Q or P^{**T} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M,K)$; if $VECT = 'P'$, $N \geq M \geq \min(N,K)$.

* *K* (input)

If $VECT = 'Q'$, the number of columns in the original M -by- K matrix reduced by SGEBRD. If $VECT = 'P'$, the number of rows in the original K -by- N matrix reduced by SGEBRD. $K \geq 0$.

* *A* (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M -by- N matrix Q or P^{**T} .

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1,M)$.

* *TAU* (input)

$(\min(M,K))$ if $VECT = 'Q'$ ($\min(N,K)$) if $VECT = 'P'$ $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P^{**T} , as returned by SGEBRD in its array argument $TAUQ$ or $TAUP$.

* *WORK* (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* *LWORK* (input)

The dimension of the array $WORK$. $LWORK \geq \max(1, \min(M,N))$. For optimum performance $LWORK \geq \min(M,N) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* *INFO* (output)

NAME

sorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

SYNOPSIS

```
SUBROUTINE SORGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER N, ILO, IHI, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGHR_64( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGHR( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGHR_64( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*                  [INFO])
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorghr(int n, int ilo, int ihi, float *a, int lda, float *tau, int *info);
```

```
void sorghr_64(long n, long ilo, long ihi, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD:

$$Q = H(i_0) H(i_0+1) \dots H(i_{hi}-1).$$

ARGUMENTS

* ***N*** (*input*)

The order of the matrix Q . $N \geq 0$.

* ***ILO*** (*input*)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_0+1:i_{hi}, i_0+1:i_{hi})$. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description of ILO.

* ***A*** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N -by- N orthogonal matrix Q .

* ***LDA*** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* ***TAU*** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEHRD.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK*** (*input*)

The dimension of the array $WORK$. $LWORK \geq IHI - ILO$. For optimum performance $LWORK \geq (IHI - ILO) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* ***INFO*** (*output*)

NAME

sorgl2 - generate an m by n real matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE SORGL2( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGL2_64( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER*8 M, N, K, LDA, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGL2( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER :: M, N, K, LDA, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGL2_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER(8) :: M, N, K, LDA, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgl2(int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorgl2_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $N \geq M$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

* ***A (input/output)***

On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A . On exit, the m -by- n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGELQF.

* ***WORK (workspace)***

dimension(M)

* ***INFO (output)***

NAME

sorglq - generate an M-by-N real matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE SORGLQ( M, N, K, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, K, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGLQ_64( M, N, K, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, K, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGLQ( M, [N], [K], A, [LDA], TAU, [WORK], [LDWORK],
*               [INFO])
INTEGER :: M, N, K, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGLQ_64( M, [N], [K], A, [LDA], TAU, [WORK], [LDWORK],
*                  [INFO])
INTEGER(8) :: M, N, K, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorglq(int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorglq_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

sorgql - generate an M-by-N real matrix Q with orthonormal columns,

SYNOPSIS

```

REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGQL_64( M, [N], [K], A, [LDA], TAU, [WORK], [LDWORK],
*                  [INFO])
INTEGER(8) :: M, N, K, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgql(int m, int n, int k, float *a, int lda, float *tau, int *info);
```

```
void sorgql_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

*** A (input/output)**

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N \cdot NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

sorgqr - generate an M-by-N real matrix Q with orthonormal columns,

SYNOPSIS

```

```

```
void sorgqr_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorgqr generates an M-by-N real matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGEQRF.

ARGUMENTS

* **M** (*input*)

The number of rows of the matrix Q. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix Q. $M \geq N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

* **A** (*input/output*)

On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

* **LDA** (*input*)

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

```

```
void sorgrq_64(long m, long n, long k, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorghq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGERQF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

sorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

SYNOPSIS

```
SUBROUTINE SORGTR( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGTR_64( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGTR( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGTR_64( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgtr(char uplo, int n, float *a, int lda, float *tau, int *info);
```

```
void sorgtr_64(char uplo, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

sorgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by SSYTRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **A** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N -by- N orthogonal matrix Q .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSYTRD.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq \max(1, N-1)$. For optimum performance $LWORK \geq (N-1) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

sormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE SORMBR( VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC,
*   WORK, LWORK, INFO)
CHARACTER * 1 VECT, SIDE, TRANS
INTEGER M, N, K, LDA, LDC, LWORK, INFO
REAL A(LDA,*), TAU(*), C(LDC,*), WORK(*)

SUBROUTINE SORMBR_64( VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C,
*   LDC, WORK, LWORK, INFO)
CHARACTER * 1 VECT, SIDE, TRANS
INTEGER*8 M, N, K, LDA, LDC, LWORK, INFO
REAL A(LDA,*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORMBR( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU,
*   C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: VECT, SIDE, TRANS
INTEGER :: M, N, K, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A, C

SUBROUTINE ORMBR_64( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA],
*   TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: VECT, SIDE, TRANS
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sormbr(char vect, char side, char trans, int m, int n, int k, float *a, int lda, float *tau, float *c, int ldc, int *info);
```

```
void sormbr_64(char vect, char side, char trans, long m, long n, long k, float *a, long lda, float *tau, float *c, long ldc, long *info);
```

PURPOSE

sormbr VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': $Q * C * Q^T$ TRANS = 'T': $Q^{**T} * C * Q^{**T}$

If VECT = 'P', SORMBR overwrites the general real M-by-N matrix C with

SIDE = 'L' SIDE = 'R'

TRANS = 'N': $P * C * P$

TRANS = 'T': $P^{**T} * C * P^{**T}$

Here Q and P^{**T} are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P^{**T} that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

if $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if $k < nq$, $P = G(1) G(2) \dots G(k)$;

if $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

ARGUMENTS

* *VECT (input)*

* *SIDE (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *K (input)*

If VECT = 'Q', the number of columns in the original matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by SGEBRD. $K \geq 0$.

* *A (input)*

(LDA, min(nq, K)) if VECT = 'Q' (LDA, nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by SGEBRD.

* *LDA (input)*

The leading dimension of the array A. If VECT = 'Q', $LDA \geq \max(1, nq)$; if VECT = 'P', $LDA \geq \max(1, \min(nq, K))$.

* *TAU (input)*

TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by SGEBRD in the array argument TAUQ or TAUP.

* ***C*** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or C^*Q^{**T} or C^*Q or P^*C or $P^{**T}C$ or C^*P or C^*P^{**T} .

* ***LDC*** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK*** (*input*)

The dimension of the array $WORK$. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if $SIDE = 'L'$, and $LWORK \geq M * NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

* ***INFO*** (*output*)

NAME

sormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE SORMHR( SIDE, TRANS, M, N, ILO, IHI, A, LDA, TAU, C, LDC,
*   WORK, LWORK, INFO)

*   TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, TRANS
INTEGER(8) :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sormhr(char side, char trans, int m, int n, int ilo, int ihi, float *a, int lda, float *tau, float *c, int ldc, int *info);
```

```
void sormhr_64(char side, char trans, long m, long n, long ilo, long ihi, float *a, long lda, float *tau, float *c, long ldc, long *info);
```

PURPOSE

sormhr overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by SGEHRD:

$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1)$.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **ILO** (*input*)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_{lo}+1:i_{hi}, i_{lo}+1:i_{hi})$. If SIDE = 'L', then $1 \leq ILO \leq IHI \leq M$, if $M > 0$, and $ILO = 1$ and $IHI = 0$, if $M = 0$; if SIDE = 'R', then $1 \leq ILO \leq IHI \leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input*)

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

* **TAU** (*input*)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1,N)$; if SIDE = 'R', $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by

XERBLA.

* *INFO (output)*

```

```
void sormrz_64(char side, char trans, long m, long n, long k, long l, float *a, long lda, float *tau, float *c, long ldc, long *info);
```

PURPOSE

sormrz overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by STZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **L** (*input*)

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by STZRZF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**H} * C$ or $C * Q^{**H}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

* ***INFO*** (*output*)

NAME

SYNOPSIS

```
SUBROUTINE SORMTR( SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC,
*   WORK, LWORK, INFO)
CHARACTER * 1 SIDE, UPLO, TRANS
INTEGER M, N, LDA, LDC, LWORK, INFO
REAL A(LDA,*), TAU(*), C(LDC,*), WORK(*)

SUBROUTINE SORMTR_64( SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC,
*   WORK, LWORK, INFO)
CHARACTER * 1 SIDE, UPLO, TRANS
INTEGER*8 M, N, LDA, LDC, LWORK, INFO
REAL A(LDA,*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORMTR( SIDE, UPLO, [TRANS], [M], [N], A, [LDA], TAU, C,
*   [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
INTEGER :: M, N, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A, C

SUBROUTINE ORMTR_64( SIDE, UPLO, [TRANS], [M], [N], A, [LDA], TAU,
*   C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
INTEGER(8) :: M, N, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sormtr(char side, char uplo, char trans, int m, int n, float *a, int lda, float *tau, float *c, int ldc, int *info);
```

```
void sormtr_64(char side, char uplo, char trans, long m, long n, float *a, long lda, float *tau, float *c, long ldc, long *info);
```

PURPOSE

sormtr overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSYTRD:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *A (input)*

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSYTRD.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

* *TAU (input)*

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* *WORK (workspace)*

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* *LWORK (input)*

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1,N)$; if SIDE = 'R', $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* *INFO (output)*

NAME

spbc0 - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then SPBFA is slightly faster. It is typical to follow a call to SPBCO with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SPBCO( A, LDA, N, NDIAG, RCOND, WORK, INFO)
INTEGER LDA, N, NDIAG, INFO
REAL RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SPBCO_64( A, LDA, N, NDIAG, RCOND, WORK, INFO)
INTEGER*8 LDA, N, NDIAG, INFO
REAL RCOND
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbc0(float *a, int lda, int n, int ndiag, float *rcond, int *info);
```

```
void spbc0_64(float *a, long lda, long n, long ndiag, float *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N \neq 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

spbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF

SYNOPSIS

```
SUBROUTINE SPBCON( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,  
*                WORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER N, NDIAG, LDA, INFO  
INTEGER WORK2(*)  
REAL ANORM, RCOND  
REAL A(LDA,*), WORK(*)  
  
SUBROUTINE SPBCON_64( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,  
*                   WORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER*8 N, NDIAG, LDA, INFO  
INTEGER*8 WORK2(*)  
REAL ANORM, RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PBCON( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],  
*               [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, NDIAG, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A  
  
SUBROUTINE PBCON_64( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],  
*                   [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NDIAG, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbcon(char uplo, int n, int ndiag, float *a, int lda, float anorm, float *rcond, int *info);
```

```
void spbcon_64(char uplo, long n, long ndiag, float *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

spbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ of the band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \text{NDIAG}+1$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the symmetric band matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

spbdi - (obsolete) compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA.

SYNOPSIS

```
SUBROUTINE SPBDI( A, LDA, N, NDIAG, DET)
  INTEGER LDA, N, NDIAG
  REAL A(LDA,*), DET(*)
```

```
SUBROUTINE SPBDI_64( A, LDA, N, NDIAG, DET)
  INTEGER*8 LDA, N, NDIAG
  REAL A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbdi(float *a, int lda, int n, int ndiag, float *det);
```

```
void spbdi_64(float *a, long lda, long n, long ndiag, float *det);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A, as computed by SPBCO or SPBFA.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= NDIAG + 1.

* **N** (*input*)

Order of the original matrix A. N >= 0.

* **NDIAG** (*input*)

Number of diagonals. N-1 >= NDIAG >= 0 but if N = 0 then NDIAG = 0.

* **DET** (*output*)

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0.

NAME

spbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE SPBEQU( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)
```

```
SUBROUTINE SPBEQU_64( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX,
* INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A

SUBROUTINE PBEQU_64( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbequ(char uplo, int n, int ndiag, float *a, int lda, float *scale, float *scond, float *amax, int *info);
```

```
void spbequ_64(char uplo, long n, long ndiag, float *a, long lda, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

spbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **SCALE** (*output*)

If INFO = 0, SCALE contains the scale factors for A.

* **SCOND** (*output*)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

* **AMAX** (*output*)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

spbfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to SPBFA with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SPBFA( A, LDA, N, NDIAG, INFO)
INTEGER LDA, N, NDIAG, INFO
REAL A(LDA,*)
```

```
SUBROUTINE SPBFA_64( A, LDA, N, NDIAG, INFO)
INTEGER*8 LDA, N, NDIAG, INFO
REAL A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbfa(float *a, int lda, int n, int ndiag, int *info);
```

```
void spbfa_64(float *a, long lda, long n, long ndiag, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value of k if the leading minor of order k is not positive definite.

NAME

spbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SPBRFS( UPLO, N, NDIAG, NRHS, A, LDA, AF, LDAF, B, LDB,
*      X, LDX, FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO

INTEGER*8 WORK2(*)
REAL A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PBRFS( UPLO, [N], NDIAG, [NRHS], A, [LDA], AF, [LDAF], B,
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:, :) :: A, AF, B, X

SUBROUTINE PBRFS_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], AF, [LDAF],
*      B, [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:, :) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbrfs(char uplo, int n, int ndiag, int nrhs, float *a, int lda, float *af, int ldaf, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void spbrfs_64(char uplo, long n, long ndiag, long nrhs, float *a, long lda, float *af, long ldaf, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

spbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) < i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j < i \leq \min(n, j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*T}U$ or $A = L^{*}L^{*T}$ of the band matrix A as computed by SPBTRF, in the same storage format as A (see A).

* **LDAF** (*input*)

The leading dimension of the array AF. LDAF \geq NDIAG+1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. LDB \geq max(1,N).

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

spbsl - (obsolete) section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SPBSL( A, LDA, N, NDIAG, B)
INTEGER LDA, N, NDIAG
REAL A(LDA,*), B(*)
```

```
SUBROUTINE SPBSL_64( A, LDA, N, NDIAG, B)
INTEGER*8 LDA, N, NDIAG
REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbsl(float *a, int lda, int n, int ndiag, float *b);
```

```
void spbsl_64(float *a, long lda, long n, long ndiag, float *b);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A , as computed by SPBCO or SPBFA.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

Number of diagonals of matrix A . $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

spbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE SPBSTF( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER N, KD, LDAB, INFO
REAL AB(LDAB,*)
```

```
SUBROUTINE SPBSTF_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, KD, LDAB, INFO
REAL AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBSTF( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL, DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBSTF_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbstf(char uplo, int n, int kd, float *ab, int ldab, int *info);
```

```
void spbstf_64(char uplo, long n, long kd, float *ab, long ldab, long *info);
```

PURPOSE

spbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.

The factorization has the form $A = S^{**T}S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & M & L \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^{**T}S$. See Further Details.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq kd+1$.

* **INFO** (*output*)

NAME

spbsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SPBSV( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SPBSV_64( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```

```
void spbsv(char uplo, int n, int ndiag, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void spbsv_64(char uplo, long n, long ndiag, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

spbsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $NDIAG+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$ of the band matrix A, in the same storage format as A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NDIAG+1$.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

spbsvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbsvx(char fact, char uplo, int n, int ndiag, int nrhs, float *a, int lda, float *af, int ldaf, char equed, float *scale, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void spbsvx_64(char fact, char uplo, long n, long ndiag, long nrhs, float *a, long lda, float *af, long ldaf, char equed, float *scale, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

spbsvx uses the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric positive definite band matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $FACT = 'E'$) as $A = U^{**T} * U$, if $UPLO = 'U'$, or

```
A = L * L^{**T}, if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.
```

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $diag(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix *A*. $N \geq 0$.

* *NDIAG* (input)

The number of superdiagonals of the matrix *A* if *UPLO* = 'U', or the number of subdiagonals if *UPLO* = 'L'. *NDIAG* ≥ 0 .

* *NRHS* (input)

The number of right-hand sides, i.e., the number of columns of the matrices *B* and *X*. *NRHS* ≥ 0 .

* *A* (input/output)

On entry, the upper or lower triangle of the symmetric band matrix *A*, stored in the first *NDIAG*+1 rows of the array, except if *FACT* = 'F' and *EQUED* = 'Y', then *A* must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. The *j*-th column of *A* is stored in the *j*-th column of the array *A* as follows: if *UPLO* = 'U', $A(\text{NDIAG}+1+i-j, j) = A(i, j)$ for $\max(1, j-\text{NDIAG}) \leq i \leq j$; if *UPLO* = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+\text{NDIAG})$. See below for further details.

On exit, if *FACT* = 'E' and *EQUED* = 'Y', *A* is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* *LDA* (input)

The leading dimension of the array *A*. *LDA* $\geq \text{NDIAG}+1$.

* *AF* (input/output)

If *FACT* = 'F', then *AF* is an input argument and on entry contains the triangular factor *U* or *L* from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ of the band matrix *A*, in the same storage format as *A* (see *A*). If *EQUED* = 'Y', then *AF* is the factored form of the equilibrated matrix *A*.

If *FACT* = 'N', then *AF* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

If *FACT* = 'E', then *AF* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ of the equilibrated matrix *A* (see the description of *A* for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array *AF*. *LDAF* $\geq \text{NDIAG}+1$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for *A*; not accessed if *EQUED* = 'N'. *SCALE* is an input argument if *FACT* = 'F'; otherwise, *SCALE* is an output argument. If *FACT* = 'F' and *EQUED* = 'Y', each element of *SCALE* must be positive.

* *B* (input/output)

On entry, the *N*-by-*NRHS* right hand side matrix *B*. On exit, if *EQUED* = 'N', *B* is not modified; if *EQUED* = 'Y', *B* is overwritten by $\text{diag}(\text{SCALE}) * B$.

* *LDB* (input)

The leading dimension of the array *B*. *LDB* $\geq \max(1, N)$.

* *X* (output)

If *INFO* = 0 or *INFO* = *N*+1, the *N*-by-*NRHS* solution matrix *X* to the original system of equations. Note that if

EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* **LDX** (*input*)

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $\text{RCOND} = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $\text{INFO} > 0$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $\text{FERR}(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - \text{XTRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

spbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE SPBTF2( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER N, KD, LDAB, INFO
REAL AB(LDAB,*)
```

```
SUBROUTINE SPBTF2_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, KD, LDAB, INFO
REAL AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTf2( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL, DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBTf2_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbtf2(char uplo, int n, int kd, float *ab, int ldab, int *info);
```

```
void spbtf2_64(char uplo, long n, long kd, float *ab, long ldab, long *info);
```

PURPOSE

spbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', & \end{aligned}$$

where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** KD (input)**

The number of super-diagonals of the matrix A if $UPLO = 'U'$, or the number of sub-diagonals if $UPLO = 'L'$. $KD \geq 0$.

*** AB (input/output)**

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U*U$ or $A = L*L'$ of the band matrix A, in the same storage format as A.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq KD+1$.

*** INFO (output)**

NAME

spbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE SPBTRF( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, LDA, INFO
REAL A(LDA,*)
```

```
SUBROUTINE SPBTRF_64( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, LDA, INFO
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE PBTRF( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE PBTRF_64( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbtrf(char uplo, int n, int ndiag, float *a, int lda, int *info);
```

```
void spbtrf_64(char uplo, long n, long ndiag, float *a, long lda, long *info);
```

PURPOSE

spbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if UPLO} = 'U', & \text{or} \\ A &= L * L^{**T}, & \text{if UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$ of the band matrix A, in the same storage format as A.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **INFO** (*output*)

NAME

spbtrs - solve a system of linear equations $A*X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U**T*U$ or $A = L*L**T$ computed by SPBTRF

SYNOPSIS

```
SUBROUTINE SPBTRS( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SPBTRS_64( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTRS( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
*               [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,*) :: A, B
```

```
SUBROUTINE PBTRS_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
*                  [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spbtrs(char uplo, int n, int ndiag, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void spbtrs_64(char uplo, long n, long ndiag, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

spbtrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPBTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ of the band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

spoco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then SPOFA is slightly faster. It is typical to follow a call to SPOCO with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE SPOCO( A, LDA, N, RCOND, WORK, INFO)
INTEGER LDA, N, INFO
REAL RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SPOCO_64( A, LDA, N, RCOND, WORK, INFO)
INTEGER*8 LDA, N, INFO
REAL RCOND
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spoco(float *a, int lda, int n, float *rcond, int *info);
```

```
void spoco_64(float *a, long lda, long n, float *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

*** WORK (workspace)**

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

spocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE SPOCON( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SPOCON_64( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE POCON( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POCON_64( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spocon(char uplo, int n, float *a, int lda, float anorm, float *rcond, int *info);
```

```
void spocon_64(char uplo, long n, float *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

spocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$ computed by SPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$, as computed by SPOTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the symmetric matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

spodi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by SPOCO, SPOFA, or SQRDC.

SYNOPSIS

```
SUBROUTINE SPODI( A, LDA, N, DET, JOB)
  INTEGER LDA, N, JOB
  REAL A(LDA,*), DET(*)
```

```
SUBROUTINE SPODI_64( A, LDA, N, DET, JOB)
  INTEGER*8 LDA, N, JOB
  REAL A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spodi(float *a, int lda, int n, float *det, int job);
```

```
void spodi_64(float *a, long lda, long n, float *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by SPOCO, SPOFA, or SQRDC. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse

- 01 inverse only
- 10 determinant only

NAME

spoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE SPOEQU( N, A, LDA, SCALE, SCOND, AMAX, INFO)
INTEGER N, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)
```

```
SUBROUTINE SPOEQU_64( N, A, LDA, SCALE, SCOND, AMAX, INFO)
INTEGER*8 N, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
INTEGER :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POEQU_64( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
INTEGER(8) :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spoequ(int n, float *a, int lda, float *scale, float *scond, float *amax, int *info);
```

```
void spoequ_64(long n, float *a, long lda, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

speoqu computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** SCALE (output)**

If INFO = 0, SCALE contains the scale factors for A.

*** SCOND (output)**

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

spofa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to SPOFA with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE SPOFA( A, LDA, N, INFO)
  INTEGER LDA, N, INFO
  REAL A(LDA,*)
```

```
SUBROUTINE SPOFA_64( A, LDA, N, INFO)
  INTEGER*8 LDA, N, INFO
  REAL A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spofa(float *a, int lda, int n, int *info);
```

```
void spofa_64(float *a, long lda, long n, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

sporfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

SYNOPSIS

```
SUBROUTINE SPORFS( UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
*      FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER WORK2(*)
REAL A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)

SUBROUTINE SPORFS_64( UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X,
*      LDX, FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER*8 WORK2(*)
REAL A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PORFS( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B, [LDB],
*      X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:, :) :: A, AF, B, X

SUBROUTINE PORFS_64( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B,
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:, :) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sporfs(char uplo, int n, int nrhs, float *a, int lda, float *af, int ldaf, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void sporfs_64(char uplo, long n, long nrhs, float *a, long lda, float *af, long ldaf, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*T}U$ or $A = L^{*L}L^{*T}$, as computed by SPOTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($3*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

sposl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by SPOCO or SPOFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SPOSL( A, LDA, N, B )
INTEGER LDA, N
REAL A(LDA,*), B(*)
```

```
SUBROUTINE SPOSL_64( A, LDA, N, B )
INTEGER*8 LDA, N
REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sposl(float *a, int lda, int n, float *b);
```

```
void sposl_64(float *a, long lda, long n, float *b);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by SPOCO or SPOFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

sposv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SPOSV( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SPOSV_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE POSV( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE POSV_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sposv(char uplo, int n, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void sposv_64(char uplo, long n, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

sposv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

sposvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SPOSVX( FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED,

REAL, DIMENSION(:,) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sposvx(char fact, char uplo, int n, int nrhs, float *a, int lda, float *af, int ldaf, char equed, float *scale, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sposvx_64(char fact, char uplo, long n, long nrhs, float *a, long lda, float *af, long ldaf, char equed, float *scale, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sposvx uses the Cholesky factorization $A = U^{**T}U$ or $A = L^{**T}L$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $FACT = 'E'$) as $A = U^{**T}U$, if $UPLO = 'U'$, or

```
A = L * L^{**T}, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $diag(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the symmetric matrix A, except if *FACT* = 'F' and *EQUED* = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. If *UPLO* = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *FACT* = 'E' and *EQUED* = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *AF* (input/output)

If *FACT* = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$, in the same storage format as A. If *EQUED* = 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

If *FACT* = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$ of the original matrix A.

If *FACT* = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if *EQUED* = 'N'. *SCALE* is an input argument if *FACT* = 'F'; otherwise, *SCALE* is an output argument. If *FACT* = 'F' and *EQUED* = 'Y', each element of *SCALE* must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if *EQUED* = 'N', B is not modified; if *EQUED* = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *X* (output)

If *INFO* = 0 or *INFO* = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if *EQUED* = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

spotf2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

SYNOPSIS

```
SUBROUTINE SPOTF2( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
REAL A(LDA,*)
```

```
SUBROUTINE SPOTF2_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE POTF2( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POTF2_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spotf2(char uplo, int n, float *a, int lda, int *info);
```

```
void spotf2_64(char uplo, long n, float *a, long lda, long *info);
```

PURPOSE

spotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', & \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** INFO (output)**

NAME

spotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

SYNOPSIS

```
SUBROUTINE SPOTRF( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
REAL A(LDA,*)
```

```
SUBROUTINE SPOTRF_64( UPLO, N, A, LDA, INFO)

REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POTRF_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spotrf(char uplo, int n, float *a, int lda, int *info);
```

```
void spotrf_64(char uplo, long n, float *a, long lda, long *info);
```

PURPOSE

spotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if UPLO} = 'U', & \text{or} \\ A &= L * L^{**T}, & \text{if UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

spotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE SPOTRI( UPLO, N, A, LDA, INFO)

SUBROUTINE POTRI( UPLO, [N], A, [LDA], [INFO])
  CHARACTER(LEN=1) :: UPLO
  INTEGER :: N, LDA, INFO
  REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POTRI_64( UPLO, [N], A, [LDA], [INFO])
  CHARACTER(LEN=1) :: UPLO
  INTEGER(8) :: N, LDA, INFO
  REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spotri(char uplo, int n, float *a, int lda, int *info);
```

```
void spotri_64(char uplo, long n, float *a, long lda, long *info);
```

PURPOSE

spotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$ computed by SPOTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$, as computed by SPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

spotrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE SPOTRS( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SPOTRS_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE POTRS( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO

REAL, DIMENSION(:,*) :: A, B
```

```
SUBROUTINE POTRS_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spotrs(char uplo, int n, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void spotrs_64(char uplo, long n, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

spotsr solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPOTRF.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$, as computed by SPOTRF.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

sppco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then SPPFA is slightly faster. It is typical to follow a call to SPPCO with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE SPPCO( A, N, RCOND, WORK, INFO)
  INTEGER N, INFO
  REAL RCOND
  REAL A(*), WORK(*)
```

```
SUBROUTINE SPPCO_64( A, N, RCOND, WORK, INFO)
  INTEGER*8 N, INFO
  REAL RCOND
  REAL A(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppco(float *a, int n, float *rcond, int *info);
```

```
void sppco_64(float *a, long n, float *rcond, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N <> 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

sppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPSTRF

SYNOPSIS

```
SUBROUTINE SPPCON( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER WORK2(*)
REAL ANORM, RCOND
REAL A(*), WORK(*)

SUBROUTINE SPPCON_64( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
REAL ANORM, RCOND
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK

SUBROUTINE PPCON_64( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppcon(char uplo, int n, float *a, float anorm, float *rcond, int *info);
```

```
void sppcon_64(char uplo, long n, float *a, float anorm, float *rcond, long *info);
```

PURPOSE

sppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the symmetric matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

$\text{dimension}(2*N)$

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

sppdi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA.

SYNOPSIS

```
SUBROUTINE SPPDI( A, N, DET, JOB)
  INTEGER N, JOB
  REAL A(*), DET(*)
```

```
SUBROUTINE SPPDI_64( A, N, DET, JOB)
  INTEGER*8 N, JOB
  REAL A(*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppdi(float *a, int n, float *det, int job);
```

```
void sppdi_64(float *a, long n, float *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by SPPCO or SPPFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse
- o 01 inverse only
- o 10 determinant only

NAME

sppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE SPPEQU( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
REAL SCOND, AMAX
REAL A(*), SCALE(*)
```

```
SUBROUTINE SPPEQU_64( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
REAL SCOND, AMAX
REAL A(*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: A, SCALE
```

```
SUBROUTINE PPEQU_64( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: A, SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppequ(char uplo, int n, float *a, float *scale, float *scond, float *amax, int *info);
```

```
void sppequ_64(char uplo, long n, float *a, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

spequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **SCALE** (*output*)

If INFO = 0, SCALE contains the scale factors for A.

* **SCOND** (*output*)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

* **AMAX** (*output*)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

sppfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to SPPFA with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE SPPFA( A, N, INFO)
  INTEGER N, INFO
  REAL A( *)
```

```
SUBROUTINE SPPFA_64( A, N, INFO)
  INTEGER*8 N, INFO
  REAL A( *)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppfa(float *a, int n, int *info);
```

```
void sppfa_64(float *a, long n, long *info);
```

ARGUMENTS

* *A* (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* *N* (*input*)

Order of the matrix A. $N \geq 0$.

* *INFO* (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SPPSL will divide by zero if called.

NAME

spprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SPPRFS( UPLO, N, NRHS, A, AF, B, LDB, X, LDX, FERR, BERR,  
*      WORK, WORK2, INFO)

```

F95 INTERFACE

```
SUBROUTINE PPRFS( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX], FERR,  
*      BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, NRHS, LDB, LDX, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL, DIMENSION(:) :: A, AF, FERR, BERR, WORK  
REAL, DIMENSION(:, :) :: B, X  
  
SUBROUTINE PPRFS_64( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX],  
*      FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NRHS, LDB, LDX, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL, DIMENSION(:) :: A, AF, FERR, BERR, WORK  
REAL, DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spprfs(char uplo, int n, int nrhs, float *a, float *af, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void spprfs_64(char uplo, long n, long nrhs, float *a, float *af, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

spprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any

element of A or B that makes X(j) an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

sppsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SPPSL( A, N, B)
INTEGER N
REAL A(*), B(*)
```

```
SUBROUTINE SPPSL_64( A, N, B)
INTEGER*8 N

```

```
void sppsl(float *a, int n, float *b);
```

```
void sppsl_64(float *a, long n, float *b);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A , as computed by SPPCO or SPPFA.

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

sppsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SPPSV( UPLO, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDB, INFO
REAL A(*), B(LDB,*)
```

```
SUBROUTINE SPPSV_64( UPLO, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDB, INFO
REAL A(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PPSV( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE PPSV_64( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppsv(char uplo, int n, int nrhs, float *a, float *b, int ldb, int *info);
```

```
void sppsv_64(char uplo, long n, long nrhs, float *a, float *b, long ldb, long *info);
```

PURPOSE

sppsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } \text{UPLO} = \text{'U'}, & \text{ or} \\ A &= L * L^{**T}, & \text{if } \text{UPLO} = \text{'L'}, \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $\text{NRHS} \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $\text{UPLO} = \text{'U'}$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $\text{UPLO} = \text{'L'}$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $\text{INFO} = 0$, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$, in the same storage format as A.

* **B** (*input/output*)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $\text{INFO} = 0$, the N-by-NRHS solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

* **INFO** (*output*)

NAME

sppsvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L^{**T}L$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE SPPSVX( FACT, UPLO, N, NRHS, A, AF, EQUED, SCALE, B, LDB,

REAL, DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sppsvox(char fact, char uplo, int n, int nrhs, float *a, float *af, char equed, float *scale, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sppsvox_64(char fact, char uplo, long n, long nrhs, float *a, float *af, char equed, float *scale, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sppsvox uses the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{**T} * U$, if UPLO = 'U', or

```
A = L * L^{**T}, if UPLO = 'L',
```

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if $FACT = 'F'$ and $EQUED = 'Y'$, then A must contain the equilibrated matrix $diag(SCALE)*A*diag(SCALE)$. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if $FACT = 'F'$ or $'N'$, or if $FACT = 'E'$ and $EQUED = 'N'$ on exit.

On exit, if $FACT = 'E'$ and $EQUED = 'Y'$, A is overwritten by $diag(SCALE)*A*diag(SCALE)$.

* *AF* (input/output)

$(N*(N+1)/2)$ If $FACT = 'F'$, then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U*U$ or $A = L*L'$, in the same storage format as A. If $EQUED = 'N'$, then AF is the factored form of the equilibrated matrix A.

If $FACT = 'N'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U*U$ or $A = L*L'$ of the original matrix A.

If $FACT = 'E'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U*U$ or $A = L*L'$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if $EQUED = 'N'$. SCALE is an input argument if $FACT = 'F'$; otherwise, SCALE is an output argument. If $FACT = 'F'$ and $EQUED = 'Y'$, each element of SCALE must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $EQUED = 'N'$, B is not modified; if $EQUED = 'Y'$, B is overwritten by $diag(SCALE) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *X* (output)

If $INFO = 0$ or $INFO = N+1$, the N-by-NRHS solution matrix X to the original system of equations. Note that if $EQUED = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(SCALE))*X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* *RCOND* (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

* *FERR* (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(3*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

spptf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE SPPTRF( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
REAL A(*)
```

```
SUBROUTINE SPPTRF_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE PPTRF( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL, DIMENSION(:) :: A
```

```
SUBROUTINE PPTRF_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spptf(char uplo, int n, float *a, int *info);
```

```
void spptf_64(char uplo, long n, float *a, long *info);
```

PURPOSE

spptf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$, in the same storage format as A.

* *INFO* (*output*)

NAME

sptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPTRF

SYNOPSIS

```
SUBROUTINE SPPTRI( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
REAL A(*)

SUBROUTINE SPPTRI_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE PPTRI( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL, DIMENSION(:) :: A

SUBROUTINE PPTRI_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sptri(char uplo, int n, float *a, int *info);

void sptri_64(char uplo, long n, float *a, long *info);
```

PURPOSE

spptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPSTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

* *INFO* (*output*)

NAME

spptrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPSTRF

SYNOPSIS

void spptrs_64(char uplo, long n, long nrhs, float *a, float *b, long ldb, long *info);
```

PURPOSE

spptrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPSTRF.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1) \cdot j / 2) = U(i, j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1) \cdot (2n-j) / 2) = L(i, j)$ for $j \leq i \leq n$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

sptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L^*D*L^{**T}$ or $A = U^{**T}*D*U$ computed by SPTTRF

SYNOPSIS

```
SUBROUTINE SPTCON( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
INTEGER N, INFO
REAL ANORM, RCOND
REAL DIAG(*), OFFD(*), WORK(*)
```

```
SUBROUTINE SPTCON_64( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
INTEGER*8 N, INFO
REAL ANORM, RCOND
REAL DIAG(*), OFFD(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCON( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
INTEGER :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: DIAG, OFFD, WORK
```

```
SUBROUTINE PTCON_64( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
INTEGER(8) :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: DIAG, OFFD, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sptcon(int n, float *diag, float *offd, float anorm, float *rcond, int *info);
```

```
void sptcon_64(long n, float *diag, float *offd, float anorm, float *rcond, long *info);
```

PURPOSE

sptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L*D*L**T$ or $A = U**T*D*U$ computed by SPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* *N (input)*

The order of the matrix A. $N \geq 0$.

* *DIAG (input)*

The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by SPTTRF.

* *OFFD (input)*

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

* *ANORM (input)*

The 1-norm of the original matrix A.

* *RCOND (output)*

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

* *WORK (workspace)*

dimension(N)

* *INFO (output)*

NAME

spteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

SYNOPSIS

```
SUBROUTINE SPTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
INTEGER N, LDZ, INFO
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SPTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
INTEGER*8 N, LDZ, INFO
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE PTEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spteqr(char compz, int n, float *d, float *e, float *z, int ldz, int *info);
```

```
void spteqr_64(char compz, long n, float *d, float *e, float *z, long ldz, long *info);
```

PURPOSE

spteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if COMPZ = 'V' or 'I', $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

sptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SPTRFS( N, NRHS, DIAG, OFFD, DIAGF, OFFDF, B, LDB, X,  
*      LDX, FERR, BERR, WORK, INFO)

```

```
void sptrfs_64(long n, long nrhs, float *diag, float *offd, float *diagf, float *offdf, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sprtrs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* ***N (input)***

The order of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* ***DIAG (input)***

The n diagonal elements of the tridiagonal matrix A.

* ***OFFD (input)***

The $(n-1)$ subdiagonal elements of the tridiagonal matrix A.

* ***DIAGF (input)***

The n diagonal elements of the diagonal matrix DIAG from the factorization computed by SPTTRF.

* ***OFFDF (input)***

The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the factorization computed by SPTTRF.

* ***B (input)***

The right hand side matrix B.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* ***X (input/output)***

On entry, the solution matrix X, as computed by SPTTRS. On exit, the improved solution matrix X.

* ***LDX (input)***

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* ***FERR (output)***

The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

sptsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE SPTSL( N, DIAG, OFFD, B )
INTEGER N
REAL DIAG( * ), OFFD( * ), B( * )

SUBROUTINE SPTSL_64( N, DIAG, OFFD, B )
INTEGER*8 N
REAL DIAG( * ), OFFD( * ), B( * )
```

C INTERFACE

```
#include <sunperf.h>

void sptsl(int n, float *diag, float *offd, float *b);

void sptsl_64(long n, float *diag, float *offd, float *b);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *DIAG* (*input*)

Main diagonal elements of A .

* *OFFD* (*input*)

Off diagonal elements of A . $OFFD(1)$ through $OFFD(N*1)$ contains the off diagonal elements; $OFFD(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

sptsv - compute the solution to a real system of linear equations $A \cdot X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

SYNOPSIS

```
SUBROUTINE SPTSV( N, NRHS, DIAG, SUB, B, LDB, INFO)
INTEGER N, NRHS, LDB, INFO
REAL DIAG(*), SUB(*), B(LDB,*)
```

```
SUBROUTINE SPTSV_64( N, NRHS, DIAG, SUB, B, LDB, INFO)
INTEGER*8 N, NRHS, LDB, INFO
REAL DIAG(*), SUB(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PTSV( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG, SUB
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE PTSV_64( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG, SUB
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sptsv(int n, int nrhs, float *diag, float *sub, float *b, int ldb, int *info);
```

```
void sptsv_64(long n, long nrhs, float *diag, float *sub, float *b, long ldb, long *info);
```

PURPOSE

sptsv computes the solution to a real system of linear equations $A \cdot X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as $A = L \cdot D \cdot L^{**T}$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization $A = L \cdot \text{DIAG} \cdot L^{**T}$.

*** SUB (input/output)**

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L \cdot \text{DIAG} \cdot L^{**T}$ factorization of A. (SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^{**T} \cdot \text{DIAG} \cdot U$ factorization of A.)

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

sptsvx - use the factorization $A = L*D*L^T$ to compute the solution to a real system of linear equations $A*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

SYNOPSIS

```

```
void sptsvx(char fact, int n, int nrhs, float *diag, float *sub, float *diagf, float *subf, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sptsvx_64(char fact, long n, long nrhs, float *diag, float *sub, float *diagf, float *subf, float *b, long ldb, float *x, long ldx,
```

float *rcond, float *ferr, float *berr, long *info);

PURPOSE

sptsvx uses the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as $A = L^*D^*L^{**T}$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form

$$A = U^{**T}D^*U.$$

2. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

*** FACT (input)**

Specifies whether or not the factored form of A has been supplied on entry.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** DIAG (input)**

The n diagonal elements of the tridiagonal matrix A.

*** SUB (input)**

The (n-1) subdiagonal elements of the tridiagonal matrix A.

*** DIAGF (input/output)**

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**T}$ factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**T}$ factorization of A.

*** SUBF (input/output)**

If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**T}$ factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**T}$ factorization of A.

*** B (input)**

The N-by-NRHS right hand side matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (output)**

If $INFO = 0$ or $INFO = N+1$, the N-by-NRHS solution matrix X.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND (output)**

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

* **FERR (output)**

The forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

* **BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

sptrtf - compute the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE SPTTRF( N, DIAG, OFFD, INFO)
INTEGER N, INFO
REAL DIAG(*), OFFD(*)

SUBROUTINE SPTTRF_64( N, DIAG, OFFD, INFO)
INTEGER*8 N, INFO
REAL DIAG(*), OFFD(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRF( [N], DIAG, OFFD, [INFO])
INTEGER :: N, INFO
REAL, DIMENSION(:) :: DIAG, OFFD

SUBROUTINE PTTRF_64( [N], DIAG, OFFD, [INFO])
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: DIAG, OFFD
```

C INTERFACE

```
#include <sunperf.h>

void sptrtf(int n, float *diag, float *offd, int *info);

void sptrtf_64(long n, float *diag, float *offd, long *info);
```

PURPOSE

sptrf computes the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** DIAG (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L^*DIAG^*L' factorization of A.

*** OFFD (input/output)**

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*DIAG^*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*DIAG^*U factorization of A.

*** INFO (output)**

NAME

sptrfs - solve a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF

SYNOPSIS

```
SUBROUTINE SPTTRS( N, NRHS, DIAG, OFFD, B, LDB, INFO)
INTEGER N, NRHS, LDB, INFO
REAL DIAG(*), OFFD(*), B(LDB,*)
```

```
SUBROUTINE SPTTRS_64( N, NRHS, DIAG, OFFD, B, LDB, INFO)
INTEGER*8 N, NRHS, LDB, INFO
REAL DIAG(*), OFFD(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PTTRS( [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG, OFFD
REAL, DIMENSION(:,) :: B
```

```
SUBROUTINE PTTRS_64( [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG, OFFD
REAL, DIMENSION(:,) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sptrfs(int n, int nrhs, float *diag, float *offd, float *b, int ldb, int *info);
```

```
void sptrfs_64(long n, long nrhs, float *diag, float *offd, float *b, long ldb, long *info);
```

PURPOSE

spttrs solves a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

*** N (input)**

The order of the tridiagonal matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input)**

The n diagonal elements of the diagonal matrix DIAG from the $L * DIAG * L'$ factorization of A.

*** OFFD (input/output)**

The (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L * DIAG * L'$ factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U * DIAG * U$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

sptts2 - solve a tridiagonal system of the form $A * X = B$ using the L*D*L' factorization of A computed by SPTTRF

SYNOPSIS

```
SUBROUTINE SPTTS2( N, NRHS, D, E, B, LDB)
  INTEGER N, NRHS, LDB
  REAL D(*), E(*), B(LDB,*)
```

```
SUBROUTINE SPTTS2_64( N, NRHS, D, E, B, LDB)
  INTEGER*8 N, NRHS, LDB
  REAL D(*), E(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SPTTS2( N, NRHS, D, E, B, [LDB])
  INTEGER :: N, NRHS, LDB
  REAL, DIMENSION(:) :: D, E
  REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE SPTTS2_64( N, NRHS, D, E, B, [LDB])
  INTEGER(8) :: N, NRHS, LDB
  REAL, DIMENSION(:) :: D, E
  REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sptts2(int n, int nrhs, float *d, float *e, float *b, int ldb);
```

```
void sptts2_64(long n, long nrhs, float *d, float *e, float *b, long ldb);
```

PURPOSE

sptts2 solves a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

*** N (input)**

The order of the tridiagonal matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** D (input)**

The n diagonal elements of the diagonal matrix D from the $L * D * L'$ factorization of A.

*** E (input)**

The (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L * D * L'$ factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U * D * U$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

NAME

sqrdc - (obsolete) compute the QR factorization of a general matrix A. It is typical to follow a call to SQRDC with a call to SQRSL to solve $Ax = b$ or to SPODI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE SQRDC( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
INTEGER LDA, N, P, JOB
INTEGER IPIVOT(*)
REAL A(LDA,*), QRAUX(*), WORK(*)
```

```
SUBROUTINE SQRDC_64( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
INTEGER*8 LDA, N, P, JOB
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), QRAUX(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sqrdc(float *a, int lda, int n, int p, float *qraux, int *ipivot, int job);
```

```
void sqrdc_64(float *a, long lda, long n, long p, float *qraux, long *ipivot, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, the upper triangle of A contains the matrix R and the strict lower triangle of A contains information that will allow construction of the matrix Q. If pivoting was requested, A contains the factorization of the original matrix A permuted by the requested pivots.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix A. $N \geq 0$.

*** P (input)**

Number of columns in the matrix A. $P \geq 0$.

*** QRAUX (output)**

On exit, contains information required to construct the orthogonal matrix Q.

*** IPIVOT (input)**

If JOB selected no pivoting, then IPIVOT is not referenced. If JOB selected pivoting, then on entry to the subroutines, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

```
IPIVOT(k) > 0   A(k,k) is an initial element.  
IPIVOT(k) = 0   A(k,k) is a free element.  
IPIVOT(k) < 0   A(k,k) is a final element.
```

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A. During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, IPIVOT(k) contains the index of the diagonal element of A that was moved into the kth position.

* **WORK** (*workspace*)

Scratch array with a dimension of N. WORK is not referenced if JOB = 0.

* **JOB** (*input*)

Determines how the factorization is done:

- o 0 with no pivoting

not 0 with pivoting

NAME

sqrsl - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by SQRDC, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SQRSL( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,
*   JOB, INFO)
INTEGER LDA, N, K, JOB, INFO
REAL A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)

SUBROUTINE SQRSL_64( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,
*   JOB, INFO)
INTEGER*8 LDA, N, K, JOB, INFO
REAL A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sqrsl(float *a, int lda, int n, int k, float *qraux, float *y, float *qy, float *qty, float *b, float *resid, float *ab, int job, int *info);
```

```
void sqrsl_64(float *a, long lda, long n, long k, float *qraux, float *y, float *qy, float *qty, float *b, float *resid, float *ab, long job, long *info);
```

ARGUMENTS

* **A** (*input*)

Part of the QR factorization of matrix A as computed by SQRDC.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Number of rows in the matrix AK where AK is described below. $N \geq 0$.

* **K** (*input*)

Number of columns in the matrix AK where AK is described below. $K \geq 0$.

* **QRAUX** (*input*)

Auxiliary output from SQRDC.

* **Y** (*input*)

Vector to be manipulated by SQRSL.

* **QY (output)**

On exit, QY contains $Q * Y$ if its computation has been requested in JOB; QY is not referenced if its computation is not requested.

* **QTY (output)**

On exit, QTY contains $QT * Y$ if its computation has been requested in JOB; QTY is not referenced if its computation is not requested.

* **B (input/output)**

On entry, the right-hand side vector b. On exit, the solution vector x. B is not referenced if its computation is not requested.

* **RESID (output)**

On exit, RESID contains the least squares residual $y - AK * b$ if its computation has been requested. RESID also is the orthogonal projection of y onto the orthogonal complement of the column space of AK. RESID is not referenced if its computation is not requested.

* **AB (output)**

On exit, AB contains the least squares approximation $AK * b$ if its computation has been requested. AB is the orthogonal projection of y onto the column space of x. AB is not referenced if its computation is not requested.

* **JOB (input)**

Integer in the form abcde; determines which operation or operations the subroutine will perform:

```
a <> 0  compute QY
b, c, d, or e <> 0      compute QTY
c <> 0  compute B
d <> 0  compute RESID
e <> 0  compute AB
```

* **INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the computation of B has been requested and R is singular; the value of k is then the index of the first zero element of R. The matrix AK is constructed from the factored orthogonal matrix Q and upper triangular matrix R from SQRDC.

NAME

srot - Apply a Given's rotation constructed by SROTG.

SYNOPSIS

```
SUBROUTINE SROT( N, X, INCX, Y, INCY, C, S )
INTEGER N, INCX, INCY
REAL C, S
REAL X(*), Y(*)
```

```
SUBROUTINE SROT_64( N, X, INCX, Y, INCY, C, S )
INTEGER*8 N, INCX, INCY
REAL C, S
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], X, [INCX], Y, [INCY], C, S )
INTEGER :: N, INCX, INCY
REAL :: C, S
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE ROT_64( [N], X, [INCX], Y, [INCY], C, S )
INTEGER(8) :: N, INCX, INCY
REAL :: C, S
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srot(int n, float *x, int incx, float *y, int incy, float c, float s);
```

```
void srot_64(long n, float *x, long incx, float *y, long incy, float c, float s);
```

PURPOSE

srot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input/output)***

$(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

*** *C (input)***

On entry, the C rotation value constructed by SROTG. Unchanged on exit.

*** *S (input)***

On entry, the S rotation value constructed by SROTG. Unchanged on exit.

NAME

srotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE SROTG( A, B, C, S )
REAL A, B, C, S

SUBROUTINE SROTG_64( A, B, C, S )
REAL A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG( A, B, C, S )
REAL :: A, B, C, S

SUBROUTINE ROTG_64( A, B, C, S )
REAL :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>

void srotg(float *a, float *b, float *c, float *s);

void srotg_64(float *a, float *b, float *c, float *s);
```

PURPOSE

srotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***A*** (*input/output*)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

* ***B*** (*input/output*)

On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or 1/C depending on which of the input values of A and B is larger.

* ***C*** (*output*)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

* ***S*** (*output*)

See the description of C.

NAME

srotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

SYNOPSIS

```
SUBROUTINE SROTM( N, X, INCX, Y, INCY, PARAM)
INTEGER N, INCX, INCY
REAL X(*), Y(*), PARAM(*)
```

```
SUBROUTINE SROTM_64( N, X, INCX, Y, INCY, PARAM)
INTEGER*8 N, INCX, INCY
REAL X(*), Y(*), PARAM(*)
```

F95 INTERFACE

```
SUBROUTINE ROTM( [N], X, [INCX], Y, [INCY], PARAM)
INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y, PARAM
```

```
SUBROUTINE ROTM_64( [N], X, [INCX], Y, [INCY], PARAM)
INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y, PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srotm(int n, float *x, int incx, float *y, int incy, float *param);
```

```
void srotm_64(long n, float *x, long incx, float *y, long incy, float *param);
```

PURPOSE

srotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

$(1 + (m - 1) * \text{abs}(INCY))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

* *PARAM (input)*

On entry, the rotation values constructed by SROTMG. Unchanged on exit.

NAME

srotmg - Construct a Gentleman's modified Given's plane rotation

SYNOPSIS

```
SUBROUTINE SROTMG( D1, D2, B1, B2, PARAM)
REAL D1, D2, B1, B2
REAL PARAM(*)
```

```
SUBROUTINE SROTMG_64( D1, D2, B1, B2, PARAM)
REAL D1, D2, B1, B2
REAL PARAM(*)
```

F95 INTERFACE

```
SUBROUTINE ROTMG( D1, D2, B1, B2, PARAM)
REAL :: D1, D2, B1, B2
REAL, DIMENSION(:) :: PARAM
```

```
SUBROUTINE ROTMG_64( D1, D2, B1, B2, PARAM)
REAL :: D1, D2, B1, B2
REAL, DIMENSION(:) :: PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srotmg(float d1, float d2, float b1, float b2, float *param);
```

```
void srotmg_64(float d1, float d2, float b1, float b2, float *param);
```

PURPOSE

srotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***D1*** (*input/output*)

On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

* ***D2*** (*input/output*)

On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

* ***B1*** (*input/output*)

On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

* ***B2*** (*input/output*)

On entry, the second element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

* ***PARAM*** (*input/output*)

On entry, PARAM(1) describes the form of the H matrix. On exit, PARAM(2..5) contain the H matrix.

NAME

ssbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

```
SUBROUTINE SSBEV( JOBZ, UPLO, N, NDIAG, A, LDA, W, Z, LDZ, WORK,
*              INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER N, NDIAG, LDA, LDZ, INFO
REAL A(LDA,*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE SSBEV_64( JOBZ, UPLO, N, NDIAG, A, LDA, W, Z, LDZ, WORK,
*              INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, NDIAG, LDA, LDZ, INFO
REAL A(LDA,*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBEV( JOBZ, UPLO, [N], NDIAG, A, [LDA], W, Z, [LDZ],
*              [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, NDIAG, LDA, LDZ, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A, Z

SUBROUTINE SBEV_64( JOBZ, UPLO, [N], NDIAG, A, [LDA], W, Z, [LDZ],
*              [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, NDIAG, LDA, LDZ, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbev(char jobz, char uplo, int n, int ndiag, float *a, int lda, float *w, float *z, int ldz, int *info);
```

```
void ssbev_64(char jobz, char uplo, long n, long ndiag, float *a, long lda, float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $NDIAG+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

$\text{dimension}(\text{MAX}(1,3*N-2))$

* **INFO** (*output*)

NAME

ssbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

REAL, DIMENSION(:, :) :: AB, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbevd(char jobz, char uplo, int n, int kd, float *ab, int ldab, float *w, float *z, int ldz, int *info);
```

```
void ssbevd_64(char jobz, char uplo, long n, long kd, float *ab, long ldab, float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and $KD+1$ of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*output*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 2$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 2$, LWORK must be at least $(1 + 5*N + 2*N**2)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK

array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array LIWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 2$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

ssbevz - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbevz(char jobz, char range, char uplo, int n, int ndiag, float *a, int lda, float *q, int ldq, float vl, float vu, int il, int iu, float abtol, int *nfound, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void ssbevz_64(char jobz, char range, char uplo, long n, long ndiag, float *a, long lda, float *q, long ldq, float vl, float vu, long il, long iu, float abtol, long *nfound, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssbevz computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **Q** (*output*)

If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. If JOBZ = 'V', then $LDQ \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

See the description of IL.

*** ABTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (output)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

*** W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(7*N)

*** IWORK2 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

ssbgst - reduce a real symmetric-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$,

SYNOPSIS

```
SUBROUTINE SSBGST( VECT, UPLO, N, KA, KB, AB, LDAB, BB, LDBB, X,
*   LDX, WORK, INFO)

CHARACTER(LEN=1) :: VECT, UPLO
INTEGER(8) :: N, KA, KB, LDAB, LDBB, LDX, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: AB, BB, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbgst(char vect, char uplo, int n, int ka, int kb, float *ab, int ldab, float *bb, int ldbb, float *x, int ldx, int *info);
```

```
void ssbgst_64(char vect, char uplo, long n, long ka, long kb, float *ab, long ldab, float *bb, long ldbb, float *x, long ldx, long *info);
```

PURPOSE

ssbgst reduces a real symmetric-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A .

B must have been previously factorized as $S**T*S$ by SPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**T*A*X$, where $X = S**(-1)*Q$ and Q is an orthogonal matrix chosen to preserve the bandwidth of A .

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B . $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix $X**T*A*X$, stored in the same format as A .

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KA+1$.

* **BB** (*input*)

The banded factor S from the split Cholesky factorization of B , as returned by SPBSTF, stored in the first $KB+1$ rows of the array.

* **LDBB** (*input*)

The leading dimension of the array BB . $LDBB \geq KB+1$.

* **X** (*output*)

If $VECT = 'V'$, the n -by- n matrix X . If $VECT = 'N'$, the array X is not referenced.

* **LDX** (*input*)

The leading dimension of the array X . $LDX \geq \max(1,N)$ if $VECT = 'V'$; $LDX \geq 1$ otherwise.

* **WORK** (*workspace*)

dimension($2*N$)

* **INFO** (*output*)

void ssbgv_64(char jobz, char uplo, long n, long ka, long kb, float *ab, long ldab, float *bb, long ldbb, float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i -th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*T^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **WORK** (*workspace*)
dimension(3*N)

* **INFO** (*output*)

void ssbgvd_64(char jobz, char uplo, long n, long ka, long kb, float *ab, long ldab, float *bb, long ldbb, float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If $INFO = 0$, the eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so $Z^*T^*B^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq 3*N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 1 + 5*N + 2*N**2$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if $LIWORK > 0$, $IWORK(1)$ returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

ssbgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

```

```
void ssbgvx(char jobz, char range, char uplo, int n, int ka, int kb, float *ab, int ldab, float *bb, int ldbb, float *q, int ldq, float vl, float vu, int il, int iu, float abstol, int *m, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void ssbgvx_64(char jobz, char range, char uplo, long n, long ka, long kb, float *ab, long ldab, float *bb, long ldbb, float *q, long ldq, float vl, float vu, long il, long iu, float abstol, long *m, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S**T*S$, as returned by SPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. LDBB \geq KB+1.

* **Q (output)**

If JOBZ = 'V', the n-by-n matrix used in the reduction of $A*x = (\text{lambda})*B*x$ to standard form, i.e. $C*x = (\text{lambda})*x$, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. If JOBZ = 'N', LDQ \geq 1. If JOBZ = 'V', LDQ \geq max(1,N).

* **VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

See the description of VL.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

See the description of IL.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

* **W (output)**

If INFO = 0, the eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so $Z**T*B*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

* **WORK (workspace)**

dimension(7*N)

* **IWORK (workspace)**

dimension(5*N)

* **IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO (output)**

NAME

ssbmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE SSBMV( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA, Y,
*               INCY)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)

SUBROUTINE SSBMV_64( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA,
*                   Y, INCY)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SBMV( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX], BETA,
*               Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

SUBROUTINE SBMV_64( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX],
*                  BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbmv(char uplo, int n, int ndiag, float alpha, float *a, int lda, float *x, int incx, float beta, float *y, int incy);
```

```
void ssbmv_64(char uplo, long n, long ndiag, float alpha, float *a, long lda, float *x, long incx, float beta, float *y, long incy);
```

PURPOSE

ssbmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry, NDIAG specifies the number of super-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
         A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$.
Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

ssbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE SSBTRD( VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK,  
* INFO)  
CHARACTER * 1 VECT, UPLO  
INTEGER N, KD, LDAB, LDQ, INFO  
REAL AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)  
  
SUBROUTINE SSBTRD_64( VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ,  
* WORK, INFO)  
CHARACTER * 1 VECT, UPLO  
INTEGER*8 N, KD, LDAB, LDQ, INFO  
REAL AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBTRD( VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER :: N, KD, LDAB, LDQ, INFO  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: AB, Q  
  
SUBROUTINE SBTRD_64( VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER(8) :: N, KD, LDAB, LDQ, INFO  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: AB, Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbtrd(char vect, char uplo, int n, int kd, float *ab, int ldab, float *d, float *e, float *q, int ldq, int *info);
```

```
void ssbtrd_64(char vect, char uplo, long n, long kd, float *ab, long ldab, float *d, float *e, float *q, long ldq, long *info);
```

PURPOSE

ssbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation:
 $Q^* T^* A Q = T$.

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T ; if $KD > 0$, the elements on the first superdiagonal (if $UPLO = 'U'$) or the first subdiagonal (if $UPLO = 'L'$) are overwritten by the off-diagonal elements of T ; the rest of AB is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KD+1$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T .

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = T(i,i+1)$ if $UPLO = 'U'$; $E(i) = T(i+1,i)$ if $UPLO = 'L'$.

* **Q** (*input/output*)

On entry, if $VECT = 'U'$, then Q must contain an N -by- N matrix X ; if $VECT = 'N'$ or $'V'$, then Q need not be set.

On exit: if $VECT = 'V'$, Q contains the N -by- N orthogonal matrix Q ; if $VECT = 'U'$, Q contains the product X^*Q ; if $VECT = 'N'$, the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq 1$, and $LDQ \geq N$ if $VECT = 'V'$ or $'U'$.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

sscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE SSCAL( N, ALPHA, Y, INCY)
  INTEGER N, INCY
  REAL ALPHA
  REAL Y(*)
```

```
SUBROUTINE SSCAL_64( N, ALPHA, Y, INCY)
  INTEGER*8 N, INCY
  REAL ALPHA
  REAL Y(*)
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
  INTEGER :: N, INCY
  REAL :: ALPHA
  REAL, DIMENSION(:) :: Y
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
  INTEGER(8) :: N, INCY
  REAL :: ALPHA
  REAL, DIMENSION(:) :: Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sscal(int n, float alpha, float *y, int incy);
```

```
void sscal_64(long n, float alpha, float *y, long incy);
```

PURPOSE

sscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(INCY)$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

ssico - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then SSIFA is slightly faster. It is typical to follow a call to SSICO with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE SSICO( A, LDA, N, IPIVOT, RCOND, WORK)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  REAL RCOND
  REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SSICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  REAL RCOND
  REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssico(float *a, int lda, int n, int *ipivot, float *rcond);
```

```
void ssico_64(float *a, long lda, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

ssidi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by SSICO or SSIFA.

SYNOPSIS

```
SUBROUTINE SSIDI( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*), INERT(*)
REAL A(LDA,*), DET(*), WORK(*)
```

```
SUBROUTINE SSIDI_64( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
REAL A(LDA,*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssidi(float *a, int lda, int n, int *ipivot, float *det, int *inert, int job);
```

```
void ssidi_64(float *a, long lda, long n, long *ipivot, float *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by SSICO or SSIFA. On exit, if the c digit of JOB <> 0, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by SSICO or SSIFA.

*** DET (output)**

On exit, if the b digit of JOB <> 0, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) =$

0.0. If the b digit of JOB = 0, DET is not referenced.

* **INERT** (*output*)

On exit, if the a digit of JOB \neq 0, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation the subroutine will perform:

```
a  $\neq$  0  Compute the inertia.  
b  $\neq$  0  Compute the determinant.  
c  $\neq$  0  Compute the inverse.
```

Note that the inverse should not be computed if SSICO has set RCOND = 0 or if SSIFA has set INFO \geq 0.

NAME

ssifa - (obsolete) compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to SSIFA with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE SSIFA( A, LDA, N, IPIVOT, INFO)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*)
```

```
SUBROUTINE SSIFA_64( A, LDA, N, IPIVOT, INFO)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssifa(float *a, int lda, int n, int *ipivot, int *info);
```

```
void ssifa_64(float *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that SSISL or SSIDI will divide by zero if called.

NAME

ssisl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by SSICO or SSIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SSISL( A, LDA, N, IPIVOT, B)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  REAL A(LDA,*), B(*)

SUBROUTINE SSISL_64( A, LDA, N, IPIVOT, B)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssisl(float *a, int lda, int n, int *ipivot, float *b);
```

```
void ssisl_64(float *a, long lda, long n, long *ipivot, float *b);
```

ARGUMENTS

*** A (input)**

UDU factorization of the matrix A , as computed by SSICO or SSIFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SSICO or SSIFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

sspc - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then SSPFA is slightly faster. It is typical to follow a call to SSPCO with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE SSPCO( A, N, IPIVOT, RCOND, WORK)
  INTEGER N
  INTEGER IPIVOT(*)
  REAL RCOND
  REAL A(*), WORK(*)

SUBROUTINE SSPCO_64( A, N, IPIVOT, RCOND, WORK)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
  REAL RCOND
  REAL A(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>

void sspco(float *a, int n, int *ipivot, float *rcond);

void sspco_64(float *a, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A . $0.0 \leq RCOND \leq 1.0$. As the value of $RCOND$ gets smaller, operations with A such as solving $Ax = b$ may become less stable. If $RCOND$ satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

sspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE SSPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, IWORK2,  
*      INFO)  
CHARACTER * 1 UPLO  
INTEGER N, INFO  
INTEGER IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL A(*), WORK(*)  
  
SUBROUTINE SSPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK,  
*      IWORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],  
*      [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: A, WORK  
  
SUBROUTINE SPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],  
*      [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspcon(char uplo, int n, float *a, int *ipivot, float anorm, float *rcond, int *info);
```

```
void sspcon_64(char uplo, long n, float *a, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

sspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* **INFO** (*output*)

NAME

sspdi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA.

SYNOPSIS

```
SUBROUTINE SSPDI( A, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER N, JOB
INTEGER IPIVOT(*), INERT(*)
REAL A(*), DET(*), WORK(*)
```

```
SUBROUTINE SSPDI_64( A, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
REAL A(*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspdi(float *a, int n, int *ipivot, float *det, int *inert, int job);
```

```
void sspdi_64(float *a, long n, long *ipivot, float *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by SSPCO or SSPFA. On exit, if the c digit of JOB $\neq 0$, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. $N \neq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SSPCO or SSPFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$. If the b digit of JOB = 0, DET is not referenced.

*** INERT (output)**

On exit, if the a digit of JOB $\neq 0$ then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation the subroutine will perform:

a <> 0 Compute the inertia.
b <> 0 Compute the determinant.
c <> 0 Compute the inverse.

Note that the inverse should not be computed if SSPCO has set RCOND = 0 or if SSPFA has set INFO <> 0.

NAME

sspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```
SUBROUTINE SSPEV( JOBZ, UPLO, N, A, W, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER N, LDZ, INFO
REAL A(*), W(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SSPEV_64( JOBZ, UPLO, N, A, W, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, LDZ, INFO
REAL A(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEV( JOBZ, UPLO, [N], A, W, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: A, W, WORK
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE SPEV_64( JOBZ, UPLO, [N], A, W, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: A, W, WORK
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspev(char jobz, char uplo, int n, float *a, float *w, float *z, int ldz, int *info);
```

```
void sspev_64(char jobz, char uplo, long n, float *a, float *w, float *z, long ldz, long *info);
```

PURPOSE

sspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension(3*N)

* **INFO** (*output*)

NAME

sspevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```

*                   IWORK, LIWORK, INFO)  
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
REAL AP(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEVD( JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK], [LWORK],  
*               [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: AP, W, WORK  
REAL, DIMENSION(:, :) :: Z  
  
SUBROUTINE SPEVD_64( JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK],  
*                   [LWORK], [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: AP, W, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspevd(char jobz, char uplo, int n, float *ap, float *w, float *z, int ldz, int *info);
```

```
void sspevd_64(char jobz, char uplo, long n, float *ap, float *w, float *z, long ldz, long *info);
```

PURPOSE

sspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **AP** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* *INFO* (output)

NAME

sspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```
SUBROUTINE SSPEVX( JOBZ, RANGE, UPLO, N, A, VL, VU, IL, IU, ABTOL,

INTEGER(8), DIMENSION(:) :: IWORK2, IFAIL
REAL :: VL, VU, ABTOL
REAL, DIMENSION(:) :: A, W, WORK
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspevx(char jobz, char range, char uplo, int n, float *a, float vl, float vu, int il, int iu, float abtol, int *nfound, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void sspevx_64(char jobz, char range, char uplo, long n, float *a, float vl, float vu, long il, long iu, float abtol, long *nfound, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

sspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix *A*. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix *A*, packed columnwise in a linear array. The *j*-th column of *A* is stored in the array *A* as follows: if **UPLO** = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if **UPLO** = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, *A* is overwritten by values generated during the reduction to tridiagonal form. If **UPLO** = 'U', the diagonal and first superdiagonal of the tridiagonal matrix *T* overwrite the corresponding elements of *A*, and if **UPLO** = 'L', the diagonal and first subdiagonal of *T* overwrite the corresponding elements of *A*.

* **VL** (*input*)

If **RANGE**='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if **RANGE** = 'A' or 'I'.

* **VU** (*input*)

See the description of **VL**.

* **IL** (*input*)

If **RANGE**='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if **RANGE** = 'A' or 'V'.

* **IU** (*input*)

See the description of **IL**.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$ABTOL + EPS * \max(|a|,|b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

* **NFOUND (input)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

* **W (output)**

If INFO = 0, the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

* **WORK (workspace)**

dimension(8*N)

* **IWORK2 (workspace)**

* **IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO (output)**

NAME

sspfa - (obsolete) compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to SSPFA with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE SSPFA( A, N, IPIVOT, INFO)
  INTEGER N, INFO
  INTEGER IPIVOT(*)
  REAL A(*)

SUBROUTINE SSPFA_64( A, N, IPIVOT, INFO)
  INTEGER*8 N, INFO
  INTEGER*8 IPIVOT(*)
  REAL A(*)
```

C INTERFACE

```
#include <sunperf.h>

void sspfa(float *a, int n, int *ipivot, int *info);

void sspfa_64(float *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that SSPSL or SSPDI will divide by zero if called.

NAME

sspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

SYNOPSIS

```
SUBROUTINE SSPGST( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
INTEGER ITYPE, N, INFO
REAL AP(*), BP(*)

SUBROUTINE SSPGST_64( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
INTEGER*8 ITYPE, N, INFO
REAL AP(*), BP(*)
```

F95 INTERFACE

```
SUBROUTINE SPGST( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, INFO
REAL, DIMENSION(:) :: AP, BP

SUBROUTINE SPGST_64( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, INFO
REAL, DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspgst(int itype, char uplo, int n, float *ap, float *bp, int *info);
```

```
void sspgst_64(long itype, char uplo, long n, float *ap, float *bp, long *info);
```

PURPOSE

sspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**T}$ or $L^{**T}*A*L$.

B must have been previously factorized as $U^{**T}*U$ or $L*L^{**T}$ by SPPTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *AP* (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *BP* (input)

The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPPTRF.

* *INFO* (output)

NAME

sspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

SYNOPSIS

```

SUBROUTINE SPGV_64( ITYPE, JOBZ, UPLO, [N], A, B, W, Z, [LDZ], [WORK],
* [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: ITYPE, N, LDZ, INFO
REAL, DIMENSION(:) :: A, B, W, WORK
REAL, DIMENSION(:,) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspgv(int itype, char jobz, char uplo, int n, float *a, float *b, float *w, float *z, int ldz, int *info);
```

```
void sspgv_64(long itype, char jobz, char uplo, long n, float *a, float *b, float *w, float *z, long ldz, long *info);
```

PURPOSE

sspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

$(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

*** B (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**T*B*Z = I$; if ITYPE = 3, $Z**T*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(3*N)

*** INFO (output)**

NAME

sspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspgvd(int itype, char jobz, char uplo, int n, float *ap, float *bp, float *w, float *z, int ldz, int *info);
```

```
void sspgvd_64(long itype, char jobz, char uplo, long n, float *ap, float *bp, float *w, float *z, long ldz, long *info);
```

PURPOSE

sspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as

follows: if ITYPE = 1 or 2, $Z^{**T}B^*Z = I$; if ITYPE = 3, $Z^{**T}inv(B)^*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1,N)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N^{**2}$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

```
void sspgvx(int itype, char jobz, char range, char uplo, int n, float *ap, float *bp, float vl, float vu, int il, int iu, float abstol, int *m, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void sspgvx_64(long itype, char jobz, char range, char uplo, long n, float *ap, float *bp, float vl, float vu, long il, long iu, float abstol, long *m, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

sspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrix pencil (A,B). $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^{**T}*U$ or $B = L*L^{**T}$, in the same storage format as B.

*** VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

*** VU (input)**

See the description of VL.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

See the description of IL.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|) ,$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{*T}BZ = I$; if $ITYPE = 3$, $Z^{*T}inv(B)Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(8*N)

*** IWORK (workspace)**

dimension(5*N)

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

sspmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE SSPMV( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER N, INCX, INCY
REAL ALPHA, BETA
REAL A(*), X(*), Y(*)
```

```
SUBROUTINE SSPMV_64( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX, INCY
REAL ALPHA, BETA
REAL A(*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SPMV( UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: A, X, Y
```

```
SUBROUTINE SPMV_64( UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspmv(char uplo, int n, float alpha, float *a, float *x, int incx, float beta, float *y, int incy);
```

```
void sspmv_64(char uplo, long n, float alpha, float *a, float *x, long incx, float beta, float *y, long incy);
```

PURPOSE

sspmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *A (input)*

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar β . When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y (input/output)*

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

NAME

sspr - perform the symmetric rank 1 operation $A := \alpha * x * x' + A$

SYNOPSIS

```
SUBROUTINE SSPR( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
INTEGER N, INCX
REAL ALPHA
REAL X(*), A(*)
```

```
SUBROUTINE SSPR_64( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX
REAL ALPHA
REAL X(*), A(*)
```

F95 INTERFACE

```
SUBROUTINE SPR( UPLO, N, ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX
REAL :: ALPHA
REAL, DIMENSION(:) :: X, A
```

```
SUBROUTINE SPR_64( UPLO, N, ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX
REAL :: ALPHA
REAL, DIMENSION(:) :: X, A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspr(char uplo, int n, float alpha, float *x, int incx, float *a);
```

```
void sspr_64(char uplo, long n, float alpha, float *x, long incx, float *a);
```

PURPOSE

sspr performs the symmetric rank 1 operation $A := \alpha * x * x' + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

NAME

sspr2 - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y (input)*

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A (input/output)*

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

NAME

ssprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```

```
void ssprfs_64(char uplo, long n, long nrhs, float *a, float *af, long *ipivot, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

ssprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(3*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

sspsl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE SSPSL( A, N, IPIVOT, B)
  INTEGER N
  INTEGER IPIVOT(*)
  REAL A(*), B(*)

SUBROUTINE SSPSL_64( A, N, IPIVOT, B)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
  REAL A(*), B(*)
```

C INTERFACE

```
#include <sunperf.h>

void sspsl(float *a, int n, int *ipivot, float *b);

void sspsl_64(float *a, long n, long *ipivot, float *b);
```

ARGUMENTS

- * **A** (*input*)
UDU factorization of the matrix A , as computed by SSPCO or SSPFA.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by SSPCO or SSPFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

sspsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

#include <sunperf.h>
```

```
void sspsv(char uplo, int n, int nrhs, float *a, int *ipivot, float *b, int ldb, int *info);
```

```
void sspsv_64(char uplo, long n, long nrhs, float *a, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

spsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if UPLO} = 'U', & \text{or} \\ A &= L * D * L^{**T}, & \text{if UPLO} = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

spsvx - use the diagonal pivoting factorization $A = U*D*U**T$ or $A = L*D*L**T$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

SYNOPSIS

```

INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: A, AF, FERR, BERR, WORK
REAL, DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspsvx(char fact, char uplo, int n, int nrhs, float *a, float *af, int *ipivot, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void sspsvx_64(char fact, char uplo, long n, long nrhs, float *a, float *af, long *ipivot, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sspsvx uses the diagonal pivoting factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as $A = U * D * U^{**T}$, if UPLO = 'U', or

```
    A = L * D * L^{**T},  if UPLO = 'L',  
where U (or L) is a product of permutation and unit upper (lower)  
triangular matrices and D is symmetric and block diagonal with  
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

$(N*(N+1)/2)$ If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

dimension(3*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

ssptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```

```
SUBROUTINE SPTRD_64( UPLO, N, AP, D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: AP, D, E, TAU
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssptrd(char uplo, int n, float *ap, float *d, float *e, float *tau, int *info);
```

```
void ssptrd_64(char uplo, long n, float *ap, float *d, float *e, float *tau, long *info);
```

PURPOSE

ssptrd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *AP* (*input*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO

* *D* (*output*)

The diagonal elements of the tridiagonal matrix T: $D(i) = A(i,i)$.

* *E* (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

* *TAU* (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* *INFO* (*output*)

NAME

ssptf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssptf(char uplo, int n, float *a, int *ipivot, int *info);
```

```
void ssptf_64(char uplo, long n, float *a, long *ipivot, long *info);
```

PURPOSE

ssprtf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

*** IPIVOT (output)**

Details of the interchanges and the block structure of D. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

NAME

ssptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE SSPTRI( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER IPIVOT(*)
REAL A(*), WORK(*)

SUBROUTINE SSPTRI_64( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPTRI( UPLO, N, A, IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT

#include <sunperf.h>

void ssptri(char uplo, int n, float *a, int *ipivot, int *info);

void ssptri_64(char uplo, long n, float *a, long *ipivot, long *info);
```

PURPOSE

ssptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by SSPTRF.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by SSPTRF.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

NAME

ssptrs - solve a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE SSPTRS( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDB, INFO
INTEGER IPIVOT(*)
REAL A(*), B(LDB,*)

SUBROUTINE SSPTRS_64( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIVOT(*)
REAL A(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SPTRS( UPLO, N, NRHS, A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B

SUBROUTINE SPTRS_64( UPLO, N, NRHS, A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssptrs(char uplo, int n, int nrhs, float *a, int *ipivot, float *b, int ldb, int *info);
```

```
void ssptrs_64(char uplo, long n, long nrhs, float *a, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

ssptrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

sstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstebz(char range, char order, int n, float vl, float vu, int il, int iu, float abstol, float *d, float *e, int *m, int *nsplit, float *w, int *iblock, int *isplit, int *info);
```

```
void sstebz_64(char range, char order, long n, float vl, float vu, long il, long iu, float abstol, float *d, float *e, long *m, long *nsplit, float *w, long *iblock, long *isplit, long *info);
```

PURPOSE

sstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its

largest element is no greater than $\text{overflow}^{1/2}$ *

$\text{underflow}^{1/4}$ in absolute value, and for greatest

accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

* **RANGE** (*input*)

* **ORDER** (*input*)

* **N** (*input*)

The order of the tridiagonal matrix T. $N \geq 0$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABSTOL** (*input*)

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then

$ULP*|T|$ will be used, where $|T|$ means the 1-norm of T .

Eigenvalues will be computed most accurately when $ABSTOL$ is set to twice the underflow threshold $2*SLAMCH('S')$, not zero.

* ***D (input)***

The n diagonal elements of the tridiagonal matrix T .

* ***E (input)***

The $(n-1)$ off-diagonal elements of the tridiagonal matrix T .

* ***M (output)***

The actual number of eigenvalues found. $0 \leq M \leq N$. (See also the description of $INFO=2,3$.)

* ***NSPLIT (output)***

The number of diagonal blocks in the matrix T . $1 \leq NSPLIT \leq N$.

* ***W (output)***

On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining $N-M$ elements as workspace.)

* ***IBLOCK (output)***

At each row/column j where $E(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if $INFO = 0$, $IBLOCK(i)$ specifies to which block (from 1 to the number of blocks) the eigenvalue $W(i)$ belongs. (SSTEBZ may use the remaining $N-M$ elements as workspace.)

* ***ISPLIT (output)***

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $ISPLIT(1)$, the second of rows/columns $ISPLIT(1)+1$ through $ISPLIT(2)$, etc., and the $NSPLIT$ -th consists of rows/columns $ISPLIT(NSPLIT-1)+1$ through $ISPLIT(NSPLIT)=N$. (Only the first $NSPLIT$ elements will actually be used, but since the user cannot know a priori what value $NSPLIT$ will have, N words must be reserved for $ISPLIT$.)

* ***WORK (workspace)***

dimension($4*N$)

* ***IWORK (workspace)***

dimension($3*N$)

* ***INFO (output)***

NAME

sstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

SYNOPSIS

```
SUBROUTINE SSTEDC( COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 COMPZ  
INTEGER N, LDZ, LWORK, LIWORK, INFO  
INTEGER IWORK(*)  
REAL D(*), E(*), Z(LDZ,*), WORK(*)  
  
SUBROUTINE SSTEDC_64( COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 COMPZ  
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEDC( COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
*      [LIWORK], [INFO])  
CHARACTER(LEN=1) :: COMPZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z  
  
SUBROUTINE STEDC_64( COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstedc(char compz, int n, float *d, float *e, float *z, int ldz, int *info);
```

```
void sstedc_64(char compz, long n, float *d, float *e, float *z, long ldz, long *info);
```

PURPOSE

sstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The dimension of the symmetric tridiagonal matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original symmetric matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$. If eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $COMPZ = 'N'$ or $N \leq 1$ then LWORK must be at least 1. If $COMPZ = 'V'$ and $N > 1$ then LWORK must be at least $(1 + 3*N + 2*N*\lg N + 3*N**2)$, where $\lg(N) =$ smallest integer k such that $2**k \geq N$. If $COMPZ = 'I'$ and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *IWORK* (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** *LIWORK* (input)**

The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$ then LIWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LIWORK must be at least $(6 + 6*N + 5*N*\lg N)$. If COMPZ = 'I' and $N > 1$ then LIWORK must be at least $(3 + 5*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** *INFO* (output)**

NAME

sstegr - (a) Compute $T\text{-}\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

SYNOPSIS

```
SUBROUTINE SSTEGR( JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstegr(char jobz, char range, int n, float *d, float *e, float vl, float vu, int il, int iu, float abstol, int *m, float *w, float *z, int ldz, int *isuppz, int *info);
```

```
void sstegr_64(char jobz, char range, long n, float *d, float *e, float vl, float vu, long il, long iu, float abstol, long *m, float *w, float *z, long ldz, long *isuppz, long *info);
```

PURPOSE

sstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,

- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently SSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine SSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. SSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : SSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix T . On exit, D is overwritten.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E is overwritten.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced

if RANGE = 'A' or 'I'.

*** VU (input)**

See the description of VL.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

See the description of IL.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues/eigenvectors. If JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

The first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ($2 \cdot i - 1$) through ISUPPZ($2 \cdot i$).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 18 \cdot N)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. $LIWORK \geq \max(1, 10 \cdot N)$

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

sstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

SYNOPSIS

```
SUBROUTINE SSTEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,  
*      IWORK, IFAIL, INFO)  
INTEGER N, M, LDZ, INFO  
INTEGER IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)  
REAL D(*), E(*), W(*), Z(LDZ,*), WORK(*)  
  
SUBROUTINE SSTEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,  
*      IWORK, IFAIL, INFO)  
INTEGER*8 N, M, LDZ, INFO  
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)  
REAL D(*), E(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],  
*      [IWORK], IFAIL, [INFO])  
INTEGER :: N, M, LDZ, INFO  
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL  
REAL, DIMENSION(:) :: D, E, W, WORK  
REAL, DIMENSION(:, :) :: Z  
  
SUBROUTINE STEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],  
*      [IWORK], IFAIL, [INFO])  
INTEGER(8) :: N, M, LDZ, INFO  
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL  
REAL, DIMENSION(:) :: D, E, W, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstein(int n, float *d, float *e, int m, float *w, int *iblock, int *isplit, float *z, int ldz, int *ifail, int *info);
```

```
void sstein_64(long n, float *d, float *e, long m, float *w, long *iblock, long *isplit, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

stein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

* ***N (input)***

The order of the matrix. $N \geq 0$.

* ***D (input)***

The n diagonal elements of the tridiagonal matrix T.

* ***E (input)***

The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

* ***M (input)***

The number of eigenvectors to be found. $0 \leq M \leq N$.

* ***W (input)***

The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBSZ with ORDER = 'B' is expected here.)

* ***IBLOCK (input)***

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)

* ***ISPLIT (input)***

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)

* ***Z (output)***

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

* ***LDZ (input)***

The leading dimension of the array Z. $LDZ \geq \max(1,N)$.

* ***WORK (workspace)***

dimension(5*N)

* ***IWORK (workspace)***

dimension(N)

* ***IFAIL (output)***

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

* ***INFO (output)***

NAME

ssteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```

```

```
void ssteqr_64(char compz, long n, float *d, float *e, float *z, long ldz, long *info);
```

PURPOSE

ssteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original symmetric matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

If $COMPZ = 'N'$, then WORK is not referenced.

* **INFO** (*output*)

NAME

ssterf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

SYNOPSIS

```
SUBROUTINE SSTERF( N, D, E, INFO)
  INTEGER N, INFO
  REAL D(*), E(*)
```

```
SUBROUTINE SSTERF_64( N, D, E, INFO)
  INTEGER*8 N, INFO
  REAL D(*), E(*)
```

F95 INTERFACE

```
SUBROUTINE STERF( [N], D, E, [INFO])
  INTEGER :: N, INFO
  REAL, DIMENSION(:) :: D, E
```

```
SUBROUTINE STERF_64( [N], D, E, [INFO])
  INTEGER(8) :: N, INFO
  REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssterf(int n, float *d, float *e, int *info);
```

```
void ssterf_64(long n, float *d, float *e, long *info);
```

PURPOSE

ssterf computes all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm.

ARGUMENTS

* *N (input)*

The order of the matrix. $N \geq 0$.

* *D (input/output)*

On entry, the n diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* *E (input/output)*

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* *INFO (output)*

NAME

sstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE SSTEVE( JOBZ, N, DIAG, OFFD, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ
INTEGER N, LDZ, INFO
REAL DIAG(*), OFFD(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SSTEVE_64( JOBZ, N, DIAG, OFFD, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ
INTEGER*8 N, LDZ, INFO
REAL DIAG(*), OFFD(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEV( JOBZ, N, DIAG, OFFD, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: DIAG, OFFD, WORK
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEV_64( JOBZ, N, DIAG, OFFD, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: DIAG, OFFD, WORK
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstev(char jobz, int n, float *diag, float *offd, float *z, int ldz, int *info);
```

```
void sstev_64(char jobz, long n, float *diag, float *offd, float *z, long ldz, long *info);
```

PURPOSE

sstev computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **DIAG** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **OFFD** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to $N-1$ of OFFD; OFFD(N) need not be set, but is used by the routine. On exit, the contents of OFFD are destroyed.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $DIAG(i)$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

If $JOBZ = 'N'$, WORK is not referenced.

* **INFO** (*output*)

NAME

sstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

SYNOPSIS

```
SUBROUTINE SSTEVD( JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ  
INTEGER N, LDZ, LWORK, LIWORK, INFO  
INTEGER IWORK(*)  
REAL D(*), E(*), Z(LDZ,*), WORK(*)  
  
SUBROUTINE SSTEVD_64( JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ  
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEVD( JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
*      [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z  
  
SUBROUTINE STEVD_64( JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstevd(char jobz, int n, float *d, float *e, float *z, int ldz, int *info);
```

```
void sstevd_64(char jobz, long n, float *d, float *e, float *z, long ldz, long *info);
```

PURPOSE

sstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A , stored in elements 1 to $N-1$ of E ; $E(N)$ need not be set, but is used by the routine. On exit, the contents of E are destroyed.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A , with the i -th column of Z holding the eigenvector associated with $D(i)$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension ($LWORK$) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array $WORK$. If $JOBZ = 'N'$ or $N \leq 1$ then $LWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then $LWORK$ must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* **LIWORK** (*input*)

The dimension of the array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$ then $LIWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then $LIWORK$ must be at least $3+5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued

by XERBLA.

* ***INFO (output)***

NAME

sstevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

SYNOPSIS

```

PURPOSE

sstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSTEVR calls SSTEGR to compute the

eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T ,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSTEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSTEVR calls SSTEGBZ and SSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

* **VU** (*input*)

See the description of VL .

* **IL** (*input*)

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

* **IU** (*input*)

See the description of IL .

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|) ,$$

where EPS is the machine precision. If $ABSTOL$ is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set $ABSTOL$ to $SLAMCH('Safe\ minimum')$. Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If $RANGE = 'A'$, $M = N$, and if $RANGE = 'I'$, $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of M is not known in advance and an upper bound must be used.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

* **ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq 20*N$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

* **LIWORK (input)**

The dimension of the array IWORK. LIWORK $\geq 10*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

sstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sstevx(char jobz, char range, int n, float *diag, float *offd, float vl, float vu, int il, int iu, float abtol, int *nfound, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void sstevx_64(char jobz, char range, long n, float *diag, float *offd, float vl, float vu, long il, long iu, float abtol, long *nfound, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

sstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **DIAG** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, DIAG may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **OFFD** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A in elements 1 to $N-1$ of OFFD; OFFD(N) need not be set. On exit, OFFD may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$ABTOL + EPS * \max(|a|,|b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (output)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

*** W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge ($\text{INFO} > 0$), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

*** WORK (workspace)**

dimension(5*N)

*** IWORK2 (workspace)**

*** IFAIL (output)**

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

*** INFO (output)**

NAME

sstsv - compute the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix

```

```
void sstsv_64(long n, long nrhs, float *l, float *d, float *subl, float *b, long ldb, long *ipiv, long *info);
```

PURPOSE

sstsv computes the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides in B.

*** L (input/output)**

REAL array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** D (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** SUBL (output)**

REAL array, dimension (N)

On exit, part of the factorization of A.

*** B (input/output)**

The columns of B contain the right hand sides.

*** LDB (input)**

The leading dimension of B as specified in a type or DIMENSION statement.

*** IPIV (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** INFO (output)**

INTEGER*8 IPIV(*)
REAL L(*), D(*), SUBL(*)
```

F95 INTERFACE

```
SUBROUTINE STTRF( [N], L, D, SUBL, IPIV, [INFO])
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: L, D, SUBL
```

```
SUBROUTINE STTRF_64( [N], L, D, SUBL, IPIV, [INFO])
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: L, D, SUBL
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssttrf(int n, float *l, float *d, float *subl, int *ipiv, int *info);
```

```
void ssttrf_64(long n, float *l, float *d, float *subl, long *ipiv, long *info);
```

PURPOSE

ssttrf computes the factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

*** *N* (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** *L* (input/output)**

REAL array, dimension (N)

On entry, the $n-1$ subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** *D* (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the $L^*D^*L^{**}H$ factorization of A.

*** *SUBL* (output)**

REAL array, dimension (N)

On exit, part of the factorization of A.

*** *IPIV* (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** *INFO* (output)**

INTEGER

NAME

ssstrs - computes the solution to a real system of linear equations $A * X = B$

SYNOPSIS

```
SUBROUTINE SSTRS( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
INTEGER N, NRHS, LDB, INFO
INTEGER IPIV(*)
REAL L(*), D(*), SUBL(*), B(LDB,*)
```

```
SUBROUTINE SSTRS_64( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIV(*)
REAL L(*), D(*), SUBL(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE STTRS( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: L, D, SUBL
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE STTRS_64( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: L, D, SUBL
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssstrs(int n, int nrhs, float *l, float *d, float *subl, float *b, int ldb, int *ipiv, int *info);
```

```
void ssstrs_64(long n, long nrhs, float *l, float *d, float *subl, float *b, long ldb, long *ipiv, long *info);
```

PURPOSE

ssttrs computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** L (input)**

REAL array, dimension (N-1)

On entry, the subdiagonal elements of LL and DD.

*** D (input)**

REAL array, dimension (N)

On entry, the diagonal elements of DD.

*** SUBL (input)**

REAL array, dimension (N-2)

On entry, the second subdiagonal elements of LL.

*** B (input/output)**

REAL array, dimension

(LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

INTEGER

The leading dimension of the array B. $LDB \geq \max(1, N)$

*** IPIV (output)**

INTEGER array, dimension (N)

Details of the interchanges and block pivot. If IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1 an interchange done; If IPIV(K) < 0, 2 by 2 pivot, no interchange required.

*** INFO (output)**

INTEGER

NAME

ssvdc - (obsolete) compute the singular value decomposition of a general matrix A.

SYNOPSIS

```
SUBROUTINE SSVDC( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
  INTEGER LDA, N, P, LDL, LDR, JOB, INFO  
  REAL A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
  
SUBROUTINE SSVDC_64( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
  INTEGER*8 LDA, N, P, LDL, LDR, JOB, INFO  
  REAL A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssvdc(float *a, int lda, int n, int p, float *svals, float *e, float *lsvec, int ldl, float *rsvec, int ldr, int job, int *info);
```

```
void ssvdc_64(float *a, long lda, long n, long p, float *svals, float *e, float *lsvec, long ldl, float *rsvec, long ldr, long job, long *info);
```

ARGUMENTS

*** A (input)**

Matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows of the matrix A. $N \geq 0$.

*** P (input)**

Number of columns of the matrix A. $P \geq 0$.

*** SVALS (input/output)**

On exit, the singular values of A arranged in descending order of magnitude.

*** E (input/output)**

On exit, normally contains zero, but see INFO below.

*** LSVEC (input/output)**

On exit, the matrix of left singular vectors; not referenced if the a digit of JOB = 0.

*** LDL (input)**

Leading dimension of LSVEC as specified in a dimension or type statement. $LDL \geq \max(1,N)$.

*** RSVEC (input/output)**

On exit, the matrix of right singular vectors; not referenced if the b digit of JOB = 0.

*** LDR (input)**

Leading dimension of RSVEC as specified in a dimension or type statement. $LDR \geq \max(1,P)$.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form ab; determines operation subroutine will perform:

```
a = 0   do not compute the left singular vectors
a = 1   return the n left singular vectors in LSVEC
a * 2   return the first min(N,P) singular vectors in LSVEC
b = 0   do not compute the right singular vectors
b = 1   return the right singular vectors in RSVEC
```

*** INFO (output)**

On exit, the singular values and their corresponding singular vectors $SVALS(INFO+1)$, $SVALS(INFO+2), \dots, SVALS(\min(N,P))$ are correct. If $INFO = 0$ then all singular values and singular vectors are correct. The matrix B defined as $LSVECT * A * RSVEC$ is the bidiagonal matrix with S on its diagonal and E on its superdiagonal. Therefore the singular values of A and B are the same.

NAME

sswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE SSWAP( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
REAL X(*), Y(*)
```

```
SUBROUTINE SSWAP_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SWAP( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE SWAP_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sswap(int n, float *x, int incx, float *y, int incy);
```

```
void sswap_64(long n, float *x, long incx, float *y, long incy);
```

PURPOSE

sswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input/output)*

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x. On exit, the y vector.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

ssycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

SYNOPSIS

```
SUBROUTINE SSYCON( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                IWORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)

SUBROUTINE SSYCON_64( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                   IWORK2, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYCON( UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
*               [IWORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

SUBROUTINE SYCON_64( UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
*                  [IWORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyscon(char uplo, int n, float *a, int lda, int *ipivot, float anorm, float *rcond, int *info);
```

```
void ssyscon_64(char uplo, long n, float *a, long lda, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

ssyscon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* **INFO** (*output*)

NAME

ssyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE SSYEV( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER N, LDA, LDWORK, INFO
REAL A(LDA,*), W(*), WORK(*)
```

```
SUBROUTINE SSYEV_64( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, LDA, LDWORK, INFO
REAL A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEV( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYEV_64( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],
* [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyev(char jobz, char uplo, int n, float *a, int lda, float *w, int *info);
```

```
void ssyev_64(char jobz, char uplo, long n, float *a, long lda, float *w, long *info);
```

PURPOSE

ssyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. $LDWORK \geq \max(1, 3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

ssyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE SSYEVD( JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, LDA, LWORK, LIWORK, INFO  
INTEGER IWORK(*)  
REAL A(LDA,*), W(*), WORK(*)  
  
SUBROUTINE SSYEVD_64( JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,  
*      LIWORK, INFO)  
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDA, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
REAL A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEVD( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDA, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: A  
  
SUBROUTINE SYEVD_64( JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDA, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyevd(char jobz, char uplo, int n, float *a, int lda, float *w, int *info);
```

```
void ssyevd_64(char jobz, char uplo, long n, float *a, long lda, float *w, long *info);
```

PURPOSE

ssyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, SSYEVD needs N^{**2} more workspace than SSYEVX.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + 2*N^{**2}$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK

array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

ssyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyevr(char jobz, char range, char uplo, int n, float *a, int lda, float vl, float vu, int il, int iu, float abstol, int *m, float *w, float *z, int ldz, int *isuppz, int *info);
```

```
void ssyevr_64(char jobz, char range, char uplo, long n, float *a, long lda, float vl, float vu, long il, long iu, float abstol, long *m, float *w, float *z, long ldz, long *isuppz, long *info);
```

PURPOSE

ssyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSYEVR calls SSTEGR to compute the

eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T ,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSYEVR calls SSTEGR when the full spectrum is requested on machines which conform to the iee-754 floating point standard. SSYEVR calls SSTEGBZ and SSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the iee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the

array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK $\geq \max(1, 26 * N)$. For optimal efficiency, LWORK $\geq (NB+6) * N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

*** LIWORK (input)**

The dimension of the array IWORK. LIWORK $\geq \max(1, 10 * N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

ssyevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE SSYEVX( JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU,

#include <sunperf.h>
```

```
void ssyevx(char jobz, char range, char uplo, int n, float *a, int lda, float vl, float vu, int il, int iu, float abtol, int *nfound, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void ssyevx_64(char jobz, char range, char uplo, long n, float *a, long lda, float vl, float vu, long il, long iu, float abtol, long *nfound, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$ABTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (output)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

*** W (output)**

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of the array WORK. $\text{LDWORK} \geq \max(1, 8 * N)$. For optimal efficiency, $\text{LDWORK} \geq (\text{NB} + 3) * N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** IWORK2 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

ssygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

SYNOPSIS

```
SUBROUTINE SSYGS2( ITYPE, UPLO, N, A, LDA, B, LDB, INFO)

```

F95 INTERFACE

```
SUBROUTINE SYGS2( ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

```
SUBROUTINE SYGS2_64( ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssygs2(int itype, char uplo, int n, float *a, int lda, float *b, int ldb, int *info);
```

```
void ssygs2_64(long itype, char uplo, long n, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

ssygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U'*U$ or $L*L'$ by SPOTRF.

ARGUMENTS

* *ITYPE (input)*

* *UPLO (input)*

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized.

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *A (input/output)*

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B (input)*

The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO (output)*

NAME

ssygst - reduce a real symmetric-definite generalized eigenproblem to standard form

SYNOPSIS

```
SUBROUTINE SSYGST( ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO

```

```
void ssygst_64(long itype, char uplo, long n, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

ssygst reduces a real symmetric-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**T}$ or $L^{**T}*A*L$.

B must have been previously factorized as $U^{**T}*U$ or $L*L^{**T}$ by SPOTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B* (input)

The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: ITYPE, N, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssygv(int itype, char jobz, char uplo, int n, float *a, int lda, float *b, int ldb, float *w, int *info);
```

```
void ssygv_64(long itype, char jobz, char uplo, long n, float *a, long lda, float *b, long ldb, float *w, long *info);
```

PURPOSE

ssygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also

positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^{*T}BZ = I$; if ITYPE = 3, $Z^{*T}inv(B)Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^{*T}U$ or $B = L^{*}L^{*T}$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of the array WORK. $LDWORK \geq \max(1,3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* *INFO (output)*

```

```
void ssygvd_64(long itype, char jobz, char uplo, long n, float *a, long lda, float *b, long ldb, float *w, long *info);
```

PURPOSE

ssygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^{*T}BZ = I$; if ITYPE = 3, $Z^{*T} \text{inv}(B)Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input/output)**

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^{*T}U$ or $B = L^{*L}L^{*T}$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** *W (output)***

If INFO = 0, the eigenvalues in ascending order.

*** *WORK (workspace)***

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** *LWORK (input)***

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *IWORK (workspace)***

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** *LIWORK (input)***

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** *INFO (output)***

REAL, DIMENSION(:, :) :: A, B, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssygvx(int itype, char jobz, char range, char uplo, int n, float *a, int lda, float *b, int ldb, float vl, float vu, int il, int iu, float abstol, int *m, float *w, float *z, int ldz, int *ifail, int *info);
```

```
void ssygvx_64(long itype, char jobz, char range, char uplo, long n, float *a, long lda, float *b, long ldb, float vl, float vu, long il, long iu, float abstol, long *m, float *w, float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrix pencil (A,B). $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

See the description of VL.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

See the description of IL.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * DLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{*T} B Z = I$; if $ITYPE = 3$, $Z^{*T} \text{inv}(B) Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, 8 * N)$. For optimal efficiency, $LWORK \geq (NB + 3) * N$, where NB is the blocksize for SSYTRD returned by ILAENV.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

dimension(5 * N)

* **IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* *INFO (output)*

NAME

ssymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE SSYMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
*               LDC)
CHARACTER * 1 SIDE, UPLO
INTEGER M, N, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE SSYMM_64( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA,
*                  C, LDC)
CHARACTER * 1 SIDE, UPLO
INTEGER*8 M, N, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYMM( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*              BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER :: M, N, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

SUBROUTINE SYMM_64( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*                 BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER(8) :: M, N, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssymm(char side, char uplo, int m, int n, float alpha, float *a, int lda, float *b, int ldb, float beta, float *c, int ldc);
```

```
void ssymm_64(char side, char uplo, long m, long n, float alpha, float *a, long lda, float *b, long ldb, float beta, float *c, long ldc);
```

PURPOSE

ssymm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE (input)*

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

* *M (input)*

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N (input)*

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

* ***B (input)***

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

* ***LDB (input)***

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

* ***BETA (input)***

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

* ***C (input/output)***

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

* ***LDC (input)***

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

ssymv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE SSYMV( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER N, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

```
SUBROUTINE SSYMV_64( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INCX, INCY

INTEGER :: N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

SUBROUTINE SYMV_64( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssymv(char uplo, int n, float alpha, float *a, int lda, float *x, int incx, float beta, float *y, int incy);
```

```
void ssymv_64(char uplo, long n, float alpha, float *a, long lda, float *x, long incx, float beta, float *y, long incy);
```

PURPOSE

ssymv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

*** UPLO (input)**

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

*** N (input)**

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

*** A (input)**

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ssyr - perform the symmetric rank 1 operation $A := \alpha * x * x' + A$

SYNOPSIS

```
SUBROUTINE SSYR( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
INTEGER N, INCX, LDA
REAL ALPHA
REAL X(*), A(LDA,*)

SUBROUTINE SSYR_64( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX, LDA
REAL ALPHA
REAL X(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYR( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X
REAL, DIMENSION(:, :) :: A

SUBROUTINE SYR_64( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyr(char uplo, int n, float alpha, float *x, int incx, float *a, int lda);
```

```
void ssyr_64(char uplo, long n, float alpha, float *x, long incx, float *a, long lda);
```

PURPOSE

ssyr performs the symmetric rank 1 operation $A := \alpha * x * x' + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

ssyr2 - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

SYNOPSIS

```
SUBROUTINE SSYR2( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
CHARACTER * 1 UPLO
INTEGER N, INCX, INCY, LDA
REAL ALPHA
REAL X(*), Y(*), A(LDA,*)

SUBROUTINE SSYR2_64( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX, INCY, LDA
REAL ALPHA
REAL X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

SUBROUTINE SYR2_64( UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyr2(char uplo, int n, float alpha, float *x, int incx, float *y, int incy, float *a, int lda);
```

```
void ssyr2_64(char uplo, long n, float alpha, float *x, long incx, float *y, long incy, float *a, long lda);
```

PURPOSE

ssyr2 performs the symmetric rank 2 operation $A := \alpha * x * y' + \alpha * y * x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

ssyr2k - perform one of the symmetric rank 2k operations $C := \alpha A B' + \alpha B A' + \beta C$ or $C := \alpha A' B + \alpha B' A + \beta C$

SYNOPSIS

```
SUBROUTINE SSYR2K( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,
*      C, LDC)

SUBROUTINE SYR2K( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],
*      BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

SUBROUTINE SYR2K_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
*      [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyr2k(char uplo, char transa, int n, int k, float alpha, float *a, int lda, float *b, int ldb, float beta, float *c, int ldc);
```

```
void ssyr2k_64(char uplo, char transa, long n, long k, float alpha, float *a, long lda, float *b, long ldb, float beta, float *c,
```

long ldc);

PURPOSE

ssyr2k K performs one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * B' + \alpha * B * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A * B + \alpha * B' * A + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * A * B + \alpha * B * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero.

Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *B* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B.

Unchanged on exit.

* **LDB** (*input*)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* **C** (*input/output*)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

ssyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE SSYRFS( UPLO, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B, LDB,

```

PURPOSE

ssyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*T}$ or $A = L * D * L^{*T}$ as computed by SSYTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($3 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ssyrk - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

SYNOPSIS

```
SUBROUTINE SSYRK( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER N, K, LDA, LDC
REAL ALPHA, BETA
REAL A(LDA,*), C(LDC,*)
```

```
SUBROUTINE SSYRK_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C,
* LDC)
CHARACTER * 1 UPLO, TRANSA
INTEGER*8 N, K, LDA, LDC
REAL ALPHA, BETA
REAL A(LDA,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYRK( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
* [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, C
```

```
SUBROUTINE SYRK_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
* C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyrk(char uplo, char transa, int n, int k, float alpha, float *a, int lda, float beta, float *c, int ldc);
```

```
void ssyrk_64(char uplo, char transa, long n, long k, float alpha, float *a, long lda, float beta, float *c, long ldc);
```

PURPOSE

ssyrk performs one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA (input)*

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A' * A + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * A' * A + \beta * C$.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K (input)*

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C (input/output)*

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

SUBROUTINE SYSV( UPLO, N, NRHS, A, [LDA], IPIVOT, B, [LDB], [WORK],
*             [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B

SUBROUTINE SYSV_64( UPLO, N, NRHS, A, [LDA], IPIVOT, B, [LDB], [WORK],
*                [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssysv(char uplo, int n, int nrhs, float *a, int lda, int *ipivot, float *b, int ldb, int *info);
```

```
void ssvsv_64(char uplo, long n, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sssvsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by SSVYTRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by SSVYTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The length of WORK. LDWORK ≥ 1 , and for best performance LDWORK $\geq N \cdot \text{NB}$, where NB is the optimal blocksize for SSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

ssysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$.

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssysvx(char fact, char uplo, int n, int nrhs, float *a, int lda, float *af, int ldaf, int *ipivot, float *b, int ldb, float *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void ssysvx_64(char fact, char uplo, long n, long nrhs, float *a, long lda, float *af, long ldaf, long *ipivot, float *b, long ldb, float *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

ssysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A . The form of the factorization is

$$A = U * D * U^{**T}, \text{ if } UPLO = 'U', \text{ or}$$
$$A = L * D * L^{**T}, \text{ if } UPLO = 'L',$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X . $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$.

* **LDAF (input)**

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

* **B (input)**

The N-by-NRHS right hand side matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK (input)**

The length of WORK. $LDWORK \geq 3 * N$, and for best performance $LDWORK \geq N * NB$, where NB is the optimal blocksize for SSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ssytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE SSYTD2( UPLO, N, A, LDA, D, E, TAU, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
REAL A(LDA,*), D(*), E(*), TAU(*)
```

```
SUBROUTINE SSYTD2_64( UPLO, N, A, LDA, D, E, TAU, INFO)
CHARACTER * 1 UPLO

REAL A(LDA,*), D(*), E(*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE SYTD2( UPLO, N, A, [LDA], D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL, DIMENSION(:) :: D, E, TAU
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYTD2_64( UPLO, N, A, [LDA], D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:) :: D, E, TAU
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytd2(char uplo, int n, float *a, int lda, float *d, float *e, float *tau, int *info);
```

```
void ssytd2_64(char uplo, long n, float *a, long lda, float *d, float *e, float *tau, long *info);
```

PURPOSE

ssytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T * A$
* $Q = T$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

On entry, the symmetric matrix A . If $UPLO = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. On exit, if $UPLO = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array TAU , represent the orthogonal matrix Q as a product of elementary reflectors; if $UPLO$

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T : $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i, i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1, i)$ if $UPLO = 'L'$.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **INFO** (*output*)

NAME

ssytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE SSYTF2( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER IPIV(*)
REAL A(LDA,*)
```

```
SUBROUTINE SSYTF2_64( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIV(*)
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYTF2( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYTF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytf2(char uplo, int n, float *a, int lda, int *ipiv, int *info);
```

```
void ssytf2_64(char uplo, long n, float *a, long lda, long *ipiv, long *info);
```

PURPOSE

ssytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U*D*U' \quad \text{or} \quad A = L*D*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

NAME

ssytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE SSYTRD( UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, LWORK, INFO
REAL A(LDA,*), D(*), E(*), TAU(*), WORK(*)
```

```
SUBROUTINE SSYTRD_64( UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, LWORK, INFO
REAL A(LDA,*), D(*), E(*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRD( UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],
*               [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E, TAU, WORK
REAL, DIMENSION(:,:) :: A
```

```
SUBROUTINE SYTRD_64( UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],
*                   [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E, TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytrd(char uplo, int n, float *a, int lda, float *d, float *e, float *tau, int *info);
```

```
void ssytrd_64(char uplo, long n, float *a, long lda, float *d, float *e, float *tau, long *info);
```

PURPOSE

ssytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation:
 $Q^* T^* A^* Q = T$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T: $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i, i+1)$ if UPLO = 'U', $E(i) = A(i+1, i)$ if UPLO = 'L'.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq 1$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

ssytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE SSYTRF( UPLO, N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), WORK(*)

SUBROUTINE SSYTRF_64( UPLO, N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
CHARACTER * 1 UPLO

INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

SUBROUTINE SYTRF_64( UPLO, N, A, [LDA], IPIVOT, [WORK], [LDWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytrf(char uplo, int n, float *a, int lda, int *ipivot, int *info);
```

```
void ssytrf_64(char uplo, long n, float *a, long lda, long *ipivot, long *info);
```

PURPOSE

ssytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U*D*U^{**T} \quad \text{or} \quad A = L*D*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK ≥ 1 . For best performance LDWORK $\geq N*NB$, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

ssytri - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

SYNOPSIS

```
SUBROUTINE SSYTRI( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE SSYTRI_64( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRI( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A
```

```
SUBROUTINE SYTRI_64( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytri(char uplo, int n, float *a, int lda, int *ipivot, int *info);
```

```
void ssytri_64(char uplo, long n, float *a, long lda, long *ipivot, long *info);
```

PURPOSE

ssytri computes the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

ssytrs - solve a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSYTRF

SYNOPSIS

```
SUBROUTINE SSYTRS( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, INFO

INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssytrs(char uplo, int n, int nrhs, float *a, int lda, int *ipivot, float *b, int ldb, int *info);
```

```
void ssytrs_64(char uplo, long n, long nrhs, float *a, long lda, long *ipivot, float *b, long ldb, long *info);
```

PURPOSE

ssytrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSYTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

stbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE STBCON( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, NDIAG, LDA, INFO  
INTEGER WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE STBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND,  
*      WORK, WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, NDIAG, LDA, INFO  
INTEGER*8 WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, NDIAG, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND,  
*      [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER(8) :: N, NDIAG, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stbcon(char norm, char uplo, char diag, int n, int ndiag, float *a, int lda, float *rcond, int *info);
```

```
void stbcon_64(char norm, char uplo, char diag, long n, long ndiag, float *a, long lda, float *rcond, long *info);
```

PURPOSE

stbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

stbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE STBMV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NDIAG, LDA, INCY
REAL A(LDA,*), Y(*)
```

```
SUBROUTINE STBMV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NDIAG, LDA, INCY
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBMV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NDIAG, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TBMV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NDIAG, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stbmv(char uplo, char transa, char diag, int n, int ndiag, float *a, int lda, float *y, int incy);
```

```
void stbmv_64(char uplo, char transa, char diag, long n, long ndiag, float *a, long lda, float *y, long incy);
```

PURPOSE

stbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $x := A*x$.

TRANS = 'T' or 't' $x := A'*x$.

TRANS = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

stbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

SYNOPSIS

```
SUBROUTINE STBRFS( UPLO, TRANSA, DIAG, N, NDIAG, NRHS, A, LDA, B,

SUBROUTINE TBRFS_64( UPLO, [TRANSA], DIAG, N, NDIAG, NRHS, A, [LDA],  
*      B, [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, LDX, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL, DIMENSION(:) :: FERR, BERR, WORK  
REAL, DIMENSION(:, :) :: A, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stbrfs(char uplo, char transa, char diag, int n, int ndiag, int nrhs, float *a, int lda, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void stbrfs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, float *a, long lda, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

stbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. STBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($3 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

stbsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE STBSV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NDIAG, LDA, INCY
REAL A(LDA,*), Y(*)
```

```
SUBROUTINE STBSV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NDIAG, LDA, INCY
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBSV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NDIAG, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

```
SUBROUTINE TBSV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NDIAG, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stbsv(char uplo, char transa, char diag, int n, int ndiag, float *a, int lda, float *y, int incy);
```

```
void stbsv_64(char uplo, char transa, char diag, long n, long ndiag, float *a, long lda, float *y, long incy);
```

PURPOSE

stbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
```

```
A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

```

```
void stbtrs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

stbtrs solves a triangular system of the form

where A is a triangular band matrix of order N , and B is an N -by $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A . $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A , stored in the first $kd+1$ rows of A . The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

stgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

SYNOPSIS

```
SUBROUTINE STGEVC( SIDE, HOWMNY, SELECT, N, A, LDA, B, LDB, VL,

*      VL, [LDVL], VR, [LDVR], MM, M, [WORK], [INFO])
CHARACTER(LEN=1) :: SIDE, HOWMNY
INTEGER(8) :: N, LDA, LDB, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A, B, VL, VR
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stgevc(char side, char howmny, logical *select, int n, float *a, int lda, float *b, int ldb, float *vl, int ldvl, float *vr, int ldvr, int mm, int *m, int *info);
```

void stgevc_64(char side, char howmny, logical *select, long n, float *a, long lda, float *b, long ldb, float *vl, long ldvl, float *vr, long ldvr, long mm, long *m, long *info);

PURPOSE

stgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{**H} * (A - wB) = 0$$

where y^{**H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices

$$(A0, B0) = (Q*A*Z^{**H}, Q*B*Z^{**H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A.

A must be block upper triangular, with 1-by-1 and 2-by-2 diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one

eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

* **SIDE** (input)

* **HOWMNY** (input)

* **SELECT** (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE..

* **N** (input)

The order of the matrices A and B. $N \geq 0$.

* **A** (input)

The upper quasi-triangular matrix A.

* **LDA** (input)

The leading dimension of array A. $LDA \geq \max(1, N)$.

* **B (input)**

The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive elements.

* **LDB (input)**

The leading dimension of array B. $LDB \geq \max(1, N)$.

* **VL (input/output)**

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix $Q*Y$; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

* **LDVL (input)**

The leading dimension of array VL. $LDVL \geq \max(1, N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix $Z*X$; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

* **LDVR (input)**

The leading dimension of the array VR. $LDVR \geq \max(1, N)$ if SIDE = 'R' or 'B'; $LDVR \geq 1$ otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. $MM \geq M$.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

* **WORK (workspace)**

dimension($6*N$)

* **INFO (output)**

NAME

stgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q * (A, B) * Z'$,

SYNOPSIS

```

REAL, DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stgexc(logical wantq, logical wantz, int n, float *a, int lda, float *b, int ldb, float *q, int ldq, float *z, int ldz, int *ifst, int *ilst, int *info);
```

```
void stgexc_64(logical wantq, logical wantz, long n, float *a, long lda, float *b, long ldb, float *q, long ldq, float *z, long ldz, long *ifst, long *ilst, long *info);
```

PURPOSE

stgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$\begin{aligned} Q(\text{in}) * A(\text{in}) * Z(\text{in})' &= Q(\text{out}) * A(\text{out}) * Z(\text{out})' \\ Q(\text{in}) * B(\text{in}) * Z(\text{in})' &= Q(\text{out}) * B(\text{out}) * Z(\text{out})' \end{aligned}$$

ARGUMENTS

* **WANTQ** (*input*)

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* **WANTZ** (*input*)

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* **N** (*input*)

The order of the matrices A and B. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

* **LDA** (*input*)

The leading dimension of the array A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

* **LDB** (*input*)

The leading dimension of the array B. LDB >= max(1,N).

* **Q** (*input/output*)

On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

* **Z** (*input/output*)

On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

* **IFST (input/output)**

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

* **ILST (input/output)**

See the description of IFST.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK >= 4*N + 16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

stgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q^* (A, B) Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

SYNOPSIS

```
SUBROUTINE STGSEN( IJOB, WANTQ, WANTZ, SELECT, N, A, LDA, B, LDB,

C INTERFACE

```
#include <sunperf.h>
```

```
void stgsen(int ijob, logical wantq, logical wantz, logical *select, int n, float *a, int lda, float *b, int ldb, float *alphan, float *alphai, float *beta, float *q, int ldq, float *z, int ldz, int *m, float *pl, float *pr, float *dif, int *info);
```

```
void stgsen_64(long ijob, logical wantq, logical wantz, logical *select, long n, float *a, long lda, float *b, long ldb, float *alphan, float *alphai, float *beta, float *q, long ldq, float *z, long ldz, long *m, float *pl, float *pr, float *dif, long *info);
```

PURPOSE

stgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q^* (A, B) Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

STGSEN also computes the generalized eigenvalues

$$w(j) = (\text{ALPHAR}(j) + i*\text{ALPHAI}(j)) / \text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, STGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

* *IJOB* (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

* *WANTQ* (input)

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* *WANTZ* (input)

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* *SELECT* (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B (input/output)**

On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **ALPHAR (output)**

On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $ALPHAR(j) + ALPHAI(j)*i$ and $BETA(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $ALPHAI(j)$ is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with $ALPHAI(j+1)$ negative.

* **ALPHAI (output)**

See the description of ALPHAR.

* **BETA (output)**

See the description of ALPHAR.

* **Q (input/output)**

On entry, if $WANTQ = .TRUE.$, Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If $WANTQ = .FALSE.$, Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$; and if $WANTQ = .TRUE.$, $LDQ \geq N$.

* **Z (input/output)**

On entry, if $WANTZ = .TRUE.$, Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If $WANTZ = .FALSE.$, Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$; If $WANTZ = .TRUE.$, $LDZ \geq N$.

* **M (output)**

The dimension of the specified pair of left and right eigenspaces (deflating subspaces). $0 \leq M \leq N$.

* **PL (output)**

If $IJOB = 1, 4$ or 5 , PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. $0 < PL, PR \leq 1$. If $M = 0$ or $M = N$, $PL = PR = 1$. If $IJOB = 0, 2$ or 3 , PL and PR are not referenced.

* **PR (output)**

See the description of PL.

* **DIF (output)**

If $IJOB \geq 2$, $DIF(1:2)$ store the estimates of Difu and Difl.

If $IJOB = 2$ or 4 , $DIF(1:2)$ are F-norm-based upper bounds on

Difu and Difl. If $IJOB = 3$ or 5 , $DIF(1:2)$ are 1-norm-based estimates of Difu and Difl. If $M = 0$ or N , $DIF(1:2) = F\text{-norm}([A, B])$. If $IJOB = 0$ or 1 , DIF is not referenced.

* **WORK (workspace)**

If $IJOB = 0$, WORK is not referenced. Otherwise, on exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 4*N+16$. If $IJOB = 1, 2$ or 4 , $LWORK \geq \max(4*N+16, 2*M*(N-M))$. If $IJOB = 3$ or 5 , $LWORK \geq \max(4*N+16, 4*M*(N-M))$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. LIWORK \geq 1. If IJOB = 1, 2 or 4, LIWORK \geq N+6. If IJOB = 3 or 5, LIWORK \geq MAX(2*M*(N-M), N+6).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

```

PURPOSE

stgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSPV from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{aligned} A &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ L \\ M-K-L \end{array} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \text{ if } M-K-L \geq 0; \\ A &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ M-K \end{array} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} \end{array} \text{ if } M-K-L < 0; \\ B &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} L \\ P-L \end{array} & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix},$$

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are "diagonal" matrices, which are of the following structures:

If $M-K-L \geq 0$,

$$\begin{aligned} D1 &= \begin{array}{ccc} & \begin{array}{cc} K & L \end{array} \\ \begin{array}{c} K \\ L \\ M-K-L \end{array} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \\ & \begin{array}{cc} K & L \end{array} \\ D2 &= \begin{array}{c} L \\ P-L \end{array} \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ L \end{array} & \begin{pmatrix} 0 & R11 & R12 \\ 0 & 0 & R22 \end{pmatrix} \end{array} \begin{array}{c} K \\ L \end{array} \end{aligned}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)),$
 $S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)),$
 $C^{**2} + S^{**2} = I.$
 R is stored in $A(1:K+L, N-K-L+1:N)$ on exit.

If $M-K-L < 0,$

$$\begin{array}{l}
 D1 = \begin{array}{cccc} & K & M-K & K+L-M \\ K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{array} \\
 D2 = \begin{array}{cccc} & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \\ & N-K-L & K & M-K & K+L-M \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{array}
 \end{array}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$

$C^{**2} + S^{**2} = I.$

$R = (R11 R12 R13)$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored $(0 R22 R23)$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the orthogonal transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1, V1,$ or $Q1.$

STGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$$U1' * A13 * Q1 = C1 * R1; V1' * B13 * Q1 = S1 * R1,$$

where $U1, V1$ and $Q1$ are orthogonal matrix, and Z' is the transpose of $Z.$ $C1$ and $S1$ are diagonal matrices satisfying

$$C1^{**2} + S1^{**2} = I,$$

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **K** (*input*)

K and L specify the subblocks in the input matrices A and B:

$A_{23} = A(K+1:\min(K+L,M), N-L+1:N)$ and $B_{13} = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by STGSJA. See Further details.

* **L** (*input*)

See the description of K.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **TOLA** (*input*)

TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$.

* **TOLB** (*input*)

See the description of TOLA.

* **ALPHA** (*output*)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$,

$BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = \text{diag}(C)$,

$BETA(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $ALPHA(K+L+1:N) = 0$ and

$BETA(K+L+1:N) = 0$.

* **BETA** (*output*)

See the description of ALPHA.

* **U** (*input*)

On entry, if `JOBV = 'U'`, `U` must contain a matrix `U1` (usually the orthogonal matrix returned by `SGGSVP`). On exit, if `JOBV = 'I'`, `U` contains the orthogonal matrix `U`; if `JOBV = 'U'`, `U` contains the product `U1*U`. If `JOBV = 'N'`, `U` is not referenced.

* ***LDU (input)***

The leading dimension of the array `U`. `LDU >= max(1,M)` if `JOBV = 'U'`; `LDU >= 1` otherwise.

* ***V (input)***

On entry, if `JOBV = 'V'`, `V` must contain a matrix `V1` (usually the orthogonal matrix returned by `SGGSVP`). On exit, if `JOBV = 'I'`, `V` contains the orthogonal matrix `V`; if `JOBV = 'V'`, `V` contains the product `V1*V`. If `JOBV = 'N'`, `V` is not referenced.

* ***LDV (input)***

The leading dimension of the array `V`. `LDV >= max(1,P)` if `JOBV = 'V'`; `LDV >= 1` otherwise.

* ***Q (input)***

On entry, if `JOBQ = 'Q'`, `Q` must contain a matrix `Q1` (usually the orthogonal matrix returned by `SGGSVP`). On exit, if `JOBQ = 'I'`, `Q` contains the orthogonal matrix `Q`; if `JOBQ = 'Q'`, `Q` contains the product `Q1*Q`. If `JOBQ = 'N'`, `Q` is not referenced.

* ***LDQ (input)***

The leading dimension of the array `Q`. `LDQ >= max(1,N)` if `JOBQ = 'Q'`; `LDQ >= 1` otherwise.

* ***WORK (workspace)***

`dimension(2*N)`

* ***NCYCLE (output)***

The number of cycles required for convergence.

* ***INFO (output)***

NAME

stgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z)

C INTERFACE

```
#include <sunperf.h>
```

```
void stgsna(char job, char howmnt, logical *select, int n, float *a, int lda, float *b, int ldb, float *vl, int ldvl, float *vr, int ldvr, float *s, float *dif, int mm, int *m, int *info);
```

```
void stgsna_64(char job, char howmnt, logical *select, long n, float *a, long lda, float *b, long ldb, float *vl, long ldvl, float *vr, long ldvr, float *s, float *dif, long mm, long *m, long *info);
```

PURPOSE

stgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z).

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):

*** HOWMNT (input)**

*** SELECT (input)**

If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

*** N (input)**

The order of the square matrix pair (A, B). N >= 0.

*** A (input)**

The upper quasi-triangular matrix A in the pair (A,B).

*** LDA (input)**

The leading dimension of the array A. LDA >= max(1,N).

*** B (input)**

The upper triangular matrix B in the pair (A,B).

*** LDB (input)**

The leading dimension of the array B. LDB >= max(1,N).

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by STGEVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. LDVL \geq 1. If JOB = 'E' or 'B', LDVL \geq N.

* **VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR \geq 1. If JOB = 'E' or 'B', LDVR \geq N.

* **S (output)**

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

* **DIF (output)**

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

* **MM (input)**

The number of elements in the arrays S and DIF. MM \geq M.

* **M (output)**

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

* **WORK (workspace)**

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK \geq N. If JOB = 'V' or 'B' LWORK \geq $2*N*(N+2)+16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If JOB = 'E', IWORK is not referenced.

* **INFO (output)**

NAME

stgsyl - solve the generalized Sylvester equation

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void stgsyl(char trans, int ijob, int m, int n, float *a, int lda, float *b, int ldb, float *c, int ldc, float *d, int ldd, float *e, int lde, float *f, int ldf, float *scale, float *dif, int *info);
```

```
void stgsyl_64(char trans, long ijob, long m, long n, float *a, long lda, float *b, long ldb, float *c, long ldc, float *d, long ldd, float *e, long lde, float *f, long ldf, float *scale, float *dif, long *info);
```

PURPOSE

stgsyl solves the generalized Sylvester equation:

$$\begin{aligned} A * R - L * B &= \text{scale} * C \\ D * R - L * E &= \text{scale} * F \end{aligned} \quad (1)$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). $0 \leq \text{SCALE} \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix} \quad (2)$$

Here I_k is the identity matrix of size k and X' is the transpose of X. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If $\text{TRANS} = 'T'$, STGSYL solves the transposed system $Z'y = \text{scale} * b$, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * (-F) \end{aligned} \quad (3)$$

This case ($\text{TRANS} = 'T'$) is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If $\text{IJOB} \geq 1$, STGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

* **TRANS** (*input*)

* **IJOB** (*input*)

Specifies what kind of functionality to be performed.

* **M** (*input*)

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

* **N** (*input*)

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

* **A** (*input*)

The upper quasi triangular matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper quasi triangular matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **D** (*input*)

The upper triangular matrix D.

* **LDD** (*input*)

The leading dimension of the array D. $LDD \geq \max(1, M)$.

* **E** (*input*)

The upper triangular matrix E.

* **LDE** (*input*)

The leading dimension of the array E. $LDE \geq \max(1, N)$.

* **F** (*input/output*)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

* **LDF** (*input*)

The leading dimension of the array F. $LDF \geq \max(1, M)$.

* **SCALE** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

* **DIF** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

* **WORK** (*workspace*)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK >= 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

dimension(M+N+2)

* **INFO** (*output*)

NAME

stpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE STPCON( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM, UPLO, DIAG
INTEGER N, INFO
INTEGER WORK2(*)
REAL RCOND
REAL A(*), WORK(*)
```

```
SUBROUTINE STPCON_64( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM, UPLO, DIAG
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
REAL RCOND
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: A, WORK

SUBROUTINE TPCON_64( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stpcon(char norm, char uplo, char diag, int n, float *a, float *rcond, int *info);
```

```
void stpcon_64(char norm, char uplo, char diag, long n, float *a, float *rcond, long *info);
```

PURPOSE

stpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

stpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE STPMV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
REAL A(*), Y(*)
```

```
SUBROUTINE STPMV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPMV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPMV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stpmv(char uplo, char transa, char diag, int n, float *a, float *y, int incy);
```

```
void stpmv_64(char uplo, char transa, char diag, long n, float *a, float *y, long incy);
```

PURPOSE

stpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*abs(INCY))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

stprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

SYNOPSIS

```
SUBROUTINE STPRFS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, X, LDX,
*      FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDB, LDX, INFO
INTEGER WORK2(*)
REAL A(*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)

SUBROUTINE STPRFS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, X,
*      LDX, FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDB, LDX, INFO
INTEGER*8 WORK2(*)
REAL A(*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPRFS( UPLO, [TRANSA], DIAG, N, NRHS, A, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: A, FERR, BERR, WORK
REAL, DIMENSION(:, :) :: B, X

SUBROUTINE TPRFS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: A, FERR, BERR, WORK
REAL, DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stprfs(char uplo, char transa, char diag, int n, int nrhs, float *a, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void stprfs_64(char uplo, char transa, char diag, long n, long nrhs, float *a, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

stprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. STPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(3*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

stpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE STPSV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
REAL A(*), Y(*)
```

```
SUBROUTINE STPSV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPSV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stpsv(char uplo, char transa, char diag, int n, float *a, float *y, int incy);
```

```
void stpsv_64(char uplo, char transa, char diag, long n, float *a, float *y, long incy);
```

PURPOSE

stpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*abs(INCY))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

stptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE STPTRI( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, INFO
REAL A(*)
```

```
SUBROUTINE STPTRI_64( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, INFO
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, INFO
REAL, DIMENSION(:) :: A
```

```
SUBROUTINE TPTRI_64( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stptri(char uplo, char diag, int n, float *a, int *info);
```

```
void stptri_64(char uplo, char diag, long n, float *a, long *info);
```

PURPOSE

stptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

* *INFO* (*output*)

NAME

stptrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE STPTRS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDB, INFO
REAL A(*), B(LDB,*)
```

```
SUBROUTINE STPTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDB, INFO
REAL A(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TPTRS( UPLO, TRANSA, DIAG, N, NRHS, A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE TPTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stptrs(char uplo, char transa, char diag, int n, int nrhs, float *a, float *b, int ldb, int *info);
```

```
void stptrs_64(char uplo, char transa, char diag, long n, long nrhs, float *a, float *b, long ldb, long *info);
```

PURPOSE

stptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N -by- $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

strans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE STRANS( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
INTEGER M, N
REAL SCALE
REAL SOURCE(*), DEST(*)
```

```
SUBROUTINE STRANS_64( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
INTEGER*8 M, N
REAL SCALE
REAL SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N
REAL :: SCALE
REAL, DIMENSION(:) :: SOURCE, DEST
```

```
SUBROUTINE TRANS_64( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N
REAL :: SCALE
REAL, DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strans(char place, float scale, float *source, int m, int n, float *dest);
```

```
void strans_64(char place, float scale, float *source, long m, long n, float *dest);
```

PURPOSE

strans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

```
PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE '  
PLACE = 'O' or 'o': DEST = SCALE * SOURCE '
```

ARGUMENTS

* **PLACE** (*input*)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place.

* **SCALE** (*input*)

Scale factor on the SOURCE matrix.

* **SOURCE** (*input/output*)

(M, N) on input. Array of (N, M) on output if in-place transpose.

* **M** (*input*)

Number of rows in the SOURCE matrix on input.

* **N** (*input*)

Number of columns in the SOURCE matrix on input.

* **DEST** (*output*)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

strco - (obsolete) estimate the condition number of a triangular matrix A. It is typical to follow a call to STRCO with a call to STRSL to solve $Ax = b$ or to STRDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE STRCO( A, LDA, N, RCOND, WORK, JOB)
INTEGER LDA, N, JOB
REAL RCOND
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE STRCO_64( A, LDA, N, RCOND, WORK, JOB)
INTEGER*8 LDA, N, JOB
REAL RCOND
REAL A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strco(float *a, int lda, int n, float *rcond, int job);
```

```
void strco_64(float *a, long lda, long n, float *rcond, long job);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

If $JOB = 0$, then A is lower triangular; otherwise A is upper triangular.

NAME

strcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE STRCON( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
*      INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, LDA, INFO  
INTEGER WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)  
  
SUBROUTINE STRCON_64( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, LDA, INFO  
INTEGER*8 WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:,) :: A  
  
SUBROUTINE TRCON_64( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER(8) :: N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strcon(char norm, char uplo, char diag, int n, float *a, int lda, float *rcond, int *info);
```

```
void strcon_64(char norm, char uplo, char diag, long n, float *a, long lda, float *rcond, long *info);
```

PURPOSE

strcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

strdi - (obsolete) compute the determinant and inverse of a triangular matrix A.

SYNOPSIS

```
SUBROUTINE STRDI( A, LDA, N, DET, JOB, INFO)
INTEGER LDA, N, JOB, INFO
REAL A(LDA,*), DET(*)
```

```
SUBROUTINE STRDI_64( A, LDA, N, DET, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
REAL A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strdi(float *a, int lda, int n, float *det, int job, int *info);
```

```
void strdi_64(float *a, long lda, long n, float *det, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, the inverse of the original matrix A if the inverse was requested, otherwise unchanged.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

* **N** (*input*)

Order of the original matrix A. N >= 0.

* **DET** (*output*)

On exit, the determinant of the matrix A. The determinant is stored as $b * (10 ** \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0.

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 010 no determinant, inverse of lower triangular A
- o 011 no determinant, inverse of upper triangular A
- o 100 determinant, no inverse

- 110 determinant, inverse of lower triangular A
- 111 determinant, inverse of upper triangular A

*** *INFO* (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Contains the index of a zero element of A if the inverse is requested and A is singular.

NAME

strevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

SYNOPSIS

```
SUBROUTINE STREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,  
* LDVR, MM, M, WORK, INFO)  
CHARACTER * 1 SIDE, HOWMNY  
INTEGER N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL SELECT(*)  
REAL T(LDT,*), VL(LDVL,*), VR(LDVR,*), WORK(*)  
  
SUBROUTINE STREVC_64( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,  
* LDVR, MM, M, WORK, INFO)  
CHARACTER * 1 SIDE, HOWMNY  
INTEGER*8 N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL*8 SELECT(*)  
REAL T(LDT,*), VL(LDVL,*), VR(LDVR,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREVC( SIDE, HOWMNY, SELECT, N, T, [LDT], VL, [LDVL], VR,  
* [LDVR], MM, M, [WORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, HOWMNY  
INTEGER :: N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL, DIMENSION(:) :: SELECT  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: T, VL, VR  
  
SUBROUTINE TREVC_64( SIDE, HOWMNY, SELECT, N, T, [LDT], VL, [LDVL],  
* VR, [LDVR], MM, M, [WORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, HOWMNY  
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL(8), DIMENSION(:) :: SELECT  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: T, VL, VR
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strevc(char side, char howmny, logical *select, int n, float *t, int ldt, float *vl, int ldvl, float *vr, int ldvr, int mm, int *m, int *info);
```

void strevc_64(char side, char howmny, logical *select, long n, float *t, long ldt, float *vl, long ldvl, float *vr, long ldvr, long mm, long *m, long *info);

PURPOSE

strevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input orthogonal

matrix. If T was obtained from the real-Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

* **SIDE** (*input*)

* **HOWMNY** (*input*)

* **SELECT** (*input/output*)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex conjugate pair w(j) and w(j+1), either SELECT(j) or SELECT(j+1) must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

* **N** (*input*)

The order of the matrix T. N >= 0.

* **T** (*input/output*)

The upper quasi-triangular matrix T in Schur canonical form.

* **LDT** (*input*)

The leading dimension of the array T. LDT >= max(1,N).

* **VL** (*input/output*)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL has the same quasi-lower triangular form as T'. If T(i,i) is a real eigenvalue, then the i-th column VL(i) of VL is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VL(i)+sqrt(-1)*VL(i+1) is the complex eigenvector

corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q^*Y ; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

* **LDVL (input)**

The leading dimension of the array VL. LDVL $\geq \max(1, N)$ if SIDE = 'L' or 'B'; LDVL ≥ 1 otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then $VR(i) + \sqrt{-1} * VR(i+1)$ is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q^*X ; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR $\geq \max(1, N)$ if SIDE = 'R' or 'B'; LDVR ≥ 1 otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. MM $\geq M$.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

* **WORK (workspace)**

dimension(3*N)

* **INFO (output)**

NAME

strex - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that the diagonal block of T with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE STREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)
CHARACTER * 1 COMPQ
INTEGER N, LDT, LDQ, IFST, ILST, INFO
REAL T(LDT,*), Q(LDQ,*), WORK(*)
```

```
SUBROUTINE STREXC_64( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK,
* INFO)
CHARACTER * 1 COMPQ
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
REAL T(LDT,*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREXC( COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
* [INFO])
CHARACTER(LEN=1) :: COMPQ
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: T, Q

SUBROUTINE TREXC_64( COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
* [INFO])
CHARACTER(LEN=1) :: COMPQ
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,) :: T, Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strexc(char compq, int n, float *t, int ldt, float *q, int ldq, int *ifst, int *ilst, int *info);
```

```
void strexc_64(char compq, long n, float *t, long ldt, float *q, long ldq, long *ifst, long *ilst, long *info);
```

PURPOSE

strex rearranges the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that the diagonal block of T with row index $IFST$ is moved to row $ILST$.

The real Schur form T is reordered by an orthogonal similarity transformation $Z^{**}T^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

T must be in Schur canonical form (as returned by `SHSEQR`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

* *COMPQ* (input)

* *N* (input)

The order of the matrix T . $N \geq 0$.

* *T* (input/output)

On entry, the upper quasi-triangular matrix T , in Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

* *LDT* (input)

The leading dimension of the array T . $LDT \geq \max(1, N)$.

* *Q* (input)

On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T . If $COMPQ = 'N'$, Q is not referenced.

* *LDQ* (input)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* *IFST* (input/output)

Specify the reordering of the diagonal blocks of T . The block with row index $IFST$ is moved to row $ILST$, by a sequence of transpositions between adjacent blocks. On exit, if $IFST$ pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; $ILST$ always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). $1 \leq IFST \leq N$; $1 \leq ILST \leq N$.

* *ILST* (input/output)

See the description of $IFST$.

* *WORK* (workspace)

dimension(N)

* *INFO* (output)

NAME

strmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$

SYNOPSIS

```
SUBROUTINE STRMM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*               LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)

SUBROUTINE STRMM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*                  B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRMM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*               [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:, :) :: A, B

SUBROUTINE TRMM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*                  [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strmm(char side, char uplo, char transa, char diag, int m, int n, float alpha, float *a, int lda, float *b, int ldb);
```

```
void strmm_64(char side, char uplo, char transa, char diag, long m, long n, float alpha, float *a, long lda, float *b, long ldb);
```

PURPOSE

strmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A'.$$

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, *TRANSA* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $\text{op}(A) = A$.

TRANSA = 'T' or 't' $\text{op}(A) = A'$.

TRANSA = 'C' or 'c' $\text{op}(A) = A'$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, *N* specifies the number of columns of B . $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** A (input)**

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

*** B (input/output)**

Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

NAME

strmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE STRMV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, LDA, INCY
REAL A(LDA,*), Y(*)
```

```
SUBROUTINE STRMV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, LDA, INCY
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRMV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

```
SUBROUTINE TRMV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strmv(char uplo, char transa, char diag, int n, float *a, int lda, float *y, int incy);
```

```
void strmv_64(char uplo, char transa, char diag, long n, float *a, long lda, float *y, long incy);
```

PURPOSE

strmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$.

Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

strrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

SYNOPSIS

```
SUBROUTINE STRRFS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, X,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void strrfs(char uplo, char transa, char diag, int n, int nrhs, float *a, int lda, float *b, int ldb, float *x, int ldx, float *ferr, float *berr, int *info);
```

```
void strrfs_64(char uplo, char transa, char diag, long n, long nrhs, float *a, long lda, float *b, long ldb, float *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

strrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. STRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

strsen - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void strsen(char job, char compq, logical *select, int n, float *t, int ldt, float *q, int ldq, float *wr, float *wi, int *m, float *s, float *sep, int *info);
```

```
void strsen_64(char job, char compq, logical *select, long n, float *t, long ldt, float *q, long ldq, float *wr, float *wi, long *m, float *s, float *sep, long *info);
```

PURPOSE

strsen reorders the real Schur factorization of a real matrix $A = Q^*T^*Q^{**}T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

* *JOB* (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

* *COMPQ* (input)

* *SELECT* (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

* *N* (input)

The order of the matrix T . $N \geq 0$.

* *T* (input/output)

On entry, the upper quasi-triangular matrix T , in Schur canonical form. On exit, T is overwritten by the reordered matrix T , again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

* *LDT* (input)

The leading dimension of the array T . $LDT \geq \max(1, N)$.

* *Q* (input)

On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the orthogonal transformation matrix which reorders T ; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If $COMPQ = 'N'$, Q is not referenced.

* *LDQ* (input)

The leading dimension of the array Q . $LDQ \geq 1$; and if $COMPQ = 'V'$, $LDQ \geq N$.

* *WR* (output)

The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are stored in the same order as on the diagonal of T, with $WR(i) = T(i,i)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) > 0$ and $WI(i+1) = -WI(i)$. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

* **WI (output)**

See the description of WR.

* **M (output)**

The dimension of the specified invariant subspace. $0 < M \leq N$.

* **S (output)**

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If JOB = 'N' or 'V', S is not referenced.

* **SEP (output)**

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If $M = 0$ or N , $SEP = \text{norm}(T)$. If JOB = 'N' or 'E', SEP is not referenced.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If JOB = 'N', $LWORK \geq \max(1,N)$; if JOB = 'E', $LWORK \geq M*(N-M)$; if JOB = 'V' or 'B', $LWORK \geq 2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If JOB = 'N' or 'E', IWORK is not referenced.

* **LIWORK (input)**

The dimension of the array IWORK. If JOB = 'N' or 'E', $LIWORK \geq 1$; if JOB = 'V' or 'B', $LIWORK \geq M*(N-M)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

strsl - (obsolete) solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE STRSL( A, LDA, N, B, JOB, INFO)
INTEGER LDA, N, JOB, INFO
REAL A(LDA,*), B(*)
```

```
SUBROUTINE STRSL_64( A, LDA, N, B, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
REAL A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strsl(float *a, int lda, int n, float *b, int job, int *info);
```

```
void strsl_64(float *a, long lda, long n, float *b, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 00 Solve $Ax = b$, A lower triangular.
- o 01 Solve $Ax = b$, A upper triangular.
- o 10 Solve $AHx = b$, A lower triangular.
- o 11 Solve $AHx = b$, A upper triangular.

- Note that $ATx = AHx$ for real matrices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns the index of the first zero diagonal element of A.

NAME

strsm - solve one of the matrix equations $op(A)X = \alpha B$, or $Xop(A) = \alpha B$

SYNOPSIS

```
SUBROUTINE STRSM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*               LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)

SUBROUTINE STRSM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*                  B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRSM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*              [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE TRSM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*                 [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strsm(char side, char uplo, char transa, char diag, int m, int n, float alpha, float *a, int lda, float *b, int ldb);
```

```
void strsm_64(char side, char uplo, char transa, char diag, long m, long n, float alpha, float *a, long lda, float *b, long ldb);
```

PURPOSE

strsm solves one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A'.$$

The matrix X is overwritten on B .

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A) * X = \alpha * B$.

SIDE = 'R' or 'r' $X * \text{op}(A) = \alpha * B$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, *TRANS* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' $\text{op}(A) = A$.

TRANS = 'T' or 't' $\text{op}(A) = A'$.

TRANS = 'C' or 'c' $\text{op}(A) = A'$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** *A (input)***

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

*** *B (input/output)***

Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

*** *LDB (input)***

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

NAME

strsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q^*T^*Q^{**}T$ with Q orthogonal)

SYNOPSIS

```
SUBROUTINE STRSNA( JOB, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void strсна(char job, char howmny, logical *select, int n, float *t, int ldt, float *vl, int ldvl, float *vr, int ldvr, float *s, float *sep, int mm, int *m, int ldwork, int *info);
```

```
void strсна_64(char job, char howmny, logical *select, long n, float *t, long ldt, float *vl, long ldvl, float *vr, long ldvr, float *s, float *sep, long mm, long *m, long ldwork, long *info);
```

PURPOSE

strсна estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q^*T^*Q^{**}T$ with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

*** HOWMNY (input)**

*** SELECT (input)**

If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input)**

The upper quasi-triangular matrix T, in Schur canonical form.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any $Q^*T^*Q^{**}T$ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

*** VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any $Q^*T^*Q^{**}T$ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR \geq 1; and if JOB = 'E' or 'B', LDVR \geq N.

* **S** (*output*)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

* **SEP** (*output*)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

* **MM** (*input*)

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM \geq M.

* **M** (*output*)

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

* **WORK** (*workspace*)

If JOB = 'E', WORK is not referenced.

* **LDWORK** (*input*)

The leading dimension of the array WORK. LDWORK \geq 1; and if JOB = 'V' or 'B', LDWORK \geq N.

* **WORK1** (*workspace*)

If JOB = 'E', WORK1 is not referenced.

* **INFO** (*output*)

NAME

strsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```

```

```
SUBROUTINE TRSV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strsv(char uplo, char transa, char diag, int n, float *a, int lda, float *y, int incy);
```

```
void strsv_64(char uplo, char transa, char diag, long n, float *a, long lda, float *y, long incy);
```

PURPOSE

strsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

strsyl - solve the real Sylvester matrix equation

SYNOPSIS

```
SUBROUTINE STRSYL( TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
*   SCALE, INFO)
CHARACTER * 1 TRANA, TRANB
INTEGER ISGN, M, N, LDA, LDB, LDC, INFO
REAL SCALE
REAL A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE STRSYL_64( TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C,
*   LDC, SCALE, INFO)
CHARACTER * 1 TRANA, TRANB
INTEGER*8 ISGN, M, N, LDA, LDB, LDC, INFO
REAL SCALE
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE TRSYL( TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,
*   [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
REAL, DIMENSION(:,:) :: A, B, C

SUBROUTINE TRSYL_64( TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB],
*   C, [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
REAL, DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strsyl(char trana, char tranb, int isgn, int m, int n, float *a, int lda, float *b, int ldb, float *c, int ldc, float *scale, int *info);
```

```
void strsyl_64(char trana, char tranb, long isgn, long m, long n, float *a, long lda, float *b, long ldb, float *c, long ldc, float
```

*scale, long *info);

PURPOSE

strsyl solves the real Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**T} , and A and B are both upper quasi-triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

* **TRANA** (*input*)

Specifies the option $\text{op}(A)$:

* **TRANB** (*input*)

Specifies the option $\text{op}(B)$:

* **ISGN** (*input*)

Specifies the sign in the equation:

* **M** (*input*)

The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

* **N** (*input*)

The order of the matrix B , and the number of columns in the matrices X and C . $N \geq 0$.

* **A** (*input*)

The upper quasi-triangular matrix A , in Schur canonical form.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper quasi-triangular matrix B , in Schur canonical form.

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, the M -by- N right hand side matrix C . On exit, C is overwritten by the solution matrix X .

* **LDC** (*input*)

The leading dimension of the array C . $LDC \geq \max(1, M)$

* **SCALE** (*output*)

The scale factor, scale , set ≤ 1 to avoid overflow in X .

** INFO (output)*

NAME

strti2 - compute the inverse of a real upper or lower triangular matrix

SYNOPSIS

```
SUBROUTINE STRTI2( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, LDA, INFO
REAL A(LDA,*)
```

```
SUBROUTINE STRTI2_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, LDA, INFO
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE TRTI2( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRTI2_64( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strti2(char uplo, char diag, int n, float *a, int lda, int *info);
```

```
void strti2_64(char uplo, char diag, long n, float *a, long lda, long *info);
```

PURPOSE

stri2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the matrix A is upper or lower triangular.

* **DIAG** (*input*)

Specifies whether or not the matrix A is unit triangular.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **INFO** (*output*)

NAME

strtri - compute the inverse of a real upper or lower triangular matrix A

SYNOPSIS

```
SUBROUTINE STRTRI( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
INTEGER N, LDA, INFO
REAL A(LDA,*)
```

```
SUBROUTINE STRTRI_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG

```

F95 INTERFACE

```
SUBROUTINE TRTRI( UPLO, DIAG, N, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRTRI_64( UPLO, DIAG, N, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strtri(char uplo, char diag, int n, float *a, int lda, int *info);
```

```
void strtri_64(char uplo, char diag, long n, float *a, long lda, long *info);
```

PURPOSE

strtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular matrix A. If *UPLO* = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If *DIAG* = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

strtrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE STRTRS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)

SUBROUTINE STRTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                   INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, NRHS, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRTRS( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
*               [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,*) :: A, B

SUBROUTINE TRTRS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B,
*                  [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strtrs(char uplo, char transa, char diag, int n, int nrhs, float *a, int lda, float *b, int ldb, int *info);
```

```
void strtrs_64(char uplo, char transa, char diag, long n, long nrhs, float *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

strtrs solves a triangular system of the form

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

stzrqf - routine is deprecated and has been replaced by routine STZRZF

SYNOPSIS

```
SUBROUTINE STZRQF( M, N, A, LDA, TAU, INFO)
INTEGER M, N, LDA, INFO
REAL A(LDA,*), TAU(*)
```

```
SUBROUTINE STZRQF_64( M, N, A, LDA, TAU, INFO)
INTEGER*8 M, N, LDA, INFO
REAL A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF( M, N, A, [LDA], TAU, [INFO])
INTEGER :: M, N, LDA, INFO
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRQF_64( M, N, A, [LDA], TAU, [INFO])
INTEGER(8) :: M, N, LDA, INFO
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stzrqf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void stzrqf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

stzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq M$.

*** A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** INFO (output)**

NAME

stzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

SYNOPSIS

```
SUBROUTINE STZRZF( M, N, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER M, N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE STZRZF_64( M, N, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER*8 M, N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TZRZF( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
INTEGER :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRZF_64( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stzrzf(int m, int n, float *a, int lda, float *tau, int *info);
```

```
void stzrzf_64(long m, long n, float *a, long lda, float *tau, long *info);
```

PURPOSE

stzrzf reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

* **M (input)**

The number of rows of the matrix A. $M \geq 0$.

* **N (input)**

The number of columns of the matrix A. $N \geq 0$.

* **A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU (output)**

The scalar factors of the elementary reflectors.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

sunperf_version - gets library information .HP 1i SUBROUTINE SUNPERF_VERSION(VERSION, PATCH, UPDATE)
.HP 1i INTEGER VERSION, PATCH, UPDATE .HP 1i

SYNOPSIS

```
SUBROUTINE SUNPERF_VERSION( VERSION, PATCH, UPDATE)
INTEGER VERSION, PATCH, UPDATE
```

```
SUBROUTINE SUNPERF_VERSION_64( VERSION, PATCH, UPDATE)
INTEGER*8 VERSION, PATCH, UPDATE
```

F95 INTERFACE

```
SUBROUTINE SUNPERF_VERSION( VERSION, PATCH, UPDATE)
INTEGER :: VERSION, PATCH, UPDATE
```

```
SUBROUTINE SUNPERF_VERSION_64( VERSION, PATCH, UPDATE)
INTEGER(8) :: VERSION, PATCH, UPDATE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sunperf_version(int *version, int *patch, int *update);
```

```
void sunperf_version_64(long *version, long *patch, long *update);
```

ARGUMENTS

* **VERSION** (*output*)

Version number of library

* **PATCH** (*output*)

Patch number of library

* **UPDATE** (*output*)

Update number of library

NAME

swiener - perform Wiener deconvolution of two signals

SYNOPSIS

```
SUBROUTINE SWIENER( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER N_POINTS, ISW, IERR
REAL ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

```
SUBROUTINE SWIENER_64( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER*8 N_POINTS, ISW, IERR
REAL ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

F95 INTERFACE

```
SUBROUTINE WIENER( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER :: N_POINTS, ISW, IERR
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

```
SUBROUTINE WIENER_64( N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
INTEGER(8) :: N_POINTS, ISW, IERR
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void swiener(int n_points, float *acor, float *xcor, float *fltr, float *erop, int *isw, int *ierr);
```

```
void swiener_64(long n_points, float *acor, float *xcor, float *fltr, float *erop, long *isw, long *ierr);
```

PURPOSE

swiener performs Wiener deconvolution of two signals.

ARGUMENTS

* *N_POINTS (input)*

On entry, the number of points in the input correlations. Unchanged on exit.

* *ACOR (input)*

On entry, autocorrelation coefficients. Unchanged on exit.

* *XCOR (input)*

On entry, cross-correlation coefficients. Unchanged on exit.

* *FLTR (output)*

On exit, filter coefficients. Unchanged on exit.

* *EROP (input)*

On exit, the prediction error.

* *ISW (output)*

On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

* *IERR (output)*

On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

NAME

use_threads - set the upper bound on the number of threads that the calling thread wants used

SYNOPSIS

```
SUBROUTINE USE_THREADS( NTHREADS )
INTEGER NTHREADS

SUBROUTINE USE_THREADS_64( NTHREADS )
INTEGER*8 NTHREADS
```

F95 INTERFACE

```
SUBROUTINE USE_THREADS( NTHREADS )
INTEGER :: NTHREADS

SUBROUTINE USE_THREADS_64( NTHREADS )
INTEGER(8) :: NTHREADS
```

C INTERFACE

```
#include <sunperf.h>

void use_threads(int nthreads);

void use_threads_64(long nthreads);
```

PURPOSE

use_threads THREADS sets an upper bound on the number of threads that the calling thread wants used. Subsequent calls to this routine result in replacement of the previous Use number for the calling thread. This counts all threads working on the callers behalf, so if it passes 2 for NTHREADS and then calls some subroutine, there will be at most 1 additional thread started to do the computation. There is no restriction that the sum of all NTHREADS from USE_THREADS calls may not exceed the number of CPUs in a system.

ARGUMENTS

NAME

using_threads - returns the current Use number set by the USE_THREADS subroutine

SYNOPSIS

```
INTEGER FUNCTION USING_THREADS( )
```

```
INTEGER*8 FUNCTION USING_THREADS_64( )
```

F95 INTERFACE

```
INTEGER FUNCTION USING_THREADS( )
```

```
INTEGER(8) FUNCTION USING_THREADS_64( )
```

C INTERFACE

```
#include <sunperf.h>
```

```
int using_threads();
```

```
long using_threads_64();
```

PURPOSE

using_threads THREADS will return the current Use number from the USE_THREADS subroutine for the calling thread.

ARGUMENTS

NAME

vbrmm, svbrmm, dvbrmm - variable block sparse row format matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                 VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,  
*                 B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*4 TRANSA, MB, N, KB, DESCRA(5), LDB, LDC, LWORK  
INTEGER*4 INDX(*), BINDX(*), RPNTR(MB+1), CPNTR(KB+1),  
*         BPNTRB(MB), BPNTRE(MB)  
REAL*4    ALPHA, BETA  
REAL*4    VAL(*), B(LDB,*), C(LDC,*), WORK(LWORK)  
SUBROUTINE DVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                 VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,  
*                 B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*4 TRANSA, MB, N, KB, DESCRA(5), LDB, LDC, LWORK  
INTEGER*4 INDX(*), BINDX(*), RPNTR(MB+1), CPNTR(KB+1),  
*         BPNTRB(MB), BPNTRE(MB)  
REAL*8    ALPHA, BETA  
REAL*8    VAL(*), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha A B + beta C  
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure

0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() scalar array of length NNZ containing matrix entries
 where NNZ is the number of nonzero point entries of a
 matrix A.
 INDX() integer array of length BNNZ+1 where BNNZ is the number of
 block entries of a matrix A such that the I-th element of
 INDX[] points to the location in VAL of the (1,1) element
 of the I-th block entry.
 BINDX() integer array of length BNNZ where BNNZ is the number of
 block entries of a matrix A consisting of the block column
 indices of the entries of A.
 RPNTR() integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
 is the row index of the first point row in the I-th block row.
 RPNTR(MB+1) is set to M+RPNTR(1).
 Thus, the number of point rows in the I-th block row is
 RPNTR(I+1)-RPNTR(I).
 CPNTR() integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1
 is the column index of the first point column in the J-th
 block column. CPNTR(KB+1) is set to K+CPNTR(1).
 Thus, the number of point columns in the J-th block column is
 CPNTR(J+1)-CPNTR(J).
 BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1
 points to location in BINDX of the first block entry of
 the I-th row of A.
 BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1)
 points to location in BINDX of the last block entry of
 the I-th row of A.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least
 MAX(M,N).
 LWORK length of WORK array

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

vbbrsm, svbrsm, dvbrsm - variable block sparse row format triangular solve

SYNOPSIS

```
SUBROUTINE SVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*                 VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, MB, N, UNITD, DESCRA(5), LDB, LDC, LWORK
INTEGER*4 INDX(*), BINDX(*), RPNTR(MB+1), CPNTR(MB+1),
*         BPNTRB(MB), BPNTRE(MB)
REAL*4     ALPHA, BETA
REAL*4     DV(*), VAL(*), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*                 VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, MB, N, UNITD, DESCRA(5), LDB, LDC, LWORK
INTEGER*4 INDX(*), BINDX(*), RPNTR(MB+1), CPNTR(MB+1),
*         BPNTRB(MB), BPNTRE(MB)
REAL*8     ALPHA, BETA
REAL*8     DV(*), VAL(*), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha D inv(A) B + beta C      C <- alpha D inv(A') B + beta C
C <- alpha inv(A) D B + beta C      C <- alpha inv(A') D B + beta C
                                     ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
MB	Number of block rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling)

DV() Array containing the diagonal entries of the block diagonal matrix D. The size of the J-th block is $RPNTR(J+1)-RPNTR(J)$ and each block contains matrix entries stored column-major. The total length of array DV is given by the formula:
sum over J from 1 to MB:
 $((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))$

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
0 : general
1 : symmetric
2 : Hermitian
3 : Triangular
4 : Skew(Anti-Symmetric)
5 : Diagonal
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL() scalar array of length NNZ containing matrix entries where NNZ is the number of nonzero point entries of a matrix A.
The main diagonal blocks of A must be triangular matrices.

INDX() integer array of length BNNZ+1 where BNNZ is the number block entries of a matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry.

BINDX() integer array of length BNNZ consisting of the block column indices of the entries of A where BNNZ is the number block entries of a matrix A.

RPNTR() integer array of length MB+1 such that $RPNTR(I)-RPNTR(1)+1$ is the row index of the first point row in the I-th block row. $RPNTR(MB+1)$ is set to $M+RPNTR(1)$.
Thus, the number of point rows in the I-th block row is $RPNTR(I+1)-RPNTR(I)$.
NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR() integer array of length MB+1 such that $CPNTR(J)-CPNTR(1)+1$ is the column index of the first point column in the J-th block column. $CPNTR(KB+1)$ is set to $K+CPNTR(1)$.
Thus, the number of point columns in the J-th block column is $CPNTR(J+1)-CPNTR(J)$.
NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB() integer array of length MB such that $BPNTRB(I)-BPNTRB(1)+1$ points to location in BINDX of the first block entry of the J-th row of A.

BPNTRE() integer array of length MB such that $BPNTRE(I)-BPNTRB(1)$ points to location in BINDX of the last block entry of the J-th row of A.

B() rectangular array with first dimension LDB.
LDB leading dimension of B

BETA Scalar parameter

C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. LWORK should be at least M * MIN(MAX_BLOCK_SIZE, N). On exit, if LWORK = -1, WORK(1) returns the minimum value for LWORK.
LWORK	length of WORK array

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

vcfftb - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCFFTB( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX
```

```
SUBROUTINE VCFFTB_64( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTB_64( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcfftb(int m, int n, complex *x, complex *xt, int mdimx, char rowcol, complex *wsave);
```

```
void vcfftb_64(long m, long n, complex *x, complex *xt, long mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

*** *M* (input)**

If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. $M \geq 0$.

*** *N* (input)**

If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. $N \geq 0$.

*** *X* (input)**

On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

*** *XT* (input)**

A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (`get_env`, `available_threads`, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

*** *MDIMX* (input)**

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

*** *ROWCOL* (input)**

Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

*** *WSAVE* (input/output)**

On entry, an array of dimension (L2+15) or greater, where $L2 = 2 * M$ if ROWCOL = ('R' or 'r'). Otherwise, $L2 = 2 * N$. WSAVE is initialized by VCFFTI.

NAME

vcfft - compute the Fourier coefficients of a periodic sequence. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCFFTF( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX
```

```
SUBROUTINE VCFFTF_64( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE F95_VCF( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,*) :: X, XT
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE F95_VCF_64( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,*) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcfft(int m, int n, complex *x, complex *xt, int mdimx, char rowcol, complex *wsave);
```

```
void vcfft_64(long m, long n, complex *x, complex *xt, long mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

*** *M* (input)**

If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. $M \geq 0$.

*** *N* (input)**

If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. $N \geq 0$.

*** *X* (input)**

On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

*** *XT* (input)**

A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (`get_env`, `available_threads`, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

*** *MDIMX* (input)**

Leading dimension of the arrays X. $MDIMX \geq M$.

*** *ROWCOL* (input)**

Indicates whether data sequences in X are stored row-wise ('R' or 'r') or column-wise ('C' or 'c').

*** *WSAVE* (input/output)**

On entry, an array of dimension (L2+15) or greater, where $L2 = 2 * M$ if ROWCOL = ('R' or 'r'). Otherwise, $L2 = 2 * N$. WSAVE is initialized by VCFFTI.

NAME

vcffti - initialize the array WSAVE, which is used in both VCFFTF and VCFFTB.

SYNOPSIS

```
SUBROUTINE VCFFTI( N, WSAVE)
COMPLEX WSAVE(*)
INTEGER N

SUBROUTINE VCFFTI_64( N, WSAVE)
COMPLEX WSAVE(*)
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI( N, WSAVE)
COMPLEX, DIMENSION(:) :: WSAVE
INTEGER :: N

SUBROUTINE VFFTI_64( N, WSAVE)
COMPLEX, DIMENSION(:) :: WSAVE
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>

void vcffti(int n, complex *wsave);

void vcffti_64(long n, complex *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(2*N + 15)$ or greater. VCFFTI needs to be called only once to initialize WSAVE before calling VCFFTF and/or VCFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCOSQB( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VCOSQB_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

```
SUBROUTINE COSQB_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcosqb(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vcosqb_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
 $N \geq 0$.

* ***X (input/output)***

On entry, the rows contain the sequences to be transformed. On exit, the quarter-wave cosine synthesis of the input.

* ***XT (input)***

A work array.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by $VCOSQI$.

NAME

vcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCOSQF( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VCOSQF_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE COSQF_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcosqf(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vcosqf_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input/output)***

On entry, an array of length N containing the sequence to be transformed. For VCOSQF, a real two-dimensional array with dimensions of $(MDIMX \times N)$ whose rows contain the sequences to be transformed. On exit, the quarter-wave cosine transform of the input.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by VCOSTI.

NAME

vcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

SYNOPSIS

```
SUBROUTINE VCOSQI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)

SUBROUTINE VCOSQI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSQI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VCOSQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vcosqi(int n, float *wsave);

void vcosqi_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. VCOSQI needs to be called only once to initialize WSAVE before calling VCOSQF and/or VCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCOST( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VCOST_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COST( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE COST_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcost(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vcost_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* ***X*** (*input/output*)

On entry, an array of length N containing the sequence to be transformed. For VCOST, a real two-dimensional array with dimensions of $(MDIMX \times (N+1))$ whose rows contain the sequences to be transformed. On exit, the cosine transform of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of $(MDIMX \times (N-1))$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by VCOSTI.

NAME

vcosti - initialize the array WSAVE, which is used in VCOST.

SYNOPSIS

```
SUBROUTINE VCOSTI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)

SUBROUTINE VCOSTI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSTI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VCOSTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vcosti(int n, float *wsave);

void vcosti_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. VCOSTI is called once to initialize WSAVE before calling VCOST and need not be called again between calls to VCOST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vdcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDCOSQB( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDCOSQB_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:,) :: X, XT
```

```
SUBROUTINE COSQB_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:,) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdcosqb(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdcosqb_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input/output)***

On entry, the rows contain the sequences to be transformed. On exit, the quarter-wave cosine synthesis of the input.

* ***XT (input)***

A work array.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by $VCOSQI$.

NAME

vdcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDCOSQF( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDCOSQF_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE COSQF_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdcosqf(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdcosqf_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, an array of length N containing the sequence to be transformed. For VCOSQF, a real two-dimensional array with dimensions of $(MDIMX \times N)$ whose rows contain the sequences to be transformed. On exit, the quarter-wave cosine transform of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by VCOSQI.

NAME

vdcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

SYNOPSIS

```
SUBROUTINE VDCOSQI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDCOSQI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSQI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VCOSQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdcosqi(int n, double *wsave);

void vdcosqi_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. VDCOSQI needs to be called only once to initialize WSAVE before calling VDCOSQF and/or VDCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vdcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VDCOST will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDCOST( M, N, X, XT, MDIMX, WSAVE)
INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDCOST_64( M, N, X, XT, MDIMX, WSAVE)
INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COST( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE COST_64( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdcost(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdcost_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* ***X*** (*input/output*)

On entry, an array of length N containing the sequence to be transformed. For VCOST, a real two-dimensional array with dimensions of $(MDIMX \times (N+1))$ whose rows contain the sequences to be transformed. On exit, the cosine transform of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of $(MDIMX \times (N-1))$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array of dimension $(2 * N + 15)$ or greater initialized by VDCOSTI.

NAME

vdcosti - initialize the array WSAVE, which is used in VCOST.

SYNOPSIS

```
SUBROUTINE VDCOSTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDCOSTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VCOSTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdcosti(int n, double *wsave);

void vdcosti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. `VDCOSTI` is called once to initialize `WSAVE` before calling `VDCOST` and need not be called again between calls to `VDCOST` if N and `WSAVE` remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vdfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDFFTB( M, N, X, XT, MDIMX, WSAVE)
INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDFFTB_64( M, N, X, XT, MDIMX, WSAVE)
INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE FFTB_64( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdfftb(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdfftb_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input)***

On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array $X(M,N)$ whose rows contain the sequences to be transformed.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(N+15)$ or greater initialized by VRFFTI.

NAME

vdfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFT followed by a call of VRFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDFFTF( M, N, X, XT, MDIMX, WSAVE)
INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDFFTF_64( M, N, X, XT, MDIMX, WSAVE)
INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE FFTF_64( [M], [N], X, XT, [MDIMX], WSAVE)
INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdfftf(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdfftf_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input)***

On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array $X(M,N)$ whose rows contain the sequences to be transformed.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(N+15)$ or greater initialized by VRFFTI.

NAME

vdffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

SYNOPSIS

```
SUBROUTINE VDFFTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDFFTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VFFTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VFFTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdffti(int n, double *wsave);

void vdffti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(N + 15)$ or greater. VRFFTI needs to be called only once to initialize WSAVE before calling VRFFTF and/or VRFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vdsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINQB( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDSINQB_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINQB_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsinqb(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdsinqb_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, a real two-dimensional array with dimensions of ($MDIMX \times N$) whose rows contain the sequences to be transformed. On exit, the quarter-wave sine synthesis of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of ($MDIMX \times N$).

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array with dimension of at least $(2 * N + 15)$ for vector subroutines, initialized by $VSINQI$.

NAME

vdsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINQF( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDSINQF_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINQF_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsinqf(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdsinqf_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input/output)***

On entry, an array of length N containing the sequence to be transformed. For VSINQF, a real two-dimensional array with dimensions of $(MDIMX \times N)$ whose rows contain the sequences to be transformed. On exit, the quarter-wave sine transform of the input.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array with dimension of at least $(2 * N + 15)$, initialized by VSINQI.

NAME

vdsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

SYNOPSIS

```
SUBROUTINE VDSINQI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDSINQI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINQI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VSINQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdsinqi(int n, double *wsave);

void vdsinqi_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array with a dimension of at least $(2 * N + 15)$. The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

vdsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINT( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDSINT_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINT_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL(8), DIMENSION(:) :: WSAVE
  REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsint(int m, int n, double *x, double *xt, int mdimx, double *wsave);
```

```
void vdsint_64(long m, long n, double *x, double *xt, long mdimx, double *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, a real two-dimensional array with dimensions of $(MDIMX \times (N+1))$ whose rows contain the sequences to be transformed. On exit, the sine transform of the input.

* ***XT*** (*input/output*)

A real two-dimensional work array with dimensions of $(MDIMX \times (N+1))$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays *X* and *XT* as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by *VSINTI*.

NAME

vdsinti - initialize the array WSAVE, which is used in subroutine VSINT.

SYNOPSIS

```
SUBROUTINE VDSINTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDSINTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VSINTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdsinti(int n, double *wsave);

void vdsinti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. *VSINTI* is called once to initialize *WSAVE* before calling *VSINT* and need not be called again between calls to *VSINT* if *N* and *WSAVE* remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vrfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VRFFTB( M, N, X, XT, MDIMX, WSAVE )
INTEGER M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VRFFTB_64( M, N, X, XT, MDIMX, WSAVE )
INTEGER*8 M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [M], [N], X, XT, [MDIMX], WSAVE )
INTEGER :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,) :: X, XT
```

```
SUBROUTINE FFTB_64( [M], [N], X, XT, [MDIMX], WSAVE )
INTEGER(8) :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vrfftb(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vrfftb_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input)***

On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array $X(M,N)$ whose rows contain the sequences to be transformed.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(N+15)$ or greater initialized by VRFFTI.

NAME

vrfft - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFT followed by a call of VRFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VRFFT( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VRFFT_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFFT( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

```
SUBROUTINE FFFT_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vrfft(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vrfft_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input)***

On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array $X(M,N)$ whose rows contain the sequences to be transformed.

* ***XT (input)***

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE (input)***

On entry, an array of dimension $(N+15)$ or greater initialized by VRFFTI.

NAME

vrffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

SYNOPSIS

```
SUBROUTINE VRFFTI( N, WSAVE)
INTEGER N
REAL WSAVE(*)

SUBROUTINE VRFFTI_64( N, WSAVE)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VFFFTI( N, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VFFFTI_64( N, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vrffti(int n, float *wsave);

void vrffti_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(N + 15)$ or greater. VRFFTI needs to be called only once to initialize WSAVE before calling VRFFTF and/or VRFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VSINQB( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VSINQB_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

```
SUBROUTINE SINQB_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:,) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsinqb(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vsinqb_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, a real two-dimensional array with dimensions of ($MDIMX \times N$) whose rows contain the sequences to be transformed. On exit, the quarter-wave sine synthesis of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of ($MDIMX \times N$).

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array with dimension of at least $(2 * N + 15)$ for vector subroutines, initialized by `VSINQI`.

NAME

vsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VSINQF( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VSINQF_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINQF_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsinqf(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vsinqf_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, an array of length N containing the sequence to be transformed. For VSINQF, a real two-dimensional array with dimensions of $(MDIMX \times N)$ whose rows contain the sequences to be transformed. On exit, the quarter-wave sine transform of the input.

* ***XT*** (*input*)

A real two-dimensional work array with dimensions of $(MDIMX \times N)$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array with dimension of at least $(2 * N + 15)$, initialized by VSINQI.

NAME

vsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

SYNOPSIS

```
SUBROUTINE VSINQI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)

SUBROUTINE VSINQI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINQI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VSINQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vsinqi(int n, float *wsave);

void vsinqi_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array with a dimension of at least $(2 * N + 15)$. The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

vsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

SYNOPSIS

```
SUBROUTINE VSINT( M, N, X, XT, MDIMX, WSAVE)
  INTEGER M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VSINT_64( M, N, X, XT, MDIMX, WSAVE)
  INTEGER*8 M, N, MDIMX
  REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINT_64( [M], [N], X, XT, [MDIMX], WSAVE)
  INTEGER(8) :: M, N, MDIMX
  REAL, DIMENSION(:) :: WSAVE
  REAL, DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsint(int m, int n, float *x, float *xt, int mdimx, float *wsave);
```

```
void vsint_64(long m, long n, float *x, float *xt, long mdimx, float *wsave);
```

ARGUMENTS

* ***M*** (*input*)

The number of sequences to be transformed. $M \geq 0$.

* ***N*** (*input*)

Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

* ***X*** (*input/output*)

On entry, a real two-dimensional array with dimensions of $(MDIMX \times (N+1))$ whose rows contain the sequences to be transformed. On exit, the sine transform of the input.

* ***XT*** (*input/output*)

A real two-dimensional work array with dimensions of $(MDIMX \times (N+1))$.

* ***MDIMX*** (*input*)

Leading dimension of the arrays *X* and *XT* as specified in a dimension or type statement. $MDIMX \geq M$.

* ***WSAVE*** (*input*)

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by *VSINTI*.

NAME

vsinti - initialize the array WSAVE, which is used in subroutine VSINT.

SYNOPSIS

```
SUBROUTINE VSINTI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)

SUBROUTINE VSINTI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VSINTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vsinti(int n, float *wsave);

void vsinti_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. *VSINTI* is called once to initialize *WSAVE* before calling *VSINT* and need not be called again between calls to *VSINT* if *N* and *WSAVE* remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vzfftb - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VZFFTB( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX
```

```
SUBROUTINE VZFFTB_64( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:, :) :: X, XT
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTB_64( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:, :) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vzfftb(int m, int n, doublecomplex *x, doublecomplex *xt, int mdimx, char rowcol, doublecomplex *wsave);
```

```
void vzfftb_64(long m, long n, doublecomplex *x, doublecomplex *xt, long mdimx, char rowcol, doublecomplex *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***X (input)***

On entry, the rows contain the sequences to be transformed.

* ***XT (input)***

A work array.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***ROWCOL (input)***

Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

* ***WSAVE (input/output)***

On entry, an array of dimension $(K+15)$ or greater, where $K = M$ if $ROWCOL = ('R' \text{ or } 'r')$. Otherwise, $K = N$. $WSAVE$ is initialized by $VZFFT1$.

NAME

vzfft - compute the Fourier coefficients of a periodic sequence. The VZFFT operations are normalized, so a call of VZFFT followed by a call of VZFTTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VZFFT( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX
```

```
SUBROUTINE VZFFT_64( M, N, X, XT, MDIMX, ROWCOL, WSAVE)
CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTF( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:, :) :: X, XT
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTF_64( [M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:, :) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vzfft(int m, int n, doublecomplex *x, doublecomplex *xt, int mdimx, char rowcol, doublecomplex *wsave);
```

```
void vzfft_64(long m, long n, doublecomplex *x, doublecomplex *xt, long mdimx, char rowcol, doublecomplex *wsave);
```

ARGUMENTS

* ***M (input)***

The number of sequences to be transformed. $M \geq 0$.

* ***N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
 $N \geq 0$.

* ***X (input)***

On entry, an array $X(M,N)$ whose rows contain the sequences to be transformed.

* ***XT (input)***

A work array.

* ***MDIMX (input)***

Leading dimension of the arrays X and XT as specified in a dimension or type statement. $MDIMX \geq M$.

* ***ROWCOL (input)***

Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

* ***WSAVE (input/output)***

On entry, an array of dimension $(K+15)$ or greater, where $K = M$ if $ROWCOL = ('R' \text{ or } 'r')$. Otherwise, $K = N$.
 $WSAVE$ is initialized by $VZFFT1$.

NAME

vzffti - initialize the array WSAVE, which is used in both VZFFTF and VZFFTB.

SYNOPSIS

```
SUBROUTINE VZFFTI( N, WSAVE)
DOUBLE COMPLEX WSAVE(*)
INTEGER N

SUBROUTINE VZFFTI_64( N, WSAVE)
DOUBLE COMPLEX WSAVE(*)
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI( N, WSAVE)
COMPLEX(8), DIMENSION(:) :: WSAVE
INTEGER :: N

SUBROUTINE VFFTI_64( N, WSAVE)
COMPLEX(8), DIMENSION(:) :: WSAVE
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>

void vzffti(int n, doublecomplex *wsave);

void vzffti_64(long n, doublecomplex *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(N + 15)$ or greater. VZFFTI needs to be called only once to initialize WSAVE before calling VZFFTF and/or VZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

zaxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE ZAXPY( N, ALPHA, X, INCX, Y, INCY)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZAXPY_64( N, ALPHA, X, INCX, Y, INCY)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY( [N], ALPHA, X, [INCX], Y, [INCY])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE AXPY_64( [N], ALPHA, X, [INCX], Y, [INCY])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zaxpy(int n, doublecomplex alpha, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
void zaxpy_64(long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zaxpy compute $y := \alpha * x + y$ where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *X (input)*

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

array of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zbdsql - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

SYNOPSIS

```
SUBROUTINE ZBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,
*      C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX VT(LDVT,*), U(LDU,*), C(LDC,*)
INTEGER N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)

SUBROUTINE ZBDSQR_64( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
*      LDU, C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX VT(LDVT,*), U(LDU,*), C(LDC,*)
INTEGER*8 N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE BDSQR( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT, [LDVT],
*      U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: VT, U, C
INTEGER :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL(8), DIMENSION(:) :: D, E, WORK

SUBROUTINE BDSQR_64( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT,
*      [LDVT], U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: VT, U, C
INTEGER(8) :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zbdsql(char uplo, int n, int ncvl, int nru, int ncc, double *d, double *e, doublecomplex *vt, int ldvt, doublecomplex *u,
int ldu, doublecomplex *c, int ldc, int *info);
```

```
void zbdsql_64(char uplo, long n, long ncvl, long nru, long ncc, double *d, double *e, doublecomplex *vt, long ldvt,
```

doublecomplex *u, long ldu, doublecomplex *c, long ldc, long *info);

PURPOSE

zbdscr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and

"Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **NCVT** (*input*)

The number of columns of the matrix VT. $NCVT \geq 0$.

* **NRU** (*input*)

The number of rows of the matrix U. $NRU \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

* **VT** (*input/output*)

On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

* **U** (*input/output*)

On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq \max(1, NRU)$.

* **C** (*input/output*)

On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

* **INFO** (*output*)

NAME

zchdc - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE ZCHDC( A, LDA, N, WORK, IPIVOT, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZCHDC_64( A, LDA, N, WORK, IPIVOT, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zchdc(doublecomplex *a, int lda, int n, int *ipivot, int job, int *info);
```

```
void zchdc_64(doublecomplex *a, long lda, long n, long *ipivot, long job, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of A. On exit, the upper triangle of the Cholesky factor, as permuted by pivoting if pivoting was selected. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** IPIVOT (input)**

If JOB selected no pivoting then IPIVOT is not referenced. On entry, if JOB selected pivoting, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

$IPIVOT(k) > 0$ $A(k,k)$ is an initial element.

$IPIVOT(k) = 0$ $A(k,k)$ is a free element.

$IPIVOT(k) < 0$ $A(k,k)$ is a final element.

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A . During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, $IPIVOT(k)$ contains the index of the diagonal element of A that was moved into the k th position.

*** *JOB* (input)**

Determines how decomposition is done:

0 without pivoting

not 0 with pivoting

*** *INFO* (output)**

On exit: Returns the index of the last positive diagonal element of the Cholesky factor. The subroutine was successful if $INFO = N$.

NAME

zchdd - (obsolete) downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE ZCHDD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN, INFO)
DOUBLE COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER LDA, N, LDZ, NZ, INFO
DOUBLE PRECISION RHO(*), COS(*)
```

```
SUBROUTINE ZCHDD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN,
* INFO)
DOUBLE COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER*8 LDA, N, LDZ, NZ, INFO
DOUBLE PRECISION RHO(*), COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zchdd(doublecomplex *a, int lda, int n, doublecomplex *x, doublecomplex *z, int ldz, int nz, doublecomplex *y, double *rho, double *cos, doublecomplex *sin, int *info);
```

```
void zchdd_64(doublecomplex *a, long lda, long n, doublecomplex *x, doublecomplex *z, long ldz, long nz, doublecomplex *y, double *rho, double *cos, doublecomplex *sin, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been downdated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be downdated with A.

* ***LDZ (input)***

Leading dimension on the array Z as specified in a dimension or type statement. $LDZ \geq \max(1, N)$.

* ***NZ (input)***

Number of vectors to be downdated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for downdating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be downdated. On exit, RHO has been downdated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input/output)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO = -1 A could not be downdated; all values are left unchanged.

INFO = 1 Some RHOs could not be downdated; all RHOs that could not be downdated are changed to -1.

NAME

zchex - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE ZCHEX( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
DOUBLE COMPLEX A(LDA,*), Z(LDZ,*), SIN(*)
INTEGER LDA, N, K, L, LDZ, NZ, JOB
DOUBLE PRECISION COS(*)
```

```
SUBROUTINE ZCHEX_64( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
DOUBLE COMPLEX A(LDA,*), Z(LDZ,*), SIN(*)
INTEGER*8 LDA, N, K, L, LDZ, NZ, JOB
DOUBLE PRECISION COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zchex(doublecomplex *a, int lda, int n, int k, int l, doublecomplex *z, int ldz, int nz, double *cos, doublecomplex *sin, int job);
```

```
void zchex_64(doublecomplex *a, long lda, long n, long k, long l, doublecomplex *z, long ldz, long nz, double *cos, doublecomplex *sin, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, the upper triangle of A contains the upper triangle of the updated factor. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** K (input)**

First column to be permuted. $1 \leq K \leq L$.

*** L (input)**

Last column to be permuted; must be strictly greater than K. $K \leq L \leq N$.

*** Z (input/output)**

Array of vectors into which the transformation U is multiplied. Not used if NZ = 0.

* **LDZ (input)**

Leading dimension of the array Z as specified in a dimension or type statement. LDZ \geq max(1,N).

* **NZ (input)**

Number of columns in the matrix Z. NZ \geq 0.

* **COS (input)**

Cosines of the transforming rotations.

* **SIN (output)**

Sines of the transforming rotations.

* **JOB (input)**

Determines the type of permutation:

1 right circular shift

2 left circular shift

NAME

zchud - (obsolete) update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE ZCHUD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
DOUBLE COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER LDA, N, LDZ, NZ
DOUBLE PRECISION RHO(*), COS(*)
```

```
SUBROUTINE ZCHUD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
DOUBLE COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER*8 LDA, N, LDZ, NZ
DOUBLE PRECISION RHO(*), COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zchud(doublecomplex *a, int lda, int n, doublecomplex *x, doublecomplex *z, int ldz, int nz, doublecomplex *y, double *rho, double *cos, doublecomplex *sin);
```

```
void zchud_64(doublecomplex *a, long lda, long n, doublecomplex *x, doublecomplex *z, long ldz, long nz, doublecomplex *y, double *rho, double *cos, doublecomplex *sin);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been updated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be updated with A.

*** LDZ (input)**

Leading dimension on the array Z as specified in a dimension or type statement. $LDZ \geq \max(1, N)$.

* ***NZ (input)***

Number of vectors to be updated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for updating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be updated. On exit, RHO has been updated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (input)***

Sines of the transforming rotations.

NAME

zcnvcor - compute the convolution or correlation of complex vectors

SYNOPSIS

```
SUBROUTINE ZCNVCOR( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRES, M, Y,  
*      IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)  
CHARACTER * 1 CNVCOR, FOUR  
DOUBLE COMPLEX X(*), Y(*), Z(*), WORK(*)  
INTEGER NX, IFX, INCX, NY, NPRES, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK  
  
SUBROUTINE ZCNVCOR_64( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRES, M,  
*      Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)  
CHARACTER * 1 CNVCOR, FOUR  
DOUBLE COMPLEX X(*), Y(*), Z(*), WORK(*)  
INTEGER*8 NX, IFX, INCX, NY, NPRES, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK
```

F95 INTERFACE

```
SUBROUTINE CNVCOR( CNVCOR, FOUR, [NX], X, IFX, [INCX], NY, NPRES, M,  
*      Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, [LWORK])  
CHARACTER(LEN=1) :: CNVCOR, FOUR  
COMPLEX(8), DIMENSION(:) :: X, Y, Z, WORK  
INTEGER :: NX, IFX, INCX, NY, NPRES, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK  
  
SUBROUTINE CNVCOR_64( CNVCOR, FOUR, [NX], X, IFX, [INCX], NY, NPRES,  
*      M, Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK,  
*      [LWORK])  
CHARACTER(LEN=1) :: CNVCOR, FOUR  
COMPLEX(8), DIMENSION(:) :: X, Y, Z, WORK  
INTEGER(8) :: NX, IFX, INCX, NY, NPRES, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zcnvcor(char cnvcor, char four, int nx, doublecomplex *x, int ifx, int incx, int ny, int npre, int m, doublecomplex *y, int ify, int inc1y,  
int inc2y, int nz, int k, doublecomplex *z, int ifz, int inc1z, int inc2z, doublecomplex *work, int lwork);
```

```
void zcnvcor_64(char cnvcor, char four, long nx, doublecomplex *x, long ifx, long incx, long ny, long npre, long m, doublecomplex *y,  
long ify, long inc1y, long inc2y, long nz, long k, doublecomplex *z, long ifz, long inc1z, long inc2z, doublecomplex *work, long lwork);
```

PURPOSE

zcnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

* **FOUR** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the real and imaginary parts of the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

* **NX** (*input*)

Length of the filter vector. $NX \geq 0$. ZCNVCOR will return immediately if $NX = 0$.

* **X** (*input*)

`dimension(*)`

Filter vector.

* **IFX** (*input*)

Index of the first element of X. $NX \geq IFX \geq 1$.

* **INCX** (*input*)

Stride between elements of the filter vector in X. $INCX > 0$.

* **NY** (*input*)

Length of the input vectors. $NY \geq 0$. ZCNVCOR will return immediately if $NY = 0$.

* **NPRE** (*input*)

The number of implicit zeros prepended to the Y vectors. $NPRE \geq 0$.

* **M** (*input*)

Number of input vectors. $M \geq 0$. ZCNVCOR will return immediately if $M = 0$.

* **Y** (*input*)

`dimension(*)`

Input vectors.

* **IFY** (*input*)

Index of the first element of Y. $NY \geq IFY \geq 1$.

* **INCIY** (*input*)

Stride between elements of the input vectors in Y. $INCIY > 0$.

* **INC2Y** (*input*)

Stride between the input vectors in Y. $INC2Y > 0$.

* **NZ** (*input*)

Length of the output vectors. $NZ \geq 0$. ZCNVCOR will return immediately if $NZ = 0$. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

* **K** (*input*)

Number of Z vectors. $K \geq 0$. If $K = 0$ then ZCNVCOR will return immediately. If $K < M$ then only the first K input vectors will be processed. If $K > M$ then M input vectors will be processed.

* **Z (output)**

dimension(*)

Result vectors.

* **IFZ (input)**

Index of the first element of Z. $NZ \geq IFZ \geq 1$.

* **INC1Z (input)**

Stride between elements of the output vectors in Z. $INC1Z > 0$.

* **INC2Z (input)**

Stride between the output vectors in Z. $INC2Z > 0$.

* **WORK (input/output)**

(input/scratch) dimension(LWORK)

Scratch space. Before the first call to ZCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to ZCNVCOR or if ZCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make ZCNVCOR run faster.

* **LWORK (input)**

Length of WORK. $LWORK \geq 2 * \text{MAX}(NX, NY, NZ) + 8$.

NAME

zcnvcor2 - compute the convolution or correlation of complex matrices

SYNOPSIS

```
SUBROUTINE ZCNVCOR2( CNVCOR, METHOD, TRANSX, SCRATCHX, TRANSY,  
*   SCRATCHY, MX, NX, X, LDX, MY, NY, MPRE, NPRES, Y, LDY, MZ, NZ, Z,

C INTERFACE

```
#include <sunperf.h>
```

```
void zcnvcor2(char cnvcor, char method, char transx, char scratchx, char transy, char scratchy, int mx, int nx, doublecomplex *x, int ldx, int my, int ny, int mpre, int npre, doublecomplex *y, int ldy, int mz, int nz, doublecomplex *z, int ldz,
```

```
doublecomplex *workin, int lwork);
```

```
void zcnvcor2_64(char cnvcor, char method, char transx, char scratchx, char transy, char scratchy, long mx, long nx,  
doublecomplex *x, long ldx, long my, long ny, long mpre, long npre, doublecomplex *y, long ldy, long mz, long nz,  
doublecomplex *z, long ldz, doublecomplex *workin, long lwork);
```

PURPOSE

zcnvcor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

*** CNVCOR (input)**

'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

*** METHOD (input)**

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

*** TRANSX (input)**

'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

*** SCRATCHX (input)**

'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

*** TRANSY (input)**

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

*** SCRATCHY (input)**

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

*** MX (input)**

Number of rows in the filter matrix. $MX \geq 0$.

*** NX (input)**

Number of columns in the filter matrix. $NX \geq 0$.

*** X (input)**

```
dimension(LDX, NX)
```

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

*** LDX (input)**

Leading dimension of the array that contains the filter matrix.

*** MY (input)**

Number of rows in the input matrix. $MY \geq 0$.

*** NY (input)**

Number of columns in the input matrix. $NY \geq 0$.

* **MPRE** (*input*)

Number of implicit zeros to prepend to each row of the input matrix. $MPRE \geq 0$.

* **NPRE** (*input*)

Number of implicit zeros to prepend to each column of the input matrix. $NPRE \geq 0$.

* **Y** (*input*)

`dimension(LDY, *)`

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

* **LDY** (*input*)

Leading dimension of the array that contains the input matrix.

* **MZ** (*input*)

Number of rows in the output matrix. $MZ \geq 0$. ZCNVCOR2 will return immediately if $MZ = 0$.

* **NZ** (*input*)

Number of columns in the output matrix. $NZ \geq 0$. ZCNVCOR2 will return immediately if $NZ = 0$.

* **Z** (*output*)

`dimension(LDZ, *)`

Result matrix.

* **LDZ** (*input*)

Leading dimension of the array that contains the result matrix. $LDZ \geq \text{MAX}(1, MZ)$.

* **WORKIN** (*input/output*)

(input/scratch) `dimension(LWORK)`

On entry for the first call to ZCNVCOR2, WORKIN(1) must contain `CMPLX(0.0,0.0)`. After the first call, WORKIN(1) must be set to `CMPLX(0.0,0.0)` iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

* **LWORK** (*input*)

Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

NAME

zcopy - Copy x to y

SYNOPSIS

```
SUBROUTINE ZCOPY( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZCOPY_64( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE COPY( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE COPY_64( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zcopy(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
void zcopy_64(long n, doublecomplex *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zdotc - compute the dot product of two vectors x and conjg(y).

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTC( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
DOUBLE COMPLEX FUNCTION ZDOTC_64( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX(8) FUNCTION DOTC( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
COMPLEX(8) FUNCTION DOTC_64( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
doublecomplex zdotc(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
doublecomplex zdotc_64(long n, doublecomplex *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zdotc compute the dot product of x and $\text{conjg}(y)$ where x and y are n -vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

* *X (input)*

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x . Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

* *Y (input)*

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y . Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y . INCY must not be zero. Unchanged on exit.

NAME

zdotu - compute the dot product of two vectors x and y.

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTU( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
DOUBLE COMPLEX FUNCTION ZDOTU_64( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX(8) FUNCTION DOT( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
COMPLEX(8) FUNCTION DOT_64( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
doublecomplex zdotu(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
doublecomplex zdotu_64(long n, doublecomplex *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zdotu compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

*** *X (input)***

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input)***

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. Unchanged on exit.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zdrot - Apply a plane rotation.

SYNOPSIS

```
SUBROUTINE ZDROT( N, CX, INCX, CY, INCY, C, S)
DOUBLE COMPLEX C, S
DOUBLE COMPLEX CX(*), CY(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZDROT_64( N, CX, INCX, CY, INCY, C, S)
DOUBLE COMPLEX C, S
DOUBLE COMPLEX CX(*), CY(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], CX, [INCX], CY, [INCY], C, S)
COMPLEX(8) :: C, S
COMPLEX(8), DIMENSION(:) :: CX, CY
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE ROT_64( [N], CX, [INCX], CY, [INCY], C, S)
COMPLEX(8) :: C, S
COMPLEX(8), DIMENSION(:) :: CX, CY
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zdrot(int n, doublecomplex *cx, int incx, doublecomplex *cy, int incy, doublecomplex c, doublecomplex s);
```

```
void zdrot_64(long n, doublecomplex *cx, long incx, doublecomplex *cy, long incy, doublecomplex c, doublecomplex s);
```

PURPOSE

zdrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *CX (input)*

Before entry, the incremented array CX must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of CX. INCX must not be zero. Unchanged on exit.

* *CY (output)*

On entry, the incremented array CY must contain the vector y. On exit, CY is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of CY. INCY must not be zero. Unchanged on exit.

* *C (input)*

On entry, the cosine.

* *S (input)*

On entry, the sin.

NAME

zdscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE ZDSCAL( N, ALPHA, Y, INCY)
DOUBLE COMPLEX Y(*)
INTEGER N, INCY
DOUBLE PRECISION ALPHA
```

```
SUBROUTINE ZDSCAL_64( N, ALPHA, Y, INCY)
DOUBLE COMPLEX Y(*)
INTEGER*8 N, INCY
DOUBLE PRECISION ALPHA
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
COMPLEX(8), DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL(8) :: ALPHA
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
COMPLEX(8), DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL(8) :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zdscal(int n, double alpha, doublecomplex *y, int incy);
```

```
void zdscal_64(long n, double alpha, doublecomplex *y, long incy);
```

PURPOSE

zdscl Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(INCY)$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

zfft2b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M \cdot N$.

SYNOPSIS

```
SUBROUTINE ZFFT2B( M, N, A, LDA, WORK, LWORK)
DOUBLE COMPLEX A(LDA,*)
INTEGER M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT2B_64( M, N, A, LDA, WORK, LWORK)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B( [M], [N], A, [LDA], WORK, LWORK)
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2B_64( [M], [N], A, [LDA], WORK, LWORK)
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfft2b(int m, int n, doublecomplex *a, int lda, double *work, int lwork);
```

```
void zfft2b_64(long m, long n, doublecomplex *a, long lda, double *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***A (input/output)***

On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***WORK (input)***

On entry, an array with dimension of at least LWORK. WORK must have been initialized by ZFFT2I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

NAME

zfft2f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE ZFFT2F( M, N, A, LDA, WORK, LWORK)
DOUBLE COMPLEX A(LDA,*)
INTEGER M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT2F_64( M, N, A, LDA, WORK, LWORK)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F( [M], [N], A, [LDA], WORK, LWORK)
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2F_64( [M], [N], A, [LDA], WORK, LWORK)
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfft2f(int m, int n, doublecomplex *a, int lda, double *work, int lwork);
```

```
void zfft2f_64(long m, long n, doublecomplex *a, long lda, double *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***A (input/output)***

On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by ZFFT2I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

NAME

zfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE ZFFT2I( M, N, WORK)
INTEGER M, N
DOUBLE PRECISION WORK(*)

SUBROUTINE ZFFT2I_64( M, N, WORK)
INTEGER*8 M, N
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFT2I( M, N, WORK)
INTEGER :: M, N
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE ZFFT2I_64( M, N, WORK)
INTEGER(8) :: M, N
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void zfft2i(int m, int n, double *work);

void zfft2i_64(long m, long n, double *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(4 * (M + N) + 30)$ or greater. ZFFT2I needs to be called only once to initialize array WORK before calling ZFFT2F and/or ZFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

zfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE ZFFT3B( M, N, K, A, LDA, LD2A, WORK, LWORK)
DOUBLE COMPLEX A(LDA,LD2A,*)
INTEGER M, N, K, LDA, LD2A, LWORK
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT3B_64( M, N, K, A, LDA, LD2A, WORK, LWORK)
DOUBLE COMPLEX A(LDA,LD2A,*)
INTEGER*8 M, N, K, LDA, LD2A, LWORK
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3B( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX(8), DIMENSION(:,:,:) :: A
INTEGER :: M, N, K, LDA, LD2A, LWORK
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3B_64( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX(8), DIMENSION(:,:,:) :: A
INTEGER(8) :: M, N, K, LDA, LD2A, LWORK
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfft3b(int m, int n, int k, doublecomplex *a, int lda, int ld2a, double *work, int lwork);
```

```
void zfft3b_64(long m, long n, long k, doublecomplex *a, long lda, long ld2a, double *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***K (input)***

Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.

* ***A (input/output)***

On entry, a three-dimensional array A(LDA,LD2A,K) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***LD2A (input)***

Second dimension of the array containing the data to be transformed. $LD2A \geq N$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by ZFFT3I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N + K) + 45)$.

NAME

zfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE ZFFT3F( M, N, K, A, LDA, LD2A, WORK, LWORK)
DOUBLE COMPLEX A(LDA,LD2A,*)
INTEGER M, N, K, LDA, LD2A, LWORK
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT3F_64( M, N, K, A, LDA, LD2A, WORK, LWORK)
DOUBLE COMPLEX A(LDA,LD2A,*)
INTEGER*8 M, N, K, LDA, LD2A, LWORK
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX(8), DIMENSION(:,:,:) :: A
INTEGER :: M, N, K, LDA, LD2A, LWORK
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3F_64( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX(8), DIMENSION(:,:,:) :: A
INTEGER(8) :: M, N, K, LDA, LD2A, LWORK
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfft3f(int m, int n, int k, doublecomplex *a, int lda, int ld2a, double *work, int lwork);
```

```
void zfft3f_64(long m, long n, long k, doublecomplex *a, long lda, long ld2a, double *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***K (input)***

Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.

* ***A (input/output)***

On entry, a three-dimensional array A(M,N,K) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***LD2A (input)***

Second dimension of the array containing the data to be transformed. $LD2A \geq N$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by ZFFT3I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N + K) + 45)$.

NAME

zfft3i - initialize the array WSAVE, which is used in both ZFFT3F and ZFFT3B.

SYNOPSIS

```
SUBROUTINE ZFFT3I( M, N, K, WORK)
  INTEGER M, N, K
  DOUBLE PRECISION WORK(*)

SUBROUTINE ZFFT3I_64( M, N, K, WORK)
  INTEGER*8 M, N, K
  DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFT3I( M, N, K, WORK)
  INTEGER :: M, N, K
  REAL(8), DIMENSION(:) :: WORK

SUBROUTINE ZFFT3I_64( M, N, K, WORK)
  INTEGER(8) :: M, N, K
  REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void zfft3i(int m, int n, int k, double *work);

void zfft3i_64(long m, long n, long k, double *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***K*** (*input*)

Number of planes to be transformed. $K \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(4 * (M + N + K) + 45)$ or greater. ZFFT3I needs to be called only once to initialize array *WORK* before calling ZFFT3F and/or ZFFT3B if *M*, *N*, *K* and *WORK* remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

zfft - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE ZFFTB( N, X, WSAVE)
DOUBLE COMPLEX X(*)
INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE ZFFTB_64( N, X, WSAVE)
DOUBLE COMPLEX X(*)
INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [N], X, WSAVE)
COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE FFTB_64( [N], X, WSAVE)
COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zfft(int n, doublecomplex *x, double *wsave);

void zfft_64(long n, doublecomplex *x, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input)*

On entry, an array of length N containing the sequence to be transformed.

* *WSAVE (input/output)*

On entry, WSAVE must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by ZFFT1.

NAME

zfft - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE ZFFTF( N, X, WSAVE)
DOUBLE COMPLEX X(*)
INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE ZFFTF_64( N, X, WSAVE)
DOUBLE COMPLEX X(*)
INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE F95_ZFFTF( [N], X, WSAVE)
COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE F95_ZFFTF_64( [N], X, WSAVE)
COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zfft(int n, doublecomplex *x, double *wsave);

void zfft_64(long n, doublecomplex *x, double *wsave);
```

ARGUMENTS

*** N (*input*)**

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
 $N \geq 0$.

*** X (*input*)**

On entry, an array of length N containing the sequence to be transformed.

*** $WSAVE$ (*input*)**

On entry, $WSAVE$ must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by ZFFT1.

NAME

zfft - initialize the array WSAVE, which is used in both ZFFTF and ZFFTB.

SYNOPSIS

```
SUBROUTINE ZFFTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE ZFFTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE ZFFTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zfft(int n, double *wsave);

void zfft_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input/output)*

On entry, an array of dimension $(4 * N + 15)$ or greater. ZFFTI needs to be called only once to initialize array WORK before calling ZFFTF and/or ZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

zfftopt - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION ZFFTOPT( LEN)
INTEGER LEN

INTEGER*8 FUNCTION ZFFTOPT_64( LEN)
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION ZFFTOPT( LEN)
INTEGER :: LEN

INTEGER(8) FUNCTION ZFFTOPT_64( LEN)
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int zfftopt(int len);

long zfftopt_64(long len);
```

PURPOSE

zfftopt computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*2*2*2$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

ZFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. ZFFTOPT will return 16 for an input of $N=16$ and return $18=2*3*3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value

returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then $N=51$ will return 51.

ARGUMENTS

NAME

zgbbrd - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

SYNOPSIS

```
SUBROUTINE ZGBBRD( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ,
* PT, LDPT, C, LDC, WORK, RWORK, INFO)
CHARACTER * 1 VECT
DOUBLE COMPLEX AB(LDAB,*), Q(LDQ,*), PT(LDPT,*), C(LDC,*), WORK(*)
INTEGER M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
DOUBLE PRECISION D(*), E(*), RWORK(*)

SUBROUTINE ZGBBRD_64( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q,
* LDQ, PT, LDPT, C, LDC, WORK, RWORK, INFO)
CHARACTER * 1 VECT
DOUBLE COMPLEX AB(LDAB,*), Q(LDQ,*), PT(LDPT,*), C(LDC,*), WORK(*)
INTEGER*8 M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
DOUBLE PRECISION D(*), E(*), RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBBRD( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D, E,
* Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [RWORK], [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: AB, Q, PT, C
INTEGER :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL(8), DIMENSION(:) :: D, E, RWORK

SUBROUTINE GBBRD_64( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D,
* E, Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [RWORK], [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: AB, Q, PT, C
INTEGER(8) :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL(8), DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbbrd(char vect, int m, int n, int ncc, int kl, int ku, doublecomplex *ab, int ldab, double *d, double *e, doublecomplex *q, int ldq, doublecomplex *pt, int ldpt, doublecomplex *c, int ldc, int *info);
```

```
void zgbbbrd_64(char vect, long m, long n, long ncc, long kl, long ku, doublecomplex *ab, long ldab, double *d, double *e, doublecomplex *q, long ldq, doublecomplex *pt, long ldpt, doublecomplex *c, long ldc, long *info);
```

PURPOSE

zgbbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

* **VECT** (*input*)

Specifies whether or not the matrices Q and P' are to be formed.

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **KL** (*input*)

The number of subdiagonals of the matrix A. $KL \geq 0$.

* **KU** (*input*)

The number of superdiagonals of the matrix A. $KU \geq 0$.

* **AB** (*input/output*)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

* **D** (*output*)

The diagonal elements of the bidiagonal matrix B.

* **E** (*output*)

The superdiagonal elements of the bidiagonal matrix B.

* **Q** (*output*)

If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq \max(1,M)$ if VECT = 'Q' or 'B'; $LDQ \geq 1$ otherwise.

* **PT** (*output*)

If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

* **LDPT** (*input*)

The leading dimension of the array PT. LDPT $\geq \max(1, N)$ if VECT = 'P' or 'B'; LDPT ≥ 1 otherwise.

* **C (input/output)**

On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^*C . C is not referenced if NCC = 0.

* **LDC (input)**

The leading dimension of the array C. LDC $\geq \max(1, M)$ if NCC > 0; LDC ≥ 1 if NCC = 0.

* **WORK (workspace)**

dimension(MAX(M,N))

* **RWORK (workspace)**

dimension(MAX(M,N))

* **INFO (output)**

NAME

zgbco - (obsolete) compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then xGBFA is slightly faster. It is typical to follow a call to xGBCO with a call to xGBSL to solve $Ax = b$ or to xGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE ZGBCO( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZGBCO_64( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbco(doublecomplex *a, int lda, int n, int nsub, int nsuper, int *ipivot, double *rcond);
```

```
void zgbco_64(doublecomplex *a, long lda, long n, long nsub, long nsuper, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of the matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

* **NSUPER** (*input*)

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

* ***IPIVOT*** (*output*)

On exit, a vector of pivot indices.

* ***RCOND*** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* ***WORK*** (*workspace*)

Scratch array with a dimension of N.

NAME

zgbcon - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

SYNOPSIS

```
SUBROUTINE ZGBCON( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER N, NSUB, NSUPER, LDA, INFO  
INTEGER IPIVOT(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION WORK2(*)
```

```
SUBROUTINE ZGBCON_64( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, NSUB, NSUPER, LDA, INFO  
INTEGER*8 IPIVOT(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,  
*      RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, NSUB, NSUPER, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE GBCON_64( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT,  
*      ANORM, RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbcon(char norm, int n, int nsub, int nsuper, doublecomplex *a, int lda, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zgbcon_64(char norm, long n, long nsub, long nsuper, doublecomplex *a, long lda, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **ANORM** (*input*)

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zgbdi - (obsolete) compute the determinant of a general matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA.

SYNOPSIS

```
SUBROUTINE ZGBDI( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
DOUBLE COMPLEX A(LDA,*), DET(*)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGBDI_64( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
DOUBLE COMPLEX A(LDA,*), DET(*)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbdi(doublecomplex *a, int lda, int n, int nsub, int nsuper, int *ipivot, doublecomplex *det);
```

```
void zgbdi_64(doublecomplex *a, long lda, long n, long nsub, long nsuper, long *ipivot, doublecomplex *det);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A, as computed by CGBCO or CGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGBCO or CGBFA.

*** *DET (output)***

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

NAME

zgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE ZGBEQU( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC, ROWCN,
*      COLCN, AMAX, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER M, N, NSUB, NSUPER, LDA, INFO
DOUBLE PRECISION ROWCN, COLCN, AMAX
DOUBLE PRECISION ROWSC(*), COLSC(*)

SUBROUTINE ZGBEQU_64( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC,
*      ROWCN, COLCN, AMAX, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, NSUB, NSUPER, LDA, INFO
DOUBLE PRECISION ROWCN, COLCN, AMAX
DOUBLE PRECISION ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*      ROWCN, COLCN, AMAX, [INFO])
COMPLEX(8), DIMENSION(:,*) :: A
INTEGER :: M, N, NSUB, NSUPER, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: ROWSC, COLSC

SUBROUTINE GBEQU_64( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*      ROWCN, COLCN, AMAX, [INFO])
COMPLEX(8), DIMENSION(:,*) :: A
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: ROWSC, COLSC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbequ(int m, int n, int nsub, int nsuper, doublecomplex *a, int lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, int *info);
```

```
void zgbequ_64(long m, long n, long nsub, long nsuper, doublecomplex *a, long lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, long *info);
```

PURPOSE

zgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** A (input)**

The band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

*** ROWSC (output)**

If $INFO = 0$, or $INFO > M$, ROWSC contains the row scale factors for A.

*** COLSC (output)**

If $INFO = 0$, COLSC contains the column scale factors for A.

*** ROWCN (output)**

If $INFO = 0$ or $INFO > M$, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If $ROWCN \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

*** COLCN (output)**

If $INFO = 0$, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If $COLCN \geq 0.1$, it is not worth scaling by COLSC.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

zgbfa - (obsolete) compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to CGBFA with a call to CGBSL to solve $Ax = b$ or to CGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE ZGBFA( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, NSUB, NSUPER, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGBFA_64( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, NSUB, NSUPER, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbfa(doublecomplex *a, int lda, int n, int nsub, int nsuper, int *ipivot, int *info);
```

```
void zgbfa_64(doublecomplex *a, long lda, long n, long nsub, long nsuper, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that CGBSL will divide by zero if called.

NAME

zgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

SYNOPSIS

```
SUBROUTINE ZGBMV( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,  
*             INCX, BETA, Y, INCY)  
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE ZGBMV_64( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,  
*             INCX, BETA, Y, INCY)  
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GBMV( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],  
*             X, [INCX], BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE GBMV_64( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],  
*             X, [INCX], BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbmv(char transa, int m, int n, int nsub, int nsuper, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex beta, doublecomplex *y, int incy);
```

```
void zgbmv_64(char transa, long m, long n, long nsub, long nsuper, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *x, long incx, doublecomplex beta, doublecomplex *y, long incy);
```

PURPOSE

zgbmv performs one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$ where α and β are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha * A * x + \beta * y$.

TRANSA = 'T' or 't' $y := \alpha * A' * x + \beta * y$.

TRANSA = 'C' or 'c' $y := \alpha * \text{conjg}(A') * x + \beta * y$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

* *NSUB* (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB must satisfy $0 \leq \text{NSUB}$. Unchanged on exit.

* *NSUPER* (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER must satisfy $0 \leq \text{NSUPER}$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku , the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to

band storage:

```
DO 20, J = 1, N
  K = NSUPER + 1 - J
  DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J + NSUB )
    A( K + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

* **LDA** (*input*)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1). Unchanged on exit.

* **X** (*input*)

(1 + (n - 1) * abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1) * abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* **INCX** (*input*)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* **Y** (*input/output*)

(1 + (m - 1) * abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1) * abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* **INCY** (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zgbfrs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbrfs(char transa, int n, int nsub, int nsuper, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zgbrfs_64(char transa, long n, long nsub, long nsuper, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(n,j+kl)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **AF** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq 2*NSUB*NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices from CGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zgbsl - (obsolete) solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZGBSL( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, NSUB, NSUPER, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGBSL_64( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, NSUB, NSUPER, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbsl(doublecomplex *a, int lda, int n, int nsub, int nsuper, int *ipivot, doublecomplex *b, int job);
```

```
void zgbsl_64(doublecomplex *a, long lda, long n, long nsub, long nsuper, long *ipivot, doublecomplex *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by CGBCO or CGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A . $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A . $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGBCO or CGBFA.

* ***B*** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* ***JOB*** (*input*)

Determines which operation this subroutine will perform:

0 solve the system $Ax = b$

not 0 solve the linear system $AHx = b$ Note that $ATx = AHx$ for real matrices.

NAME

zgbsv - compute the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

SYNOPSIS

```
SUBROUTINE ZGBSV( N, NSUB, NSUPER, NRHS, A, LDA, IPIVOT, B, LDB,
*              INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)

SUBROUTINE ZGBSV_64( N, NSUB, NSUPER, NRHS, A, LDA, IPIVOT, B, LDB,
*              INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GBSV( [N], NSUB, NSUPER, [NRHS], A, [LDA], IPIVOT, B,
*              [LDB], [INFO])
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE GBSV_64( [N], NSUB, NSUPER, [NRHS], A, [LDA], IPIVOT, B,
*              [LDB], [INFO])
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbsv(int n, int nsub, int nsuper, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zgbsv_64(long n, long nsub, long nsuper, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgbsv computes the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with $KL+KU$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** $NSUB$ (input)**

The number of subdiagonals within the band of A . $NSUB \geq 0$.

*** $NSUPER$ (input)**

The number of superdiagonals within the band of A . $NSUPER \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j -th column of A is stored in the j -th column of the array A as follows:
 $A(NSUB+NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A . $LDA \geq 2*NSUB+NSUPER+1$.

*** $IPIVOT$ (output)**

The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

*** B (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

*** $INFO$ (output)**

NAME

zgbsvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
SUBROUTINE ZGBSVX( FACT, TRANSA, N, NSUB, NSUPER, NRHS, A, LDA, AF,

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbsvx(char fact, char transa, int n, int nsub, int nsuper, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf,
int *ipivot, char equed, double *rowsc, double *colsc, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond,
double *ferr, double *berr, int *info);
```

```
void zgbsvx_64(char fact, char transa, long n, long nsub, long nsuper, long nrhs, doublecomplex *a, long lda, doublecomplex
*af, long ldaf, long *ipivot, char equed, double *rowsc, double *colsc, doublecomplex *b, long ldb, doublecomplex *x, long
ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zgbsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N': diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $\text{TRANS} = 'N'$) or $\text{diag}(R)$ (if $\text{TRANS} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $\text{NRHS} \geq 0$.

* **A** (*input/output*)

On entry, the matrix A in band storage, in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(\text{NSUPER} + 1 + i - j, j) = A(i, j)$ for $\max(1, j - \text{NSUPER}) \leq i \leq \min(N, j + \text{NSUB})$

If $\text{FACT} = 'F'$ and EQUED is not $'N'$, then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC . A is not modified if $\text{FACT} = 'F'$ or $'N'$, or if $\text{FACT} = 'E'$ and $\text{EQUED} = 'N'$ on exit.

On exit, if $\text{EQUED} \neq 'N'$, A is scaled as follows: $\text{EQUED} = 'ROWSC': A := \text{diag}(\text{ROWSC}) * A$

$\text{EQUED} = 'COLSC': A := A * \text{diag}(\text{COLSC})$

$\text{EQUED} = 'B': A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \text{NSUB} + \text{NSUPER} + 1$.

* **AF** (*input/output*)

If $\text{FACT} = 'F'$, then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$. If $\text{EQUED} \neq 'N'$, then AF is the factored form of the equilibrated matrix A.

If $\text{FACT} = 'N'$, then AF is an output argument and on exit returns details of the LU factorization of A.

If $\text{FACT} = 'E'$, then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF** (*input*)

The leading dimension of the array AF. $\text{LDAF} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

If $\text{FACT} = 'F'$, then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A =$

$L*U$ as computed by CGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A .

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A .

* **EQUED (input)**

Specifies the form of equilibration that was done.

* **ROWSC (input/output)**

The row scale factors for A . If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

* **COLSC (input/output)**

The column scale factors for A . If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

* **B (input/output)**

On entry, the right hand side matrix B . On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC})*B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC})*B$.

* **LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **X (output)**

If INFO = 0 or INFO = $N+1$, the N -by- N RHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC}))*X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC}))*X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

* **LDX (input)**

The leading dimension of the array X . $LDX \geq \max(1,N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK (workspace)**

$\text{dimension}(2*N)$

* **WORK2 (workspace)**

On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A .

** INFO (output)*

NAME

zgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE ZGBTF2( M, N, KL, KU, AB, LDAB, IPIV, INFO)
DOUBLE COMPLEX AB(LDAB,*)
INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)

INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE GBTF2_64( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
COMPLEX(8), DIMENSION(:, :) :: AB
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgbtf2(int m, int n, int kl, int ku, doublecomplex *ab, int ldab, int *ipiv, int *info);
```

```
void zgbtf2_64(long m, long n, long kl, long ku, doublecomplex *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

zgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** KL (input)**

The number of subdiagonals within the band of A. $KL \geq 0$.

*** KU (input)**

The number of superdiagonals within the band of A. $KU \geq 0$.

*** AB (input/output)**

On entry, the matrix A in band storage, in rows $KL+1$ to $2*KL+KU+1$; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $KL+KU$ superdiagonals in rows 1 to $KL+KU+1$, and the multipliers used during the factorization are stored in rows $KL+KU+2$ to $2*KL+KU+1$. See below for further details.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIV(i)$.

*** INFO (output)**

```

PURPOSE

zgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***NSUB*** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* ***NSUPER*** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* ***A*** (*input/output*)

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

* ***IPIVOT*** (*output*)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIVOT(i)$.

* ***INFO*** (*output*)

NAME

zgbtrs - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

SYNOPSIS

```
void zgbtrs_64(char transa, long n, long nsub, long nsuper, long nrhs, doublecomplex *a, long lda, long *ipivot,
doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgbtrs solves a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

zgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

SYNOPSIS

```
SUBROUTINE ZGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
CHARACTER * 1 JOB, SIDE
DOUBLE COMPLEX V(LDV,*)
INTEGER N, ILO, IHI, M, LDV, INFO
DOUBLE PRECISION SCALE(*)
```

```
SUBROUTINE ZGEBAK_64( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV,
* INFO)
CHARACTER * 1 JOB, SIDE
DOUBLE COMPLEX V(LDV,*)
INTEGER*8 N, ILO, IHI, M, LDV, INFO
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX(8), DIMENSION(:, :) :: V
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE

SUBROUTINE GEBAK_64( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX(8), DIMENSION(:, :) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgebak(char job, char side, int n, int ilo, int ihi, double *scale, int m, doublecomplex *v, int ldv, int *info);
```

```
void zgebak_64(char job, char side, long n, long ilo, long ihi, double *scale, long m, doublecomplex *v, long ldv, long *info);
```

PURPOSE

zgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

ARGUMENTS

* ***JOB (input)***

Specifies the type of backward transformation required:

* ***SIDE (input)***

* ***N (input)***

The number of rows of the matrix V. $N \geq 0$.

* ***ILO (input)***

The integer ILO determined by CGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI (input)***

The integer IHI determined by CGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***SCALE (input)***

Details of the permutation and scaling factors, as returned by CGEBAL.

* ***M (input)***

The number of columns of the matrix V. $M \geq 0$.

* ***V (input/output)***

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

* ***LDV (input)***

The leading dimension of the array V. $LDV \geq \max(1,N)$.

* ***INFO (output)***

NAME

zgebal - balance a general complex matrix A

SYNOPSIS

```
SUBROUTINE ZGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, ILO, IHI, INFO
DOUBLE PRECISION SCALE(*)
```

```

INTEGER :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE GEBAL_64( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgebal(char job, int n, doublecomplex *a, int lda, int *ilo, int *ihi, double *scale, int *info);
```

```
void zgebal_64(char job, long n, doublecomplex *a, long lda, long *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

zgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

*** JOB (input)**

Specifies the operations to be performed on A:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ILO (output)**

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $l = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** IHI (output)**

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $l = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** SCALE (output)**

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1$

*** INFO (output)**

NAME

zgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

SYNOPSIS

```
SUBROUTINE ZGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
*                INFO)
DOUBLE COMPLEX A(LDA,*), TAUQ(*), TAUP(*), WORK(*)
INTEGER M, N, LDA, LWORK, INFO
DOUBLE PRECISION D(*), E(*)

SUBROUTINE ZGEBRD_64( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
*                   INFO)
DOUBLE COMPLEX A(LDA,*), TAUQ(*), TAUP(*), WORK(*)
INTEGER*8 M, N, LDA, LWORK, INFO
DOUBLE PRECISION D(*), E(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
*               [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAUQ, TAUP, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E

SUBROUTINE GEBRD_64( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
*                  [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAUQ, TAUP, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgebrd(int m, int n, doublecomplex *a, int lda, double *d, double *e, doublecomplex *tauq, doublecomplex *taup, int *info);
```

```
void zgebrd_64(long m, long n, doublecomplex *a, long lda, double *d, double *e, doublecomplex *tauq, doublecomplex *taup, long *info);
```

PURPOSE

zgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: Q^*H
 $A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

*** M (input)**

The number of rows in the matrix A. $M \geq 0$.

*** N (input)**

The number of columns in the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** D (output)**

The diagonal elements of the bidiagonal matrix B: $D(i) = A(i, i)$.

*** E (output)**

The off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

*** TAUQ (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

*** TAUP (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, M, N)$. For optimum performance $LWORK \geq (M+N)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

zgeco - (obsolete) compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then CGEFA is slightly faster. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZGECO( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZGECO_64( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeco(doublecomplex *a, int lda, int n, int *ipivot, double *rcond);
```

```
void zgeco_64(doublecomplex *a, long lda, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets

smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

zgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE ZGECON( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)
```

```
SUBROUTINE ZGECON_64( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GECON( NORM, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE GECON_64( NORM, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgecon(char norm, int n, doublecomplex *a, int lda, double anorm, double *rcond, int *info);
```

```
void zgecon_64(char norm, long n, doublecomplex *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

zgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ANORM (input)**

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

zgedi - (obsolete) compute the determinant and inverse of a general matrix A, which has been LU-factored by CGECO or CGEFA.

SYNOPSIS

```
SUBROUTINE ZGEDI( A, LDA, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGEDI_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgedi(doublecomplex *a, int lda, int n, int *ipivot, doublecomplex *det, int job);
```

```
void zgedi_64(doublecomplex *a, long lda, long n, long *ipivot, doublecomplex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the LU factorization of the matrix A, as computed by CGECO or CGEFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise it is unchanged.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGECO or CGEFA.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \geq |DET(1)| \geq 10.0$ or $DET(1) = 0.0$.

*** WORK (workspace)**

Scratch array with a dimension of N.

* ***JOB*** (*input*)

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

zgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE ZGEEQU( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN, AMAX,
*                INFO)
  DOUBLE COMPLEX A(LDA,*)
  INTEGER M, N, LDA, INFO
  DOUBLE PRECISION ROWCN, COLCN, AMAX
  DOUBLE PRECISION ROWSC(*), COLSC(*)

SUBROUTINE ZGEEQU_64( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN,
*                   AMAX, INFO)
  DOUBLE COMPLEX A(LDA,*)
  INTEGER*8 M, N, LDA, INFO
  DOUBLE PRECISION ROWCN, COLCN, AMAX
  DOUBLE PRECISION ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*               AMAX, [INFO])
  COMPLEX(8), DIMENSION(:, :) :: A
  INTEGER :: M, N, LDA, INFO
  REAL(8) :: ROWCN, COLCN, AMAX
  REAL(8), DIMENSION(:) :: ROWSC, COLSC

SUBROUTINE GEEQU_64( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*                  AMAX, [INFO])
  COMPLEX(8), DIMENSION(:, :) :: A
  INTEGER(8) :: M, N, LDA, INFO
  REAL(8) :: ROWCN, COLCN, AMAX
  REAL(8), DIMENSION(:) :: ROWSC, COLSC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeequ(int m, int n, doublecomplex *a, int lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, int *info);
```

```
void zgeequ_64(long m, long n, doublecomplex *a, long lda, double *rowsc, double *colsc, double *rowcn, double *colcn,
```

double *amax, long *info);

PURPOSE

zgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input)**

The M-by-N matrix whose equilibration factors are to be computed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** ROWSC (output)**

If INFO = 0 or INFO > M, ROWSC contains the row scale factors for A.

*** COLSC (output)**

If INFO = 0, COLSC contains the column scale factors for A.

*** ROWCN (output)**

If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If ROWCN ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

*** COLCN (output)**

If INFO = 0, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCN ≥ 0.1 , it is not worth scaling by COLSC.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

zgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

SYNOPSIS

```
SUBROUTINE ZGEES( JOBZ, SORTEV, SELECT, N, A, LDA, NOUT, W, Z, LDZ,
*      WORK, LDWORK, WORK2, WORK3, INFO)

DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GEES( JOBZ, SORTEV, SELECT, [N], A, [LDA], NOUT, W, Z,
*      [LDZ], [WORK], [LDWORK], [WORK2], [WORK3], [INFO])
CHARACTER(LEN=1) :: JOBZ, SORTEV
COMPLEX(8), DIMENSION(:) :: W, WORK
COMPLEX(8), DIMENSION(:, :) :: A, Z
INTEGER :: N, LDA, NOUT, LDZ, LDWORK, INFO
LOGICAL :: SELECT
LOGICAL, DIMENSION(:) :: WORK3
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE GEES_64( JOBZ, SORTEV, SELECT, [N], A, [LDA], NOUT, W, Z,
*      [LDZ], [WORK], [LDWORK], [WORK2], [WORK3], [INFO])
CHARACTER(LEN=1) :: JOBZ, SORTEV
COMPLEX(8), DIMENSION(:) :: W, WORK
COMPLEX(8), DIMENSION(:, :) :: A, Z
INTEGER(8) :: N, LDA, NOUT, LDZ, LDWORK, INFO
LOGICAL(8) :: SELECT
LOGICAL(8), DIMENSION(:) :: WORK3
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgees(char jobz, char sortev, logical(*select)(COMPLEX*16), int n, doublecomplex *a, int lda, int *nout,  
doublecomplex *w, doublecomplex *z, int ldz, int *info);
```

```
void zgees_64(char jobz, char sortev, logical(*select)(COMPLEX*16), long n, doublecomplex *a, long lda, long *nout,  
doublecomplex *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOUT** (*output*)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

* **W** (*output*)

W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

* **Z** (*output*)

If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ \geq 1; if JOBZ = 'V', LDZ \geq N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **WORK3** (*workspace*)

Not referenced if SORTEV = 'N'.

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeesx(char jobz, char sortev, logical(*select)(COMPLEX*16), char sense, int n, doublecomplex *a, int lda, int *nout, doublecomplex *w, doublecomplex *z, int ldz, double *rcone, double *rconv, int *info);
```

```
void zgeesx_64(char jobz, char sortev, logical(*select)(COMPLEX*16), char sense, long n, doublecomplex *a, long lda, long *nout, doublecomplex *w, doublecomplex *z, long ldz, double *rcone, double *rconv, long *info);
```

PURPOSE

zgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. N >= 0.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOUT (output)**

If $SORTEV = 'N'$, $NOUT = 0$. If $SORTEV = 'S'$, $NOUT =$ number of eigenvalues for which $SELECT$ is true.

* **W (output)**

W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

* **Z (output)**

If $JOBZ = 'V'$, Z contains the unitary matrix Z of Schur vectors. If $JOBZ = 'N'$, Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **RCONE (output)**

If $SENSE = 'E'$ or $'B'$, RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if $SENSE = 'N'$ or $'V'$.

* **RCONV (output)**

If $SENSE = 'V'$ or $'B'$, RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if $SENSE = 'N'$ or $'E'$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* **LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, 2*N)$. Also, if $SENSE = 'E'$ or $'V'$ or $'B'$, $LDWORK \geq 2*NOUT*(N-NOUT)$, where NOUT is the number of selected eigenvalues computed by this routine. Note that $2*NOUT*(N-NOUT) \leq N*N/2$. For good performance, LDWORK must generally be larger.

* **WORK2 (workspace)**

C INTERFACE

```
#include <sunperf.h>
```

```
void zggev(char jobvl, char jobvr, int n, doublecomplex *a, int lda, doublecomplex *w, doublecomplex *vl, int ldvl, doublecomplex *vr, int ldvr, int *info);
```

```
void zggev_64(char jobvl, char jobvr, long n, doublecomplex *a, long lda, doublecomplex *w, doublecomplex *vl, long ldvl, doublecomplex *vr, long ldvr, long *info);
```

PURPOSE

zggev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

W contains the computed eigenvalues.

* **VL** (*output*)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:,j)$, the j-th column of VL.

* **LDVL** (*input*)

The leading dimension of the array VL. LDVL \geq 1; if JOBVL = 'V', LDVL \geq N.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:,j)$, the j-th column of VR.

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR \geq 1; if JOBVR = 'V', LDVR \geq N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

```

PURPOSE

zgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right

eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{*-1}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

* **BALANC** (*input*)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

W contains the computed eigenvalues.

* **VL** (*output*)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:, j)$, the j-th column of VL.

* **LDVL** (*input*)

The leading dimension of the array VL. $LDVL \geq 1$; if JOBVL = 'V', $LDVL \geq N$.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:, j)$, the j-th column of VR.

* **LDVR** (*input*)

The leading dimension of the array VR. $LDVR \geq 1$; if JOBVR = 'V', $LDVR \geq N$.

* **ILO** (*output*)

ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

* **IHI** (*output*)

ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

* **SCALE** (*output*)

Details of the permutations and scaling factors applied when balancing A. If $P(j)$ is the index of the row and column interchanged with row and column j, and $D(j)$ is the scaling factor applied to row and column j, then $SCALE(J) = P(J)$, for $J = 1, \dots, ILO-1$

* **ABNRM** (*output*)

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

* **RCONE** (*output*)

RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

* **RCONV** (*output*)

RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK $\geq \max(1, 2*N)$, and if SENSE = 'V' or 'B', LDWORK $\geq N*N+2*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zgefa - (obsolete) compute the LU factorization of a general matrix A. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE ZGEFA( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)

SUBROUTINE ZGEFA_64( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void zgefa(doublecomplex *a, int lda, int n, int *ipivot, int *info);

void zgefa_64(doublecomplex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that CGESL will divide by zero if called.

```

PURPOSE

zgegs routine is deprecated and has been replaced by routine CGGES.

CGEGS computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver CGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices

which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B.

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **ALPHA** (*output*)

On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. $ALPHA(j)$, $j=1,\dots,N$ and $BETA(j)$, $j=1,\dots,N$ are the diagonals of the complex Schur form (A,B) output by CGEGS. The $BETA(j)$ will be non-negative real.

Note: the quotients $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

* **BETA** (*output*)

See the description of ALPHA.

* **VSL** (*input*)

If $JOBVSL = 'V'$, VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if $JOBVSL = 'N'$.

* **LDVSL** (*input*)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

* **VSR** (*input*)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

* **LDVSR** (*input*)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, 2*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get block sizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the block sizes for CGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is $N*(NB+1)$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

PURPOSE

zgegv routine is deprecated and has been replaced by routine CGGEV.

CGEGV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - w B) r = 0$. A left generalized eigenvector is a vector l such that $l^*H * (A - w B) = 0$, where l^*H is the

conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **ALPHA** (*output*)

On exit, $ALPHA(j)/VL(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/VL(j)$ may easily over- or underflow, and $VL(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and VL always less than and usually comparable with $\text{norm}(B)$.

* **BETA** (*output*)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVL = 'N'$.

* **VL (output)**

If `JOBVL = 'V'`, the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVL = 'N'`.

* **LDVL (input)**

The leading dimension of the matrix VL. `LDVL >= 1`, and if `JOBVL = 'V'`, `LDVL >= N`.

* **VR (output)**

If `JOBVR = 'V'`, the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVR = 'N'`.

* **LDVR (input)**

The leading dimension of the matrix VR. `LDVR >= 1`, and if `JOBVR = 'V'`, `LDVR >= N`.

* **WORK (workspace)**

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

* **LDWORK (input)**

The dimension of the array WORK. `LDWORK >= max(1, 2*N)`. For good performance, `LDWORK` must generally be larger. To compute the optimal value of `LDWORK`, call `ILAENV` to get block sizes (for `CGEQRF`, `CUNMQR`, and `CUNGQR`.) Then compute: `NB` as the `MAX` of the block sizes for `CGEQRF`, `CUNMQR`, and `CUNGQR`; The optimal `LDWORK` is `MAX(2*N, N*(NB+1))`.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

* **WORK2 (workspace)**

* **INFO (output)**

NAME

zgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

SYNOPSIS

```
SUBROUTINE ZGHRD( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER N, ILO, IHI, LDA, LWORKIN, INFO
```

```
SUBROUTINE ZGHRD_64( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN,
* INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
```

F95 INTERFACE

```
SUBROUTINE GEHRD( [N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORKIN
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
```

```
SUBROUTINE GEHRD_64( [N], ILO, IHI, A, [LDA], TAU, [WORKIN],
* [LWORKIN], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORKIN
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgehrd(int n, int ilo, int ihi, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgehrd_64(long n, long ilo, long ihi, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** ILO (input)**

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

*** IHI (input)**

See the description of ILO.

*** A (input/output)**

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** TAU (output)**

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

*** WORKIN (workspace)**

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

*** LWORKIN (input)**

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

*** INFO (output)**

NAME

zgelqf - compute an LQ factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE ZGELQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

```

DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GELQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgelqf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgelqf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgelqf computes an LQ factorization of a complex M-by-N matrix A: $A = L * Q$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO

SUBROUTINE GELS_64( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*                 [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgels(char transa, int m, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zgels_64(char transa, long m, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A * X \|$.
2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.
3. If TRANS = 'C' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{**H} * X = B$.
4. If TRANS = 'C' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A^{**H} * X \|$.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

* **TRANSA** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. if $M \geq N$, A is overwritten by details of its QR factorization as returned by CGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by CGELQF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANS = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void zgelsd(int m, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, double *s, double rcond, int *rank, int *info);
```

```
void zgelsd_64(long m, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, double *s, double rcond, long *rank, long *info);
```

PURPOSE

zgelsd computes the minimum-norm solution to a real linear least squares problem: minimize $\|b - A*x\|_2$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **S (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m, n))$.

* **RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

* **RANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 1$. The exact minimum amount of workspace needed depends on M, N and NRHS. If $M \geq N$, $LWORK \geq 2 * N + N * NRHS$. If $M < N$, $LWORK \geq 2 * M + M * NRHS$. For good performance, LWORK should generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

If $M \geq N$, $LRWORK \geq 8 * N + 2 * N * SMLSIZ + 8 * N * NLVL + N * NRHS$. If $M < N$, $LRWORK \geq 8 * M + 2 * M * SMLSIZ + 8 * M * NLVL + M * NRHS$. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $NLVL = \text{INT}(\text{LOG}_2(\text{MIN}(M, N) / (SMLSIZ + 1))) + 1$

* **IWORK (workspace)**

$LIWORK \geq 3 * \text{MINMN} * NLVL + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M, N)$.

* **INFO (output)**

```

PURPOSE

zgels computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm($\|b - A*x\|$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,M,N)$.

*** SING (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $SING(1)/SING(\min(m,n))$.

*** RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $SING(i) \leq RCOND * SING(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

*** IRANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * SING(1)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK ≥ 1 , and also: LDWORK $\geq 2 \cdot \min(M,N) + \max(M,N, NRHS)$ For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

```

PURPOSE

zgelsx routine is deprecated and has been replaced by routine CGELSY.

CGELSX computes the minimum-norm solution to a complex linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$[\ 0 \ R22 \]$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $N+1:M$ in that column.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPIVOT (input)***

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***IRANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

$(\min(M, N) + \max(N, 2 * \min(M, N) + NRHS))$,

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

zgelsy - compute the minimum-norm solution to a complex linear least squares problem

SYNOPSIS

```
SUBROUTINE ZGELSY( M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK,
*   WORK, LWORK, RWORK, INFO)
  DOUBLE COMPLEX A(LDA,*), B(LDB,*), WORK(*)

```

```
void zgelsy(int m, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *jpvt, double rcond, int *rank, int *info);
```

```
void zgelsy_64(long m, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *jpvt, double rcond, long *rank, long *info);
```

PURPOSE

zgelsy computes the minimum-norm solution to a complex linear least squares problem: minimize $\|A * X - B\|$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$\begin{bmatrix} & 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The permutation of matrix B (the right hand side) is faster and more simple.
 - o The call to the subroutine xGEQPF has been substituted by the the call to the subroutine xGEQ3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
 - o Matrix B (the right hand side) is updated with Blas-3.
-

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPVT (input/output)***

On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***RANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq MN + \max(2 * MN, N + 1, MN + NRHS)$ where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq MN + \max(2 * MN, NB * (N + 1), MN + MN * NB, MN + NB * NRHS)$ where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***RWORK (workspace)***

dimension(2*N)

* ***INFO (output)***

NAME

zgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

SYNOPSIS

```
SUBROUTINE ZGEMM( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, K, LDA, LDB, LDC

SUBROUTINE ZGEMM_64( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, K, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE GEMM( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
*      B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER :: M, N, K, LDA, LDB, LDC

SUBROUTINE GEMM_64( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A,
*      [LDA], B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgemm(char transa, char transb, int m, int n, int k, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex beta, doublecomplex *c, int ldc);
```

```
void zgemm_64(char transa, char transb, long m, long n, long k, doublecomplex alpha, doublecomplex *a, long lda,
```

doublecomplex *b, long ldb, doublecomplex beta, doublecomplex *c, long ldc);

PURPOSE

zgemm performs one of the matrix-matrix operations

$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$ or $\text{op}(X) = \text{conjg}(X')$, α and β are scalars, and A , B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

* *TRANSA (input)*

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *TRANSB (input)*

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = \text{conjg}(B')$.

Unchanged on exit.

* *M (input)*

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. $M \geq 0$. Unchanged on exit.

* *N (input)*

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *K (input)*

On entry, K specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. $K \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

K when TRANSA = 'N' or 'n', and is M otherwise. Before entry with TRANSA = 'N' or 'n', the leading M by K part

of the array A must contain the matrix A, otherwise the leading K by M part of the array A must contain the matrix A. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then $LDA \geq \max(1, M)$, otherwise $LDA \geq \max(1, K)$. Unchanged on exit.

*** B (input)**

n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, otherwise $LDB \geq \max(1, n)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix $(\alpha * \text{op}(A) * \text{op}(B) + \text{beta} * C)$.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

zgenv - perform one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^* x + \beta y$, or $y := \alpha \text{conjg}(A') x + \beta y$

SYNOPSIS

```
SUBROUTINE ZGEMV( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,  
*             INCY)  
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER M, N, LDA, INCX, INCY
```

```
SUBROUTINE ZGEMV_64( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,  
*             INCY)  
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER*8 M, N, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GEMV( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],  
*             BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, INCX, INCY
```

```
SUBROUTINE GEMV_64( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],  
*             BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgemv(char transa, int m, int n, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex beta, doublecomplex *y, int incy);
```

```
void zgemv_64(char transa, long m, long n, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *x, long incx, doublecomplex beta, doublecomplex *y, long incy);
```

PURPOSE

zgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^T x + \beta y$, or $y := \alpha \text{conjg}(A) x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

*** TRANSA (input)**

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A) x + \beta y$.

Unchanged on exit.

*** M (input)**

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar α . Unchanged on exit.

*** A (input)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) \cdot \text{abs}(\text{INCX}))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) \cdot \text{abs}(\text{INCX}))$ otherwise. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* ***Y*** (*input/output*)

$(1 + (m - 1) * \text{abs}(\text{ INCY }))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{ INCY }))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* ***INCY*** (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zgeqlf - compute a QL factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE ZGEQLF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE ZGEQLF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GEQLF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GEQLF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqlf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgeqlf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgeqlf computes a QL factorization of a complex M-by-N matrix A: $A = Q * L$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m < n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

zgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE ZGEQP3( M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK,
*                INFO)
  DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
  INTEGER M, N, LDA, LWORK, INFO
  INTEGER JPVT(*)
  DOUBLE PRECISION RWORK(*)

SUBROUTINE ZGEQP3_64( M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK,
*                   INFO)
  DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
  INTEGER*8 M, N, LDA, LWORK, INFO
  INTEGER*8 JPVT(*)
  DOUBLE PRECISION RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*               [RWORK], [INFO])
  COMPLEX(8), DIMENSION(:) :: TAU, WORK
  COMPLEX(8), DIMENSION(:, :) :: A
  INTEGER :: M, N, LDA, LWORK, INFO
  INTEGER, DIMENSION(:) :: JPVT
  REAL(8), DIMENSION(:) :: RWORK

SUBROUTINE GEQP3_64( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*                  [RWORK], [INFO])
  COMPLEX(8), DIMENSION(:) :: TAU, WORK
  COMPLEX(8), DIMENSION(:, :) :: A
  INTEGER(8) :: M, N, LDA, LWORK, INFO
  INTEGER(8), DIMENSION(:) :: JPVT
  REAL(8), DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqp3(int m, int n, doublecomplex *a, int lda, int *jpvt, doublecomplex *tau, int *info);
```

```
void zgeqp3_64(long m, long n, doublecomplex *a, long lda, long *jpvt, doublecomplex *tau, long *info);
```

PURPOSE

zgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(M,N)$ elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** JPVT (input/output)**

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A^*P (a leading column); if $JPVT(J)=0$, the J-th column of A is a free column. On exit, if $JPVT(J)=K$, then the J-th column of A^*P was the K-th column of A.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** WORK (workspace)**

On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq N+1$. For optimal performance $LWORK \geq (N+1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** RWORK (workspace)**

dimension(2*N)

*** INFO (output)**

void zgeqpf_64(long m, long n, doublecomplex *a, long lda, long *jpivot, doublecomplex *tau, long *info);
```

PURPOSE

zgeqpf routine is deprecated and has been replaced by routine CGEQP3.

CGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***JPIVOT (input)***

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is permuted to the front of A^*P (a leading column); if $JPIVOT(i) = 0$, the i-th column of A is a free column. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***TAU (output)***

The scalar factors of the elementary reflectors.

* ***WORK (workspace)***

dimension(N)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

zgeqrf - compute a QR factorization of a complex M-by-N matrix A

```

```
SUBROUTINE GEQRF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqrf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgeqrf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgeqrf computes a QR factorization of a complex M-by-N matrix A: $A = Q * R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(M,N)$ -by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

zgerc - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

SYNOPSIS

```
SUBROUTINE ZGERC( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE ZGERC_64( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GERCC( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GERCC_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgerc(int m, int n, doublecomplex alpha, doublecomplex *x, int incx, doublecomplex *y, int incy, doublecomplex *a, int lda);
```

```
void zgerc_64(long m, long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zgerc performs the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$ where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** *M (input)***

On entry, M specifies the number of rows of the matrix A . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of the matrix A . $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

*** *X (input)***

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

*** *INCX (input)***

On entry, $INCX$ specifies the increment for the elements of X . $INCX$ must not be zero. Unchanged on exit.

*** *Y (input)***

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

*** *INCY (input)***

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

*** *A (input/output)***

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

```

```
void zgerfs(char transa, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zgerfs_64(char transa, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

*** TRANSA (input)**

Specifies the form of the system of equations:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input)**

The original N-by-N matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** AF (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

*** LDAF (input)**

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

*** IPIVOT (input)**

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

*** B (input)**

The right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (input/output)**

On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zgerqf - compute an RQ factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE ZGERQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GERQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgerqf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgerqf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgerqf computes an RQ factorization of a complex M-by-N matrix A: $A = R * Q$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray $A(1:m, n-m+1:n)$ contains the M-by-M upper triangular matrix R; if $m \geq n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of $\min(m, n)$ elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

```
SUBROUTINE GER_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeru(int m, int n, doublecomplex alpha, doublecomplex *x, int incx, doublecomplex *y, int incy, doublecomplex *a, int lda);
```

```
void zgeru_64(long m, long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zgeru performs the rank 1 operation $A := \alpha * x * y' + A$ where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** M (input)**

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

*** X (input)**

$(1 + (m - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** Y (input)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

*** A (input/output)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

zgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgesdd(char jobz, int m, int n, doublecomplex *a, int lda, double *s, doublecomplex *u, int ldu, doublecomplex *vt, int ldvt, int *info);
```

```
void zgesdd_64(char jobz, long m, long n, doublecomplex *a, long lda, double *s, doublecomplex *u, long ldu, doublecomplex *vt, long ldvt, long *info);
```

PURPOSE

zgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written $A = U * SIGMA * conjugate-transpose(V)$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns $VT = V^{*}H$, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** JOBZ (input)**

Specifies options for computing all or part of the matrix U:

*** M (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of $V^{*}H$ (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** S (output)**

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

*** U (output)**

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = min(M,N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O'

and $M < N$, U contains the M -by- M unitary matrix U ; if $JOBZ = 'S'$, U contains the first $\min(M,N)$ columns of U (the left singular vectors, stored columnwise); if $JOBZ = 'O'$ and $M \geq N$, or $JOBZ = 'N'$, U is not referenced.

* **LDU (input)**

The leading dimension of the array U . $LDU \geq 1$; if $JOBZ = 'S'$ or $'A'$ or $JOBZ = 'O'$ and $M < N$, $LDU \geq M$.

* **VT (output)**

If $JOBZ = 'A'$ or $JOBZ = 'O'$ and $M \geq N$, VT contains the N -by- N unitary matrix V^*H ; if $JOBZ = 'S'$, VT contains the first $\min(M,N)$ rows of V^*H (the right singular vectors, stored rowwise); if $JOBZ = 'O'$ and $M < N$, or $JOBZ = 'N'$, VT is not referenced.

* **LDVT (input)**

The leading dimension of the array VT . $LDVT \geq 1$; if $JOBZ = 'A'$ or $JOBZ = 'O'$ and $M \geq N$, $LDVT \geq N$; if $JOBZ = 'S'$, $LDVT \geq \min(M,N)$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK (input)**

The dimension of the array $WORK$. $LWORK \geq 1$. if $JOBZ = 'N'$, $LWORK \geq 2 \cdot \min(M,N) + \max(M,N)$. if $JOBZ = 'O'$, $LWORK \geq 2 \cdot \min(M,N) \cdot \min(M,N) + 2 \cdot \min(M,N) + \max(M,N)$. if $JOBZ = 'S'$ or $'A'$, $LWORK \geq \min(M,N) \cdot \min(M,N) + 2 \cdot \min(M,N) + \max(M,N)$. For good performance, $LWORK$ should generally be larger. If $LWORK < 0$ but other input arguments are legal, $WORK(1)$ returns optimal $LWORK$.

* **RWORK (workspace)**

If $JOBZ = 'N'$, $LRWORK \geq 7 \cdot \min(M,N)$. Otherwise, $LRWORK \geq 5 \cdot \min(M,N) \cdot \min(M,N) + 5 \cdot \min(M,N)$

* **IWORK (workspace)**

$\text{dimension}(8 \cdot \min(M,N))$

* **INFO (output)**

NAME

zgesl - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been LU- factored by CGECO or CGEFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZGESL( A, LDA, N, IPIVOT, B, JOB)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGESL_64( A, LDA, N, IPIVOT, B, JOB)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgesl(doublecomplex *a, int lda, int n, int *ipivot, doublecomplex *b, int job);
```

```
void zgesl_64(doublecomplex *a, long lda, long n, long *ipivot, doublecomplex *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by CGECO or CGEFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1,N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGECO or CGEFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** JOB (input)**

Determines which operation the subroutine will perform:

o 0 Solve the system $Ax = b$.

not 0 Solve the linear system $AHx = b$. Note that $ATx = AHx$ for real matrices.

NAME

zgesv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE ZGESV( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGESV_64( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GESV( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GESV_64( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgesv(int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zgesv_64(long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgesv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

*** B (input/output)**

On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

zgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

SYNOPSIS

```
SUBROUTINE ZGESVD( JOB, JOBVT, M, N, A, LDA, SING, U, LDU, VT,

```

```
void zgesvd_64(char jobu, char jobvt, long m, long n, doublecomplex *a, long lda, double *sing, doublecomplex *u, long ldu, doublecomplex *vt, long ldvt, long *info);
```

PURPOSE

zgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written = U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**H, not V.

ARGUMENTS

*** JOB***U* (*input*)

Specifies options for computing all or part of the matrix U:

*** JOB***VT* (*input*)

Specifies options for computing all or part of the matrix V**H:

*** M** (*input*)

The number of rows of the input matrix A. M >= 0.

*** N** (*input*)

The number of columns of the input matrix A. N >= 0.

*** A** (*input/output*)

On entry, the M-by-N matrix A. On exit, if JOB_U = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOB_{VT} = 'O', A is overwritten with the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOB_U .ne. 'O' and JOB_{VT} .ne. 'O', the contents of A are destroyed.

*** LDA** (*input*)

The leading dimension of the array A. LDA >= max(1,M).

*** SING** (*output*)

The singular values of A, sorted so that SING(i) >= SING(i+1).

*** U** (*input*)

(LDU,M) if JOB_U = 'A' or (LDU,min(M,N)) if JOB_U = 'SING'. If JOB_U = 'A', U contains the M-by-M unitary matrix U; if JOB_U = 'SING', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOB_U = 'N' or 'O', U is not referenced.

*** LDU** (*input*)

The leading dimension of the array U. $LDU \geq 1$; if $JOBV = 'SING'$ or $'A'$, $LDU \geq M$.

* ***VT (input)***

If $JOBVT = 'A'$, VT contains the N-by-N unitary matrix $V^{*}H$; if $JOBVT = 'SING'$, VT contains the first $\min(m,n)$ rows of $V^{*}H$ (the right singular vectors, stored rowwise); if $JOBVT = 'N'$ or $'O'$, VT is not referenced.

* ***LDVT (input)***

The leading dimension of the array VT. $LDVT \geq 1$; if $JOBVT = 'A'$, $LDVT \geq N$; if $JOBVT = 'SING'$, $LDVT \geq \min(M,N)$.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq 1$. $LDWORK \geq 2 * \min(M,N) + \max(M,N)$. For good performance, $LDWORK$ should generally be larger.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

* ***WORK2 (workspace)***

On exit, if $INFO > 0$, $WORK2(1:\min(M,N)-1)$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A, and singular vectors related by U and VT.

* ***INFO (output)***

NAME

zgesvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$,

```

PURPOSE

zgesvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(R)*A*\text{diag}(C)$ and B by $\text{diag}(R)*B$ (if TRANS='N') or $\text{diag}(C)*B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = P * L * U,
```

where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if TRANS = 'N') or $\text{diag}(R)$ (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$

EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input/output*)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P * L * U$ as computed by CGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the equilibrated matrix A.

* **EQUED** (*input*)

Specifies the form of equilibration that was done.

* **ROWSC** (*input/output*)

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED

= 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

*** COLSC (input/output)**

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

*** LDB (input)**

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

*** LDX (input)**

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

*** INFO (output)**

NAME

zgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE ZGETF2( M, N, A, LDA, IPIV, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER M, N, LDA, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE ZGETF2_64( M, N, A, LDA, IPIV, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE GETF2_64( [M], [N], A, [LDA], IPIV, [INFO])
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetf2(int m, int n, doublecomplex *a, int lda, int *ipiv, int *info);
```

```
void zgetf2_64(long m, long n, doublecomplex *a, long lda, long *ipiv, long *info);
```

PURPOSE

zgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

*** INFO (output)**

NAME

zgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

SYNOPSIS

```

PURPOSE

zgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

*** INFO (output)**

NAME

zgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE ZGETRI( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGETRI_64( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GETRI_64( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetri(int n, doublecomplex *a, int lda, int *ipivot, int *info);
```

```
void zgetri_64(long n, doublecomplex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by CGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** IPIVOT (input)**

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

*** WORK (workspace)**

On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimal performance $LDWORK \geq N*NB$, where NB is the optimal blocksize returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetrs(char transa, int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zgetrs_64(char transa, long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgetrs solves a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

zggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

SYNOPSIS

```
SUBROUTINE ZGGBAK( JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V,
* LDV, INFO)
CHARACTER * 1 JOB, SIDE
DOUBLE COMPLEX V(LDV,*)

C INTERFACE

```
#include <sunperf.h>
```

```
void zggbak(char job, char side, int n, int ilo, int ihi, double *lscale, double *rscale, int m, doublecomplex *v, int ldv, int *info);
```

```
void zggbak_64(char job, char side, long n, long ilo, long ihi, double *lscale, double *rscale, long m, doublecomplex *v, long ldv, long *info);
```

PURPOSE

zggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

ARGUMENTS

* **JOB** (*input*)

Specifies the type of backward transformation required:

* **SIDE** (*input*)

* **N** (*input*)

The number of rows of the matrix V. $N \geq 0$.

* **ILO** (*input*)

The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **IHI** (*input*)

The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **LSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

* **RSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

* **M** (*input*)

The number of columns of the matrix V. $M \geq 0$.

* **V** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On exit, V is overwritten by the transformed eigenvectors.

* **LDV** (*input*)

The leading dimension of the matrix V. $LDV \geq \max(1, N)$.

* **INFO** (*output*)

NAME

zggbal - balance a pair of general complex matrices (A,B)

SYNOPSIS

```
SUBROUTINE ZGGBAL( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
*   WORK, INFO)
CHARACTER * 1 JOB
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, LDA, LDB, ILO, IHI, INFO
DOUBLE PRECISION LSCALE(*), RSCALE(*), WORK(*)

SUBROUTINE ZGGBAL_64( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE,
*   RSCALE, WORK, INFO)
CHARACTER * 1 JOB
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, LDA, LDB, ILO, IHI, INFO
DOUBLE PRECISION LSCALE(*), RSCALE(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GGBAL( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX(8), DIMENSION(:,) :: A, B
INTEGER :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK

SUBROUTINE GGBAL_64( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX(8), DIMENSION(:,) :: A, B
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zggbal(char job, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *ilo, int *ihi, double *lscale, double *rscale, int *info);
```

```
void zggbal_64(char job, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *ilo, long *ihi, double
```

*lscale, double *rscale, long *info);

PURPOSE

zggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

*** JOB (input)**

Specifies the operations to be performed on A and B:

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input)**

On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** ILO (output)**

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.
If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** IHI (output)**

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.

*** LSCALE (input)**

Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

*** RSCALE (input)**

Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

*** WORK (workspace)**

dimension(6*N)

*** INFO (output)**

```
#include <sunperf.h>
```

```
void zgges(char jobvsl, char jobvsr, char sort, logical(*delztg)(COMPLEX*16,COMPLEX*16), int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *sdim, doublecomplex *alpha, doublecomplex *beta, doublecomplex *vsl, int ldvsl, doublecomplex *vsr, int ldvsr, int *info);
```

```
void zgges_64(char jobvsl, char jobvsr, char sort, logical(*delztg)(COMPLEX*16,COMPLEX*16), long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *sdim, doublecomplex *alpha, doublecomplex *beta, doublecomplex *vsl, long ldvsl, doublecomplex *vsr, long ldvsr, long *info);
```

PURPOSE

zgges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A, B) = ((VSL) * S * (VSR) ** H, (VSL) * T * (VSR) ** H)$$

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **DELZTG** (*input*)

DELZTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELZTG is not referenced. If SORT = 'S', DELZTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if DELZTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy DELZTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA (input)**

The leading dimension of A. $LDA \geq \max(1, N)$.

* **B (input/output)**

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB (input)**

The leading dimension of B. $LDB \geq \max(1, N)$.

* **SDIM (output)**

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELZTG is true.

* **ALPHA (output)**

On exit, ALPHA(j)/BETA(j), $j=1, \dots, N$, will be the generalized eigenvalues. ALPHA(j), $j=1, \dots, N$ and BETA(j), $j=1, \dots, N$ are the diagonals of the complex Schur form (A,B) output by CGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **BETA (output)**

See description of ALPHA.

* **VSL (input)**

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL (input)**

The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if JOBVSL = 'V', $LDVSL \geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if JOBVSR = 'V', $LDVSR \geq N$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 2*N)$. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

dimension(8*N)

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

*vsl, long ldvsl, doublecomplex *vsr, long ldvsr, double *rconde, double *rcondv, long *info);
```

PURPOSE

zggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization $A,B = (VSL) S (VSR)^*H, (VSL) T (VSR)^*H$

where $(VSR)^*H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$ or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **DELCTG** (*input*)

DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy $DELCTG(ALPHA(j),BETA(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

* **A (input/output)**

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA (input)**

The leading dimension of A. $LDA \geq \max(1, N)$.

* **B (input/output)**

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB (input)**

The leading dimension of B. $LDB \geq \max(1, N)$.

* **SDIM (output)**

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true.

* **ALPHA (output)**

On exit, ALPHA(j)/BETA(j), $j=1, \dots, N$, will be the generalized eigenvalues. ALPHA(j) and BETA(j), $j=1, \dots, N$ are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **BETA (output)**

See description of ALPHA.

* **VSL (input)**

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL (input)**

The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if JOBVSL = 'V', $LDVSL \geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if JOBVSR = 'V', $LDVSR \geq N$.

* **RCONDE (output)**

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* **RCONDV (output)**

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 2*N$. If SENSE = 'E', 'V', or 'B', $LWORK \geq \max(2*N, 2*SDIM*(N-SDIM))$.

* **RWORK (workspace)**

Real workspace.

* **IWORK (workspace)**

Not referenced if SENSE = 'N'. On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of the array WORK. $LIWORK \geq N+2$.

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

PURPOSE

zggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j).$$

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHA** (*output*)

On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **BETA** (*output*)

See description of ALPHA.

* **VL** (*output*)

If $JOBVL = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $JOBVL = 'N'$.

* ***LDVL (input)***

The leading dimension of the matrix VL . $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

* ***VR (output)***

If $JOBVR = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

* ***LDVR (input)***

The leading dimension of the matrix VR . $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK (input)***

The dimension of the array $WORK$. $LWORK \geq \max(1, 2*N)$. For good performance, $LWORK$ must generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* ***RWORK (workspace)***

dimension($8*N$)

* ***INFO (output)***

```

PURPOSE

zggevz computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B .$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **BALANC** (*input*)

Specifies the balance option to be performed:

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VL, and VR. $N \geq 0$.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **ALPHA** (*output*)

On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotient $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $ALPHA/BETA$. However, ALPHA will be always less than and usually comparable with $norm(A)$ in magnitude, and BETA always less than and usually comparable with $norm(B)$.

* **BETA** (*output*)

See description of ALPHA.

* **VL** (*output*)

If JOBVL = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if JOBVL = 'V', $LDVL \geq N$.

* **VR** (*output*)

If JOBVR = 'V', the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if JOBVR = 'N'.

* **LDVR** (*input*)

The leading dimension of the matrix VR. $LDVR \geq 1$, and if JOBVR = 'V', $LDVR \geq N$.

* **ILO** (*output*)

ILO is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1,\dots,ILO-1$ or $i = IHI+1,\dots,N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

* **IHI** (*output*)

IHI is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1,\dots,ILO-1$ or $i = IHI+1,\dots,N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

* **LSCALE** (*output*)

Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1

* **RSCALE (output)**

Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1

* **ABNRM (output)**

The one-norm of the balanced matrix A.

* **BBNRM (output)**

The one-norm of the balanced matrix B.

* **RCONDE (output)**

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If SENSE = 'V', RCONDE is not referenced.

* **RCONDV (output)**

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK \geq max(1,2*N). If SENSE = 'N' or 'E', LWORK \geq 2*N. If SENSE = 'V' or 'B', LWORK \geq 2*N*N+2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

Real workspace.

* **IWORK (workspace)**

If SENSE = 'E', IWORK is not referenced.

* **BWORK (workspace)**

If SENSE = 'N', BWORK is not referenced.

* **INFO (output)**

COMPLEX(8), DIMENSION(:) :: D, X, Y, WORK
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: N, M, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zggglm(int n, int m, int p, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *d, doublecomplex *x, doublecomplex *y, int *info);
```

```
void zggglm_64(long n, long m, long p, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *d, doublecomplex *x, doublecomplex *y, long *info);
```

PURPOSE

zggglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $0 \leq M \leq N$.

*** P (input)**

The number of columns of the matrix B. $P \geq N-M$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** D (input/output)**

On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

*** X (output)**

On exit, X and Y are the solutions of the GLM problem.

*** Y (output)**

On exit, X and Y are the solutions of the GLM problem.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal block sizes for CGEQRF, CGERQF, CUNMQR and CUNMRO.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

zgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```

```
SUBROUTINE GGHRD_64( COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],  
* Q, [LDQ], Z, [LDZ], [INFO])  
CHARACTER(LEN=1) :: COMPQ, COMPZ  
COMPLEX(8), DIMENSION(:,*) :: A, B, Q, Z  
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgghrd(char compq, char compz, int n, int ilo, int ihi, doublecomplex *a, int lda, doublecomplex *b, int ldb,  
doublecomplex *q, int ldq, doublecomplex *z, int ldz, int *info);
```

```
void zgghrd_64(char compq, char compz, long n, long ilo, long ihi, doublecomplex *a, long lda, doublecomplex *b, long ldb,  
doublecomplex *q, long ldq, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)' \quad 1 * B * Z1' = (Q1*Q) * T * (Z1*Z)'$$

ARGUMENTS

* **COMPQ** (input)

* **COMPZ** (input)

* **N** (input)

The order of the matrices A and B. $N \geq 0$.

* **ILO** (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* **IHI** (input)

See description of ILO.

* **A** (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

* **LDA** (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* **B** (input/output)

On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

* **LDB** (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **Q** (input/output)

If COMPQ='N': Q is not referenced.

If COMPQ='I': on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by $Q1*Q$.

* **LDQ** (input)

The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

* **Z** (input/output)

If COMPZ='N': Z is not referenced.

If COMPZ='I': on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is the product of the

Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by Z1*Z.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

* **INFO** (*output*)

COMPLEX(8), DIMENSION(:) :: C, D, X, WORK
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgglse(int m, int n, int p, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *c, doublecomplex *d, doublecomplex *x, int *info);
```

```
void zgglse_64(long m, long n, long p, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *c, doublecomplex *d, doublecomplex *x, long *info);
```

PURPOSE

zggls solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } \| c - A*x \|_2 \quad \text{subject to} \quad B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that $P \leq N \leq M+P$, and

$$\text{rank}(B) = P \quad \text{and} \quad \text{rank} \left(\begin{array}{c} A \\ B \end{array} \right) = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** P (input)**

The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** C (input/output)**

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

*** D (input/output)**

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

*** X (output)**

On exit, X is the solution of the LSE problem.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. LDWORK $\geq \max(1, M+N+P)$. For optimum performance LDWORK $\geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (output)

NAME

```

```
void zggqrf_64(long n, long m, long p, doublecomplex *a, long lda, doublecomplex *tau, doublecomplex *b, long ldb, doublecomplex *taub, long *info);
```

PURPOSE

zggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if $N \geq M$, $R = \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}$, or if $N < M$, $R = \begin{pmatrix} R_{11} & R_{12} \\ 0 & 0 \end{pmatrix}$

where R_{11} is upper triangular, and

if $N \leq P$, $T = \begin{pmatrix} 0 & T_{12} \\ 0 & 0 \end{pmatrix}$, or if $N > P$, $T = \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix}$

where T_{12} or T_{21} is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'^*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of matrix Z.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $M \geq 0$.

*** P (input)**

The number of columns of the matrix B. $P \geq 0$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **TAUB (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

  COMPLEX(8), DIMENSION(:) :: TAU, TAUB, WORK
  COMPLEX(8), DIMENSION(:,:) :: A, B
  INTEGER(8) :: M, P, N, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zggrqf(int m, int p, int n, doublecomplex *a, int lda, doublecomplex *tau, doublecomplex *b, int ldb, doublecomplex *taub, int *info);
```

```
void zggrqf_64(long m, long p, long n, doublecomplex *a, long lda, doublecomplex *tau, doublecomplex *b, long ldb, doublecomplex *taub, long *info);
```

PURPOSE

zggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if $M \leq N$, $R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} M$, or if $M > N$, $R = \begin{pmatrix} R_{11} \\ \end{pmatrix} M-N, N-M \begin{pmatrix} R_{21} \end{pmatrix} N-N$

where R_{12} or R_{21} is upper triangular, and

if $P \geq N$, $T = \begin{pmatrix} T_{11} \end{pmatrix} N$, or if $P < N$, $T = \begin{pmatrix} T_{11} & T_{12} \\ \end{pmatrix} P, \begin{pmatrix} 0 \end{pmatrix} P-N \begin{pmatrix} T_{21} & T_{22} \end{pmatrix} P-N$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*inv(B)$:

$$A*inv(B) = (R*inv(T))*Z'$$

where $inv(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of the matrix Z.

ARGUMENTS

* M (input)

The number of rows of the matrix A. $M \geq 0$.

* P (input)

The number of rows of the matrix B. $P \geq 0$.

* N (input)

The number of columns of the matrices A and B. $N \geq 0$.

* A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray $A(1:M, N-M+1:N)$ contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

* LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* TAUA (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

* B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P, N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** TAUB (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK \geq $\max(1, N, M, P)$. For optimum performance LWORK \geq $\max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

zggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

SYNOPSIS

REAL(8), DIMENSION(:) :: ALPHA, BETA, WORK2
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{pmatrix} = \begin{matrix} P-L & (& 0 & 0 & 0 &) \\ & N-K-L & K & M-K & K+L-M \\ K & (& 0 & R_{11} & R_{12} & R_{13} &) \\ M-K & (& 0 & 0 & R_{22} & R_{23} &) \\ K+L-M & (& 0 & 0 & 0 & R_{33} &) \end{matrix}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1), ... , BETA(M) ),
C**2 + S**2 = I.
(R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33 is stored
( 0 R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.

```

The routine computes C, S, R, and optionally the unitary

transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V^T.$$

If (A',B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem: A'*A x = lambda* B'*B x.

In some literature, the GSVD of A and B is presented in the form U'*A*X = (0 D1), V'*B*X = (0 D2)

where U and V are orthogonal and X is nonsingular, and D1 and D2 are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q \cdot \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}$$

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. M >= 0.

* **N** (*input*)

The number of columns of the matrices A and B. N >= 0.

* **P** (*input*)

The number of rows of the matrix B. P >= 0.

* **K** (*output*)

On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of (A',B').

*** L (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose. $K + L =$ effective numerical rank of (A',B)'

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if $M - K - L < 0$. See Purpose for details.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** ALPHA (output)**

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $ALPHA(K+1:N) = 0$,

$BETA(1:K) = 0$, and if $M - K - L \geq 0$, $ALPHA(K+1:K+L) = C$,

$BETA(K+1:K+L) = S$, or if $M - K - L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and $ALPHA(K+L+1:N) = 0$

$BETA(K+L+1:N) = 0$

*** BETA (output)**

See description of ALPHA.

*** U (output)**

If $JOB_U = 'U'$, U contains the M-by-M unitary matrix U. If $JOB_U = 'N'$, U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1, M)$ if $JOB_U = 'U'$; $LDU \geq 1$ otherwise.

*** V (output)**

If $JOB_V = 'V'$, V contains the P-by-P unitary matrix V. If $JOB_V = 'N'$, V is not referenced.

*** LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1, P)$ if $JOB_V = 'V'$; $LDV \geq 1$ otherwise.

*** Q (output)**

If $JOB_Q = 'Q'$, Q contains the N-by-N unitary matrix Q. If $JOB_Q = 'N'$, Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if $JOB_Q = 'Q'$; $LDQ \geq 1$ otherwise.

*** WORK (workspace)**

$\text{dimension}(\text{MAX}(3 * N, M, P) + N)$

*** WORK2 (workspace)**

*** IWORK3 (output)**

On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for $I = K + 1$, $\min(M, K + L)$ swap $ALPHA(I)$ and $ALPHA(IWORK3(I))$ endfor such that $ALPHA(1) \geq ALPHA(2) \geq \dots \geq ALPHA(N)$.

*** INFO (output)**

NAME

zggsvp - compute unitary matrices U, V and Q such that $N-K-L \times K \times L \times U^* A Q = K \times (0 \ A12 \ A13)$ if $M-K-L \geq 0$

SYNOPSIS

long ldq, long *info);
```

PURPOSE

zggsvp computes unitary matrices U, V and Q such that $L \begin{pmatrix} 0 & 0 & A23 \end{pmatrix}$

$$\begin{aligned} & \begin{matrix} M-K-L & (& 0 & & 0 & & 0 &) \\ & & N-K-L & & K & & L & \\ = & & K & (& 0 & & A12 & & A13 &) & \text{if } M-K-L < 0; \\ & & M-K & (& 0 & & 0 & & A23 &) \\ & & & & N-K-L & & K & & L & \\ V' * B * Q = & & L & (& 0 & & 0 & & B13 &) \\ & & P-L & (& 0 & & 0 & & 0 &) \end{matrix} \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal. $K+L$ = the effective numerical rank of the (M+P)-by-N matrix (A',B)'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CCGSVD.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **TOLA (input)**

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

* **TOLB (input)**

See description of TOLA.

* **K (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose section. $K + L =$ effective numerical rank of (A',B)'.

* **L (output)**

See the description of K.

* **U (input)**

If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

* **LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

* **V (input)**

If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

* **LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

* **Q (input)**

If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

* **IWORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(2*N)

* **TAU (workspace)**

dimension(N)

* **WORK (workspace)**

dimension(MAX(3*N, M, P))

* **INFO (output)**

C INTERFACE

```
#include <sunperf.h>
```

```
void zgtcon(char norm, int n, doublecomplex *low, doublecomplex *diag, doublecomplex *up1, doublecomplex *up2, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zgtcon_64(char norm, long n, doublecomplex *low, doublecomplex *diag, doublecomplex *up1, doublecomplex *up2, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UP1** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **ANORM** (*input*)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **INFO** (*output*)

NAME

*diagf, doublecomplex *upf1, doublecomplex *upf2, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr,
long *info);
```

PURPOSE

zgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **LOW** (*input*)

The (n-1) subdiagonal elements of A.

* **DIAG** (*input*)

The diagonal elements of A.

* **UP** (*input*)

The (n-1) superdiagonal elements of A.

* **LOWF** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

* **DIAGF** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPF1** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UPF2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zgtsl - (obsolete) solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZGTSL( N, SUB, DIAG, SUPER, B, INFO)
DOUBLE COMPLEX SUB(*), DIAG(*), SUPER(*), B(*)
INTEGER N, INFO
```

```
SUBROUTINE ZGTSL_64( N, SUB, DIAG, SUPER, B, INFO)
DOUBLE COMPLEX SUB(*), DIAG(*), SUPER(*), B(*)
INTEGER*8 N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgtsl(int n, doublecomplex *sub, doublecomplex *diag, doublecomplex *super, doublecomplex *b, int *info);
```

```
void zgtsl_64(long n, doublecomplex *sub, doublecomplex *diag, doublecomplex *super, doublecomplex *b, long *info);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *SUB* (*input*)

Subdiagonal of A . $SUB(2)$ through $SUB(N)$ contain the subdiagonal and $SUB(1)$ is not referenced.

* *DIAG* (*input*)

Diagonal of A .

* *SUPER* (*input*)

Superdiagonal of A . $SUPER(1)$ through $SUPER(N-1)$ contain the superdiagonal and $SUPER(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* *INFO* (*output*)

On exit:

$INFO = 0$ Subroutine completed normally.

INFO > 0 Returns a value k when the kth element of the diagonal becomes exactly zero.

NAME

zgtsv - solve the equation $A \cdot X = B$,

SYNOPSIS

```
SUBROUTINE ZGTSV( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
DOUBLE COMPLEX LOW(*), DIAG(*), UP(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
```

```
SUBROUTINE ZGTSV_64( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
DOUBLE COMPLEX LOW(*), DIAG(*), UP(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE GTSV( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:) :: LOW, DIAG, UP
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE GTSV_64( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:) :: LOW, DIAG, UP
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgtsv(int n, int nrhs, doublecomplex *low, doublecomplex *diag, doublecomplex *up, doublecomplex *b, int ldb, int *info);
```

```
void zgtsv_64(long n, long nrhs, doublecomplex *low, doublecomplex *diag, doublecomplex *up, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgtsv solves the equation

where A is an N -by- N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments DU and DL .

ARGUMENTS

* ***N*** (*input*)

The order of the matrix A . $N \geq 0$.

* ***NRHS*** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* ***LOW*** (*input/output*)

On entry, LOW must contain the $(n-1)$ subdiagonal elements of A . On exit, LOW is overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A , in $LOW(1)$, ..., $LOW(n-2)$.

* ***DIAG*** (*input/output*)

On entry, $DIAG$ must contain the diagonal elements of A . On exit, $DIAG$ is overwritten by the n diagonal elements of U .

* ***UP*** (*input/output*)

On entry, UP must contain the $(n-1)$ superdiagonal elements of A . On exit, UP is overwritten by the $(n-1)$ elements of the first superdiagonal of U .

* ***B*** (*input/output*)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

* ***LDB*** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* ***INFO*** (*output*)

NAME

doublecomplex *diagf, doublecomplex *upf1, doublecomplex *upf2, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

PURPOSE

zgtsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.
 2. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

*** FACT (input)**

Specifies whether or not the factored form of A has been supplied on entry.

*** TRANSA (input)**

Specifies the form of the system of equations:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** LOW (input)**

The (n-1) subdiagonal elements of A.

*** DIAG (input)**

The n diagonal elements of A.

*** UP (input/output)**

The (n-1) superdiagonal elements of A.

*** LOWF (input/output)**

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

*** DIAGF (input/output)**

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

*** UPF1 (input/output)**

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

*** UPF2 (input/output)**

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

* ***IPIVOT*** (*input/output*)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* ***B*** (*input*)

The N-by-NRHS right hand side matrix B.

* ***LDB*** (*input*)

The leading dimension of the array B. LDB \geq max(1,N).

* ***X*** (*output*)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* ***LDX*** (*input*)

The leading dimension of the array X. LDX \geq max(1,N).

* ***RCOND*** (*output*)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

* ***FERR*** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* ***WORK*** (*workspace*)

dimension(2*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgttrf(int n, doublecomplex *low, doublecomplex *diag, doublecomplex *up1, doublecomplex *up2, int *ipivot, int *info);
```

```
void zgttrf_64(long n, doublecomplex *low, doublecomplex *diag, doublecomplex *up1, doublecomplex *up2, long *ipivot, long *info);
```

PURPOSE

zgttrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

*** N (input)**

The order of the matrix A.

*** LOW (input/output)**

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

*** DIAG (input/output)**

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

*** UP1 (input/output)**

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

*** UP2 (output)**

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

*** INFO (output)**

doublecomplex *up2, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgttrs solves one of the systems of equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, with a tridiagonal matrix A using the LU factorization computed by CGTTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPI** (*input*)

The (n-1) elements of the first super-diagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second super-diagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B** (*input/output*)

On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

* **LDB** (*input*)

The leading dimension of the array B. LDB >= max(1,N).

* **INFO** (*output*)

NAME

zhbev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbev(char jobz, char uplo, int n, int ndiag, doublecomplex *a, int lda, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhbev_64(char jobz, char uplo, long n, long ndiag, doublecomplex *a, long lda, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension(N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbevd(char jobz, char uplo, int n, int kd, doublecomplex *ab, int ldab, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhbevd_64(char jobz, char uplo, long n, long kd, doublecomplex *ab, long ldab, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and $KD+1$ of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least N. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

* **LRWORK (input)**

The dimension of array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N. If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

```

PURPOSE

zhbevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **Q** (*output*)

If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. If JOBZ = 'V', then $LDQ \geq \max(1,N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

* **NFOUND (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

* **W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

* **WORK (workspace)**

dimension(N)

* **WORK2 (workspace)**

* **IWORK3 (workspace)**

* **IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO (output)**

NAME

zbgst - reduce a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$,

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbgsst(char vect, char uplo, int n, int ka, int kb, doublecomplex *ab, int ldab, doublecomplex *bb, int ldbb, doublecomplex *x, int ldx, int *info);
```

```
void zhbgsst_64(char vect, char uplo, long n, long ka, long kb, doublecomplex *ab, long ldab, doublecomplex *bb, long ldbb, doublecomplex *x, long ldx, long *info);
```

PURPOSE

zhbgsst reduces a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A .

B must have been previously factorized as $S**H*S$ by CPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**H*A*X$, where $X = S**(-1)*Q$ and Q is a unitary matrix chosen to preserve the bandwidth of A .

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B . $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix $X**H*A*X$, stored in the same format as A .

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KA+1$.

* **BB** (*input*)

The banded factor S from the split Cholesky factorization of B , as returned by CPBSTF, stored in the first $kb+1$ rows of the array.

* **LDBB** (*input*)

The leading dimension of the array BB . $LDBB \geq KB+1$.

* **X** (*output*)

If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

* **LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N) if VECT = 'V'; LDX \geq 1 otherwise.

* **WORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

zhbgv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

SYNOPSIS

void zhbgy_64(char jobz, char uplo, long n, long ka, long kb, doublecomplex *ab, long ldab, doublecomplex *bb, long ldbb, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhbgy computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If $INFO = 0$, the eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H*B*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **WORK** (*workspace*)

dimension(N)

* **RWORK** (*workspace*)

dimension(3*N)

* **INFO** (*output*)

NAME

zbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbgyd(char jobz, char uplo, int n, int ka, int kb, doublecomplex *ab, int ldab, doublecomplex *bb, int ldbb, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhbgyd_64(char jobz, char uplo, long n, long ka, long kb, doublecomplex *ab, long ldab, doublecomplex *bb, long ldbb, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhbgyd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB (input)**

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **Z (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **WORK (workspace)**

On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 2*N^2$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

On exit, if $INFO=0$, $RWORK(1)$ returns the optimal LRWORK.

* **LRWORK (input)**

The dimension of array RWORK. If $N \leq 1$, $LRWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LRWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LRWORK \geq 1 + 5*N + 2*N^2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if $INFO=0$, $IWORK(1)$ returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of array IWORK. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

```

PURPOSE

zhbvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB (input)**

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **Q (output)**

If JOBZ = 'V', the n-by-n matrix used in the reduction of $A^*x = (\lambda)B^*x$ to standard form, i.e. $C^*x = (\lambda)B^*x$, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. If JOBZ = 'N', $LDQ \geq 1$. If JOBZ = 'V', $LDQ \geq \max(1,N)$.

* **VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **WORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(7*N)

* ***IWORK*** (*workspace*)

dimension(5*N)

* ***IFAIL*** (*output*)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* ***INFO*** (*output*)

NAME

zhbmV - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE ZHBMV( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA, Y,
*              INCY)
CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)
INTEGER N, NDIAG, LDA, INCX, INCY

SUBROUTINE ZHBMV_64( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA,
*                  Y, INCY)
CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HBMV( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX], BETA,
*              Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCX, INCY

SUBROUTINE HBMV_64( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX],
*                  BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbmV(char uplo, int n, int ndiag, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex beta, doublecomplex *y, int incy);
```

void zhbmvm_64(char uplo, long n, long ndiag, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *x, long incx, doublecomplex beta, doublecomplex *y, long incy);

PURPOSE

zhbmvm performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry, NDIAG specifies the number of super-diagonals of the matrix A. NDIAG must satisfy $0 \leq \text{NDIAG}$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  M = NDIAG + 1 - J
  DO 10, I = MAX( 1, J - NDIAG ), J
    A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
      O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

```

PURPOSE

zhbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD+1$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i,i+1)$ if UPLO = 'U'; $E(i) = T(i+1,i)$ if UPLO = 'L'.

* **Q** (*input/output*)

On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product $X*Q$; if VECT = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq 1$, and $LDQ \geq N$ if VECT = 'V' or 'U'.

* **WORK** (*workspace*)
dimension(N)

* **INFO** (*output*)

NAME

zhecon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

SYNOPSIS

```

```

```
void zhecon(char uplo, int n, doublecomplex *a, int lda, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zhecon_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zhecon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** A (input)**

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

*** LDA (input)**

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CHETRF.

*** ANORM (input)**

The 1-norm of the original matrix A .

*** RCOND (output)**

The reciprocal of the condition number of the matrix A , computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

*** WORK (workspace)**

$\text{dimension}(2*N)$

*** INFO (output)**

NAME

zheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

SYNOPSIS

```
SUBROUTINE ZHEEV( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, WORK2,
*             INFO)

CHARACTER(LEN=1) :: JOBZ, UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK2

SUBROUTINE HEEV_64( JOBZ, UPLO, [N], A, [LDA], W, [WORK], [LDWORK],
*             [WORK2], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zheev(char jobz, char uplo, int n, doublecomplex *a, int lda, double *w, int *info);
```

```
void zheev_64(char jobz, char uplo, long n, doublecomplex *a, long lda, double *w, long *info);
```

PURPOSE

zheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. $LDWORK \geq \max(1, 2*N-1)$. For optimal efficiency, $LDWORK \geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zheevd(char jobz, char uplo, int n, doublecomplex *a, int lda, double *w, int *info);
```

```
void zheevd_64(char jobz, char uplo, long n, doublecomplex *a, long lda, double *w, long *info);
```

PURPOSE

zheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The length of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $N + 1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (*workspace*)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

*** LRWORK (input)**

The dimension of the array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N . If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

zheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, CHEEVR calls CSTEGR to compute the

eigenspectrum using Relatively Robust Representations. CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" LDL^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : CHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR calls SSTEGBZ and CSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A

corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z , i.e., the indices indicating the nonzero elements in Z . The i -th eigenvector is nonzero only in elements $ISUPPZ(2*i-1)$ through $ISUPPZ(2*i)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

*** LWORK (input)**

The length of the array $WORK$. $LWORK \geq \max(1, 2*N)$. For optimal efficiency, $LWORK \geq (NB+1)*N$, where NB is the max of the blocksize for $CHETRD$ and for $CUNMTR$ as returned by $ILAENV$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

*** RWORK (workspace)**

On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal (and minimal) $LRWORK$.

*** LRWORK (input)**

The length of the array $RWORK$. $LRWORK \geq \max(1, 24*N)$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

*** IWORK (workspace)**

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal (and minimal) $LIWORK$.

*** LIWORK (input)**

The dimension of the array $IWORK$. $LIWORK \geq \max(1, 10*N)$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

*** INFO (output)**

```
void zheevx_64(char jobz, char range, char uplo, long n, doublecomplex *a, long lda, double vl, double vu, long il, long iu,  
double abtol, long *nfound, double *w, doublecomplex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU$

$\leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

*** *ABTOL* (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If $ABTOL$ is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $ABTOL$ is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting $ABTOL$ to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** *NFOUND* (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If $RANGE = 'A'$, $NFOUND = N$, and if $RANGE = 'I'$, $NFOUND = IU - IL + 1$.

*** *W* (output)**

On normal exit, the first $NFOUND$ elements contain the selected eigenvalues in ascending order.

*** *Z* (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first $NFOUND$ columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $IFAIL$. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of $NFOUND$ is not known in advance and an upper bound must be used.

*** *LDZ* (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** *WORK* (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

*** *LDWORK* (input)**

The length of the array $WORK$. $LDWORK \geq \max(1, 2 * N - 1)$. For optimal efficiency, $LDWORK \geq (NB + 1) * N$, where NB is the max of the blocksize for $CHETRD$ and for $CUNMTR$ as returned by $ILAENV$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

*** *WORK2* (workspace)**

*** *IWORK3* (workspace)**

*** *IFAIL* (output)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first $NFOUND$ elements of $IFAIL$ are zero. If $INFO > 0$, then $IFAIL$ contains the indices of the eigenvectors that failed to converge. If $JOBZ = 'N'$, then $IFAIL$ is not referenced.

*** *INFO* (output)**

NAME

zhegs2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

SYNOPSIS

```

```
void zhegs2(int itype, char uplo, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zhegs2_64(long itype, char uplo, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhags2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U*U$ or $L*L'$ by CPOTRF.

ARGUMENTS

* *ITYPE (input)*

* *UPLO (input)*

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized.

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *A (input/output)*

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B (input)*

The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO (output)*

NAME

```

```
void zhegst_64(long itype, char uplo, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by CPOTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* *B* (input)

The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *INFO* (output)

```

```
void zhegv_64(long itype, char jobz, char uplo, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, double *w, long *info);
```

PURPOSE

zhegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian and B is also

positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*\text{inv}(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L^*L^*H$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. LDWORK $\geq \max(1, 2*N-1)$. For optimal efficiency, LDWORK $\geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void zhegvd(int itype, char jobz, char uplo, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, double *w, int *info);
```

```
void zhegvd_64(long itype, char jobz, char uplo, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, double *w, long *info);
```

PURPOSE

zhegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input/output)**

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK (input)**

The length of the array $WORK$. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq N + 1$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 2*N + N**2$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

* **RWORK (workspace)**

On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal $LRWORK$.

* **LRWORK (input)**

The dimension of the array $RWORK$. If $N \leq 1$, $LRWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LRWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LRWORK \geq 1 + 5*N + 2*N**2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* **IWORK (workspace)**

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* **LIWORK (input)**

The dimension of the array $IWORK$. If $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

* **INFO (output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

*** VL (input)**

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

*** VU (input)**

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

*** IL (input)**

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

*** IU (input)**

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If $ABSTOL$ is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $ABSTOL$ is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO>0$, indicating that some eigenvectors did not converge, try setting $ABSTOL$ to $2*SLAMCH('S')$.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If $RANGE = 'A'$, $M = N$, and if $RANGE = 'I'$, $M = IU-IL+1$.

*** W (output)**

The first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If $JOBZ = 'N'$, then Z is not referenced. If $JOBZ = 'V'$, then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^*T*B*Z = I$; if $ITYPE = 3$, $Z^*T*inv(B)*Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $IFAIL$. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

*** LWORK (input)**

The length of the array $WORK$. $LWORK \geq \max(1,2*N-1)$. For optimal efficiency, $LWORK \geq (NB+1)*N$, where NB is the blocksize for $CHETRD$ returned by $ILAENV$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$

array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (*workspace*)

dimension(7*N)

* **IWORK** (*workspace*)

dimension(5*N)

* **IFAIL** (*output*)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO** (*output*)

NAME

zhemm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE ZHEMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,

CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhemm(char side, char uplo, int m, int n, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb,
doublecomplex beta, doublecomplex *c, int ldc);
```

```
void zhemm_64(char side, char uplo, long m, long n, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *b,
```

long ldb, doublecomplex beta, doublecomplex *c, long ldc);

PURPOSE

zhemm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE* (input)

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on

exit.

* **LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

* **B (input)**

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

* **LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least $\max(1, m)$. Unchanged on exit.

* **BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

* **C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

* **LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, m)$. Unchanged on exit.

NAME

zhemv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE ZHEMV( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA, BETA

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCX, INCY
```

```
SUBROUTINE HEMV_64( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhemv(char uplo, int n, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex beta, doublecomplex *y, int incy);
```

```
void zhemv_64(char uplo, long n, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *x, long incx,
```

doublecomplex beta, doublecomplex *y, long incy);

PURPOSE

zhemv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

zher - perform the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$

SYNOPSIS

```
SUBROUTINE ZHER( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
DOUBLE COMPLEX X(*), A(LDA,*)
INTEGER N, INCX, LDA
DOUBLE PRECISION ALPHA
```

```
SUBROUTINE ZHER_64( UPLO, N, ALPHA, X, INCX, A, LDA)
CHARACTER * 1 UPLO
DOUBLE COMPLEX X(*), A(LDA,*)
INTEGER*8 N, INCX, LDA
DOUBLE PRECISION ALPHA
```

F95 INTERFACE

```
SUBROUTINE HER( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, INCX, LDA
REAL(8) :: ALPHA
```

```
SUBROUTINE HER_64( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: X
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, INCX, LDA
REAL(8) :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zher(char uplo, int n, double alpha, doublecomplex *x, int incx, doublecomplex *a, int lda);
```

```
void zher_64(char uplo, long n, double alpha, doublecomplex *x, long incx, doublecomplex *a, long lda);
```

PURPOSE

zher performs the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

zher2 - perform the hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$

SYNOPSIS

```

```

```
void zher2_64(char uplo, long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zher2 performs the hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

*** UPLO (input)**

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

*** N (input)**

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar α . Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

*** Y (input)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

*** A (input/output)**

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

NAME

zher2k - perform one of the Hermitian rank 2k operations $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$
or $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$

SYNOPSIS

```

CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL(8) :: BETA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zher2k(char uplo, char transa, int n, int k, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb, double beta, doublecomplex *c, int ldc);
```

```
void zher2k_64(char uplo, char transa, long n, long k, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *b, long ldb, double beta, doublecomplex *c, long ldc);
```

PURPOSE

zher2k K performs one of the Hermitian rank 2k operations $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$ where alpha and beta are scalars with beta real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

*** B (input)**

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** C (input/output)**

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

zherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE ZHERFS( UPLO, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B, LDB,
*      X, LDX, FERR, BERR, WORK, WORK2, INFO)

```

PURPOSE

zherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The Hermitian matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. **AF** contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*H}$ or $A = L * D * L^{*H}$ as computed by CHETRF.

* **LDAF** (*input*)

The leading dimension of the array **AF**. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zherk - perform one of the Hermitian rank k operations $C := \alpha * A * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * A + \beta * C$

SYNOPSIS

```
SUBROUTINE ZHERK( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

INTEGER N, K, LDA, LDC
DOUBLE PRECISION ALPHA, BETA

SUBROUTINE ZHERK_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C,
*                   LDC)
CHARACTER * 1 UPLO, TRANSA
DOUBLE COMPLEX A(LDA,*), C(LDC,*)
INTEGER*8 N, K, LDA, LDC
DOUBLE PRECISION ALPHA, BETA
```

F95 INTERFACE

```
SUBROUTINE HERK( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
*              [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8), DIMENSION(:,*) :: A, C
INTEGER :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA

SUBROUTINE HERK_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
*                  C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8), DIMENSION(:,*) :: A, C
INTEGER(8) :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zherk(char uplo, char transa, int n, int k, double alpha, doublecomplex *a, int lda, double beta, doublecomplex *c, int ldc);
```

```
void zherk_64(char uplo, char transa, long n, long k, double alpha, doublecomplex *a, long lda, double beta, doublecomplex
```

*c, long ldc);

PURPOSE

zherk performs one of the Hermitian rank k operations $C := \alpha * A * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * A + \beta * C$ where alpha and beta are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $C := \alpha * A * \text{conjg}(A') + \beta * C$.

TRANS = 'C' or 'c' $C := \alpha * \text{conjg}(A') * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper

triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

SUBROUTINE HESV_64( UPLO, [N], [NRHS], A, [LDA], IPIVOT, B, [LDB],
* [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhesv(char uplo, int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zhesv_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhesv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**H}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**H}$ or $A = L * D * L^{**H}$ as computed by CHETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CHETRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The length of WORK. LDWORK ≥ 1 , and for best performance LDWORK $\geq N \cdot NB$, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

zhesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhesvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zhesvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zhesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A . The form of the factorization is

```
A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

*** LDA (input)**

The leading dimension of the array A. LDA \geq max(1,N).

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$.

*** LDAF (input)**

The leading dimension of the array AF. LDAF \geq max(1,N).

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) $>$ 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) $<$ 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) $<$ 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHETRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK $\geq 2*N$, and for best performance LDWORK $\geq N*NB$, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zhetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE ZHETF2( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
INTEGER IPIV(*)

SUBROUTINE ZHETF2_64( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE HETF2( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO

INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE HETF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhetf2(char uplo, int n, doublecomplex *a, int lda, int *ipiv, int *info);
```

```
void zhetf2_64(char uplo, long n, doublecomplex *a, long lda, long *ipiv, long *info);
```

PURPOSE

zhetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

C INTERFACE

```
#include <sunperf.h>
```

```
void zhetrdr(char uplo, int n, doublecomplex *a, int lda, double *d, double *e, doublecomplex *tau, int *info);
```

```
void zhetrdr_64(char uplo, long n, doublecomplex *a, long lda, double *d, double *e, doublecomplex *tau, long *info);
```

PURPOSE

zhetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation:
 $Q^{*H} * A * Q = T$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T: $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i, i+1)$ if UPLO = 'U', $E(i) = A(i+1, i)$ if UPLO = 'L'.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq 1$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

zhetrf - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE ZHETRF( UPLO, N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)

SUBROUTINE HETRF_64( UPLO, [N], A, [LDA], IPIVOT, [WORK], [LDWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhetrf(char uplo, int n, doublecomplex *a, int lda, int *ipivot, int *info);
```

```
void zhetrf_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zhetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U*D*U**H \quad \text{or} \quad A = L*D*L**H$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A . $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

*** LDWORK (input)**

The length of $WORK$. $LDWORK \geq 1$. For best performance $LDWORK \geq N*NB$, where NB is the block size returned by $ILAENV$.

*** INFO (output)**

NAME

zhetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF

SYNOPSIS

```
void zhetri(char uplo, int n, doublecomplex *a, int lda, int *ipivot, int *info);
```

```
void zhetri_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zhetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHETRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

zhets - solve a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by CHETRF

SYNOPSIS

```

```
void zhets(char uplo, int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zhets_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhetsr solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by CHETRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

zhgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues

$w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i) B) = 0$ If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right

SYNOPSIS

```
SUBROUTINE ZHGEQZ( JOB, COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB,
*      ALPHA, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)
CHARACTER * 1 JOB, COMPQ, COMPZ

REAL(8), DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhgeqz(char job, char compq, char compz, int n, int ilo, int ihi, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *alpha, doublecomplex *beta, doublecomplex *q, int ldq, doublecomplex *z, int ldz, int *info);
```

```
void zhgeqz_64(char job, char compq, char compz, long n, long ilo, long ihi, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *alpha, doublecomplex *beta, doublecomplex *q, long ldq, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation A are then $\text{ALPHA}(1),\dots,\text{ALPHA}(N)$, and of B are $\text{BETA}(1),\dots,\text{BETA}(N)$.

If $\text{JOB}='S'$ and COMPQ and COMPZ are 'V' or 'I', then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

$$(\text{in}) A(\text{in}) Z(\text{in})^* = Q(\text{out}) A(\text{out}) Z(\text{out})^* \quad (\text{in}) B(\text{in}) Z(\text{in})^* = Q(\text{out}) B(\text{out}) Z(\text{out})^*$$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

* **JOB** (input)

* **COMPQ** (input)

* **COMPZ** (input)

* **N** (input)

The order of the matrices A , B , Q , and Z . $N \geq 0$.

* **ILO** (input)

It is assumed that A is already upper triangular in rows and columns $1:\text{ILO}-1$ and $\text{IHI}+1:N$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

* **IHI** (input)

It is assumed that A is already upper triangular in rows and columns $1:\text{ILO}-1$ and $\text{IHI}+1:N$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

* **A** (input)

On entry, the N -by- N upper Hessenberg matrix A . Elements below the subdiagonal must be zero. If $\text{JOB}='S'$, then on exit A and B will have been simultaneously reduced to upper triangular form. If $\text{JOB}='E'$, then on exit A will have been destroyed.

* **LDA** (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

* **B** (input)

On entry, the N -by- N upper triangular matrix B . Elements below the diagonal must be zero. If $\text{JOB}='S'$, then on exit A and B will have been simultaneously reduced to upper triangular form. If $\text{JOB}='E'$, then on exit B will have been

destroyed.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **ALPHA (output)**

The diagonal elements of A when the pair (A,B) has been reduced to Schur form. $ALPHA(i)/BETA(i)$ $i=1,\dots,N$ are the generalized eigenvalues.

* **BETA (output)**

The diagonal elements of B when the pair (A,B) has been reduced to Schur form. $ALPHA(i)/BETA(i)$ $i=1,\dots,N$ are the generalized eigenvalues. A and B are normalized so that $BETA(1),\dots,BETA(N)$ are non-negative real numbers.

* **Q (input/output)**

If $COMPQ='N'$, then Q will not be referenced. If $COMPQ='V'$ or $'I'$, then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$. If $COMPQ='V'$ or $'I'$, then $LDQ \geq N$.

* **Z (input/output)**

If $COMPZ='N'$, then Z will not be referenced. If $COMPZ='V'$ or $'I'$, then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$. If $COMPZ='V'$ or $'I'$, then $LDZ \geq N$.

* **WORK (workspace)**

On exit, if $INFO \geq 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1,N)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

zhico - (obsolete) compute the UDU factorization and condition number of a Hermitian matrix A. If the condition number is not needed then xHIFA is slightly faster. It is typical to follow a call to xHICO with a call to xHISL to solve $Ax = b$ or to xHIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZHICO( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZHICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhico(doublecomplex *a, int lda, int n, int *ipivot, double *rcond);
```

```
void zhico_64(doublecomplex *a, long lda, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

zhidi - (obsolete) compute the determinant, inertia, and inverse of a Hermitian matrix A, which has been UDU-factored by CHICO or CHIFA.

SYNOPSIS

```
SUBROUTINE ZHIDI( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*), INERT(*)
DOUBLE PRECISION DET(*)
```

```
SUBROUTINE ZHIDI_64( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
DOUBLE PRECISION DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhidi(doublecomplex *a, int lda, int n, int *ipivot, double *det, int *inert, int job);
```

```
void zhidi_64(doublecomplex *a, long lda, long n, long *ipivot, double *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CHICO or CHIFA. On exit, if the c digit of JOB <> 0, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by CHICO or CHIFA.

*** DET (output)**

On exit, if the b digit of JOB ≥ 0 , then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0. If the b digit of JOB < 0 , DET is not referenced.

* **INERT (output)**

On exit, if the a digit of JOB $\neq 0$, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK (workspace)**

Scratch array with a dimension of N.

* **JOB (input)**

Integer in the form abc; determines operation the subroutine will perform:

a $\neq 0$	Compute the inertia.
b $\neq 0$	Compute the determinant.
c $\neq 0$	Compute the inverse.

NAME

zhifa - (obsolete) compute the UDU factorization of a Hermitian matrix A. It is typical to follow a call to CHIFA with a call to CHISL to solve $Ax = b$ or to CHIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZHIFA( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZHIFA_64( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhifa(doublecomplex *a, int lda, int n, int *ipivot, int *info);
```

```
void zhifa_64(doublecomplex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CHISL or CHIDI will divide by zero if called.

NAME

zhisl - (obsolete) solve the linear system $Ax = b$ for a Hermitian matrix A , which has been UDU-factored by CHICO or CHIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZHISL( A, LDA, N, IPIVOT, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N
INTEGER IPIVOT(*)

SUBROUTINE ZHISL_64( A, LDA, N, IPIVOT, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void zhisl(doublecomplex *a, int lda, int n, int *ipivot, doublecomplex *b);
void zhisl_64(doublecomplex *a, long lda, long n, long *ipivot, doublecomplex *b);
```

ARGUMENTS

- * **A** (*input*)
UDU factorization of the matrix A , as computed by CHICO or CHIFA.
- * **LDA** (*input*)
Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by CHICO or CHIFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

zhpc - (obsolete) compute the UDU factorization and condition number of a Hermitian matrix A in packed storage. If the condition number is not needed then xHPFA is slightly faster. It is typical to follow a call to xHPCO with a call to xHPSL to solve $Ax = b$ or to xHPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE ZHPCO( A, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZHPCO_64( A, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpc(doublecomplex *a, int n, int *ipivot, double *rcond);
```

```
void zhpc_64(doublecomplex *a, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A . $0.0 \leq RCOND \leq 1.0$. As the value of $RCOND$ gets smaller, operations with A such as solving $Ax = b$ may become less stable. If $RCOND$ satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

zhpccon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

SYNOPSIS

```
SUBROUTINE ZHPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND

SUBROUTINE ZHPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE HPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND

SUBROUTINE HPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpccon(char uplo, int n, doublecomplex *a, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zhpcon_64(char uplo, long n, doublecomplex *a, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zhpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CHPTRF.

*** ANORM (input)**

The 1-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

*** WORK (workspace)**

$\text{dimension}(2*N)$

*** INFO (output)**

NAME

zhpdi - (obsolete) compute the determinant, inertia, and inverse of a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA.

SYNOPSIS

```
SUBROUTINE ZHPDI( A, N, IPIVOT, DET, INERT, WORK, JOB)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, JOB
INTEGER IPIVOT(*), INERT(*)
DOUBLE PRECISION DET(*)
```

```
SUBROUTINE ZHPDI_64( A, N, IPIVOT, DET, INERT, WORK, JOB)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
DOUBLE PRECISION DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpdi(doublecomplex *a, int n, int *ipivot, double *det, int *inert, int job);
```

```
void zhpdi_64(doublecomplex *a, long n, long *ipivot, double *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix, as computed by CHPCO or CHPFA. On exit, if the c digit of JOB <> 0, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by CHPCO or CHPFA.

*** DET (output)**

On exit, if the b digit of JOB <> 0, then DET contains the determinant of the matrix A. The determinant is stored as b * (10 ** expon) where b is stored in DET(1) and expon is stored in DET(2). 1.0 <= |DET(1)| <= 10.0 or DET(1) = 0.0. If the b digit of JOB = 0, DET is not referenced.

*** INERT (output)**

On exit, if the a digit of JOB \neq 0, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation subroutine will perform:

a \neq 0 Compute the inertia.
b \neq 0 Compute the determinant.
c \neq 0 Compute the inverse.

NAME

zhpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

SYNOPSIS

COMPLEX(8), DIMENSION(:) :: A, WORK
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpev(char jobz, char uplo, int n, doublecomplex *a, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhpev_64(char jobz, char uplo, long n, doublecomplex *a, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension($\max(1,2*N-1)$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zhpevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

SYNOPSIS

```

CHARACTER(LEN=1) :: JOBZ, UPLO  
COMPLEX(8), DIMENSION(:) :: AP, WORK  
COMPLEX(8), DIMENSION(:, :) :: Z  
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpevd(char jobz, char uplo, int n, doublecomplex *ap, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhpevd_64(char jobz, char uplo, long n, doublecomplex *ap, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **AP** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least N. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* ***RWORK (workspace)***

dimension ($LRWORK$) On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal $LRWORK$.

* ***LRWORK (input)***

The dimension of array $RWORK$. If $N \leq 1$, $LRWORK$ must be at least 1. If $JOBZ = 'N'$ and $N > 1$, $LRWORK$ must be at least N . If $JOBZ = 'V'$ and $N > 1$, $LRWORK$ must be at least $1 + 5*N + 2*N**2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* ***IWORK (workspace)***

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* ***LIWORK (input)***

The dimension of array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$, $LIWORK$ must be at least $3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

* ***INFO (output)***

void zhpevx(char jobz, char range, char uplo, int n, doublecomplex *a, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, doublecomplex *z, int ldz, int *ifail, int *info);
```

```
void zhpevx_64(char jobz, char range, char uplo, long n, doublecomplex *a, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, doublecomplex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zhpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$ABTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

*** W (output)**

If INFO = 0, the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** IWORK3 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

zhpfa - (obsolete) compute the UDU factorization of a Hermitian matrix A in packed storage. It is typical to follow a call to CHPFA with a call to CHPSL to solve $Ax = b$ or to CHPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE ZHPFA( A, N, IPIVOT, INFO)
DOUBLE COMPLEX A(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZHPFA_64( A, N, IPIVOT, INFO)
DOUBLE COMPLEX A(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpfa(doublecomplex *a, int n, int *ipivot, int *info);
```

```
void zhpfa_64(doublecomplex *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the k th pivot block is singular to indicate that CHPSL or CHPDI will divide by zero if called.

NAME

zhpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

SYNOPSIS

```
SUBROUTINE ZHPGST( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), BP(*)
INTEGER ITYPE, N, INFO
```

```
SUBROUTINE ZHPGST_64( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), BP(*)
INTEGER*8 ITYPE, N, INFO
```

F95 INTERFACE

```
SUBROUTINE HPGST( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: AP, BP
INTEGER :: ITYPE, N, INFO
```

```
SUBROUTINE HPGST_64( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: AP, BP
INTEGER(8) :: ITYPE, N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpgst(int itype, char uplo, int n, doublecomplex *ap, doublecomplex *bp, int *info);
```

```
void zhpgst_64(long itype, char uplo, long n, doublecomplex *ap, doublecomplex *bp, long *info);
```

PURPOSE

zhpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**}H)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**}H)$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**}H$ or $L^{**}H*A*L$.

B must have been previously factorized as $U^{**}H*U$ or $L*L^{**}H$ by CPPTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *AP* (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *BP* (input)

The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

* *INFO* (output)

NAME

zhpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

SYNOPSIS

```
SUBROUTINE ZHPGV( ITYPE, JOBZ, UPLO, N, A, B, W, Z, LDZ, WORK,  
*              WORK2, INFO)  
CHARACTER * 1 JOBZ, UPLO

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpgv(int itype, char jobz, char uplo, int n, doublecomplex *a, doublecomplex *b, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhpgv_64(long itype, char jobz, char uplo, long n, doublecomplex *a, doublecomplex *b, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

*** B (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpgvd(int itype, char jobz, char uplo, int n, doublecomplex *ap, doublecomplex *bp, double *w, doublecomplex *z, int ldz, int *info);
```

```
void zhpgvd_64(long itype, char jobz, char uplo, long n, doublecomplex *ap, doublecomplex *bp, double *w, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{*}H^{*}B^{*}Z = I$; if $ITYPE = 3$, $Z^{*}H^{*}inv(B)^{*}Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* ***LDZ (input)***

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK (input)***

The dimension of array $WORK$. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 2*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

* ***RWORK (workspace)***

On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal $LRWORK$.

* ***LRWORK (input)***

The dimension of array $RWORK$. If $N \leq 1$, $LRWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LRWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LRWORK \geq 1 + 5*N + 2*N^{*}2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* ***IWORK (workspace)***

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* ***LIWORK (input)***

The dimension of array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

* ***INFO (output)***

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpgvx(int itype, char jobz, char range, char uplo, int n, doublecomplex *ap, doublecomplex *bp, double vl, double vu, int il, int iu, double abstol, int *m, double *w, doublecomplex *z, int ldz, int *ifail, int *info);
```

```
void zhpgvx_64(long itype, char jobz, char range, char uplo, long n, doublecomplex *ap, doublecomplex *bp, double vl, double vu, long il, long iu, double abstol, long *m, double *w, doublecomplex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zhpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$, in the same storage format as B.

*** VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

*** VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^* H^* B^* Z = I$; if $ITYPE = 3$, $Z^* H^* \text{inv}(B)^* Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(2*N)

*** RWORK (workspace)**

dimension(7*N)

*** IWORK (workspace)**

dimension(5*N)

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

zhpmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE ZHPMV( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(*), X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZHPMV_64( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(*), X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HPMV( UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: A, X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE HPMV_64( UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: A, X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpmv(char uplo, int n, doublecomplex alpha, doublecomplex *a, doublecomplex *x, int incx, doublecomplex beta, doublecomplex *y, int incy);
```

```
void zhpmv_64(char uplo, long n, doublecomplex alpha, doublecomplex *a, doublecomplex *x, long incx, doublecomplex beta, doublecomplex *y, long incy);
```

PURPOSE

zhpmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

zhpr - perform the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$

SYNOPSIS

```
SUBROUTINE ZHPR( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
DOUBLE COMPLEX X(*), A(*)
INTEGER N, INCX
DOUBLE PRECISION ALPHA
```

```
SUBROUTINE ZHPR_64( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO

```

```
SUBROUTINE HPR_64( UPLO, [N], ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: X, A
INTEGER(8) :: N, INCX
REAL(8) :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpr(char uplo, int n, double alpha, doublecomplex *x, int incx, doublecomplex *a);
```

```
void zhpr_64(char uplo, long n, double alpha, doublecomplex *x, long incx, doublecomplex *a);
```

PURPOSE

zhpr performs the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

NAME

zhpr2 - perform the Hermitian rank 2 operation $A := \alpha * x * \text{conj}(y') + \text{conj}(\alpha) * y * \text{conj}(x') + A$

SYNOPSIS

CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y, A
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE HPR2_64( UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A)
CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y, A
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpr2(char uplo, int n, doublecomplex alpha, doublecomplex *x, int incx, doublecomplex *y, int incy, doublecomplex *a);
```

```
void zhpr2_64(char uplo, long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a);
```

PURPOSE

zhpr2 performs the Hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

NAME

zhprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

```

PURPOSE

zhprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

zhpsl - (obsolete) solve the linear system $Ax = b$ for a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA, and vectors b and x .

SYNOPSIS

```

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpsv(char uplo, int n, int nrhs, doublecomplex *a, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zhpsv_64(char uplo, long n, long nrhs, doublecomplex *a, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhpsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**H}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**H}$ or $A = L * D * L^{**H}$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

zhpsvx - use the diagonal pivoting factorization $A = U*D*U**H$ or $A = L*D*L**H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpsvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, doublecomplex *af, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zhpsvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *af, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zhpsvx uses the diagonal pivoting factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as $A = U * D * U^{**}H$, if $UPLO = 'U'$, or

```
    A = L * D * L^{**}H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A .
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

zhptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

```

```
void zhptrd_64(char uplo, long n, doublecomplex *ap, double *d, double *e, doublecomplex *tau, long *info);
```

PURPOSE

zhptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **AP** (*input*)

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if $UPLO = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array TAU , represent the unitary matrix Q as a product of elementary reflectors; if $UPLO$

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T : $D(i) = A(i,i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i,i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1,i)$ if $UPLO = 'L'$.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **INFO** (*output*)

NAME

zhptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE ZHPTRF( UPLO, N, A, IPIVOT, INFO)

#include <sunperf.h>

void zhptrf(char uplo, int n, doublecomplex *a, int *ipivot, int *info);

void zhptrf_64(char uplo, long n, doublecomplex *a, long *ipivot, long *info);
```

PURPOSE

zhptf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{*H} \quad \text{or} \quad A = L^*D^*L^{*H}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L , stored as a packed triangular matrix overwriting A (see below for further details).

* *IPIVOT* (output)

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

* *INFO* (output)

NAME

zhptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

SYNOPSIS

```
SUBROUTINE ZHPTRI( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO

INTEGER IPIVOT(*)

SUBROUTINE ZHPTRI_64( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HPTRI( UPLO, [N], A, IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE HPTRI_64( UPLO, [N], A, IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zhptri(char uplo, int n, doublecomplex *a, int *ipivot, int *info);

void zhptri_64(char uplo, long n, doublecomplex *a, long *ipivot, long *info);
```

PURPOSE

zhptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if $INFO = 0$, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j -th column of $inv(A)$ is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = inv(A)(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = inv(A)(i,j)$ for $j \leq i \leq n$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHPTRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

zhptrs - solve a system of linear equations $A^*X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

SYNOPSIS

COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE HPTRS_64( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhptrs(char uplo, int n, int nrhs, doublecomplex *a, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zhptrs_64(char uplo, long n, long nrhs, doublecomplex *a, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zhptrs solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{*H}$ or $A = L \cdot D \cdot L^{*H}$ computed by CHPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHPTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void zhsein(char side, char eigsrc, char initv, logical *select, int n, doublecomplex *h, int ldh, doublecomplex *w,  
doublecomplex *vl, int ldvl, doublecomplex *vr, int ldvr, int mm, int *m, int *ifail, int *ifailr, int *info);
```

```
void zhsein_64(char side, char eigsrc, char initv, logical *select, long n, doublecomplex *h, long ldh, doublecomplex *w,  
doublecomplex *vl, long ldvl, doublecomplex *vr, long ldvr, long mm, long *m, long *ifail, long *ifailr, long *info);
```

PURPOSE

zhsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

* *SIDE (input)*

* *EIGSRC (input)*

Specifies the source of eigenvalues supplied in W:

* *INITV (input)*

* *SELECT (input)*

Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue W(j), SELECT(j) must be set to .TRUE..

* *N (input)*

The order of the matrix H. N >= 0.

* *H (input)*

The upper Hessenberg matrix H.

* *LDH (input)*

The leading dimension of the array H. LDH >= max(1,N).

* *W (input/output)*

On entry, the eigenvalues of H. On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

* *VL (input/output)*

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. LDVL $\geq \max(1, N)$ if SIDE = 'L' or 'B'; LDVL ≥ 1 otherwise.

*** VR (input/output)**

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. LDVR $\geq \max(1, N)$ if SIDE = 'R' or 'B'; LDVR ≥ 1 otherwise.

*** MM (input)**

The number of columns in the arrays VL and/or VR. MM $\geq M$.

*** M (output)**

The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

*** WORK (workspace)**

dimension(N*N)

*** RWORK (workspace)**

dimension(N)

*** IFAILL (output)**

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

*** IFAILR (output)**

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

*** INFO (output)**

NAME

zhseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{*} H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

SYNOPSIS

```
SUBROUTINE ZHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH, W, Z, LDZ, WORK,
*                LWORK, INFO)

SUBROUTINE HSEQR( JOB, COMPZ, N, ILO, IHI, H, [LDH], W, Z, [LDZ],
*               [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
COMPLEX(8), DIMENSION(:) :: W, WORK
COMPLEX(8), DIMENSION(:, :) :: H, Z
INTEGER :: N, ILO, IHI, LDH, LDZ, LWORK, INFO

SUBROUTINE HSEQR_64( JOB, COMPZ, N, ILO, IHI, H, [LDH], W, Z, [LDZ],
*                  [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
COMPLEX(8), DIMENSION(:) :: W, WORK
COMPLEX(8), DIMENSION(:, :) :: H, Z
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhseqr(char job, char compz, int n, int ilo, int ihi, doublecomplex *h, int ldh, doublecomplex *w, doublecomplex *z, int ldz, int *info);
```

```
void zhseqr_64(char job, char compz, long n, long ilo, long ihi, doublecomplex *h, long ldh, doublecomplex *w,
```

doublecomplex *z, long ldz, long *info);

PURPOSE

zhseqr computes the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**}H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q: $A = Q^{*}H^{*}Q^{**}H = (QZ)^{*}T^{*}(QZ)^{**}H$.

ARGUMENTS

* **JOB** (*input*)

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix H. $N \geq 0$.

* **ILO** (*input*)

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **IHI** (*input*)

See the description of ILO.

* **H** (*input/output*)

On entry, the upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If JOB = 'E', the contents of H are unspecified on exit.

* **LDH** (*input*)

The leading dimension of the array H. $LDH \geq \max(1,N)$.

* **W** (*output*)

The computed eigenvalues. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with $W(i) = H(i,i)$.

* **Z** (*input*)

If COMPZ = 'N': Z is not referenced.

If COMPZ = 'I': on entry, Z need not be set, and on exit, Z contains the unitary matrix Z of the Schur vectors of H. If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI); on exit Z contains $Q^{*}Z$. Normally Q is the unitary matrix generated by CUNGHR after the call to CGEHRD which formed the Hessenberg matrix H.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq \max(1,N)$ if COMPZ = 'I' or 'V'; $LDZ \geq 1$ otherwise.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK $\geq \max(1, N)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (output)

NAME

zlarz - apply a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right

SYNOPSIS

```

* [WORK])
CHARACTER(LEN=1) :: SIDE
COMPLEX(8) :: TAU
COMPLEX(8), DIMENSION(:) :: V, WORK
COMPLEX(8), DIMENSION(:, :) :: C
INTEGER(8) :: M, N, L, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zlarz(char side, int m, int n, int l, doublecomplex *v, int incv, doublecomplex tau, doublecomplex *c, int ldc);
```

```
void zlarz_64(char side, long m, long n, long l, doublecomplex *v, long incv, doublecomplex tau, doublecomplex *c, long ldc);
```

PURPOSE

zlarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C.

* **N** (*input*)

The number of columns of the matrix C.

* **L** (*input*)

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

* **V** (*input*)

The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

* **INCV** (*input*)

The increment between elements of v. INCV <> 0.

* **TAU** (*input*)

The value tau in the representation of H.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

* **LDC** (*input*)

The leading dimension of the array C. LDC >= max(1,M).

* **WORK** (*workspace*)

(N) if SIDE = 'L' or (M) if SIDE = 'R'. SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

void zlarzb_64(char side, char trans, char direct, char storev, long m, long n, long k, long l, doublecomplex *v, long ldv, doublecomplex *t, long ldt, doublecomplex *c, long ldc, long ldwork);
```

PURPOSE

zlarzb applies a complex block reflector H or its transpose H^*H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **DIRECT** (*input*)

Indicates how H is formed from a product of elementary reflectors

* **STOREV** (*input*)

Indicates how the vectors which define the elementary reflectors are stored:

* **M** (*input*)

The number of rows of the matrix C.

* **N** (*input*)

The number of columns of the matrix C.

* **K** (*input*)

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

* **L** (*input*)

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **V** (*input*)

If STOREV = 'C', $NV = K$; if STOREV = 'R', $NV = L$.

* **LDV** (*input*)

The leading dimension of the array V. If STOREV = 'C', $LDV \geq L$; if STOREV = 'R', $LDV \geq K$.

* **T** (*input*)

The triangular K-by-K matrix T in the representation of the block reflector.

* **LDT** (*input*)

The leading dimension of the array T. $LDT \geq K$.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* **WORK** (*workspace*)

$\text{dimension}(\max(M,N),K)$

* **LDWORK** (*input*)

The leading dimension of the array WORK. If SIDE = 'L', $LDWORK \geq \max(1,N)$; if SIDE = 'R', $LDWORK \geq \max(1,M)$.

NAME

zlarzt - form the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE ZLARZT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER N, K, LDV, LDT
```

```
SUBROUTINE ZLARZT_64( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:, :) :: V, T
INTEGER :: N, K, LDV, LDT
```

```
SUBROUTINE LARZT_64( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:, :) :: V, T
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zlarzt(char direct, char storev, int n, int k, doublecomplex *v, int ldv, doublecomplex *tau, doublecomplex *t, int ldt);
```

```
void zlarzt_64(char direct, char storev, long n, long k, doublecomplex *v, long ldv, doublecomplex *tau, doublecomplex *t, long ldt);
```

PURPOSE

zlarzt forms the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If $DIRECT = 'F'$, $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If $DIRECT = 'B'$, $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If $STOREV = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array V , and

$$H = I - V * T * V'$$

If $STOREV = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array V , and

$$H = I - V' * T * V$$

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

*** *DIRECT* (input)**

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

*** *STOREV* (input)**

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):

*** *N* (input)**

The order of the block reflector H . $N \geq 0$.

*** *K* (input)**

The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

*** *V* (input)**

(LDV,K) if $STOREV = 'C'$ (LDV,N) if $STOREV = 'R'$ The matrix V . See further details.

*** *LDV* (input)**

The leading dimension of the array V . If $STOREV = 'C'$, $LDV \geq \max(1,N)$; if $STOREV = 'R'$, $LDV \geq K$.

*** *TAU* (input)**

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$.

*** *T* (input)**

The k by k triangular factor T of the block reflector. If $DIRECT = 'F'$, T is upper triangular; if $DIRECT = 'B'$, T is lower triangular. The rest of the array is not used.

*** *LDT* (input)**

The leading dimension of the array T . $LDT \geq K$. .SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following

example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

$V =$	<pre> (v1 v2 v3) 1 . . . 1 . . . 1 </pre>	V	<pre> /-----V-----\ (v1 v1 v1 v1 v1 1) (v2 v2 v2 v2 v2 1) (v3 v3 v3 v3 v3 . . 1 . .) </pre>
-------	---	-----	---

DIRECT = 'B' and STOREV = 'C': DIRECT = 'B' and STOREV = 'R':

$V =$	<pre> 1 . 1 . . 1 (v1 v2 v3) </pre>	V	<pre> /-----V-----\ (1 v1 v1 v1 v1 v1) (. 1 v2 v2 v2 v2 v2) (. . 1 . . . v3 v3 v3 v3 v3) </pre>
-------	---	-----	---

```

(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

* **C2 (input/output)**

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

* **LDC (input)**

The leading dimension of the arrays C1 and C2. LDC \geq max(1,M).

* **WORK (workspace)**

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

zpbco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then xPBFA is slightly faster. It is typical to follow a call to xPBCO with a call to xPBSL to solve $Ax = b$ or to xPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE ZPBCO( A, LDA, N, NDIAG, RCOND, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, NDIAG, INFO
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZPBCO_64( A, LDA, N, NDIAG, RCOND, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, NDIAG, INFO
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbco(doublecomplex *a, int lda, int n, int ndiag, double *rcond, int *info);
```

```
void zpbco_64(doublecomplex *a, long lda, long n, long ndiag, double *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N \neq 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

zpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF

SYNOPSIS

```
SUBROUTINE ZPBCON( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,
*                WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, NDIAG, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)

SUBROUTINE ZPBCON_64( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,
*                   WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, NDIAG, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PBCON( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],
*               [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE PBCON_64( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],
*                   [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbcon(char uplo, int n, int ndiag, doublecomplex *a, int lda, double anorm, double *rcond, int *info);
```

```
void zpbcon_64(char uplo, long n, long ndiag, doublecomplex *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

zpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'.
 $\text{NDIAG} \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ of the band matrix A, stored in the first $\text{NDIAG}+1$ rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(\text{kd}+1+i-j, j) = U(i, j)$ for $\max(1, j-\text{kd}) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$ for $j \leq i \leq \min(n, j+\text{kd})$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \text{NDIAG}+1$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian band matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zpbdi - (obsolete) compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA.

SYNOPSIS

```
SUBROUTINE ZPBDI( A, LDA, N, NDIAG, DET)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, NDIAG
DOUBLE PRECISION DET(*)

SUBROUTINE ZPBDI_64( A, LDA, N, NDIAG, DET)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, NDIAG
DOUBLE PRECISION DET(*)
```

C INTERFACE

```
#include <sunperf.h>

void zpbdi(doublecomplex *a, int lda, int n, int ndiag, double *det);
void zpbdi_64(doublecomplex *a, long lda, long n, long ndiag, double *det);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A, as computed by CPBCO or CPBFA.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= NDIAG + 1.

* **N** (*input*)

Order of the original matrix A. N >= 0.

* **NDIAG** (*input*)

Number of diagonals. N-1 >= NDIAG >= 0 but if N = 0 then NDIAG = 0.

* **DET** (*output*)

On exit, the determinant of the matrix A. The determinant is stored as b * (10 ** expon) where b is stored in DET(1) and expon is stored in DET(2). 1.0 <= |DET(1)| <= 10.0 or DET(1) = 0.0.

NAME

zpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE ZPBEQU( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, NDIAG, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

```
SUBROUTINE ZPBEQU_64( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX,
* INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, NDIAG, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbequ(char uplo, int n, int ndiag, doublecomplex *a, int lda, double *scale, double *scond, double *amax, int *info);
```

```
void zpbequ_64(char uplo, long n, long ndiag, doublecomplex *a, long lda, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

zpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **SCALE** (*output*)

If $INFO = 0$, $SCALE$ contains the scale factors for A .

* **SCOND** (*output*)

If $INFO = 0$, $SCALE$ contains the ratio of the smallest $SCALE(i)$ to the largest $SCALE(i)$. If $SCOND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by $SCALE$.

* **AMAX** (*output*)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

zpbfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to CPBFA with a call to CPBSL to solve $Ax = b$ or to CPBDI to compute the determinant of A.

SYNOPSIS

REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbrfs(char uplo, int n, int ndiag, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zpbrfs_64(char uplo, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) < i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j < i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A as computed by CPBTRF, in the same storage format as A (see A).

* **LDAF** (*input*)

The leading dimension of the array AF. LDAF \geq NDIAG+1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. LDB \geq max(1,N).

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zpbsl - (obsolete) section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZPBSL( A, LDA, N, NDIAG, B)
DOUBLE COMPLEX A(LDA,*), B(*)

```

```
void zpbsl_64(doublecomplex *a, long lda, long n, long ndiag, doublecomplex *b);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by CPBCO or CPBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** NDIAG (input)**

Number of diagonals of matrix A . $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

zpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE ZPBSTF( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AB(LDAB,*)
INTEGER N, KD, LDAB, INFO
```

```
SUBROUTINE ZPBSTF_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AB(LDAB,*)
INTEGER*8 N, KD, LDAB, INFO
```

F95 INTERFACE

```
SUBROUTINE PBSTF( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: AB
INTEGER :: N, KD, LDAB, INFO
```

```
SUBROUTINE PBSTF_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbstf(char uplo, int n, int kd, doublecomplex *ab, int ldab, int *info);
```

```
void zpbstf_64(char uplo, long n, long kd, doublecomplex *ab, long ldab, long *info);
```

PURPOSE

zpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.

The factorization has the form $A = S^{**}H^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & M & L \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A. $N \geq 0$.

* *KD* (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* *AB* (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^{**}H^*S$. See Further Details.

* *LDAB* (input)

The leading dimension of the array AB. $LDAB \geq kd+1$.

* *INFO* (output)

NAME

zpbsv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```

* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbsv(char uplo, int n, int ndiag, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zpbsv_64(char uplo, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpbsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite band matrix and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{*H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{*H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** NDIAG (input)**

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U^{*H} * U$ or $A = L * L^{*H}$ of the band matrix A , in the same storage format as A .

*** LDA (input)**

The leading dimension of the array A . $LDA \geq NDIAG+1$.

*** B (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

zpbsvx - use the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbsvx(char fact, char uplo, int n, int ndiag, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, char equed, double *scale, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zpbsvx_64(char fact, char uplo, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, char equed, double *scale, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zpbsvx uses the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B  
Whether or not the system will be equilibrated depends on the  
scaling of the matrix A, but if equilibration is used, A is  
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{*}H^{*}U$, if UPLO = 'U', or

```
A = L * L^{*}H, if UPLO = 'L',  
where U is an upper triangular band matrix, and L is a lower  
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* *NDIAG* (input)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* *NRHS* (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X . $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $NDIAG+1$ rows of the array, except if $FACT = 'F'$ and $EQUED = 'Y'$, then A must contain the equilibrated matrix $\text{diag}(SCALE)*A*\text{diag}(SCALE)$. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if $FACT = 'E'$ and $EQUED = 'Y'$, A is overwritten by $\text{diag}(SCALE)*A*\text{diag}(SCALE)$.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* *AF* (input/output)

If $FACT = 'F'$, then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the band matrix A , in the same storage format as A (see A). If $EQUED = 'Y'$, then AF is the factored form of the equilibrated matrix A .

If $FACT = 'N'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$.

If $FACT = 'E'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF . $LDAF \geq NDIAG+1$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A ; not accessed if $EQUED = 'N'$. $SCALE$ is an input argument if $FACT = 'F'$; otherwise, $SCALE$ is an output argument. If $FACT = 'F'$ and $EQUED = 'Y'$, each element of $SCALE$ must be positive.

* *B* (input/output)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $EQUED = 'N'$, B is not modified; if $EQUED = 'Y'$, B is overwritten by $\text{diag}(SCALE) * B$.

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* *X* (output)

If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X to the original system of equations. Note that if

EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* **LDX** (*input*)

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $\text{RCOND} = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $\text{INFO} > 0$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $\text{FERR}(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - \text{XTRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE ZPBTF2( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AB(LDAB,*)
INTEGER N, KD, LDAB, INFO
```

```
SUBROUTINE ZPBTF2_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX AB(LDAB,*)
INTEGER*8 N, KD, LDAB, INFO
```

F95 INTERFACE

```
SUBROUTINE PBTf2( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: AB
INTEGER :: N, KD, LDAB, INFO
```

```
SUBROUTINE PBTf2_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbtf2(char uplo, int n, int kd, doublecomplex *ab, int ldab, int *info);
```

```
void zpbtf2_64(char uplo, long n, long kd, doublecomplex *ab, long ldab, long *info);
```

PURPOSE

zpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** KD (input)**

The number of super-diagonals of the matrix A if $UPLO = 'U'$, or the number of sub-diagonals if $UPLO = 'L'$. $KD \geq 0$.

*** AB (input/output)**

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U'U$ or $A = L'L'$ of the band matrix A, in the same storage format as A.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq KD+1$.

*** INFO (output)**

NAME

zpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE ZPBTRF( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, NDIAG, LDA, INFO
```

```
SUBROUTINE ZPBTRF_64( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, NDIAG, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE PBTRF( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INFO
```

```
SUBROUTINE PBTRF_64( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbtrf(char uplo, int n, int ndiag, doublecomplex *a, int lda, int *info);
```

```
void zpbtrf_64(char uplo, long n, long ndiag, doublecomplex *a, long lda, long *info);
```

PURPOSE

zpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{*H} * U, & \text{if } \text{UPLO} = 'U', & \text{ or} \\ A &= L * L^{*H}, & \text{if } \text{UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L^*L^{*H}$ of the band matrix A, in the same storage format as A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \text{NDIAG}+1$.

* **INFO** (*output*)

NAME

zpbtrs - solve a system of linear equations $A^*X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPBTRF

SYNOPSIS

```
SUBROUTINE ZPBTRS( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO

SUBROUTINE PBTRS_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
*                  [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbtrs(char uplo, int n, int ndiag, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zpbtrs_64(char uplo, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpbtrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPBTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ of the band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

zpoco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then xPOFA is slightly faster. It is typical to follow a call to xPOCO with a call to xPOSL to solve $Ax = b$ or to xPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZPOCO( A, LDA, N, RCOND, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, INFO
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZPOCO_64( A, LDA, N, RCOND, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, INFO
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpoco(doublecomplex *a, int lda, int n, double *rcond, int *info);
```

```
void zpoco_64(doublecomplex *a, long lda, long n, double *rcond, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

zpocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPOTRF

SYNOPSIS

```
SUBROUTINE ZPOCON( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)

SUBROUTINE ZPOCON_64( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE POCON( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE POCON_64( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpocon(char uplo, int n, doublecomplex *a, int lda, double anorm, double *rcond, int *info);
```

```
void zpocon_64(char uplo, long n, doublecomplex *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

zpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ computed by CPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$, as computed by CPOTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zpodl - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by CPOCO, CPOFA, or CQRDC.

SYNOPSIS

```
SUBROUTINE ZPODI( A, LDA, N, DET, JOB)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, JOB
DOUBLE PRECISION DET(*)

SUBROUTINE ZPODI_64( A, LDA, N, DET, JOB)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, JOB
DOUBLE PRECISION DET(*)
```

C INTERFACE

```
#include <sunperf.h>

void zpodl(doublecomplex *a, int lda, int n, double *det, int job);

void zpodl_64(doublecomplex *a, long lda, long n, double *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by CPOCO, CPOFA, or CQRDC. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA $\geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. N ≥ 0 .

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0.

*** JOB (input)**

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

zpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE ZPOEQU( N, A, LDA, SCALE, SCOND, AMAX, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

```
SUBROUTINE ZPOEQU_64( N, A, LDA, SCALE, SCOND, AMAX, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE POEQU_64( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpoequ(int n, doublecomplex *a, int lda, double *scale, double *scond, double *amax, int *info);
```

```
void zpoequ_64(long n, doublecomplex *a, long lda, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

zpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** SCALE (output)**

If INFO = 0, SCALE contains the scale factors for A.

*** SCOND (output)**

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

zpofo - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to CPOFA with a call to CPOSL to solve $Ax = b$ or to CPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZPOFA( A, LDA, N, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
```

```
SUBROUTINE ZPOFA_64( A, LDA, N, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpofo(doublecomplex *a, int lda, int n, int *info);
```

```
void zpofo_64(doublecomplex *a, long lda, long n, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

zporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

SYNOPSIS

```
SUBROUTINE ZPORFS( UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
*      FERR, BERR, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), WORK(*)

DOUBLE COMPLEX A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), WORK(*)
INTEGER*8 N, NRHS, LDA, LDAF, LDB, LDX, INFO
DOUBLE PRECISION FERR(*), BERR(*), WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PORFS( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B, [LDB],
*      X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A, AF, B, X
INTEGER :: N, NRHS, LDA, LDAF, LDB, LDX, INFO
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2

SUBROUTINE PORFS_64( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B,
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A, AF, B, X
INTEGER(8) :: N, NRHS, LDA, LDAF, LDB, LDX, INFO
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zporfs(char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zporfs_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$, as computed by CPOTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

zposl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by CPOCO or CPOFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZPOSL( A, LDA, N, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N
```

```
SUBROUTINE ZPOSL_64( A, LDA, N, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zposl(doublecomplex *a, int lda, int n, doublecomplex *b);
```

```
void zposl_64(doublecomplex *a, long lda, long n, doublecomplex *b);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by CPOCO or CPOFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

zposv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE ZPOSV( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE ZPOSV_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE POSV( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE POSV_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zposv(char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zposv_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zposv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**H} * U, & \text{if } \text{UPLO} = \text{'U'}, & \text{ or} \\ A &= L * L^{**H}, & \text{if } \text{UPLO} = \text{'L'}, \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $\text{NRHS} \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If $\text{UPLO} = \text{'U'}$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $\text{UPLO} = \text{'L'}$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $\text{INFO} = 0$, the factor U or L from the Cholesky factorization $A = U^{**H} * U$ or $A = L * L^{**H}$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $\text{INFO} = 0$, the N-by-NRHS solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

* **INFO** (*output*)

NAME

zposvx - use the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zposvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, char equed, double *scale, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zposvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, char equed, double *scale, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zposvx uses the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B  
Whether or not the system will be equilibrated depends on the  
scaling of the matrix A, but if equilibration is used, A is  
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{*}H^{*}U$, if UPLO = 'U', or

```
A = L * L^{*}H, if UPLO = 'L',  
where U is an upper triangular matrix and L is a lower triangular  
matrix.
```

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the Hermitian matrix A, except if *FACT* = 'F' and *EQUED* = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. If *UPLO* = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *FACT* = 'E' and *EQUED* = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *AF* (output)

If *FACT* = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$, in the same storage format as A. If *EQUED* = 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

If *FACT* = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$ of the original matrix A.

If *FACT* = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if *EQUED* = 'N'. *SCALE* is an input argument if *FACT* = 'F'; otherwise, *SCALE* is an output argument. If *FACT* = 'F' and *EQUED* = 'Y', each element of *SCALE* must be positive.

* *B* (input/output)

On entry, the N-by-NRHS righthand side matrix B. On exit, if *EQUED* = 'N', B is not modified; if *EQUED* = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *X* (output)

If *INFO* = 0 or *INFO* = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if *EQUED* = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

zpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

SYNOPSIS

```
SUBROUTINE ZPOTF2( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE ZPOTF2_64( UPLO, N, A, LDA, INFO)

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE POTF2_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpotf2(char uplo, int n, doublecomplex *a, int lda, int *info);
```

```
void zpotf2_64(char uplo, long n, doublecomplex *a, long lda, long *info);
```

PURPOSE

zpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', & \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** INFO (output)**

```

```
void zpotrf(char uplo, int n, doublecomplex *a, int lda, int *info);
```

```
void zpotrf_64(char uplo, long n, doublecomplex *a, long lda, long *info);
```

PURPOSE

zpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**H}U$ or $A = L * L^{**H}$.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

zpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF

SYNOPSIS

```
SUBROUTINE ZPOTRI( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE ZPOTRI_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTRI( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE POTRI_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpotri(char uplo, int n, doublecomplex *a, int lda, int *info);
```

```
void zpotri_64(char uplo, long n, doublecomplex *a, long lda, long *info);
```

PURPOSE

zpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$, as computed by CPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

zpotrs - solve a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U \cdot H \cdot U$ or $A = L \cdot L^H$ computed by CPOTRF

SYNOPSIS

```
SUBROUTINE ZPOTRS( UPLO, N, NRHS, A, LDA, B, LDB, INFO)

```

```
void zpotrs(char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void zpotrs_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpotrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPOTRF.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$, as computed by CPOTRF.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

zppco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then CPPFA is slightly faster. It is typical to follow a call to CPPCO with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZPPCO( A, N, RCOND, WORK, INFO)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, INFO
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZPPCO_64( A, N, RCOND, WORK, INFO)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppco(doublecomplex *a, int n, double *rcond, int *info);
```

```
void zppco_64(doublecomplex *a, long n, double *rcond, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N <> 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

zppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

SYNOPSIS

```
SUBROUTINE ZPPCON( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)

SUBROUTINE ZPPCON_64( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE PPCON_64( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppcon(char uplo, int n, doublecomplex *a, double anorm, double *rcond, int *info);
```

```
void zppcon_64(char uplo, long n, doublecomplex *a, double anorm, double *rcond, long *info);
```

PURPOSE

zppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

$\text{dimension}(2*N)$

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zppdi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA.

SYNOPSIS

```
SUBROUTINE ZPPDI( A, N, DET, JOB)
DOUBLE COMPLEX A(*)
INTEGER N, JOB
DOUBLE PRECISION DET(*)

SUBROUTINE ZPPDI_64( A, N, DET, JOB)
DOUBLE COMPLEX A(*)
INTEGER*8 N, JOB
DOUBLE PRECISION DET(*)
```

C INTERFACE

```
#include <sunperf.h>

void zppdi(doublecomplex *a, int n, double *det, int job);

void zppdi_64(doublecomplex *a, long n, double *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by CPPCO or CPPFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse
- o 01 inverse only

- 10 determinant only

NAME

zppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE ZPPEQU( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*)
INTEGER N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

```
SUBROUTINE ZPPEQU_64( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*)
INTEGER*8 N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
INTEGER :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE PPEQU_64( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
INTEGER(8) :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppequ(char uplo, int n, doublecomplex *a, double *scale, double *scond, double *amax, int *info);
```

```
void zppequ_64(char uplo, long n, doublecomplex *a, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

zppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **SCALE** (*output*)

If $INFO = 0$, $SCALE$ contains the scale factors for A .

* **SCOND** (*output*)

If $INFO = 0$, $SCALE$ contains the ratio of the smallest $SCALE(i)$ to the largest $SCALE(i)$. If $SCOND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by $SCALE$.

* **AMAX** (*output*)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

zppfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to CPPFA with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZPPFA( A, N, INFO)

```

F95 INTERFACE

```
SUBROUTINE PPRFS( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX], FERR,
*      BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, AF, WORK
COMPLEX(8), DIMENSION(:, :) :: B, X
INTEGER :: N, NRHS, LDB, LDX, INFO
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2

SUBROUTINE PPRFS_64( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX],
*      FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, AF, WORK
COMPLEX(8), DIMENSION(:, :) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpprfs(char uplo, int n, int nrhs, doublecomplex *a, doublecomplex *af, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zpprfs_64(char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *af, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**H}U$ or $A = L*L^{**H}$, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

zpsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZPPSL( A, N, B)

INTEGER*8 N, NRHS, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE PPSV( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE PPSV_64( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppsv(char uplo, int n, int nrhs, doublecomplex *a, doublecomplex *b, int ldb, int *info);
```

```
void zppsv_64(char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zppsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** *UPLO* (input)**

*** *N* (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** *NRHS* (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** *A* (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**H} * U$ or $A = L * L^{**H}$, in the same storage format as A .

*** *B* (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** *LDB* (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** *INFO* (output)**

COMPLEX(8), DIMENSION(:, :) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: SCALE, FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppsvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, doublecomplex *af, char equed, double *scale, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zppsvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *af, char equed, double *scale, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zppsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^*U$, if UPLO = 'U', or

```
A = L * L', if UPLO = 'L',
```

where U is an upper triangular matrix, L is a lower triangular matrix, and ' indicates conjugate transpose.

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if $FACT = 'F'$ and $EQUED = 'Y'$, then A must contain the equilibrated matrix $diag(SCALE)*A*diag(SCALE)$. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if $FACT = 'F'$ or $'N'$, or if $FACT = 'E'$ and $EQUED = 'N'$ on exit.

On exit, if $FACT = 'E'$ and $EQUED = 'Y'$, A is overwritten by $diag(SCALE)*A*diag(SCALE)$.

* *AF* (input/output)

If $FACT = 'F'$, then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$, in the same storage format as A. If $EQUED = 'N'$, then AF is the factored form of the equilibrated matrix A.

If $FACT = 'N'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the original matrix A.

If $FACT = 'E'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if $EQUED = 'N'$. SCALE is an input argument if $FACT = 'F'$; otherwise, SCALE is an output argument. If $FACT = 'F'$ and $EQUED = 'Y'$, each element of SCALE must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $EQUED = 'N'$, B is not modified; if $EQUED = 'Y'$, B is overwritten by $diag(SCALE) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *X* (output)

If $INFO = 0$ or $INFO = N+1$, the N-by-NRHS solution matrix X to the original system of equations. Note that if $EQUED = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(SCALE))*X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* *RCOND* (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

* *FERR* (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

zpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE ZPPTRF( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpptrf(char uplo, int n, doublecomplex *a, int *info);
```

```
void zpptrf_64(char uplo, long n, doublecomplex *a, long *info);
```

PURPOSE

zpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**H}U$ or $A = L*L^{**H}$, in the same storage format as A.

* *INFO* (*output*)

NAME

zpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

SYNOPSIS

```
SUBROUTINE ZPPTRI( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*)
INTEGER N, INFO

SUBROUTINE ZPPTRI_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

SUBROUTINE PPTRI_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpptri(char uplo, int n, doublecomplex *a, int *info);

void zpptri_64(char uplo, long n, doublecomplex *a, long *info);
```

PURPOSE

zpptri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

* *INFO* (*output*)

NAME

zpptrs - solve a system of linear equations $A^*X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPPTRF

SYNOPSIS

```

```
void zpptrs_64(char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpptrs solves a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPPTRF.

ARGUMENTS

* *UPLO (input)*

* *N (input)*

The order of the matrix A . $N \geq 0$.

* *NRHS (input)*

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A (input)*

The triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* *B (input/output)*

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB (input)*

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* *INFO (output)*

NAME

zptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**}H$ or $A = U^{**}H^*D^*U$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE ZPTCON( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
DOUBLE COMPLEX OFFD(*)
INTEGER N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION DIAG(*), WORK(*)

SUBROUTINE ZPTCON_64( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
DOUBLE COMPLEX OFFD(*)
INTEGER*8 N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION DIAG(*), WORK(*)
```

F95 INTERFACE

SUBROUTINE PTCN( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: OFFD
INTEGER :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: DIAG, WORK

SUBROUTINE PTCN_64( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: OFFD
INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: DIAG, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zptcon(int n, double *diag, doublecomplex *offd, double anorm, double *rcond, int *info);
```

```
void zptcon_64(long n, double *diag, doublecomplex *offd, double anorm, double *rcond, long *info);
```

PURPOSE

zptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L**H$ or $A = U**H*D*U$ computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* *N (input)*

The order of the matrix A. $N \geq 0$.

* *DIAG (input)*

The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by CPTTRF.

* *OFFD (input)*

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

* *ANORM (input)*

The 1-norm of the original matrix A.

* *RCOND (output)*

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

* *WORK (workspace)*

* *INFO (output)*

NAME

zpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

SYNOPSIS

```
SUBROUTINE ZPTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

```
SUBROUTINE ZPTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER*8 N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE PTEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpteqr(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);
```

```
void zpteqr_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if COMPZ = 'V' or 'I', $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

zptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```

doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

*** UPLO (input)**

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input)**

The n real diagonal elements of the tridiagonal matrix A.

*** OFFD (input)**

The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

*** DIAGF (input)**

The n diagonal elements of the diagonal matrix DIAG from the factorization computed by CPTTRF.

*** OFFDF (input)**

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

*** B (input)**

The right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (input/output)**

On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

*** FERR (output)**

The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension(N)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

zptsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZPTSL( N, DIAG, OFFD, B)
DOUBLE COMPLEX DIAG(*), OFFD(*), B(*)
INTEGER N
```

```
SUBROUTINE ZPTSL_64( N, DIAG, OFFD, B)
DOUBLE COMPLEX DIAG(*), OFFD(*), B(*)
INTEGER*8 N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zptsl(int n, doublecomplex *diag, doublecomplex *offd, doublecomplex *b);
```

```
void zptsl_64(long n, doublecomplex *diag, doublecomplex *offd, doublecomplex *b);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *DIAG* (*input*)

Main diagonal elements of A .

* *OFFD* (*input*)

Off diagonal elements of A . $OFFD(1)$ through $OFFD(N*1)$ contains the off diagonal elements; $OFFD(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

zptsv - compute the solution to a complex system of linear equations $A*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

SYNOPSIS

```
SUBROUTINE ZPTSV( N, NRHS, DIAG, SUB, B, LDB, INFO)
DOUBLE COMPLEX SUB(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
DOUBLE PRECISION DIAG(*)
```

```

DOUBLE COMPLEX SUB(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
DOUBLE PRECISION DIAG(*)
```

F95 INTERFACE

```
SUBROUTINE PTVS( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:) :: SUB
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: DIAG
```

```
SUBROUTINE PTVS_64( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
COMPLEX(8), DIMENSION(:) :: SUB
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zptsv(int n, int nrhs, double *diag, doublecomplex *sub, doublecomplex *b, int ldb, int *info);
```

```
void zptsv_64(long n, long nrhs, double *diag, doublecomplex *sub, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zptsv computes the solution to a complex system of linear equations $A*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as $A = L*D*L^{**H}$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization $A = L*DIAG*L^{**H}$.

*** SUB (input/output)**

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*DIAG*L^{**H}$ factorization of A. SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^{**H}*DIAG*U$ factorization of A.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

zptsvx - use the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

SYNOPSIS

doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zptsvx_64(char fact, long n, long nrhs, double *diag, doublecomplex *sub, double *diagf, doublecomplex *subf,  
doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zptsvx uses the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the matrix A is factored as $A = L^*D^*L^{**}H$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form

$$A = U^{**}H^*D^*U.$$

2. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

*** *FACT* (input)**

Specifies whether or not the factored form of the matrix A is supplied on entry.

*** *N* (input)**

The order of the matrix A . $N \geq 0$.

*** *NRHS* (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X . $NRHS \geq 0$.

*** *DIAG* (input)**

The n diagonal elements of the tridiagonal matrix A .

*** *SUB* (input)**

The $(n-1)$ subdiagonal elements of the tridiagonal matrix A .

*** *DIAGF* (input/output)**

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG*L^{**H}$ factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG*L^{**H}$ factorization of A.

*** *SUBF* (input/output)**

If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG*L^{**H}$ factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG*L^{**H}$ factorization of A.

*** *B* (input)**

On entry, the N-by-NRHS right hand side matrix B. Unchanged on exit.

*** *LDB* (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** *X* (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** *LDX* (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** *RCOND* (output)**

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

*** *FERR* (output)**

The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j).

*** *BERR* (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** *WORK* (workspace)**

dimension(N)

*** *WORK2* (workspace)**

dimension(N)

*** *INFO* (output)**

NAME

zpttrf - compute the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE ZPTTRF( N, DIAG, OFFD, INFO)
DOUBLE COMPLEX OFFD(*)
INTEGER N, INFO
DOUBLE PRECISION DIAG(*)

SUBROUTINE ZPTTRF_64( N, DIAG, OFFD, INFO)
DOUBLE COMPLEX OFFD(*)
INTEGER*8 N, INFO
DOUBLE PRECISION DIAG(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRF( [N], DIAG, OFFD, [INFO])
COMPLEX(8), DIMENSION(:) :: OFFD
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: DIAG

SUBROUTINE PTTRF_64( [N], DIAG, OFFD, [INFO])
COMPLEX(8), DIMENSION(:) :: OFFD
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>

void zpttrf(int n, double *diag, doublecomplex *offd, int *info);
void zpttrf_64(long n, double *diag, doublecomplex *offd, long *info);
```

PURPOSE

zpttrf computes the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A . The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

*** *N* (input)**

The order of the matrix A . $N \geq 0$.

*** *DIAG* (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix $DIAG$ from the L^*DIAG^*L' factorization of A .

*** *OFFD* (input/output)**

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the L^*DIAG^*L' factorization of A . *OFFD* can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*DIAG^*U factorization of A .

*** *INFO* (output)**

NAME

zpttrs - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE ZPTTRS( UPLO, N, NRHS, DIAG, OFFD, B, LDB, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX OFFD(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO

COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpttrs(char uplo, int n, int nrhs, double *diag, doublecomplex *offd, doublecomplex *b, int ldb, int *info);
```

```
void zpttrs_64(char uplo, long n, long nrhs, double *diag, doublecomplex *offd, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpttrs solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

* **UPLO** (*input*)

Specifies the form of the factorization and whether the vector OFFD is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L.

* **N** (*input*)

The order of the tridiagonal matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **DIAG** (*input*)

The n diagonal elements of the diagonal matrix DIAG from the factorization $A = U * DIAG * U$ or $A = L * DIAG * L'$.

* **OFFD** (*input/output*)

If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U * DIAG * U$. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L * DIAG * L'$.

* **B** (*input/output*)

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

zptts2 - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U'D*U$ or $A = L*D*L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE ZPTTS2( IUPLO, N, NRHS, D, E, B, LDB)
DOUBLE COMPLEX E(*), B(LDB,*)
INTEGER IUPLO, N, NRHS, LDB
DOUBLE PRECISION D(*)
```

```
SUBROUTINE ZPTTS2_64( IUPLO, N, NRHS, D, E, B, LDB)
DOUBLE COMPLEX E(*), B(LDB,*)
INTEGER*8 IUPLO, N, NRHS, LDB
DOUBLE PRECISION D(*)
```

F95 INTERFACE

```
SUBROUTINE ZPTTS2( IUPLO, N, NRHS, D, E, B, [LDB])
COMPLEX(8), DIMENSION(:) :: E
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: IUPLO, N, NRHS, LDB
REAL(8), DIMENSION(:) :: D
```

```
SUBROUTINE ZPTTS2_64( IUPLO, N, NRHS, D, E, B, [LDB])
COMPLEX(8), DIMENSION(:) :: E
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: IUPLO, N, NRHS, LDB
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zptts2(int iuplo, int n, int nrhs, double *d, doublecomplex *e, doublecomplex *b, int ldb);
```

```
void zptts2_64(long iuplo, long n, long nrhs, double *d, doublecomplex *e, doublecomplex *b, long ldb);
```

PURPOSE

zptts2 solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

*** IUPLO (input)**

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L.

*** N (input)**

The order of the tridiagonal matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** D (input)**

The n diagonal elements of the diagonal matrix D from the factorization $A = U * D * U$ or $A = L * D * L'$.

*** E (input)**

If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U * D * U$.
If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L * D * L'$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

NAME

zqrdc - (obsolete) compute the QR factorization of a general matrix A. It is typical to follow a call to CQRDC with a call to CQRSL to solve $Ax = b$ or to CPODI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE ZQRDC( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), QRAUX(*), WORK(*)
INTEGER LDA, N, P, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZQRDC_64( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), QRAUX(*), WORK(*)
INTEGER*8 LDA, N, P, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zqrdc(doublecomplex *a, int lda, int n, int p, doublecomplex *qraux, int *ipivot, int job);
```

```
void zqrdc_64(doublecomplex *a, long lda, long n, long p, doublecomplex *qraux, long *ipivot, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, the upper triangle of A contains the matrix R and the strict lower triangle of A contains information that will allow construction of the matrix Q. If pivoting was requested, A contains the factorization of the original matrix A permuted by the requested pivots.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix A. $N \geq 0$.

*** P (input)**

Number of columns in the matrix A. $P \geq 0$.

*** QRAUX (output)**

On exit, contains information required to construct the orthogonal matrix Q.

*** IPIVOT (input)**

If JOB selected no pivoting, then IPIVOT is not referenced. If JOB selected pivoting, then on entry to the subroutines, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

```
IPIVOT(k) > 0   A(k,k) is an initial element.  
IPIVOT(k) = 0   A(k,k) is a free element.  
IPIVOT(k) < 0   A(k,k) is a final element.
```

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A. During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, IPIVOT(k) contains the index of the diagonal element of A that was moved into the kth position.

* **WORK** (*workspace*)

Scratch array with a dimension of N. WORK is not referenced if JOB = 0.

* **JOB** (*input*)

Determines how the factorization is done:

- o 0 with no pivoting

not 0 with pivoting

NAME

zqrs1 - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by CQRDC, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZQRSL( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,  
*      JOB, INFO)  
DOUBLE COMPLEX A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)  
INTEGER LDA, N, K, JOB, INFO
```

```
SUBROUTINE ZQRSL_64( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,  
*      JOB, INFO)  
DOUBLE COMPLEX A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)  
INTEGER*8 LDA, N, K, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zqrs1(doublecomplex *a, int lda, int n, int k, doublecomplex *qraux, doublecomplex *y, doublecomplex *qy,  
doublecomplex *qty, doublecomplex *b, doublecomplex *resid, doublecomplex *ab, int job, int *info);
```

```
void zqrs1_64(doublecomplex *a, long lda, long n, long k, doublecomplex *qraux, doublecomplex *y, doublecomplex *qy,  
doublecomplex *qty, doublecomplex *b, doublecomplex *resid, doublecomplex *ab, long job, long *info);
```

ARGUMENTS

*** A (input)**

Part of the QR factorization of matrix A as computed by CQRDC.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix AK where AK is described below. $N \geq 0$.

*** K (input)**

Number of columns in the matrix AK where AK is described below. $K \geq 0$.

*** QRAUX (input)**

Auxiliary output from CQRDC.

*** Y (input)**

Vector to be manipulated by CQRSL.

* **QY (output)**

On exit, QY contains $Q * Y$ if its computation has been requested in JOB; QY is not referenced if its computation is not requested.

* **QTY (output)**

On exit, QTY contains $QT * Y$ if its computation has been requested in JOB; QTY is not referenced if its computation is not requested.

* **B (input/output)**

On entry, the right-hand side vector b. On exit, the solution vector x. B is not referenced if its computation is not requested.

* **RESID (output)**

On exit, RESID contains the least squares residual $y - AK * b$ if its computation has been requested. RESID also is the orthogonal projection of y onto the orthogonal complement of the column space of AK. RESID is not referenced if its computation is not requested.

* **AB (output)**

On exit, AB contains the least squares approximation $AK * b$ if its computation has been requested. AB is the orthogonal projection of y onto the column space of x. AB is not referenced if its computation is not requested.

* **JOB (input)**

Integer in the form abcde; determines which operation or operations the subroutine will perform:

```
a <> 0  compute QY
b, c, d, or e <> 0      compute QTY
c <> 0  compute B
d <> 0  compute RESID
e <> 0  compute AB
```

* **INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the computation of B has been requested and R is singular; the value of k is then the index of the first zero element of R. The matrix AK is constructed from the factored orthogonal matrix Q and upper triangular matrix R from CQRDC.

NAME

zrot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex

SYNOPSIS

```
SUBROUTINE ZROT( N, X, INCX, Y, INCY, C, S )
DOUBLE COMPLEX S
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
DOUBLE PRECISION C
```

```
SUBROUTINE ZROT_64( N, X, INCX, Y, INCY, C, S )
DOUBLE COMPLEX S
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], X, [INCX], Y, [INCY], C, S )
COMPLEX(8) :: S
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
REAL(8) :: C
```

```
SUBROUTINE ROT_64( [N], X, [INCX], Y, [INCY], C, S )
COMPLEX(8) :: S
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zrot(int n, doublecomplex *x, int incx, doublecomplex *y, int incy, double c, doublecomplex s);
```

```
void zrot_64(long n, doublecomplex *x, long incx, doublecomplex *y, long incy, double c, doublecomplex s);
```

PURPOSE

zrot CROT applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex.

ARGUMENTS

* *N (input)*

The number of elements in the vectors X and Y.

* *X (output)*

On input, the vector X. On output, X is overwritten with $C*X + S*Y$.

* *INCX (input)*

The increment between successive values of Y. $INCX \neq 0$.

* *Y (output)*

On input, the vector Y. On output, Y is overwritten with $-CONJG(S)*X + C*Y$.

* *INCY (input)*

The increment between successive values of Y. $INCY \neq 0$.

* *C (input)*

* *S (input)*

$\forall \theta \in \mathbb{R}$ C and S define a rotation $\begin{bmatrix} C & S \\ -\text{conjg}(S) & C \end{bmatrix}$ where $C^2 + S^2 = 1$.

NAME

zrotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE ZROTG( A, B, C, S)
DOUBLE COMPLEX A, B, S
DOUBLE PRECISION C
```

```
SUBROUTINE ZROTG_64( A, B, C, S)
DOUBLE COMPLEX A, B, S
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROTG( A, B, C, S)
COMPLEX(8) :: A, B, S
REAL(8) :: C
```

```
SUBROUTINE ROTG_64( A, B, C, S)
COMPLEX(8) :: A, B, S
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zrotg(doublecomplex *a, doublecomplex *b, double *c, doublecomplex *s);
```

```
void zrotg_64(doublecomplex *a, doublecomplex *b, double *c, doublecomplex *s);
```

PURPOSE

zrotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***A*** (*input/output*)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

* ***B*** (*input/output*)

On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or 1/C depending on which of the input values of A and B is larger.

* ***C*** (*output*)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

* ***S*** (*output*)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

zscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE ZSCAL( N, ALPHA, Y, INCY)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX Y(*)
INTEGER N, INCY
```

```
SUBROUTINE ZSCAL_64( N, ALPHA, Y, INCY)
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: Y
INTEGER :: N, INCY
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zscal(int n, doublecomplex alpha, doublecomplex *y, int incy);
```

```
void zscal_64(long n, doublecomplex alpha, doublecomplex *y, long incy);
```

PURPOSE

zscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(INCY)$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

zsico - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then CSIFA is slightly faster. It is typical to follow a call to CSICO with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZSICO( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZSICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsico(doublecomplex *a, int lda, int n, int *ipivot, double *rcond);
```

```
void zsico_64(doublecomplex *a, long lda, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

zsidi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by CSICO or CSIFA.

SYNOPSIS

```
SUBROUTINE ZSIDE( A, LDA, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZSIDE_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsidi(doublecomplex *a, int lda, int n, int *ipivot, doublecomplex *det, int job);
```

```
void zsidi_64(doublecomplex *a, long lda, long n, long *ipivot, doublecomplex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CSICO or CSIFA. On exit, if the c digit of JOB $\neq 0$, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSICO or CSIFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) =$

0.0. If the b digit of JOB = 0, DET is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form bc; determines operation the subroutine will perform:

```
b <> 0  Compute the determinant.  
c <> 0  Compute the inverse.
```

Note that the inverse should not be computed if CSICO has set RCOND = 0 or if CSIFA has set INFO >= 0.

NAME

zsifa - (obsolete) compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to CSIFA with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZSIFA( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZSIFA_64( A, LDA, N, IPIVOT, INFO)
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsifa(doublecomplex *a, int lda, int n, int *ipivot, int *info);
```

```
void zsifa_64(doublecomplex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CSISL or CSIDI will divide by zero if called.

NAME

zsisl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by CSICO or CSIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZSISL( A, LDA, N, IPIVOT, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N
INTEGER IPIVOT(*)

SUBROUTINE ZSISL_64( A, LDA, N, IPIVOT, B)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsisl(doublecomplex *a, int lda, int n, int *ipivot, doublecomplex *b);
```

```
void zsisl_64(doublecomplex *a, long lda, long n, long *ipivot, doublecomplex *b);
```

ARGUMENTS

*** A (input)**

UDU factorization of the matrix A , as computed by CSICO or CSIFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSICO or CSIFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

zspco - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then CSPFA is slightly faster. It is typical to follow a call to CSPCO with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZSPCO( A, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZSPCO_64( A, N, IPIVOT, RCOND, WORK)
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zspco(doublecomplex *a, int n, int *ipivot, double *rcond);
```

```
void zspco_64(doublecomplex *a, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

zspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSPTRF

SYNOPSIS

```
SUBROUTINE ZSPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND

SUBROUTINE ZSPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE SPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND

SUBROUTINE SPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zspcon(char uplo, int n, doublecomplex *a, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zspcon_64(char uplo, long n, doublecomplex *a, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by CSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSPTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

$\text{dimension}(2 * N)$

* **INFO** (*output*)

NAME

zspdi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by CSPCO or CSPFA.

SYNOPSIS

```
SUBROUTINE ZSPDI( A, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(*), DET(*), WORK(*)
INTEGER N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZSPDI_64( A, N, IPIVOT, DET, WORK, JOB)
DOUBLE COMPLEX A(*), DET(*), WORK(*)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zspdi(doublecomplex *a, int n, int *ipivot, doublecomplex *det, int job);
```

```
void zspdi_64(doublecomplex *a, long n, long *ipivot, doublecomplex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CSPCO or CSPFA. On exit, if the c digit of JOB $\neq 0$, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. $N \neq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSPCO or CSPFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$. If the b digit of JOB = 0, DET is not referenced.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form bc; determines operation the subroutine will perform:

b <> 0 Compute the determinant.
c <> 0 Compute the inverse.

Note that the inverse should not be computed if CSPCO has set RCOND = 0 or if CSPFA has set INFO <> 0.

NAME

zspfa - (obsolete) compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to CSPFA with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE ZSPFA( A, N, IPIVOT, INFO)
DOUBLE COMPLEX A(*)
INTEGER N, INFO
INTEGER IPIVOT(*)

SUBROUTINE ZSPFA_64( A, N, IPIVOT, INFO)
DOUBLE COMPLEX A(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void zspfa(doublecomplex *a, int n, int *ipivot, int *info);

void zspfa_64(doublecomplex *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CSPSL or CSPDI will divide by zero if called.

NAME

zsprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

SUBROUTINE SPRFS_64( UPLO, N, NRHS, A, AF, IPIVOT, B, [LDB], X, [LDX],
*      FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, AF, WORK
COMPLEX(8), DIMENSION(:, :) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsprfs(char uplo, int n, int nrhs, doublecomplex *a, doublecomplex *af, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void zsprfs_64(char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *af, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{*T}$ or $A = L*D*L^{*T}$ as computed by CSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(2*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPSV_64( UPLO, N, NRHS, A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpsv(char uplo, int n, int nrhs, doublecomplex *a, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zpsv_64(char uplo, long n, long nrhs, doublecomplex *a, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if UPLO} = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if UPLO} = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

zpsvx - use the diagonal pivoting factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

SYNOPSIS

```

```
void zpsvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, doublecomplex *af, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zpsvx uses the diagonal pivoting factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as $A = U * D * U^{**T}$, if UPLO = 'U', or

```
    A = L * D * L^{**T}, if UPLO = 'L',  
    where U (or L) is a product of permutation and unit upper (lower)  
    triangular matrices and D is symmetric and block diagonal with  
    1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

zsptf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>

void zsptf(char uplo, int n, doublecomplex *a, int *ipivot, int *info);

void zsptf_64(char uplo, long n, doublecomplex *a, long *ipivot, long *info);
```

PURPOSE

zsptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A . $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L , stored as a packed triangular matrix overwriting A (see below for further details).

* *IPIVOT* (*output*)

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

* *INFO* (*output*)

NAME

zsptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

```

```
void zsptri_64(char uplo, long n, doublecomplex *a, long *ipivot, long *info);
```

PURPOSE

zsptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSPTRF.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CSPTRF.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

REAL(8), DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zstedc(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);
```

```
void zstedc_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The dimension of the symmetric tridiagonal matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$. If eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $COMPZ = 'N'$ or $'I'$, or $N \leq 1$, LWORK must be at least 1. If $COMPZ = 'V'$ and $N > 1$, LWORK must be at least $N*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (*workspace*)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

*** LRWORK (input)**

The dimension of the array RWORK. If COMPZ = 'N' or $N \leq 1$, LRWORK must be at least 1. If COMPZ = 'V' and $N > 1$, LRWORK must be at least $1 + 3*N + 2*N*\lg N + 3*N**2$, where $\lg(N)$ = smallest integer k such that $2**k \geq N$. If COMPZ = 'I' and $N > 1$, LRWORK must be at least $1 + 4*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If COMPZ = 'V' or $N > 1$, LIWORK must be at least $6 + 6*N + 5*N*\lg N$. If COMPZ = 'I' or $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

zstegr - Compute $T\text{-}\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

```

PURPOSE

zstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,

- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently CSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine CSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. CSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : CSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix T . On exit, D is overwritten.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E is overwritten.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced

if RANGE = 'A' or 'I'.

*** VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $V_L < V_U$. Not referenced if RANGE = 'A' or 'I'.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues/eigenvectors. If JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

The first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements $ISUPPZ(2 \cdot i - 1)$ through $ISUPPZ(2 \cdot i)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 18 \cdot N)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. $LIWORK \geq \max(1, 10 \cdot N)$

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

zstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

SYNOPSIS

```
SUBROUTINE ZSTEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
DOUBLE COMPLEX Z(LDZ,*)
INTEGER N, M, LDZ, INFO
INTEGER IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
DOUBLE PRECISION D(*), E(*), W(*), WORK(*)

SUBROUTINE ZSTEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
DOUBLE COMPLEX Z(LDZ,*)
INTEGER*8 N, M, LDZ, INFO
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
DOUBLE PRECISION D(*), E(*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN( [N], D, E, [M], W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
*      [IWORK], IFAIL, [INFO])
COMPLEX(8), DIMENSION(:,*) :: Z
INTEGER :: N, M, LDZ, INFO
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK

SUBROUTINE STEIN_64( [N], D, E, [M], W, IBLOCK, ISPLIT, Z, [LDZ],
*      [WORK], [IWORK], IFAIL, [INFO])
COMPLEX(8), DIMENSION(:,*) :: Z
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zstein(int n, double *d, double *e, int m, double *w, int *iblock, int *isplit, doublecomplex *z, int ldz, int *ifail, int *info);
```

```
void zstein_64(long n, double *d, double *e, long m, double *w, long *iblock, long *isplit, doublecomplex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back

transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

*** N (input)**

The order of the matrix. $N \geq 0$.

*** D (input)**

The n diagonal elements of the tridiagonal matrix T.

*** E (input)**

The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.

*** M (input)**

The number of eigenvectors to be found. $0 \leq M \leq N$.

*** W (input)**

The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBSZ with ORDER = 'B' is expected here.)

*** IBLOCK (input)**

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)

*** ISPLIT (input)**

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)

*** Z (output)**

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(5*N)

* ***IWORK*** (*workspace*)

dimension(N)

* ***IFAIL*** (*output*)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

* ***INFO*** (*output*)

NAME

zsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE ZSTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

```
SUBROUTINE ZSTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER*8 N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE STEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsteqr(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);
```

```
void zsteqr_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);
```

PURPOSE

zsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

* *COMPZ* (*input*)

* *N* (*input*)

The order of the matrix. $N \geq 0$.

* *D* (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* *E* (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, *E* has been destroyed.

* *Z* (*input*)

On entry, if $COMPZ = 'V'$, then *Z* contains the unitary matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, *Z* contains the orthonormal eigenvectors of the original Hermitian matrix, and if $COMPZ = 'I'$, *Z* contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then *Z* is not referenced.

* *LDZ* (*input*)

The leading dimension of the array *Z*. $LDZ \geq 1$, and if eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* *WORK* (*workspace*)

If $COMPZ = 'N'$, then *WORK* is not referenced.

* *INFO* (*output*)

NAME

zstsv - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

SYNOPSIS

```
SUBROUTINE ZSTSV( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE ZSTSV_64( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE STSV( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE STSV_64( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zstsv(int n, int nrhs, doublecomplex *l, doublecomplex *d, doublecomplex *subl, doublecomplex *b, int ldb, int *ipiv, int *info);
```

```
void zstsv_64(long n, long nrhs, doublecomplex *l, doublecomplex *d, doublecomplex *subl, doublecomplex *b, long ldb, long *ipiv, long *info);
```

PURPOSE

zstsv computes the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides in B.

*** L (input/output)**

COMPLEX array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** D (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** SUBL (output)**

COMPLEX array, dimension (N)

On exit, part of the factorization of A.

*** B (input/output)**

The columns of B contain the right hand sides.

*** LDB (input)**

The leading dimension of B as specified in a type or DIMENSION statement.

*** IPIV (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** INFO (output)**

INTEGER

NAME

zsttrf - compute the factorization of a complex Hermitian tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE ZSTTRF( N, L, D, SUBL, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*)
INTEGER N, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE ZSTTRF_64( N, L, D, SUBL, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*)
INTEGER*8 N, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE STTRF( [N], L, D, SUBL, IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE STTRF_64( [N], L, D, SUBL, IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsttrf(int n, doublecomplex *l, doublecomplex *d, doublecomplex *subl, int *ipiv, int *info);
```

```
void zsttrf_64(long n, doublecomplex *l, doublecomplex *d, doublecomplex *subl, long *ipiv, long *info);
```

PURPOSE

zsttrf computes the $L^*D^*L^{**}H$ factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** L (input/output)**

COMPLEX array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** D (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** SUBL (output)**

COMPLEX array, dimension (N)

On exit, part of the factorization of A.

*** IPIV (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** INFO (output)**

INTEGER

NAME

zsttrs - computes the solution to a complex system of linear equations $A * X = B$

SYNOPSIS

```
SUBROUTINE ZSTTRS( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE ZSTTRS_64( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
DOUBLE COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE STTRS( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE STTRS_64( N, NRHS, L, D, SUBL, B, [LDB], IPIV, [INFO])
COMPLEX(8), DIMENSION(:) :: L, D, SUBL
COMPLEX(8), DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsttrs(int n, int nrhs, doublecomplex *l, doublecomplex *d, doublecomplex *subl, doublecomplex *b, int ldb, int *ipiv, int *info);
```

```
void zsttrs_64(long n, long nrhs, doublecomplex *l, doublecomplex *d, doublecomplex *subl, doublecomplex *b, long ldb, long *ipiv, long *info);
```

PURPOSE

zstrs computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** L (input)**

COMPLEX array, dimension (N-1)

On entry, the subdiagonal elements of LL and DD.

*** D (input)**

COMPLEX array, dimension (N)

On entry, the diagonal elements of DD.

*** SUBL (input)**

COMPLEX array, dimension (N-2)

On entry, the second subdiagonal elements of LL.

*** B (input/output)**

COMPLEX array, dimension (LDB, NRHS)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

INTEGER

The leading dimension of the array B. $LDB \geq \max(1, N)$

*** IPIV (output)**

INTEGER array, dimension (N)

Details of the interchanges and block pivot. If IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1 an interchange done; If IPIV(K) < 0, 2 by 2 pivot, no interchange required.

*** INFO (output)**

INTEGER

NAME

zsvdc - (obsolete) compute the singular value decomposition of a general matrix A.

SYNOPSIS

```
SUBROUTINE ZSVDC( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
DOUBLE COMPLEX A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
INTEGER LDA, N, P, LDL, LDR, JOB, INFO
```

```
SUBROUTINE ZSVDC_64( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
DOUBLE COMPLEX A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
INTEGER*8 LDA, N, P, LDL, LDR, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsvdc(doublecomplex *a, int lda, int n, int p, doublecomplex *svals, doublecomplex *e, doublecomplex *lsvec, int ldl,  
doublecomplex *rsvec, int ldr, int job, int *info);
```

```
void zsvdc_64(doublecomplex *a, long lda, long n, long p, doublecomplex *svals, doublecomplex *e, doublecomplex *lsvec,  
long ldl, doublecomplex *rsvec, long ldr, long job, long *info);
```

ARGUMENTS

*** A (input)**

Matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows of the matrix A. $N \geq 0$.

*** P (input)**

Number of columns of the matrix A. $P \geq 0$.

*** SVALS (input/output)**

On exit, the singular values of A arranged in descending order of magnitude.

*** E (input/output)**

On exit, normally contains zero, but see INFO below.

*** LSVEC (input/output)**

On exit, the matrix of left singular vectors; not referenced if the a digit of JOB = 0.

*** LDL (input)**

Leading dimension of LSVEC as specified in a dimension or type statement. $LDL \geq \max(1, N)$.

*** RSVEC (input/output)**

On exit, the matrix of right singular vectors; not referenced if the b digit of JOB = 0.

*** LDR (input)**

Leading dimension of RSVEC as specified in a dimension or type statement. $LDR \geq \max(1, P)$.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form ab; determines operation subroutine will perform:

a = 0	do not compute the left singular vectors
a = 1	return the n left singular vectors in LSVEC
a * 2	return the first min(N,P) singular vectors in LSVEC
b = 0	do not compute the right singular vectors
b = 1	return the right singular vectors in RSVEC

*** INFO (output)**

On exit, the singular values and their corresponding singular vectors $SVALS(INFO+1)$, $SVALS(INFO+2), \dots, SVALS(\min(N, P))$ are correct. If $INFO = 0$ then all singular values and singular vectors are correct. The matrix B defined as $LSVECT * A * RSVEC$ is the bidiagonal matrix with S on its diagonal and E on its superdiagonal. Therefore the singular values of A and B are the same.

NAME

zswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE ZSWAP( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZSWAP_64( N, X, INCX, Y, INCY)
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE SWAP( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE SWAP_64( [N], X, [INCX], Y, [INCY])
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zswap(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
void zswap_64(long n, doublecomplex *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input/output)*

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x. On exit, the y vector.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

zsycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSYTRF

SYNOPSIS

```
SUBROUTINE ZSYCON( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND

SUBROUTINE ZSYCON_64( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                   INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE SYCON( UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
*               [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND

SUBROUTINE SYCON_64( UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND,
*                  [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsycon(char uplo, int n, doublecomplex *a, int lda, int *ipivot, double anorm, double *rcond, int *info);
```

```
void zsycon_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zsycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **INFO** (*output*)

NAME

zsymm - perform one of the matrix-matrix operations $C := \alpha*A*B + \beta*C$ or $C := \alpha*B*A + \beta*C$

SYNOPSIS

```
SUBROUTINE ZSYMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
*               LDC)
CHARACTER * 1 SIDE, UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, LDA, LDB, LDC

SUBROUTINE ZSYMM_64( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA,
*                  C, LDC)
CHARACTER * 1 SIDE, UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYMM( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*              BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE SYMM_64( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*                 BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsymm(char side, char uplo, int m, int n, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex beta, doublecomplex *c, int ldc);
```

```
void zsymm_64(char side, char uplo, long m, long n, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *b,
```

long ldb, doublecomplex beta, doublecomplex *c, long ldc);

PURPOSE

zsymm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE* (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

*** B (input)**

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

zsy2k - perform one of the symmetric rank 2k operations $C := \alpha A B' + \alpha B A' + \beta C$ or $C := \alpha A' B + \alpha B' A + \beta C$

SYNOPSIS

```
SUBROUTINE ZSYR2K( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,
*      C, LDC)
CHARACTER * 1 UPLO, TRANSA
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER N, K, LDA, LDB, LDC

SUBROUTINE ZSYR2K_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 N, K, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYR2K( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],
*      BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER :: N, K, LDA, LDB, LDC

SUBROUTINE SYR2K_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
*      [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,*) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsy2k(char uplo, char transa, int n, int k, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex beta, doublecomplex *c, int ldc);
```

void zsy2k_64(char uplo, char transa, long n, long k, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex beta, doublecomplex *c, long ldc);

PURPOSE

zsy2k K performs one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA (input)*

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * B' + \alpha * B * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A * B + \alpha * B' * A + \beta * C$.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K (input)*

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *B (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

* **LDB** (*input*)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* **C** (*input/output*)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

void zsyrfc_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zsyrfc improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. **AF** contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by **CSYTRF**.

* **LDAF** (*input*)

The leading dimension of the array **AF**. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by **CSYTRF**.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by **CSYTRS**. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

#include <sunperf.h>
```

```
void zsyrk(char uplo, char transa, int n, int k, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex beta,
doublecomplex *c, int ldc);
```

```
void zsyrk_64(char uplo, char transa, long n, long k, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex beta,
doublecomplex *c, long ldc);
```

PURPOSE

zsyrc performs one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A' * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

*             [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsysv(char uplo, int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zsysv_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zsysv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by CSYTRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The length of WORK. LDWORK ≥ 1 , and for best performance LDWORK $\geq N \cdot NB$, where NB is the optimal blocksize for CSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

zsysvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsysvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void zsysvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zsysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A . The form of the factorization is

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

*** LDA (input)**

The leading dimension of the array A. LDA \geq max(1,N).

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ as computed by CSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$.

*** LDAF (input)**

The leading dimension of the array AF. LDAF \geq max(1,N).

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIVOT(k) $>$ 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) $<$ 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) $<$ 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSYTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK $\geq 2*N$, and for best performance LDWORK $\geq N*NB$, where NB is the optimal blocksize for CSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

zsytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE ZSYTF2( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
INTEGER IPIV(*)

SUBROUTINE ZSYTF2_64( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE SYTF2( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE SYTF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsytf2(char uplo, int n, doublecomplex *a, int lda, int *ipiv, int *info);
```

```
void zsytf2_64(char uplo, long n, doublecomplex *a, long lda, long *ipiv, long *info);
```

PURPOSE

zsytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

NAME

```

```
void zsytrf_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zsytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U*D*U^{**T} \quad \text{or} \quad A = L*D*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK ≥ 1 . For best performance LDWORK $\geq N*NB$, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

zsytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSYTRF

SYNOPSIS

```
SUBROUTINE ZSYTRI( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
```

```

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRI( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SYTRI_64( UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsytri(char uplo, int n, doublecomplex *a, int lda, int *ipivot, int *info);
```

```
void zsytri_64(char uplo, long n, doublecomplex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zsytri computes the inverse of a complex symmetric indefinite matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if $INFO = 0$, the (symmetric) inverse of the original matrix. If $UPLO = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if $UPLO = 'L'$ the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **WORK** (*workspace*)

dimension(2*N)

* **INFO** (*output*)

NAME

zsytrs - solve a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^* \cdot T$ or $A = L \cdot D \cdot L^* \cdot T$ computed by CSYTRF

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsytrs(char uplo, int n, int nrhs, doublecomplex *a, int lda, int *ipivot, doublecomplex *b, int ldb, int *info);
```

```
void zsytrs_64(char uplo, long n, long nrhs, doublecomplex *a, long lda, long *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zsytrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^* \cdot T$ or $A = L \cdot D \cdot L^* \cdot T$ computed by CSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

ztbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE ZTBCON( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER N, NDIAG, LDA, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)  
  
SUBROUTINE ZTBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND,  
*      WORK, WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, NDIAG, LDA, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, NDIAG, LDA, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2  
  
SUBROUTINE TBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, [LDA], RCOND,  
*      [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztbcon(char norm, char uplo, char diag, int n, int ndiag, doublecomplex *a, int lda, double *rcond, int *info);
```

```
void ztbcon_64(char norm, char uplo, char diag, long n, long ndiag, doublecomplex *a, long lda, double *rcond, long *info);
```

PURPOSE

ztbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** UPLO (input)**

*** DIAG (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

*** A (input)**

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NDIAG+1$.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension($2*N$)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

ztbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE ZTBMV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER N, NDIAG, LDA, INCY
```

```
SUBROUTINE ZTBMV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCY
```

```
SUBROUTINE TBMV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztbmv(char uplo, char transa, char diag, int n, int ndiag, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztbmv_64(char uplo, char transa, char diag, long n, long ndiag, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

ztbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $x := A*x$.

TRANS = 'T' or 't' $x := A'*x$.

TRANS = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
         A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ztbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

SYNOPSIS

```

SUBROUTINE TBRFS_64( UPLO, [TRANSA], DIAG, N, NDIAG, NRHS, A, [LDA],  
*      B, [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A, B, X  
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, LDX, INFO  
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztbrfs(char uplo, char transa, char diag, int n, int ndiag, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void ztbrfs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

ztbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. CTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* ***LDX (input)***

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* ***FERR (output)***

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension($2 * N$)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

ztbsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE ZTBSV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER N, NDIAG, LDA, INCY
```

```
SUBROUTINE ZTBSV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBSV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCY
```

```
SUBROUTINE TBSV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztbsv(char uplo, char transa, char diag, int n, int ndiag, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztbsv_64(char uplo, char transa, char diag, long n, long ndiag, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

zbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
```

```
A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N  
        = 1 - J  
      O 10, I = J, MIN( N, J + NDIAG )  
        A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

*** Y (input/output)**

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

NAME

ztbtrs - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
void ztbtrs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, doublecomplex *a, long lda, doublecomplex  
*b, long ldb, long *info);
```

PURPOSE

ztbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if $INFO = 0$, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztgevc(char side, char howmny, logical *select, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *vl, int ldvl, doublecomplex *vr, int ldvr, int mm, int *m, int *info);
```

```
void ztgevc_64(char side, char howmny, logical *select, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *vl, long ldvl, doublecomplex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ztgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{*H} * (A - wB) = 0$$

where y^{*H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input unitary matrices. If (A,B) was obtained from the generalized Schur factorization of an original pair of matrices

$$(A0, B0) = (Q*A*Z^{*H}, Q*B*Z^{*H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A.

ARGUMENTS

* *SIDE* (input)

* *HOWMNY* (input)

* *SELECT* (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input)

The upper triangular matrix A.

* *LDA* (input)

The leading dimension of array A. $LDA \geq \max(1,N)$.

* ***B (input)***

The upper triangular matrix B. B must have real diagonal elements.

* ***LDB (input)***

The leading dimension of array B. $LDB \geq \max(1,N)$.

* ***VL (input/output)***

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q^*Y ; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

* ***LDVL (input)***

The leading dimension of array VL. $LDVL \geq \max(1,N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

* ***VR (input/output)***

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z^*X ; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

* ***LDVR (input)***

The leading dimension of the array VR. $LDVR \geq \max(1,N)$ if SIDE = 'R' or 'B'; $LDVR \geq 1$ otherwise.

* ***MM (input)***

The number of columns in the arrays VL and/or VR. $MM \geq M$.

* ***M (output)***

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

* ***WORK (workspace)***

dimension($2*N$)

* ***RWORK (workspace)***

dimension($2*N$)

* ***INFO (output)***

NAME

ztgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE ZTGEXC( WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
*   IFST, ILST, INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL WANTQ, WANTZ
```

```
SUBROUTINE ZTGEXC_64( WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z,
*   LDZ, IFST, ILST, INFO)
DOUBLE COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER*8 N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL*8 WANTQ, WANTZ
```

F95 INTERFACE

```
SUBROUTINE TGEXC( WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ],
*   Z, [LDZ], IFST, ILST, [INFO])
COMPLEX(8), DIMENSION(:, :) :: A, B, Q, Z
INTEGER :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL :: WANTQ, WANTZ
```

```
SUBROUTINE TGEXC_64( WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ],
*   Z, [LDZ], IFST, ILST, [INFO])
COMPLEX(8), DIMENSION(:, :) :: A, B, Q, Z
INTEGER(8) :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL(8) :: WANTQ, WANTZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztgexc(logical wantq, logical wantz, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *q, int ldq, doublecomplex *z, int ldz, int *ifst, int *ilst, int *info);
```

```
void ztgexc_64(logical wantq, logical wantz, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *q, long ldq, doublecomplex *z, long ldz, long *ifst, long *ilst, long *info);
```

PURPOSE

ztgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$\begin{aligned} Q(\text{in}) * A(\text{in}) * Z(\text{in})' &= Q(\text{out}) * A(\text{out}) * Z(\text{out})' \\ Q(\text{in}) * B(\text{in}) * Z(\text{in})' &= Q(\text{out}) * B(\text{out}) * Z(\text{out})' \end{aligned}$$

ARGUMENTS

*** WANTQ (input)**

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

*** WANTZ (input)**

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input/output)**

On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** Q (input/output)**

On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$; If WANTQ = .TRUE., $LDQ \geq N$.

*** Z (input/output)**

On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$; If WANTZ = .TRUE., $LDZ \geq N$.

*** IFST (input/output)**

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

* ***ILST*** (*input/output*)

See the description of IFST.

* ***INFO*** (*output*)

NAME

ztgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q^*(A, B)Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

*b, long ldb, doublecomplex *alpha, doublecomplex *beta, doublecomplex *q, long ldq, doublecomplex *z, long ldz, long
*m, double *pl, double *pr, double *dif, long *info);
```

PURPOSE

ztgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ZTGSEN also computes the generalized eigenvalues

$$w(j) = \text{ALPHA}(j) / \text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A11, B11), (A22, B22)]$ and $\text{Difl}[(A11, B11), (A22, B22)]$, i.e. the separation(s) between the matrix pairs (A11, B11) and (A22, B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

* *IJOB (input)*

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

* *WANTQ (input)*

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* *WANTZ (input)*

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* *SELECT (input)*

SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue $w(j)$, SELECT(j) must be set to .TRUE..

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *A (input/output)*

On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* *B (input/output)*

On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *ALPHA (output)*

The diagonal elements of A and B, respectively, when the pair (A,B) has been reduced to generalized Schur form. ALPHA(i)/BETA(i) $i=1,\dots,N$ are the generalized eigenvalues.

* *BETA (output)*

See the description of ALPHA.

* *Q (input/output)*

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

* *LDQ (input)*

The leading dimension of the array Q. $LDQ \geq 1$. If WANTQ = .TRUE., $LDQ \geq N$.

* *Z (input/output)*

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

* *LDZ (input)*

The leading dimension of the array Z. $LDZ \geq 1$. If WANTZ = .TRUE., $LDZ \geq N$.

* *M (output)*

The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) $0 \leq M \leq N$.

*** PL (output)**

If IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.

$0 < PL, PR \leq 1$. If $M = 0$ or $M = N$, $PL = PR = 1$. If IJOB = 0, 2, or 3 PL, PR are not referenced.

*** PR (output)**

See the description of PL.

*** DIF (output)**

If IJOB ≥ 2 , DIF(1:2) store the estimates of Difu and Difl.

If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on

Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If $M = 0$ or N , DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

*** WORK (workspace)**

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK ≥ 1 If IJOB = 1, 2 or 4, LWORK $\geq 2 * M * (N - M)$ If IJOB = 3 or 5, LWORK $\geq 4 * M * (N - M)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. LIWORK ≥ 1 . If IJOB = 1, 2 or 4, LIWORK $\geq N + 2$; If IJOB = 3 or 5, LIWORK $\geq \text{MAX}(N + 2, 2 * M * (N - M))$;

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

ztgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{aligned} A &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ L \\ M-K-L \end{array} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \text{ if } M-K-L \geq 0; \\ A &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ M-K \end{array} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} \end{array} \text{ if } M-K-L < 0; \\ B &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} L \\ P-L \end{array} & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix},$$

where U, V and Q are unitary matrices, Z' denotes the conjugate transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are "diagonal" matrices, which are of the following structures:

If $M-K-L \geq 0$,

$$\begin{aligned} D1 &= \begin{array}{ccc} & \begin{array}{cc} K & L \end{array} \\ \begin{array}{c} K \\ L \\ M-K-L \end{array} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \\ D2 &= \begin{array}{ccc} & \begin{array}{cc} K & L \end{array} \\ \begin{array}{c} L \\ P-L \end{array} & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{array}{ccc} & \begin{array}{cc} N-K-L & K & L \end{array} \\ \begin{array}{c} K \\ L \end{array} & \begin{pmatrix} 0 & R11 & R12 \\ 0 & 0 & R22 \end{pmatrix} \end{array} \begin{array}{c} K \\ L \end{array} \end{aligned}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)),$
 $S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)),$
 $C^{**2} + S^{**2} = I.$
 R is stored in $A(1:K+L, N-K-L+1:N)$ on exit.

If $M-K-L < 0$,

$$\begin{array}{l}
 D1 = \begin{array}{cccc} & K & M-K & K+L-M \\ K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{array} \\
 D2 = \begin{array}{cccc} & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \\ & N-K-L & K & M-K & K+L-M \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{array}
 \end{array}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$

$C^{**2} + S^{**2} = I.$

$R = (R11 \ R12 \ R13)$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored $(0 \ R22 \ R23)$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1$, $V1$, or $Q1$.

CTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$$U1' * A13 * Q1 = C1 * R1; \quad V1' * B13 * Q1 = S1 * R1,$$

where $U1$, $V1$ and $Q1$ are unitary matrix, and Z' is the conjugate transpose of Z . $C1$ and $S1$ are diagonal matrices satisfying

$$C1^{**2} + S1^{**2} = I,$$

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **K** (*input*)

K and L specify the subblocks in the input matrices A and B:

$A_{23} = A(K+1:\text{MIN}(K+L,M), N-L+1:N)$ and $B_{13} = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by CTGSJA. See the Further Details section below.

* **L** (*input*)

See the description of K.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\text{MIN}(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **TOLA** (*input*)

TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \text{MAX}(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \text{MAX}(P, N) * \text{norm}(B) * \text{MACHEPS}$.

* **TOLB** (*input*)

See the description of TOLA.

* **ALPHA** (*output*)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $\text{ALPHA}(1:K) = 1$,

$\text{BETA}(1:K) = 0$, and if $M-K-L \geq 0$, $\text{ALPHA}(K+1:K+L) = \text{diag}(C)$,

$\text{BETA}(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $\text{ALPHA}(K+1:M) = C$, $\text{ALPHA}(M+1:K+L) = 0$

$\text{BETA}(K+1:M) = S$, $\text{BETA}(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $\text{ALPHA}(K+L+1:N) = 0$

$\text{BETA}(K+L+1:N) = 0$.

* **BETA** (*output*)

See the description of ALPHA.

* **U** (*input*)

On entry, if `JOBV = 'U'`, `U` must contain a matrix `U1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBV = 'I'`, `U` contains the unitary matrix `U`; if `JOBV = 'U'`, `U` contains the product `U1*U`. If `JOBV = 'N'`, `U` is not referenced.

* ***LDU (input)***

The leading dimension of the array `U`. `LDU` \geq $\max(1, M)$ if `JOBV = 'U'`; `LDU` \geq 1 otherwise.

* ***V (input)***

On entry, if `JOBV = 'V'`, `V` must contain a matrix `V1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBV = 'I'`, `V` contains the unitary matrix `V`; if `JOBV = 'V'`, `V` contains the product `V1*V`. If `JOBV = 'N'`, `V` is not referenced.

* ***LDV (input)***

The leading dimension of the array `V`. `LDV` \geq $\max(1, P)$ if `JOBV = 'V'`; `LDV` \geq 1 otherwise.

* ***Q (input)***

On entry, if `JOBQ = 'Q'`, `Q` must contain a matrix `Q1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBQ = 'I'`, `Q` contains the unitary matrix `Q`; if `JOBQ = 'Q'`, `Q` contains the product `Q1*Q`. If `JOBQ = 'N'`, `Q` is not referenced.

* ***LDQ (input)***

The leading dimension of the array `Q`. `LDQ` \geq $\max(1, N)$ if `JOBQ = 'Q'`; `LDQ` \geq 1 otherwise.

* ***WORK (workspace)***

dimension(2*N)

* ***NCYCLE (output)***

The number of cycles required for convergence.

* ***INFO (output)***

```

PURPOSE

ztgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):

*** HOWMNT (input)**

*** SELECT (input)**

If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

*** N (input)**

The order of the square matrix pair (A, B). $N \geq 0$.

*** A (input)**

The upper triangular matrix A in the pair (A,B).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input)**

The upper triangular matrix B in the pair (A, B).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and If JOB = 'E' or 'B', $LDVL \geq N$.

* **VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEVC. If JOB = 'V', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR \geq 1; If JOB = 'E' or 'B', LDVR \geq N.

* **S (output)**

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

* **DIF (output)**

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of DIF1. If JOB = 'E', DIF is not referenced.

* **MM (input)**

The number of elements in the arrays S and DIF. MM \geq M.

* **M (output)**

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

* **WORK (workspace)**

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK \geq 1. If JOB = 'V' or 'B', LWORK \geq 2*N*N.

* **IWORK (workspace)**

If JOB = 'E', IWORK is not referenced.

* **INFO (output)**

COMPLEX(8), DIMENSION(:, :) :: A, B, C, D, E, F  
INTEGER(8) :: IJOB, M, N, LDA, LDB, LDC, LDD, LDE, LDF, LWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8) :: SCALE, DIF
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztgsyl(char trans, int ijob, int m, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *c, int ldc, doublecomplex *d, int ldd, doublecomplex *e, int lde, doublecomplex *f, int ldf, double *scale, double *dif, int *info);
```

```
void ztgsyl_64(char trans, long ijob, long m, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *c, long ldc, doublecomplex *d, long ldd, doublecomplex *e, long lde, doublecomplex *f, long ldf, double *scale, double *dif, long *info);
```

PURPOSE

ztgsyl solves the generalized Sylvester equation:

$$\begin{aligned} A * R - L * B &= \text{scale} * C \\ D * R - L * E &= \text{scale} * F \end{aligned} \quad (1)$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). $0 \leq \text{SCALE} \leq 1$

is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} * b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix}, \quad (2)$$

Here I_x is the identity matrix of size x and X' is the conjugate transpose of X. $\text{Kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If $\text{TRANS} = 'C'$, y in the conjugate transposed system $Z' * y = \text{scale} * b$ is solved for, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * -F \end{aligned} \quad (3)$$

This case ($\text{TRANS} = 'C'$) is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If $\text{IJOB} \geq 1$, CTGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

ARGUMENTS

* **TRANS** (*input*)

* **IJOB** (*input*)

Specifies what kind of functionality to be performed.

* **M** (*input*)

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

* **N** (*input*)

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

* **A** (*input*)

The upper triangular matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper triangular matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **D** (*input*)

The upper triangular matrix D.

* **LDD** (*input*)

The leading dimension of the array D. $LDD \geq \max(1, M)$.

* **E** (*input*)

The upper triangular matrix E.

* **LDE** (*input*)

The leading dimension of the array E. $LDE \geq \max(1, N)$.

* **F** (*input/output*)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

* **LDF** (*input*)

The leading dimension of the array F. $LDF \geq \max(1, M)$.

* **SCALE** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma\text{-min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

* **DIF** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma\text{-min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

* **WORK** (*workspace*)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO=0 then WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK >= 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

If IJOB = 0, IWORK is not referenced.

* **INFO** (*output*)

NAME

ztpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE ZTPCON( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM, UPLO, DIAG
DOUBLE COMPLEX A(*), WORK(*)
INTEGER N, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION WORK2(*)
```

```
SUBROUTINE ZTPCON_64( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM, UPLO, DIAG
DOUBLE COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE TPCON_64( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztpcon(char norm, char uplo, char diag, int n, doublecomplex *a, double *rcond, int *info);
```

```
void ztpcon_64(char norm, char uplo, char diag, long n, doublecomplex *a, double *rcond, long *info);
```

PURPOSE

ztpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ztpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE ZTPMV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER N, INCY
```

```
SUBROUTINE ZTPMV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER :: N, INCY
```

```
SUBROUTINE TPMV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztpmv(char uplo, char transa, char diag, int n, doublecomplex *a, doublecomplex *y, int incy);
```

```
void ztpmv_64(char uplo, char transa, char diag, long n, doublecomplex *a, doublecomplex *y, long incy);
```

PURPOSE

ztpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1,1), A(2) and A(3) contain a(1,2) and a(2,2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1,1), A(2) and A(3) contain a(2,1) and a(3,1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*\text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

ztpfrs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

SYNOPSIS

```

COMPLEX(8), DIMENSION(:) :: A, WORK  
COMPLEX(8), DIMENSION(:, :) :: B, X  
INTEGER :: N, NRHS, LDB, LDX, INFO  
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2  
  
SUBROUTINE TPRFS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, B, [LDB], X,  
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A, WORK  
COMPLEX(8), DIMENSION(:, :) :: B, X  
INTEGER(8) :: N, NRHS, LDB, LDX, INFO  
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztprfs(char uplo, char transa, char diag, int n, int nrhs, doublecomplex *a, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void ztprfs_64(char uplo, char transa, char diag, long n, long nrhs, doublecomplex *a, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

ztprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. CTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

ztpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE ZTPSV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER N, INCY
```

```
SUBROUTINE ZTPSV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPSV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER :: N, INCY
```

```
SUBROUTINE TPSV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztpsv(char uplo, char transa, char diag, int n, doublecomplex *a, doublecomplex *y, int incy);
```

```
void ztpsv_64(char uplo, char transa, char diag, long n, doublecomplex *a, doublecomplex *y, long incy);
```

PURPOSE

ztpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*\text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

ztptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE ZTPTRI( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
DOUBLE COMPLEX A(*)
INTEGER N, INFO
```

```
SUBROUTINE ZTPTRI_64( UPLO, DIAG, N, A, INFO)

COMPLEX(8), DIMENSION(:) :: A
INTEGER :: N, INFO
```

```
SUBROUTINE TPTRI_64( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztptri(char uplo, char diag, int n, doublecomplex *a, int *info);
```

```
void ztptri_64(char uplo, char diag, long n, doublecomplex *a, long *info);
```

PURPOSE

ztptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

* *INFO* (*output*)

NAME

ztptrs - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
SUBROUTINE ZTPTRS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, INFO)

INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztptrs(char uplo, char transa, char diag, int n, int nrhs, doublecomplex *a, doublecomplex *b, int ldb, int *info);
```

```
void ztptrs_64(char uplo, char transa, char diag, long n, long nrhs, doublecomplex *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

ztptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N -by- $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

ztrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE ZTRANS( PLACE, SCALE, SOURCE, M, N, DEST)

INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrans(char place, doublecomplex scale, doublecomplex *source, int m, int n, doublecomplex *dest);
```

```
void ztrans_64(char place, doublecomplex scale, doublecomplex *source, long m, long n, doublecomplex *dest);
```

PURPOSE

ztrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'T' or 'i', and DEST when PLACE = 'O' or 'o'.

```
PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE '  
PLACE = 'O' or 'o': DEST = SCALE * SOURCE '
```

ARGUMENTS

* **PLACE** (*input*)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place.

* **SCALE** (*input*)

Scale factor on the SOURCE matrix.

* **SOURCE** (*input/output*)

on input. Array of (N, M) on output if in-place transpose.

* **M** (*input*)

Number of rows in the SOURCE matrix on input.

* **N** (*input*)

Number of columns in the SOURCE matrix on input.

* **DEST** (*output*)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

ztrco - (obsolete) estimate the condition number of a triangular matrix A. It is typical to follow a call to xTRCO with a call to xTRSL to solve $Ax = b$ or to xTRDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE ZTRCO( A, LDA, N, RCOND, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB
DOUBLE PRECISION RCOND
```

```
SUBROUTINE ZTRCO_64( A, LDA, N, RCOND, WORK, JOB)
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB
DOUBLE PRECISION RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrco(doublecomplex *a, int lda, int n, double *rcond, int job);
```

```
void ztrco_64(doublecomplex *a, long lda, long n, double *rcond, long job);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

If $JOB = 0$, then A is lower triangular; otherwise A is upper triangular.

NAME

ztrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE ZTRCON( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
*      INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER N, LDA, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)  
  
SUBROUTINE ZTRCON_64( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, LDA, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2  
  
SUBROUTINE TRCON_64( NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrcon(char norm, char uplo, char diag, int n, doublecomplex *a, int lda, double *rcond, int *info);
```

```
void ztrcon_64(char norm, char uplo, char diag, long n, doublecomplex *a, long lda, double *rcond, long *info);
```

PURPOSE

ztrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** UPLO (input)**

*** DIAG (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

dimension(N)

*** INFO (output)**

NAME

ztrdi - (obsolete) compute the determinant and inverse of a triangular matrix A.

SYNOPSIS

```
SUBROUTINE ZTRDI( A, LDA, N, DET, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), DET(*)
INTEGER LDA, N, JOB, INFO
```

```
SUBROUTINE ZTRDI_64( A, LDA, N, DET, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), DET(*)
INTEGER*8 LDA, N, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrdi(doublecomplex *a, int lda, int n, doublecomplex *det, int job, int *info);
```

```
void ztrdi_64(doublecomplex *a, long lda, long n, doublecomplex *det, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, the inverse of the original matrix A if the inverse was requested, otherwise unchanged.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

* **N** (*input*)

Order of the original matrix A. N >= 0.

* **DET** (*output*)

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0.

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 010 no determinant, inverse of lower triangular A
- o 011 no determinant, inverse of upper triangular A
- o 100 determinant, no inverse

- 110 determinant, inverse of lower triangular A
- 111 determinant, inverse of upper triangular A

*** *INFO* (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Contains the index of a zero element of A if the inverse is requested and A is singular.

NAME

ztrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

SYNOPSIS

```
SUBROUTINE ZTREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,  
* LDVR, MM, M, WORK, RWORK, INFO)

CHARACTER(LEN=1) :: SIDE, HOWMNY  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: T, VL, VR  
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL(8), DIMENSION(:) :: SELECT  
REAL(8), DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrevc(char side, char howmny, logical *select, int n, doublecomplex *t, int ldt, doublecomplex *vl, int ldvl, doublecomplex *vr, int ldvr, int mm, int *m, int *info);
```

```
void ztrevc_64(char side, char howmny, logical *select, long n, doublecomplex *t, long ldt, doublecomplex *vl, long ldvl, doublecomplex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ztrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T^*x = w^*x, \quad y'^*T = w^*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary

matrix. If T was obtained from the Schur factorization of an original matrix $A = Q^*T^*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

* *SIDE* (input)

* *HOWMNY* (input)

* *SELECT* (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

* *N* (input)

The order of the matrix T. $N \geq 0$.

* *T* (input/output)

The upper triangular matrix T. T is modified, but restored on exit.

* *LDT* (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

* *VL* (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to $T(i, i)$. if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

* **LDVL (input)**

The leading dimension of the array VL. LDVL $\geq \max(1, N)$ if SIDE = 'L' or 'B'; LDVL ≥ 1 otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q^*X ; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR $\geq \max(1, N)$ if SIDE = 'R' or 'B'; LDVR ≥ 1 otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. MM $\geq M$.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

* **WORK (workspace)**

dimension(2*N)

* **RWORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

ztrexc - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE ZTREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
CHARACTER * 1 COMPQ
DOUBLE COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE ZTREXC_64( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
CHARACTER * 1 COMPQ
DOUBLE COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC( COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
CHARACTER(LEN=1) :: COMPQ
COMPLEX(8), DIMENSION(:, :) :: T, Q
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE TREXC_64( COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST,
* [INFO])
CHARACTER(LEN=1) :: COMPQ
COMPLEX(8), DIMENSION(:, :) :: T, Q
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrexc(char compq, int n, doublecomplex *t, int ldt, doublecomplex *q, int ldq, int ifst, int ilst, int *info);
```

```
void ztrexc_64(char compq, long n, doublecomplex *t, long ldt, doublecomplex *q, long ldq, long ifst, long ilst, long *info);
```

PURPOSE

ztrexc reorders the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index $IFST$ is moved to row $ILST$.

The Schur form T is reordered by a unitary similarity transformation $Z^{**}H^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

ARGUMENTS

* *COMPQ (input)*

* *N (input)*

The order of the matrix T . $N \geq 0$.

* *T (input/output)*

On entry, the upper triangular matrix T . On exit, the reordered upper triangular matrix.

* *LDT (input)*

The leading dimension of the array T . $LDT \geq \max(1, N)$.

* *Q (input)*

On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the unitary transformation matrix Z which reorders T . If $COMPQ = 'N'$, Q is not referenced.

* *LDQ (input)*

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* *IFST (input)*

Specify the reordering of the diagonal elements of T : The element with row index $IFST$ is moved to row $ILST$ by a sequence of transpositions between adjacent elements. $1 \leq IFST \leq N$; $1 \leq ILST \leq N$.

* *ILST (input)*

See the description of $IFST$.

* *INFO (output)*

NAME

ztrmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conj}(A')$

SYNOPSIS

```
SUBROUTINE ZTRMM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*             LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB

SUBROUTINE ZTRMM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*             B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRMM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*             [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER :: M, N, LDA, LDB

SUBROUTINE TRMM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*             [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrmm(char side, char uplo, char transa, char diag, int m, int n, doublecomplex alpha, doublecomplex *a, int lda, doublecomplex *b, int ldb);
```

void ztrmm_64(char side, char uplo, char transa, char diag, long m, long n, doublecomplex alpha, doublecomplex *a, long lda, doublecomplex *b, long ldb);

PURPOSE

ztrmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, *TRANSA* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $\text{op}(A) = A$.

TRANSA = 'T' or 't' $\text{op}(A) = A'$.

TRANSA = 'C' or 'c' $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** A (input)**

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

*** B (input/output)**

Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least $\max(1, M)$. Unchanged on exit.

NAME

ztrmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$

SYNOPSIS

```
SUBROUTINE ZTRMV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY
```

```
SUBROUTINE ZTRMV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRMV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRMV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrmv(char uplo, char transa, char diag, int n, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztrmv_64(char uplo, char transa, char diag, long n, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

ztrmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $x := A*x$.

TRANS = 'T' or 't' $x := A'*x$.

TRANS = 'C' or 'c' $x := \text{conjg}(A)*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$.

Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ztrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

SYNOPSIS

```
SUBROUTINE ZTRRFS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, X,

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A, B, X  
INTEGER(8) :: N, NRHS, LDA, LDB, LDX, INFO  
REAL(8), DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrrfs(char uplo, char transa, char diag, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *ferr, double *berr, int *info);
```

```
void ztrrfs_64(char uplo, char transa, char diag, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

ztrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. CTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ztrsen - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

SYNOPSIS

INTEGER(8) :: N, LDT, LDQ, M, LWORK, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL(8) :: S, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsen(char job, char compq, logical *select, int n, doublecomplex *t, int ldt, doublecomplex *q, int ldq, doublecomplex *w, int *m, double *s, double *sep, int *info);
```

```
void ztrsen_64(char job, char compq, logical *select, long n, doublecomplex *t, long ldt, doublecomplex *q, long ldq, doublecomplex *w, long *m, double *s, double *sep, long *info);
```

PURPOSE

ztrsen reorders the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

*** COMPQ (input)**

*** SELECT (input)**

SELECT specifies the eigenvalues in the selected cluster. To select the j-th eigenvalue, SELECT(j) must be set to .TRUE..

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input/output)**

On entry, the upper triangular matrix T. On exit, T is overwritten by the reordered matrix T, with the selected eigenvalues as the leading diagonal elements.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** Q (input)**

On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

*** W (output)**

The reordered eigenvalues of T, in the same order as they appear on the diagonal of T.

*** M (output)**

The dimension of the specified invariant subspace. $0 \leq M \leq N$.

* ***S*** (output)

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

* ***SEP*** (output)

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

* ***WORK*** (workspace)

If JOB = 'N', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* ***LWORK*** (input)

The dimension of the array WORK. If JOB = 'N', LWORK \geq 1; if JOB = 'E', LWORK = $M*(N-M)$; if JOB = 'V' or 'B', LWORK \geq $2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO*** (output)

NAME

ztrsl - (obsolete) solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE ZTRSL( A, LDA, N, B, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, JOB, INFO
```

```
SUBROUTINE ZTRSL_64( A, LDA, N, B, JOB, INFO)
DOUBLE COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsl(doublecomplex *a, int lda, int n, doublecomplex *b, int job, int *info);
```

```
void ztrsl_64(doublecomplex *a, long lda, long n, doublecomplex *b, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 00 Solve $Ax = b$, A lower triangular.
- o 01 Solve $Ax = b$, A upper triangular.
- o 10 Solve $AHx = b$, A lower triangular.
- o 11 Solve $AHx = b$, A upper triangular.

- Note that $ATx = AHx$ for real matrices.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns the index of the first zero diagonal element of A.

NAME

ztrsm - solve one of the matrix equations $op(A)X = \alpha B$, or $Xop(A) = \alpha B$

SYNOPSIS

```
SUBROUTINE ZTRSM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*             LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB

SUBROUTINE ZTRSM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*             B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRSM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*             [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER :: M, N, LDA, LDB

SUBROUTINE TRSM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*             [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsm(char side, char uplo, char transa, char diag, int m, int n, doublecomplex alpha, doublecomplex *a, int lda,
doublecomplex *b, int ldb);
```

```
void ztrsm_64(char side, char uplo, char transa, char diag, long m, long n, doublecomplex alpha, doublecomplex *a, long lda,
```

doublecomplex *b, long ldb);

PURPOSE

ztrsm solves one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A' \quad \text{or} \quad \text{op}(A) = \text{conjg}(A').$$

The matrix X is overwritten on B .

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A) * X = \alpha * B$.

SIDE = 'R' or 'r' $X * \text{op}(A) = \alpha * B$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, *TRANS* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' $\text{op}(A) = A$.

TRANS = 'T' or 't' $\text{op}(A) = A'$.

TRANS = 'C' or 'c' $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of B. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** A (input)**

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

*** B (input/output)**

Before entry, the leading M by N part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. $LDB \geq \max(1, M)$. Unchanged on exit.

NAME

ztrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**}H$ with Q unitary)

SYNOPSIS

CHARACTER(LEN=1) :: JOB, HOWMNY  
COMPLEX(8), DIMENSION(:, :) :: T, VL, VR, WORK  
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, LDWORK, INFO  
LOGICAL(8), DIMENSION(:) :: SELECT  
REAL(8), DIMENSION(:) :: S, SEP, WORK1
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsna(char job, char howmny, logical *select, int n, doublecomplex *t, int ldt, doublecomplex *vl, int ldvl, doublecomplex *vr, int ldvr, double *s, double *sep, int mm, int *m, int ldwork, int *info);
```

```
void ztrsna_64(char job, char howmny, logical *select, long n, doublecomplex *t, long ldt, doublecomplex *vl, long ldvl, doublecomplex *vr, long ldvr, double *s, double *sep, long mm, long *m, long ldwork, long *info);
```

PURPOSE

ztrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**}H$ with Q unitary).

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

*** HOWMNY (input)**

*** SELECT (input)**

If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input)**

The upper triangular matrix T.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any $Q^*T^*Q^{**}H$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CHSEIN or CTREVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

*** VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any $Q^*T^*Q^{**}H$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CHSEIN or CTREVC. If JOB = 'V', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. $LDVR \geq 1$; and if JOB = 'E' or 'B', $LDVR \geq N$.

*** S (output)**

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of

the array. Thus $S(j)$, $SEP(j)$, and the j -th columns of VL and VR all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected). If $JOB = 'V'$, S is not referenced.

* ***SEP (output)***

If $JOB = 'V'$ or $'B'$, the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If $JOB = 'E'$, SEP is not referenced.

* ***MM (input)***

The number of elements in the arrays S (if $JOB = 'E'$ or $'B'$) and/or SEP (if $JOB = 'V'$ or $'B'$). $MM \geq M$.

* ***M (output)***

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If $HOWMNY = 'A'$, M is set to N .

* ***WORK (workspace)***

If $JOB = 'E'$, $WORK$ is not referenced.

* ***LDWORK (input)***

The leading dimension of the array $WORK$. $LDWORK \geq 1$; and if $JOB = 'V'$ or $'B'$, $LDWORK \geq N$.

* ***WORK1 (workspace)***

If $JOB = 'E'$, $WORK1$ is not referenced.

* ***INFO (output)***

NAME

ztrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conj}(A')*x = b$

SYNOPSIS

```
SUBROUTINE ZTRSV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY
```

```
SUBROUTINE ZTRSV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRSV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRSV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsv(char uplo, char transa, char diag, int n, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztrsv_64(char uplo, char transa, char diag, long n, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

ztrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A')*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

ztrsyl - solve the complex Sylvester matrix equation

void ztrsyl_64(char trana, char tranb, long isgn, long m, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb,
```

doublecomplex *c, long ldc, double *scale, long *info);

PURPOSE

ztrsyl solves the complex Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**H} , and A and B are both upper triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

ARGUMENTS

* **TRANA** (*input*)

Specifies the option $\text{op}(A)$:

* **TRANB** (*input*)

Specifies the option $\text{op}(B)$:

* **ISGN** (*input*)

Specifies the sign in the equation:

* **M** (*input*)

The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

* **N** (*input*)

The order of the matrix B , and the number of columns in the matrices X and C . $N \geq 0$.

* **A** (*input*)

The upper triangular matrix A .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper triangular matrix B .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, the M -by- N right hand side matrix C . On exit, C is overwritten by the solution matrix X .

* **LDC** (*input*)

The leading dimension of the array C . $LDC \geq \max(1, M)$

* **SCALE** (*output*)

The scale factor, scale , set ≤ 1 to avoid overflow in X .

* **INFO** (*output*)

NAME

ztrti2 - compute the inverse of a complex upper or lower triangular matrix

SYNOPSIS

```
SUBROUTINE ZTRTI2( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE ZTRTI2_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTI2( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE TRTI2_64( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrti2(char uplo, char diag, int n, doublecomplex *a, int lda, int *info);
```

```
void ztrti2_64(char uplo, char diag, long n, doublecomplex *a, long lda, long *info);
```

PURPOSE

ztrti2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the matrix A is upper or lower triangular.

* **DIAG** (*input*)

Specifies whether or not the matrix A is unit triangular.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **INFO** (*output*)

NAME

ztrtri - compute the inverse of a complex upper or lower triangular matrix A

SYNOPSIS

```

```

```
void ztrtri_64(char uplo, char diag, long n, doublecomplex *a, long lda, long *info);
```

PURPOSE

ztrtri computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular matrix A. If *UPLO* = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If *DIAG* = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

ztrtrs - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$.

SYNOPSIS

```
SUBROUTINE ZTRTRS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO

SUBROUTINE ZTRTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                   INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTRS( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
*               [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO

SUBROUTINE TRTRS_64( UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B,
*                  [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrtrs(char uplo, char transa, char diag, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);
```

```
void ztrtrs_64(char uplo, char transa, char diag, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *b, long ldb, long *info);
```

PURPOSE

ztrtrs solves a triangular system of the form

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

ztzrqf - routine is deprecated and has been replaced by routine CTZRZF

SYNOPSIS

```
SUBROUTINE ZTZRQF( M, N, A, LDA, TAU, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*)
INTEGER M, N, LDA, INFO
```

```
SUBROUTINE ZTZRQF_64( M, N, A, LDA, TAU, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*)
INTEGER*8 M, N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRQF( [M], [N], A, [LDA], TAU, [INFO])
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, INFO
```

```
SUBROUTINE TZRQF_64( [M], [N], A, [LDA], TAU, [INFO])
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztzrqf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void ztzrqf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

ztzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq M$.

*** A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** INFO (output)**

NAME

ztzrzf - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

SYNOPSIS

```
SUBROUTINE ZTZRF( M, N, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LWORK, INFO
```

```
SUBROUTINE ZTZRF_64( M, N, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRF( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK, INFO
```

```
SUBROUTINE TZRF_64( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztzrf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void ztzrf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

ztzrzf reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

* **M (input)**

The number of rows of the matrix A. $M \geq 0$.

* **N (input)**

The number of columns of the matrix A. $N \geq 0$.

* **A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU (output)**

The scalar factors of the elementary reflectors.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

zung2l - generate an m by n complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE ZUNG2L( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, INFO
```

```
SUBROUTINE ZUNG2L_64( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE UNG2L( M, [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, INFO
```

```
SUBROUTINE UNG2L_64( M, [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zung2l(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zung2l_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zung2l L generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

* **M (input)**

The number of rows of the matrix Q. $M \geq 0$.

* **N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

* **K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

* **A (input/output)**

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k columns of its array argument A. On exit, the m-by-n matrix Q.

* **LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

* **WORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

zung2r - generate an m by n complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE ZUNG2R( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, INFO
```

```
SUBROUTINE ZUNG2R_64( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, K, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zung2r(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zung2r_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zung2r R generates an m by n complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

*** A (input/output)**

On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k columns of its array argument A. On exit, the m by n matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

NAME

zungbr - generate one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form

SYNOPSIS

```
SUBROUTINE ZUNGBR( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGBR_64( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGBR( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGBR_64( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
*                  [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungbr(char vect, int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zungbr_64(char vect, long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungbr generates one of the complex unitary matrices Q or P^{**H} determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P^{**H}$. Q and P^{**H} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and CUNGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and CUNGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{**H} is of order N :

if $k < n$, $P^{**H} = G(k) \dots G(2) G(1)$ and CUNGBR returns the first m rows of P^{**H} , where $n \geq m \geq k$;

if $k \geq n$, $P^{**H} = G(n-1) \dots G(2) G(1)$ and CUNGBR returns P^{**H} as an N -by- N matrix.

ARGUMENTS

* *VECT (input)*

Specifies whether the matrix Q or the matrix P^{**H} is required, as defined in the transformation applied by CGEBRD:

* *M (input)*

The number of rows of the matrix Q or P^{**H} to be returned. $M \geq 0$.

* *N (input)*

The number of columns of the matrix Q or P^{**H} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M,K)$; if $VECT = 'P'$, $N \geq M \geq \min(N,K)$.

* *K (input)*

If $VECT = 'Q'$, the number of columns in the original M -by- K matrix reduced by CGEBRD. If $VECT = 'P'$, the number of rows in the original K -by- N matrix reduced by CGEBRD. $K \geq 0$.

* *A (input/output)*

On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M -by- N matrix Q or P^{**H} .

* *LDA (input)*

The leading dimension of the array A . $LDA \geq M$.

* *TAU (input)*

$(\min(M,K))$ if $VECT = 'Q'$ ($\min(N,K)$) if $VECT = 'P'$ $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P^{**H} , as returned by CGEBRD in its array argument $TAUQ$ or $TAUP$.

* *WORK (workspace)*

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* *LWORK (input)*

The dimension of the array $WORK$. $LWORK \geq \max(1, \min(M,N))$. For optimum performance $LWORK \geq \min(M,N) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

** INFO (output)*

NAME

zunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

SYNOPSIS

```
SUBROUTINE ZUNGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGHR_64( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGHR( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE UNGHR_64( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunghr(int n, int ilo, int ihi, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zunghr_64(long n, long ilo, long ihi, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by CGEHRD:

$$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1).$$

ARGUMENTS

* ***N*** (*input*)

The order of the matrix Q . $N \geq 0$.

* ***ILO*** (*input*)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_{lo}+1:i_{hi}, i_{lo}+1:i_{hi})$. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description of IHI.

* ***A*** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N -by- N unitary matrix Q .

* ***LDA*** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* ***TAU*** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEHRD.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK*** (*input*)

The dimension of the array $WORK$. $LWORK \geq IHI - ILO$. For optimum performance $LWORK \geq (IHI - ILO) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* ***INFO*** (*output*)

NAME

zungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE ZUNGL2( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, INFO
```

```
SUBROUTINE ZUNGL2_64( M, N, K, A, LDA, TAU, WORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGL2( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, INFO
```

```
SUBROUTINE UNGL2_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungl2(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zungl2_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungl2 generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k)' \cdot \dots \cdot H(2)' \cdot H(1)'$$

as returned by CGELQF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q. $N \geq M$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

* ***A (input/output)***

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the m by n matrix Q.

* ***LDA (input)***

The first dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (input)***

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

* ***WORK (workspace)***

dimension(M)

* ***INFO (output)***

NAME

zunglq - generate an M-by-N complex matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE ZUNGLQ( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGLQ_64( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGLQ( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGLQ_64( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunglq(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zunglq_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zunglq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k)' \cdot \dots \cdot H(2)' \cdot H(1)'$$

as returned by CGELQF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

zungql - generate an M-by-N complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE ZUNGQL( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGQL_64( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGQL( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGQL_64( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungql(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zungql_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

*** A (input/output)**

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, N)$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

zungqr - generate an M-by-N complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE ZUNGQR( M, N, K, A, LDA, TAU, WORKIN, LWORKIN, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER M, N, K, LDA, LWORKIN, INFO
```

```
SUBROUTINE ZUNGQR_64( M, N, K, A, LDA, TAU, WORKIN, LWORKIN, INFO)
DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER*8 M, N, K, LDA, LWORKIN, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGQR( M, [N], [K], A, [LDA], TAU, [WORKIN], [LWORKIN],
*               [INFO])

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungqr(int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zungqr_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF.

ARGUMENTS

* **M** (*input*)

The number of rows of the matrix Q. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix Q. $M \geq N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

* **A** (*input/output*)

On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

* **LDA** (*input*)

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

* **WORKIN** (*workspace*)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

* **LWORKIN** (*input*)

The dimension of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

* **INFO** (*output*)

NAME

```

```
void zungrq_64(long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungrq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

zungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

SYNOPSIS

```
SUBROUTINE ZUNGTR( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER N, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGTR_64( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGTR( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, LDA, LWORK, INFO
```

```
SUBROUTINE UNGTR_64( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungtr(char uplo, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zungtr_64(char uplo, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by CHETRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **A** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N -by- N unitary matrix Q .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq N$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHETRD.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq N-1$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

zunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE ZUNMBR( VECT, SIDE, TRANS, M, N, K, A, LDA, TAU, C, LDC,  
*      WORK, LWORK, INFO)  
CHARACTER * 1 VECT, SIDE, TRANS

SUBROUTINE UNMBR( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU,  
*      C, [LDC], [WORK], [LWORK], [INFO])  
CHARACTER(LEN=1) :: VECT, SIDE, TRANS  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A, C  
INTEGER :: M, N, K, LDA, LDC, LWORK, INFO
```

```
SUBROUTINE UNMBR_64( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA],  
*      TAU, C, [LDC], [WORK], [LWORK], [INFO])  
CHARACTER(LEN=1) :: VECT, SIDE, TRANS  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A, C  
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunmbr(char vect, char side, char trans, int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau,  
doublecomplex *c, int ldc, int *info);
```

```
void zunmbr_64(char vect, char side, char trans, long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau,  
doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmbr VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N':
 $Q * C * Q$ TRANS = 'C': $Q^{**H} * C * Q^{**H}$

If VECT = 'P', CUNMBR overwrites the general complex M-by-N matrix C with

SIDE = 'L' SIDE = 'R'

TRANS = 'N': $P * C * P$

TRANS = 'C': $P^{**H} * C * P^{**H}$

Here Q and P^{**H} are the unitary matrices determined by CGEBRD when reducing a complex matrix A to bidiagonal form:
 $A = Q * B * P^{**H}$. Q and P^{**H} are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P^{**H} that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

if $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if $k < nq$, $P = G(1) G(2) \dots G(k)$;

if $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

ARGUMENTS

* *VECT (input)*

* *SIDE (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *K (input)*

If VECT = 'Q', the number of columns in the original matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by CGEBRD. $K \geq 0$.

* *A (input)*

(LDA, min(nq, K)) if VECT = 'Q' (LDA, nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by CGEBRD.

* *LDA (input)*

The leading dimension of the array A. If VECT = 'Q', $LDA \geq \max(1, nq)$; if VECT = 'P', $LDA \geq \max(1, \min(nq, K))$.

* *TAU (input)*

TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned

by CGEBRD in the array argument TAUQ or TAUP.

* ***C*** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**H}C$ or C^*Q^{**H} or C^*Q or P^*C or $P^{**H}C$ or C^*P or C^*P^{**H} .

* ***LDC*** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK*** (*input*)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if $SIDE = 'L'$, and $LWORK \geq M * NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO*** (*output*)

```
SUBROUTINE UNMHR( SIDE, [TRANS], [M], [N], ILO, IHI, A, [LDA], TAU,
*      C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, TRANS
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A, C
INTEGER :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO

SUBROUTINE UNMHR_64( SIDE, [TRANS], [M], [N], ILO, IHI, A, [LDA],
*      TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, TRANS
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A, C
INTEGER(8) :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunmhr(char side, char trans, int m, int n, int ilo, int ihi, doublecomplex *a, int lda, doublecomplex *tau, doublecomplex *c, int ldc, int *info);
```

```
void zunmhr_64(char side, char trans, long m, long n, long ilo, long ihi, doublecomplex *a, long lda, doublecomplex *tau, doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmhr overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1)$.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **ILO** (*input*)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_{lo}+1:i_{hi}, i_{lo}+1:i_{hi})$. If SIDE = 'L', then $1 \leq ILO \leq IHI \leq M$, if $M > 0$, and $ILO = 1$ and $IHI = 0$, if $M = 0$; if SIDE = 'R', then $1 \leq ILO \leq IHI \leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input*)

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$ if SIDE = 'L'; $LDA \geq \max(1, N)$ if SIDE = 'R'.

* **TAU** (*input*)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK

array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

*                   [LDC], [WORK], [LWORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, TRANS  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A, C  
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunmrq(char side, char trans, int m, int n, int k, doublecomplex *a, int lda, doublecomplex *tau, doublecomplex *c, int ldc, int *info);
```

```
void zunmrq_64(char side, char trans, long m, long n, long k, doublecomplex *a, long lda, doublecomplex *tau, doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmrq overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{*H}C$ or C^*Q^{*H} or C^*Q .

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by

XERBLA.

* *INFO (output)*

void zunmrz_64(char side, char trans, long m, long n, long k, long l, doublecomplex *a, long lda, doublecomplex *tau,
doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmrz overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE (input)**

* **TRANS (input)**

* **M (input)**

The number of rows of the matrix C. $M \geq 0$.

* **N (input)**

The number of columns of the matrix C. $N \geq 0$.

* **K (input)**

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **L (input)**

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **A (input)**

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

* **C (input/output)**

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

* **LDC (input)**

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

* ***INFO (output)***

```

```
void zunmtr_64(char side, char uplo, char trans, long m, long n, doublecomplex *a, long lda, doublecomplex *tau,
doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmtr overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *A (input)*

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHETRD.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

* *TAU (input)*

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* *WORK (workspace)*

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* *LWORK (input)*

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1,N)$; if SIDE = 'R', $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* *INFO (output)*

NAME

zupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

SYNOPSIS

```
SUBROUTINE ZUPGTR( UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)

```

```
void zupgtr_64(char uplo, long n, doublecomplex *ap, doublecomplex *tau, doublecomplex *q, long ldq, long *info);
```

PURPOSE

zupgtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by CHPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* *UPLO (input)*

* *N (input)*

The order of the matrix Q . $N \geq 0$.

* *AP (input)*

The vectors which define the elementary reflectors, as returned by CHPTRD.

* *TAU (input)*

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHPTRD.

* *Q (output)*

The N -by- N unitary matrix Q .

* *LDQ (input)*

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* *WORK (workspace)*

dimension($N-1$)

* *INFO (output)*

(N) if SIDE = 'L' (M) if SIDE = 'R'

* *INFO (output)*

NAME

zvmul - compute the scaled product of complex vectors

SYNOPSIS

```
SUBROUTINE ZVMUL( N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX X(*), Y(*), Z(*)
INTEGER N, INCX, INCY, INCZ
```

```
SUBROUTINE ZVMUL_64( N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX X(*), Y(*), Z(*)
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL( [N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y, Z
INTEGER :: N, INCX, INCY, INCZ
```

```
SUBROUTINE VMUL_64( [N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y, Z
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zvmul(int n, doublecomplex alpha, doublecomplex *x, int incx, doublecomplex *y, int incy, doublecomplex beta, doublecomplex *z, int incz);
```

```
void zvmul_64(long n, doublecomplex alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex beta, doublecomplex *z, long incz);
```

PURPOSE

zvmul computes the scaled product of complex vectors:

$$z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$$

for $1 \leq i \leq N$.

ARGUMENTS

*** *N (input)***

Length of the vectors. $N \geq 0$. ZVMUL will return immediately if $N = 0$.

*** *ALPHA (input)***

Scale factor on the multiplicand vectors.

*** *X (input)***

dimension(*)

Multiplicand vector.

*** *INCX (input)***

Stride between elements of the multiplicand vector X. $INCX > 0$.

*** *Y (input)***

dimension(*)

Multiplicand vector.

*** *INCY (input)***

Stride between elements of the multiplicand vector Y. $INCY > 0$.

*** *BETA (input)***

Scale factor on the product vector.

*** *Z (input/output)***

dimension(*)

Product vector. On exit, $z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$.

*** *INCZ (input)***

Stride between elements of Z. $INCZ > 0$.
